Core	SDMA Main Core	The core sub-block clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-block clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-block clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-block clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the Arm platform modifies the channel running conditions.	None
Arm platform Control	SDMA Main Core & Arm platform peripheral	The Arm platform peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on <i>SDMA main clock</i> ; it is active when the Arm platform or the SDMA modifies the contents of one of these registers.	None
Burst DMA	SDMA Main Core & Arm platform DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the Arm platform DMA clock and drives registers that are connected to the Arm platform DMA bus outside the SDMA. Both clocks are enabled	Disabled when Core sub-block clock is disabled

Table continues on the next page...

Table 7-12. Sub-blocks Clocks (continued)

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
		during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	
Peripheral DMA	SDMA Main Core & Arm platform DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the Arm platform DMA clock and drives registers that are connected to the Arm platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the Arm platform peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to Synchronization Implementation .	When enabled, all other clocks are systematically on (clock gating is off)

7.2.4.6.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis.

Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

7.2.4.6.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG.

The following table describes these modes, and shows how to switch from one mode to another.

Table 7-13. Power Modes

Power Mode	Sub-blocks							Comments
	Core	Mem ories	Sche duler	Arm platf orm Control	Burs t DMA	Perip heral DMA	OnC E	
SLEEP	off ¹	off	wait ²	wait	off	off	off	Set when the PCU state is either <i>Sleep</i> or <i>Sleep after Reset</i> and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on ³	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: <i>Program, Data, Change of Flow, Error in Loop, Debug, Functional Unit, Save, or Restore</i> .
DEBUG	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either <i>clk_gating_off</i> pin high or ONCE_ENB[0] set).

1. *off*: no clock
2. *wait*: only clocked when accessed or stimulated
3. *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in [SLEEP Mode](#).

7.2.4.6.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode.

However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in [Stop Mode Response](#).

7.2.4.6.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

7.2.4.6.1.3.3 *DEBUG Mode*

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA.

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

7.2.4.6.1.4 **Stop Mode Response**

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode.

If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMA's clocks can be turned off.

7.2.4.6.2 **Reset**

After reset (either received from the reset block or a software reset required by the Arm platform), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated.

Activating a channel can be done by the Arm platform after programming a positive priority and setting the channel bit in the EVTpend register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes

7.2.4.7 **Software Interface**

Appendix A fully describes the SDMA Application Programming Interface (API).

7.2.4.8 Initialization Information

This section discusses the following:

- [Hardware Reset](#)
- [Channel Script Execution](#)
- [Initialization and Script Execution Setup Sequence](#)

7.2.4.8.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents.

The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The Arm platform will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the Arm platform first creates some channel control blocks (CCB) and buffer descriptors (BD) in Arm platform memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (SDMA_MC0PTR) to the address of the first control block. [Data Structures for Boot Code and Channel Scripts](#) provides an overview of the data structure for the CCB and BD's. The SDMA_HSTART, SDMA_HOSTOVR and SDMA_EVT OVR registers are then configured according to [Runnable Channels Evaluation](#) to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (SDMA_CHN0ADDR) in the program memory. The reset value of SDMA_CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (SDMA_MC0PTR) to determine the location of the Channel Control Block (SDMA_CCB) in Arm platform memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its Arm platform Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the SDMA_CHN0ADDR register in the Arm platform programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

7.2.4.8.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters allowed to the buffer. All these items must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the Arm platform by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The Arm platform selects which trigger conditions that must occur for the channel to start by configuring the SDMA_CHNENBL, SDMA_HOSTOVR and SDMA_EVT OVR registers. The trigger events include Arm platform setting HE (SDMA_HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can become active according to its priority compared with other runnable channels when the selected trigger(s) cause the condition described in [Runnable Channels Evaluation](#) to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to [SDMA Scripts](#) for complete script documentation. [Buffer Descriptor Format](#) provides an overview of the buffer descriptor format.

7.2.4.8.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and SDMA_CHNENBLn registers have unpredictable contents after this reset.
- Initialize SDMA_CHNENBLn registers to map DMA request events to desired channels.

- Configure SDMA_CHNPRIn registers to select priority for runnable channels. A non-zero priority is required for the channel to run.
- Configure the SDMA_CONFIG register to select DMA to SDMA core clock ratio .
- Set up channel control blocks and buffer descriptors in Arm platform to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference [Data Structures for Boot Code and Channel Scripts](#).
- Configure SDMA_MC0PTR register with base address of Arm platform Channel Control Block base address.
- Initialize SDMA_CHNENBLn registers to map DMA request events to associated channel. Reference [Mapping DMA Requests to Pending Channels](#).
- Configure SDMA_CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure SDMA_HOSTOVR (HO) and SDMA_EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference [Runnable Channels Evaluation](#).
- Set bit 0 of the SDMA_HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] andDO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_SDMA_INTR register, or by optional interrupt to the Arm platform.
- Set the LOCK bit in the SDMA_SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scripts can now be run by enabling the selected software or hardware trigger event according to [Runnable Channels Evaluation](#).

7.2.4.9 SDMA Programming Model

This section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the Arm platform memory maps. The Arm platform processor has no access to any hardware resource described, except when those resources are described in Arm Platform Memory Map and Control Register Summary. .

7.2.4.9.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time.

This chapter lists the components of every channel state.

7.2.4.9.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the loop instruction, but otherwise can be used for any purpose.

7.2.4.9.3 Functional Unit State

Each channel context has some state that is part of the functional units.

The specific allocation of this state is part of the functional unit definition that is described in [Burst DMA Unit Programming](#), [Peripheral DMA Unit Programming](#) .

This state must be saved/restored on context switches.

7.2.4.9.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction.

A low order bit of zero selects the most significant half of the word.¹

7.2.4.9.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.
- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (CLRF and loop). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.

1. For example, big-Endian.

- Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the loop instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.

- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the loop instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch GReg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

7.2.4.9.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions.

Instructions are available to transfer its contents to and from a general register.

7.2.4.9.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the loop instruction to the location immediately following it.

7.2.4.9.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the loop instruction to the location of the next instruction after the loop.

7.2.4.9.4 Context Switching-Programming

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units.

The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode ([Context Switching](#)), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a done or yield(ge) instruction, SDMA goes into "real" context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel i is $CONTEXT_BASE + 24*i$ or $CONTEXT_BASE + 32*i$ where $CONTEXT_BASE$ equals 0x0800. The table below presents the layout of a channel context in memory:

Table 7-14. Layout of a Channel Context in Memory for SDMA

7.2.4.9.5 Address Space

The SDMA has four internal buses which are listed here.

- The Instruction bus reads instructions from the memory. Its address map is described in [Instruction Memory Map](#).
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in [Data Memory Map](#).
- The Functional Units bus (FUBUS) accesses the , Burst DMA, Peripheral DMA . The addressing mechanism is further detailed in [Functional Units Programming Model](#).
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and

otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

7.2.4.9.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus.

Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a jmp to handle routines.

Table 7-15. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Block Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	-	0	4 Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	-	0	8 Kbyte internal RAM with channels context and user data/routines.

7.2.4.9.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA.

This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)
- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the Arm platform)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GRegn). The mapping between the general purpose register contents and the address bus is given in the following table:

Table 7-16. GRegn to DMBUS Address Mapping

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 7-17. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbyte	4 Kbyte internal ROM with boot code and standard routines

7.2.4.10 SDMA Initialization

Appendix A describes the setup of the SDMA . This section provides a quick description of several initialization procedures.

NOTE

There may be differences with the actual implementation in the API.

7.2.4.10.1 Hardware Reset-SDMA

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content.

The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

7.2.4.10.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register-detailed in [Configuration Register \(SDMAARM_CONFIG\)](#)-to determine the Arm platform DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (see [Channel Enable RAM \(SDMAARM_CHNENBLn\)](#)).
3. Program the channel control registers-[Channel Event Override \(SDMAARM_EVTOVR\)](#), [Channel BP Override \(SDMAARM_DSPOVR\)](#), [Channel BP Override \(SDMA_HOSTOVR\)](#), and [Channel Event Pending \(SDMAARM_EVTPEND\)](#)-according to the channel allocation.
4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A).
5. Trigger channel 0 with the [Channel Start \(SDMAARM_HSTART\)](#) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

7.2.4.10.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the [Configuration Register \(SDMAARM_CONFIG\)](#)[Channel Enable RAM \(SDMAARM_CHNENBLn\)](#), [Channel Event Override \(SDMAARM_EVTOVR\)](#), [Channel BP Override \(SDMAARM_DSPOVR\)](#), [Channel Arm platform Override \(SDMAARM_HOSTOVR\)](#), and [Channel Event Pending \(SDMAARM_EVTPEND\)](#).

2. Use the OnCE (either via its JTAG interface or its Arm platform control registers) to download any code in the SDMA RAM. [Accessing the Memory](#) describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in [Channel 0 Boot Address \(SDMAARM_CHN0ADDR\)](#). (This register default address points to the standard boot script.)

7.2.4.10.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The Arm platform manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the Arm platform via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the Arm platform can enable any channel that becomes active and begins fetching and executing instructions from its script.

7.2.4.11 Instruction Description

The following sections introduce the instruction of the SDMA.

Instruction set details are available in [Instruction Set](#).

7.2.4.11.1 Scheduling Instructions

The following are scheduling instructions:

- done-The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The done 5 has a special usage reserved for debug, as explained in [Debug Instructions](#).

- **yield**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.
- **yieldge**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- **notify**-The notify instruction affects the scheduling bits, but does not cause rescheduling.

7.2.4.11.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied.

Otherwise, control passes to the next sequential instruction.

- **BF**-Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- **BT**-Branch if True. The branch is taken if the T bit in the processor status is one (true).
- **BSF**-Branch if Source Fault. The branch is taken if the SF bit in the processor status is one.
- **BDF**-Branch if Destination Fault. The branch is taken if the DF bit in the processor status is one.

7.2.4.11.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer.

Absolute transfers have a 14-bit address field that replaces the current PC.

- **JMP**-Jump. Causes the processor to jump to an absolute address encoded in the instruction itself.
- **JSR**-Jump to Subroutine. Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.

- **JMPR**-Jump through Register. Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- **JSRR**-Jump to Subroutine through Register. Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

7.2.4.11.4 Subroutine Return Instructions

The following are subroutine return instructions:

- **RET**-Return from Subroutine. The RET restores the contents of RPC to PC.
- **LDRPC**-Load from RPC to Register. The LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

7.2.4.11.5 Loop Instruction

The following is a loop instruction:

LOOP-Enters Loop Mode. Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

7.2.4.11.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- **CLRF**-Clear Fault Flags. This instruction clears any combination of SF and DF.
- **MOV r,s**-This moves data from GReg[s] to GReg[r].
- **LDI r,immediate**-This loads GReg[r] with a zero-extended immediate value.

7.2.4.11.7 Logic Instructions

The following are logic instructions:

- **XORr,s**-This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- **XORIr,immediate**-This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- **ORr,s**-This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].

- **ORIr,immediate**-This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- **ANDNr,s**-This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- **ANDNIr,immediate**-This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- **ANDr,s**-This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- **ANDIr,immediate**-This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

7.2.4.11.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- **ADD r,s**-This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- **ADDI r,immediate**-This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- **SUB r,s**-This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- **SUBIr,immediate**-This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

7.2.4.11.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- **CMPEQ r,s**-This sets T when registers GReg[r] and GReg[s] are equal.
- **CMPEQIr,immediate**-This sets T when register GReg[r] and the zero-extended immediate value are equal.
- **CMPLTr,s**-This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- **CMPHS r,s**-This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

7.2.4.11.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- TSTr,s-This performs an and between GReg[r] and GReg[s], and sets T if the result is not zero.
- TSTIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and sets T if the result is not zero.

7.2.4.11.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3 , b_2 , b_1 , b_0 .

- RORBr-The rotate right byte. The result is b_0 , b_3 , b_2 , b_1 .
- REVBr-The reverse bytes in word. The result is b_0 , b_1 , b_2 , b_3 .
- REVBLOr-The reverse, two low-order bytes. The result is b_3 , b_2 , b_0 , b_1 .

7.2.4.11.12 Bit Shift Instructions

The following are bit shift instructions:

- ROR1r-The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- LSR1r-The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- ASR1r-The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- LSL1r-The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

7.2.4.11.13 Bit Manipulation Instructions

- BCLRi,r,n-The bit clear is immediate; clears bit number i in register r .
- BSETi,r,n-The bit set is immediate; sets bit number i in register r .
- BTSTi,r,n-The bit test is immediate; tests bit number i in register r (T becomes equal to the selected register bit).

7.2.4.11.14 SDMA Memory Access Instructions

All memory accesses are 32 bits.

Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s.

All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault.

What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- LDr,(b,d)-The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- STr,(b,d)-The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

7.2.4.11.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus.

Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See [Functional Units Programming Model](#).

There are two functional unit instructions, as follows:

- LDFr,fub-The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- STFr,fub-The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

7.2.4.11.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the [Illegal Instruction Trap Address \(SDMAARM_ILLINSTADDR\)](#) register (the default value is 0x0001).

ILLEGAL-Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

7.2.4.11.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT-The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug block only.
- done 5-This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in [Saving the Context](#).
- CpShReg-This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in [Restoring the Context](#).

7.2.4.12 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus.

Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in the following table. In order to establish a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 7-18. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit Programming	SDMSA	Memory Source Address Register	Memory Source Address Register (MSA)
	MDA	Memory Destination Address Register	Memory Destination Address Register (MDA)
	MD	Memory Data Buffer Register	Memory Data Buffer Register (MD)

Table continues on the next page...

Table 7-18. Functional Unit Registers (continued)

Functional Unit	Register	Register Name	Section/Page
			(Write) Burst DMA Write (stf) (Read) Burst DMA Read (ldf)
	MS	Memory State Register	State Register (MS)
Peripheral DMA Unit Programming	PSA	Peripheral Source Address Register	Peripheral Source Address Register (PSA)
	PDA	Peripheral Destination Address Register	Peripheral Destination Address Register (PDA)
	PD	Peripheral Data Buffer Register	Peripheral Data Register (PD) (Write) Peripheral DMA Write (stf)-Write Mode (Read) Peripheral DMA Read (ldf)-Read Mode
	PS	Peripheral State Register	Peripheral State Register (PS)

More information regarding the functional units can be found in [Peripheral DMA Unit](#), and [Burst DMA Unit](#).

7.2.4.12.1 Burst DMA Unit Programming

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus.

There are four registers associated with the burst DMA unit: a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS). The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

7.2.4.12.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EXTMC memory associated with the next read data transfer. It has byte granularity.

Reading the register with the ldf instruction has no side effects, and gives the address value in the EXTMC memory of the next data that is read by the SDMA during an ldf MD instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen-In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)-In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

7.2.4.12.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EXTMC memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the ldf instruction has no side effects. It gives the address value in the EXTMC memory where the next SDMA data (stf r,MD instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen-In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)-The MDA register is incremented by the number of bytes transferred during write cycles.

7.2.4.12.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO.

This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode).

The MD register is in write mode after a writing in MDA or after an stf MD instruction.

In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EXTMC controller are based on burst accesses.

An `ldf r,MD|SIZE` instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An `stf r,MD|SIZE` instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EXTMC (reading or writing), no immediate error is possible because the block manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EXTMC memory mapping. The only potential error, in this mode, would be the error sent back by the EXTMC controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in [Burst DMA Unit Error Management](#).

7.2.4.12.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

Table 7-19. SDMA_MS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																

Table 7-20. SDMA_MS Field Descriptions

Field	Description
31-22	Reserved

Table continues on the next page...

**Table 7-20. SDMA_MS Field Descriptions
(continued)**

Field	Description
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen-MSA is not modified. 1 Incremented-MSA is incremented by the number of transferred bytes during read access.
19-18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16 dtype	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses. 0 Frozen-MDA is not modified. 1 Incremented-MDA is incremented by the number of transferred bytes during write access.
15-12	Reserved
11 y	Conditional Yielding selector. When selected, theyield/yieldge instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by stf MD instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an ldf MD instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 <i>reserved</i> 10 Error mode 11 error read burst
7-6	Reserved
5-0 n	Number of bytes in the MD FIFO.

7.2.4.12.1.5 Burst DMA Write (stf)

When received from a stf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 7-21. STF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								
MD			f	cpy				sz
MS								

Table 7-22. STF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value

Table continues on the next page...

Table 7-22. STF Code Bit Field Descriptions (continued)

Field	Description
	1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in the table below (unused bits should always be cleared).

Table 7-23. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.
00_0_1_00_00	stf r,MSAIFR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSAIPF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.
00_1_1_00_00	stf r,MSAIPFIFR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDAIFR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MDISZ0IFL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MDISZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MDISZ8IFL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MDISZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MDISZ16IFL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MDISZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MDISZ32IFL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MDICPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of r register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MSISZO	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as clref MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the stf r,MD instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an ldf from MS before terminating a channel in order to check the final error status. (The ldf from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every stf MD instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

7.2.4.12.1.6 Burst DMA Read (ldf)

When received from an ldf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 7-24. LDF Code Bits

Register	7	6	5	4	3	2	1	0							
MSA	s				r										
MDA															
MD									p						
MS															

Table 7-25. LDF Code Bit Field Descriptions

Field	Description
7-6	Functional Unit selector
s	00 for Burst DMA
5	Prefetch Flag
p (MD)	0 no prefetch 1 automatic prefetch

Table continues on the next page...

Table 7-25. LDF Code Bit Field Descriptions (continued)

Field	Description
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The table below lists the possible write instructions (unused bits should always be cleared).

Table 7-26. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an ldf MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MDISZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MDISZ8IPF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MDISZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MDISZ16IPF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MDISZ32	32-bit (word) read
00_1_0_10_11	ldf r,MDISZ32IPF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

7.2.4.12.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed.

When the RISC core requires a prefetch ($p = 1$) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of $MDA[1:0] = 0x0$), the auto-flush is triggered immediately after the write of the 32'nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an stf MDISZ8 is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an stf MDISZ16 is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an stf MDISZ32 is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.

- Therefore, if an stf MD|SZ32 is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (stf) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

For example, consider the case where data is written using a byte access, stf MD|SZ8. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.
- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EXTMC controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush (which occurs only at the beginning of a misaligned write transfer) no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

7.2.4.12.1.8 Data Alignment and Endianness-Burst DMA Unit

7.2.4.12.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). The following table shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 7-27. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

7.2.4.12.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. The following table shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 7-28. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww x0 x1 x2 x3 ?? ?? ?? ??
01	tt uu vv ww xx ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	10	tt uu vv ww xx x0 ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	11	tt uu vv ww xx x0 x1 ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	01	tt uu vv ww xx x0 x1 x2 x3 ?? ?? ??

		sz16	?? ?? x0 x1	00	tt uu vv ww xx yy x0 x1 ?? ?? ?? ??
		sz32	x0 x1 x2 x3	10	tt uu vv ww xx yy x0 x1 x2 x3 ?? ??
11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0

Table continues on the next page...

Table 7-28. FIFO Write Configuration (continued)

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
					x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an ldf MD is executed after stf MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a stfMDISZ0|FL instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

7.2.4.12.1.8.3 Endianness-Burst DMA Unit

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian.

Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

7.2.4.12.1.9 Burst DMA Unit Copy Mode

A mechanism is available to perform fast Arm-to-Arm transfers.

Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag).

It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an stf MDICPY is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)-given by the SDMA general register (4 LSB)-is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Burst DMA copy mode example

Smart Direct Memory Access Controller (SDMA)

```
    ldi r0,@src
    stf r0,MSA                // Source address setup
    ldi r1,@dst
    stf r1,MSA                // Destination address setup
    ldi r0,0x64               // data transfer counter
    ldi r1,0x8

MAIN_XFER:
    cmphs r0,r1              // Is r0 >= 0x8
    bf LAST_XFER            // If not, jump to last transfer label
    stf r1,MD|CPY           // Copy 8 words from MSA to MDA address.
    subi r0,0x8             // Decrement counter
    jmp MAIN_XFER           // return to main transfer loop

LAST_XFER:
    stf r0,MD|CPY
```

The main transfer loop is executed 12 times; then r0 equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

7.2.4.12.1.10 Burst DMA Unit Error Management

Another point to consider is the management of errors.

Because the DMA immediately sends an acknowledge to the RISC core (except for the stf MS|SZO|FLS instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access.

This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the ldf copy or stf copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after ldf instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a stf MDICOPY instruction will cancel the error mode. The following table shows when an immediate error is sent back according to the executed instruction.

Table 7-29. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (IU IPF) stf rn, MDA stf rn, MDICOPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the stf MDICOPY, a copy loop is executed.
stf rn, MS	NO	MS is updated.
ldf rn, MS ldf rn, MSA ldf rn, MDA	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 7-30. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an stf MSISZ0 instruction.
ldf rn, MS ldf rn, MSA ldf rn, MDA	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	Yes	Whatever the DMA direction (read or write), an ldf rn triggers an immediate error.

7.2.4.12.1.11 Conditional Yielding-Burst DMA Unit

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Hardware Loop

```

loop
load Rn,source           // can be ldf or ld
<computation>           // can be done through functional units
store Rn,dest            // can be st or stf
done 0                   // yield

```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes-conditional or always-true-for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

7.2.4.12.2 Peripheral DMA Unit Programming

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the Arm platform.

Its goal is to perform data transfers between any blocks connected to the DMA bus of this platform. These blocks are either peripherals or memories. The peripheral DMA could be seen as the Arm platform DMA controller.

The DMA performs data transfers in three modes:

- Read mode, where data is read from peripherals or from memory connected to the Arm platform and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode-When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.
- Incremented mode-When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.
- Decrement mode-In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

7.2.4.12.2.1 Peripheral Source Address Register (PSA)

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an ldf MD instruction. Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all ldf MD instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (ssize). If source is a memory in incremented mode, first programmed in word mode (stf PSA|SZ32I), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the stf PSA instruction as described in the write section. The ssize and stype registers are part of the DMA status register (PS).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

7.2.4.12.2.2 Peripheral Destination Address Register (PDA)

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PDA) to store the address value
- A 2-bit register (dtype) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (dsize) to store the destination target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an stfMD instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the stf PDA instruction and may also generate an error in case of incorrect programming.

7.2.4.12.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to PD will automatically flush the new input data.

The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an ldf instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag-part of PS-is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

7.2.4.12.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer.

Although all PS fields can be written by an stf instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

Table 7-31. PS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ssize		stype		dsize		dtype

R	0	0	0	0	0	d	e		0	0	0	0	0	n		
W																

Table 7-32. PS Field Descriptions

Field	Description
31-24	Reserved
23-22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics. 00 <i>reserved</i> 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
21-20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
19-18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics. 00 <i>reserved</i> 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
17-16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
15-11	Reserved
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by stf PD instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an ldf PD instruction. Reading PDA or PSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 <i>reserved</i> 10 Error mode 11 Error read
7-3	Reserved

Table continues on the next page...

Table 7-32. PS Field Descriptions (continued)

Field	Description
2-0 n	number of bytes in PD

NOTE

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

7.2.4.12.2.5 Peripheral DMA Write (stf)-Write Mode

When written by an stf instruction, the function code bits are interpreted as follows:

Table 7-33. STF Code Bits

Register	7	6	5	4	3	2	1	0	
PSA	s		p	ar	am		sz		
PDA									
PD			pdsel						
PS			pssel						

Table 7-34. STF Code Bits Field Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3-2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen-Address registers are not modified after the transfer. 01 Incremented-Address registers are incremented by the number of transferred bytes. 10 Decrement-Address registers are decremented by the number of transferred bytes. 11 Updated-PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1-0 sz	Transfer Size 00 reserved

Table continues on the next page...

Table 7-34. STF Code Bits Field Descriptions (continued)

Field	Description
	01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5-0 pdssel	PD access selector 001000 is the only valid option
5-0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible stf instructions, the following table provides only a short list of all the possible write instructions:

11_01_10_01 11_01_10_10 11_01_10_11	stf Rn, PDAISZ8 ID stf Rn, PDAISZ16ID stf Rn, PDAISZ32ID	<ul style="list-style-type: none"> • Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA-1, 2, or 4 after write PD.
11_01_11_01 11_01_11_10 11_01_11_11	stf Rn, PDAISZ8 IU stf Rn, PDAISZ16 IU stf Rn, PDAI SZ32 IU	<ul style="list-style-type: none"> • <i>Update</i> destination pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PDA value is not modified by Rn • bytes present in PD are lost
11_00_10_00	stf Rn, PD	<ul style="list-style-type: none"> • Write "dsize" bytes of Rn in PD and automatically flush to destination target
11_11_11_11	stf Rn, PS	<ul style="list-style-type: none"> • Write status register
11_00_11_00	stf Rn, clrefPS	<ul style="list-style-type: none"> • Clear error flag if set

NOTE

When writing PD, size information is not important: It is embedded in the dsize field of PDA register. If dsize is 1, 2, or 4, then one, two, or four bytes from Rn is written to the PD register, and automatically flushed out to the destination target.

7.2.4.12.2.6 Peripheral DMA Read (ldf)-Read Mode

When received from an ldf instruction, the function code bits are interpreted as follows.

Table 7-36. LDF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s			ar	a			
PDA								
PD		p		cpy				
PS			pssel					

Table 7-37. LDF Code Bits Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
4 cpy (PD)	Copy Mode 0 standard access 1 copy mode access
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5-0 pssel	PS access selector 111111 is the only valid option to read PS

Table 7-38. Peripheral DMA LDF Instruction List

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PDIPF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PDICOPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are <i>not</i> the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

NOTE

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

7.2.4.12.2.7 Peripheral DMA Unit Copy Mode

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers.

Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for transfers that involve two targets of the same data path width.

Since copy mode is invoked with an ldf instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

7.2.4.12.2.8 Error Management

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

7.2.4.12.2.8.1 Immediate Errors

The following table lists all incorrect DMA register setups.

Table 7-39. Immediate Errors with Peripheral DMA

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSAISZ16IF stf Rn, PSAISZ16II stf Rn, PDAISZ16IF stf Rn, PDAISZ16II	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSAISZ32IF stf Rn, PSAISZ32II stf Rn, PDAISZ32IF stf Rn, PDAISZ32II	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]-PDA[1:0]	DMA instruction	Comments

Table continues on the next page...

Table 7-39. Immediate Errors with Peripheral DMA (continued)

Rn[1:0] values	DMA instruction	Comments
0x01 0x10 0x11	stf Rn, PSAISZ32IU stf Rn, PDAISZ32IU	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSAISZ16IU stf Rn, PDAISZ16IU	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	Comments	
stf Rn,PD ldf Rn,PD		If PDA size (dsize) has never been set up before an stf PD instruction (dsize=0) If PSA size (ssize) has never been set up before an ldf PD instruction (ssize=0)
ldf Rn,PDICPY		Copy mode is possible only between two targets whose data path width is identical. It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.

7.2.4.12.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an ldf PD or stf PD instruction would be the error of the previous DMA cycle.

Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral).

When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: [Read Error \(First Phase\)](#), [Write Error and Read Error \(Second Phase\)](#), and [Copy Mode Errors](#) handling.

7.2.4.12.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next ldf PD instruction and writing PSA, PDA, or PD will cancel the error flag.

The block returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. The following table details which instructions can be executed in this mode.

Table 7-40. Possibilities in ERROR READ Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn, PDICOPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the ldf PDICOPY, a copy loop is executed.
stf rn, PS	NO	PS is updated.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

7.2.4.12.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in [Read Error \(First Phase\)](#), when an ldf PD is executed while the block is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, stf instructions may raise an immediate error, and ldf instructions will not (as detailed in the table below).

Table 7-41. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an stf PS instruction.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Whatever the DMA direction (read or write), an ldf rn, PD instruction will show an immediate error.

7.2.4.12.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in [Read Error \(First Phase\)](#) and [Write Error and Read Error \(Second Phase\)](#) : It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an ldf instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another ldf instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual stf PD instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual stf PD instruction.

7.2.4.12.2.8.6 Error Check Example

The following code illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first bdf instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the ldf PS instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an ldf command sets the SF flag and any error returned on an stf instruction sets the DF flag. This can create a situation as shown in the example where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an ldf instruction.

Peripheral DMA Error Check

```

    clrf    0           // Clear SF and DF flags
    stf    R4, PD      // Write data to memory
    bdf    error_routine // Check for immediate error from write to PD.
    ldf    r3, PS      // Read PS (PS value in R3 can be ignored)
    bsf    error_routine // Check for bus error from "stf R4,PD"
                    // SF is set because it is a ldf instruction, even though
                    // the original error was a destination fault

```

7.2.4.12.2.9 Peripheral DMA Unit Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a stf PD instruction—assuming PDA is correctly programmed—it is automatically flushed to the destination.

An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

7.2.4.12.3 OnCE and Real-Time Debug

The On-Chip Emulation block (OnCE) is the debug interface to the SDMA.

It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core. The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

7.2.4.12.3.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the Arm platform Control interface when the OnCE is controlled by the Arm platform, as described in the "Using BP" section.

7.2.4.12.3.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core.

A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see [Arm platform Channel 0 Pointer \(SDMAARM_MC0PTR\)](#)): You can modify them through a regular memory access or the Arm platform control interface.

7.2.4.12.3.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

7.2.4.12.3.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode.

No hardware step execution mode is implemented in the OnCE, but this feature may be implemented at the software level with this instruction.

7.2.4.12.3.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status.

Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

7.2.4.13 The OnCE Controller

The OnCE controller receives commands from the Arm platform or from the JTAG controller. Each command is interpreted before being sent to the core.

7.2.4.13.1 OnCE Commands

A small set of commands supports the communication between the OnCE and the external world.

This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE. Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: The following table presents their formats.

Table 7-42. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TARM platform controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE. The nature of the associated data field is clearly identified. The `dmov` command is followed by a 32-bit data value (which is a data value for the SDMA); the `exec_once` and the `exec_core` commands are followed by a 16-bit data value (which is an instruction for the SDMA); the `rstatus` command is followed by a 16-bit control value (which is the content of the OnCE status register); the `rbuffer` command is followed by a 32-bit data value. The `debug_rqst` and the `run_core` commands are followed by a single bit data field (this is a bypass value). Finally, the `bypass` instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

7.2.4.13.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one Arm platform access to the OnCE is provided.

7.2.4.13.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal.

It produces shift-enable signals (`shift_ir` and `shift_dr`), and updates enable signals (`update_ir` and `update_dr`). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the `shift_ir` state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an `update_ir` signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (`bp_en`), instruction enable signal (`inst_en`), data enable (`data_en`), and status enable signal (`stat_en`).

During the `shift_dr` state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the Arm platform access is enabled.

7.2.4.13.2.2 Using the Arm platform

The Arm platform access to the OnCE is not the standard access, but it is required if the JTAG is not available.

For example, if the SDMA ROM is out of use on a chip in production, and the Arm platform needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an Arm platform access to the OnCE.

To drive the OnCE, the Arm platform uses some registers contained in the Arm platform Control block of the SDMA. These registers are accessed through the Arm platform peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the Arm platform Control block is listed below:

- **ONCE_ENB** register (1 bit, read/write)-This 1-bit register enables the Arm platform access to the OnCE. When this bit is set, the signals from the JTAG are ignored. When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.
- **ONCE_CMD** register (4 bits, read/write)-This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing "0001" in this register, a `dmov` command is executed.

NOTE

On the Arm platform side, the rstatus and bypass commands are not supported. This register is reset on a JTAG reset.

- **ONCE_DATA** register (32 bits, read/write)-This 32-bit register is connected to the SDMA data register. This register is used when executing a dmov or rbuffer command.

NOTE

Before requesting a dmov command, the 32-bit data to transfer must be written in the **ONCE_DATA** register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- **ONCE_INSTR** register (16 bits, read/write)-This 16-bit register is connected to the SDMA instruction register. This register is used when executing an exec_core or an exec_once command.

NOTE

Before requesting an exec_core or an exec_once command, the appropriate instruction must be written in the **ONCE_INSTR** register. This register is reset on a JTAG reset.

- **ONCE_STAT** register (16 bits, read only)-A read access to the **ONCE_STAT** register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the Arm platform controls the OnCE, therefore no register is defined in the Arm platform Control block to access the bypass register.

7.2.4.13.2.3 Conflicts Between the JTAG and the Arm platform Accesses

When Arm platform access to the SDMA OnCE is enabled (that is, when the bit in the **ONCE_ENB** register is set), the JTAG access is disabled. This guarantees that the block is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a dmov command from debug mode (with neither 0xffffffff nor 0x0 as dmov value: 0x5a5a5a5a is good).

- Execute another dmov command (the value here is not important).
- The returned value from the latter dmov command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

7.2.4.13.3 Executing a Command from the OnCE

All the commands defined in [OnCE Commands](#) can be accessed through the JTAG. The Arm platform can access all these commands except the rstatus command.

On the Arm platform side, the OnCE status is directly accessed by reading the ONCE_STAT register.

7.2.4.13.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: rstatus and rbuffer. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: dmov, run_core, exec_core, exec_once, and debug_rqst. These commands are core status dependent, as follows:

- During user mode only the debug_rqst is taken into account.
- During debug mode, all these commands are taken into account except the debug_rqst. For example, an exec_once command requested while not in debug mode has no effect.

7.2.4.13.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is sent after decoding the update_dr state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the Arm platform side, the request is sent after detecting a write access to the ONCE_CMD register. All the registers involved in this operation must be loaded first.

The following is an example of an `exec_core` command execution from the Arm platform side: After writing '010' in the `ONCE_CMD` register, the OnCE controller asks the SDMA to execute the instruction contained in the `ONCE_INSTR` register. The instruction involved should be available in the `ONCE_INSTR` register before the beginning of the execution.

7.2.4.13.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- **rstatus command execution**-The `rstatus` command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the `capture_dr` state, and shifted out after 16 TCK clock cycles in the `shift_dr` state. The `rstatus` command is not supported on the Arm platform side, but a status register is provided instead. The `rstatus` may be performed in both debug and user modes.
- **dmov command execution**-The `dmov` command accesses SDMA internal registers. Executing a `dmov` instruction exchanges the 32-bit data values between the SDMA data register and the general register `GReg[1]`.
- If the JTAG is used, the content of `GReg1` is captured in the SDMA data register during the `capture_dr` state, then it is shifted out after 32 TCK clock cycles in the `shift_dr` state. During the `update_dr` state, `GReg1` is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the Arm platform side, the data values contained in `GReg1` and the SDMA data register are exchanged after detecting a write access to the `ONCE_CMD` register. The `ONCE_DATA` register must therefore be loaded first.
- **exec_once command execution**-The `exec_once` command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.
- **Change of flow instructions as well as instructions that may cause a context switch are not supported:** The comprehensive list comprises `done/yield/yiedge` (except `done 5`), `BF`, `BT`, `BSF`, `BDF`, `JMP`, `JSR`, `JMPR`, `JSRR`, `RET`, and `LOOP`, as well as all the illegal instructions.

No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the `rstatus` OnCE command, monitoring the `debug_mode` pin, or checking the [OnCE Status Register \(SDMAARM_ONCE_STAT\)](#) register via the Arm platform control interface.

NOTE

Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. A request is sent to the core when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- run_core command execution-The run_core command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in [Restoring the Context](#).
- If the JTAG is used, a 1-bit bypass value is shifted in the bypass register in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the core is rerun when detecting a write access to the ONCE_CMD register.
- exec_core command execution-The exec_core command resumes program execution from any address. The 16-bit instruction provided with the exec_core overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted from any address. After executing an exec_core command, the SDMA leaves debug mode. The exec_core command is usually used with a jmp instruction.
- If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the SDMA reruns when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a jump to address 0x100 instruction.
- debug_rqst command execution-The debug_rqst command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the shift_dr state. A debug request is sent to the SDMA when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the debug request is sent when detecting a write access to the ONCE_CMD register. When the SDMA is already in debug mode, this command is simply ignored.
- rbuffer command execution-The rbuffer command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is

captured in the SDMA data register during the capture_dr state. The register is completely shifted out after maintaining the shift_dr state during 32 TCK clock cycles. If the OnCE is driven from the Arm platform side, the content of the RTB is captured in the ONCE_DATA register after detecting a write access to the ONCE_CMD register.

- bypass command execution-This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

7.2.4.13.4 Registers Descriptions

See [SDMACORE](#), and [SDMAARM](#), for detailed information on each register.

7.2.4.13.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request.

This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

7.2.4.13.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers-the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: addra_cond or addrb_cond. Every address register is cleared on a JTAG reset.

7.2.4.13.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit *i* of this register is set, then bit *i* of the

address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

7.2.4.13.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the data_cond condition.

The event cell data register is cleared on a JTAG reset.

7.2.4.13.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data.

Setting bit i of the event cell data mask register means that bit i of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

7.2.4.13.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode.

Refer to [Real Time Buffer](#) for more details.

7.2.4.13.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions.

The event cell control register is cleared on a JTAG reset. See also [OnCE Event Detection Unit](#) for more details.

7.2.4.13.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer.

See [Trace Buffer](#) for more details.

7.2.4.13.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register.

Refer to [OnCE Status Register \(SDMAARM_ONCE_STAT\)](#) for detailed description of the individual fields in the OSTAT register.

The following figure shows the OSTAT structure.

Table 7-43. OnCE Status Register (OnCE)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PST[3:0]				RCV	EDR	ODR	SWB	MST					ECDR[2:0]		

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the Arm platform control interface, and when ECDR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an rstatus command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the Arm platform access. Executing the rstatus command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the exec_once command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

7.2.4.13.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

7.2.4.13.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see [Figure 7-10](#)) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, $TCK < CLK/8$, limitation guarantees that all operations are performed as expected.

7.2.4.13.5.2 Synchronization Implementation

The figure found here shows the synchronization mechanism.

Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the `posedge_detected` and `negedge_detected` nets that are used to sample the TDI and TMS inputs into the respective `tdi` and `tms` flip-flops, and update the `tdo` flip-flop to yield the TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

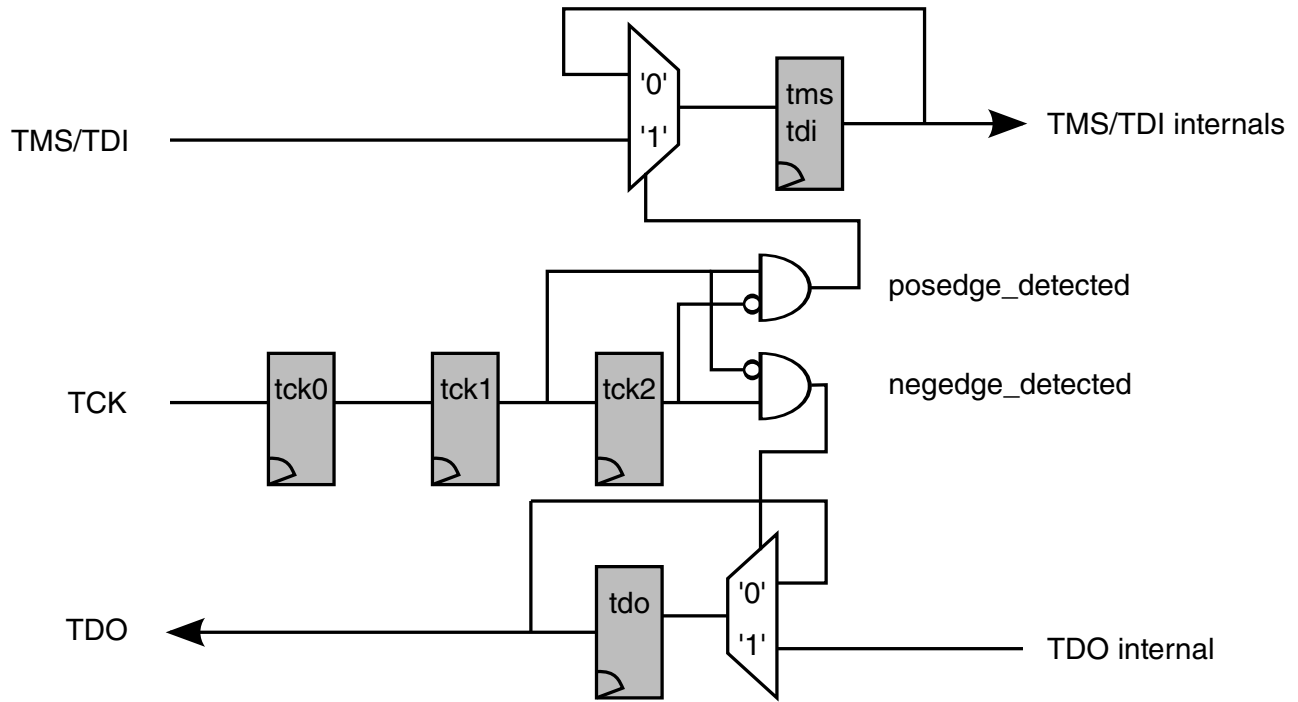

Figure 7-10. OnCE Synchronization Layer

The following figure shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

Figure 7-11. Synchronization Timings

7.2.4.13.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

7.2.4.14 Using the OnCE

This section provides the elements necessary to run the OnCE during a debug process.

In addition to the basic set of commands described in [OnCE Commands](#), more complex commands can be built to meet users' requirements.

7.2.4.14.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed.

This is the case for instances when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the `clk_gating_off` input.
- For the Arm platform access, the SDMA clock gating is automatically turned off when the Arm platform access is enabled (see [OnCE Enable \(SDMAARM_ONCE_ENB\)](#)).

7.2.4.14.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA.

It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA.

Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

7.2.4.14.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch.

The request is ignored when the core is already in debug mode. Refer to [Figure 7-3](#), which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

7.2.4.14.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see [Activating Clocks in Debug Mode](#)). The debug request line should be not be maintained high when the SDMA is in debug mode.

NOTE

The debug_rqst command (from the OnCE command set) is not supported during system reset.

7.2.4.14.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a debug_rqst command.

The debug_rqst command can be sent by the JTAG access or by an access on the Arm platform side (if the Arm platform access is enabled).

7.2.4.14.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

7.2.4.14.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus.

See [OnCE Event Detection Unit](#) for more details.

7.2.4.14.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the `exec_once` command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution.

Some instructions are not supported by the `exec_once` command: `done/yield/yiedge` (except `done 5`), `BF`, `BT`, `BSF`, `BDF`, `JMP`, `JSR`, `JMPR`, `JSRR`, `RET`, and `LOOP`, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

7.2.4.14.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the Arm platform and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);           // executing my_command with a data field
my_command(-);                    // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an Arm platform access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in); // returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

7.2.4.14.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like `dmov` or `exec_once`), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus();          // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-);    // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

7.2.4.14.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags.

Use the general register `GReg[1]` as an intermediate register to export the entire context of the SDMA.

The following example shows how to save `GReg[0]`, `GReg[1]`, `GReg[2]` and `GReg[3]`. The sequence of commands used to export additional general registers is very similar to this.

Save `GReg[0]`, `GReg[1]`, `GReg[2]`, and `GReg[3]`

```
GReg1_data = dmov(-);          // the value exported is the content of
GReg[1]
exec_once("mov GReg1,GReg0");  // puts the content of GReg[0] into
GReg[1]
GReg0_data = dmov(-);          // the value exported is the content of
GReg[0]
exec_once("mov GReg1, GReg2");  // puts the content of GReg[2] into
GReg[1]
GReg2_data = dmov(-);          // the value exported is the content of
GReg[2]
exec_once("mov GReg1, GReg3");  // puts the content of GReg[3] into
GReg[1]
GReg3_data = dmov(-);          // the value exported is the content of
GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a `done 5`, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the

values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5"); // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Exporting the Context

```
dmov(ctx_base_addr); // loading GReg[1] with the channel
context base address
exec_once("ld GReg0, (GReg1,0)"); // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)"); // get SPC-EPC into GReg1
Loop_data = dmov(-); // read back the value of Loop registers
exec_once("mov GReg1, GReg0"); // puts the PC info into GReg1
PC_data = dmov(-); // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

7.2.4.14.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE.

The example found hereshows how it is possible to modify the current channel context.

Modifying the Current Channel Context

```
dmov(Loop_data); // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1"); // copy to GReg[0]
dmov(PC_data); // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1"); // copy to GReg[2]
dmov(ctx_base_addr); // put channel context base address into
GReg[1]
exec_once("st GReg0, (GReg1,1)"); // restore Loop context
exec_once("st GReg2, (GReg1,0)"); // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once("cpShReg"); // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

The following example shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Restoring the General Register Context

```

dmov(GReg3_data); // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1"); // restore GReg[3]
dmov(GReg2_data); // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1"); // restore GReg[2]
dmov(GReg0_data); // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1"); // restore GReg[0]
dmov(GReg1_data); // restore GReg[1]

```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a mov instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a mov to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The cpShReg instruction is meant to provide a means for changing these register contents via the context memory.

7.2.4.14.5.4 Accessing the Memory

In the example shown here, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```

macro READ:           dmov(target_addr); // put the target
address in GReg[1]   exec_once("ld GReg1, (GReg1,0)"); // execute the
load instruction     res_data = dmov(-); // exports the result
data value

```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```

macro WRITE:           dmov(target_addr); // puts the
target address in GReg[1] exec_once("mov GReg0, GReg1"); // puts the target
address in GReg[0]     dmov(target_data); // puts the target
data in GReg[1]       exec_once("st GReg1, (GReg0,0)"); // performs the
store operation

```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

7.2.4.14.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA.

Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-); // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the `exec_core` command. The data field provided with this command must be the encoding of a jump instruction.

```
exec_core("jmp start_addr"); // rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

7.2.4.14.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

The following example shows the macro functions `READ` and `WRITE`, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2); // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the "bkpt_addr"
```

```

instr_save = READ(bkpt_addr/2);           // save the instruction before
overwriting                               // store the bkpt instruction
STORE("bkpt instruction",bkpt_addr/2);
in memory
exec_core("jmp run_addr");               // rerun the SDMA
rstatus(-);                             // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);          // restore the instruction
overwritten

```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

7.2.4.14.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

7.2.4.14.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers.

A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true.

Figure 7-12. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic block that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

The following figure shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference

values located in memory mapped registers—the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

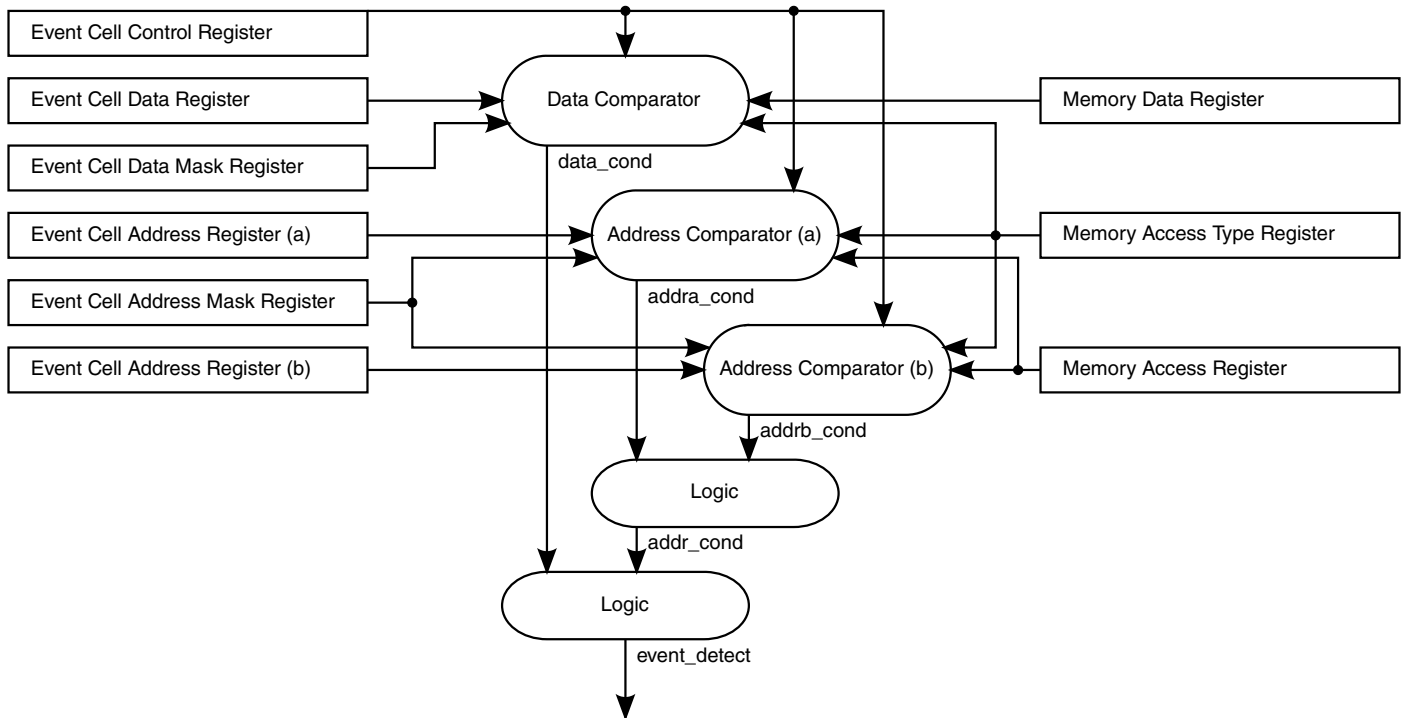

Figure 7-13. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

7.2.4.14.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

7.2.4.14.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE.

When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port `clk_gating_off`. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

When the OnCE is accessed through the Arm platform Control interface, clock gating is automatically turned off. This is done when bit 0 of the `ONCE_ENB` register (see [OnCE Enable \(SDMAARM_ONCE_ENB\)](#)) is set. A write access to this register is possible even when the OnCE clock is not running. If the Arm platform access is used, the bit in the `ONCE_ENB` register must be set before any attempt to access any other OnCE register.

7.2.4.14.7.2 Resets

The OnCE reset is different from the SDMA main reset.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

7.2.4.14.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution.

The content of this register may be exported through JTAG ports without stopping the core.

7.2.4.14.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution.

The following figure shows an overview of the Trace Buffer.

Figure 7-14. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is as follows:

```
exec_once("mov r1, TB");           // stores the oldest change-of-flow in
GReg1
dmov(-);                          // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

7.2.4.14.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE.

Executing an `rbuffer` command (see [The OnCE Controller](#) for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a `rbuffer` command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

7.2.4.14.8.3 Emulation Pin

The `debug_matched_event` emulation pin reflects the matching condition status detected by the Event Detection Unit.

Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

7.2.4.14.8.4 Real-Time Debug Outputs

The table found here shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 7-44. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	<p>The core_state bits reflect the state of the SDMA core.</p> <ul style="list-style-type: none"> • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the core idle state); the "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel</p>
debug_yield	<p>Pulse that is active when a yield (done 0) or a yieldge (done 1) instruction is executed.</p> <p>0 - 1 yield/yieldge executed</p>
debug_core_run	<p>Active when the SDMA core is executing instructions.</p> <p>0 Debug or sleep mode</p>

Table continues on the next page...

Table 7-44. Real-Time Debug Output Pins (continued)

Pin	Description
	1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (ld, st, ldf, or stf instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, "no access" is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 PSA 6 PDA 7 PD 8 PS 9 RESERVED 10 RESERVED 11 RESERVED 12 RESERVED 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register

Table continues on the next page...

Table 7-44. Real-Time Debug Output Pins (continued)

Pin	Description
	18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1) (as described in SDMAARM). The following two parameters are available for every line: <ul style="list-style-type: none"> • CNF-Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]-Gives the number of the DMA request or channel to monitor

The `matched_event` emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the [Configuration Register \(SDMAARM_CONFIG\)](#) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

7.2.5 Instruction Set

7.2.5.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

```

x...x - don't care

rrr - destination/source general register

sss - additional source general register

bbb - general register used as address base register

dddd - address displacement

nnnn - bit number
uuuuuuu - function unit command bits

pppppppp - branch displacement (signed)

iiiiiii - 8-bit immediate

jjj - control bit to clear

ff - flag to clear
00000jjj00000000 - done (done,yield,wait)
00000jjj00000001 - notify
00000xxx00000010 - reserved
00000xxx00000011 - reserved

7.2.5.2 SDMA Instruction Set

This section describes all the useful instructions from the SDMA set.

Table 7-45. SDMA Instruction List

Instruction	Description	Page
ADD	Addition	ADD (Addition)
ADDI	Add with Immediate Value	ADDI (Add with Immediate Value)
AND	Logical AND	AND (Logical AND)
ANDI	Logical AND with Immediate Value	ANDI (Logical AND with Immediate Value)
ANDN	Logical AND NOT	ANDN (Logical AND NOT)
ANDNI	Logical AND with Negated Immediate Value	ANDNI (Logical AND with Negated Immediate Value)
ASR1	Arithmetic Shift Right by 1 Bit	ASR1 (Arithmetic Shift Right by 1 Bit)
BCLRI	Bit Clear Immediate	BCLRI1 (Bit Clear Immediate)
BDF	Conditional Branch if Destination Fault	BDF (Conditional Branch if Destination Fault)
BF	Conditional Branch if False	Functional Units Programming Model
BSETI	Bit Set Immediate	BSETI (Bit Set Immediate)
BSF	Conditional Branch if Source Fault	BSF (Conditional Branch if Source Fault)
BT	Conditional Branch if True	BT (Conditional Branch if True)
BTSTI	Bit Test immediate	BTSTI (Bit Test immediate)
CLRF	Clear Arm platform flags	CLRF (Clear Arm platform flags)
CMPEQ	Compare for Equal	CMPEQ (Compare for Equal)
CMPEQI	Compare with Immediate for Equal	CMPEQI (Compare with Immediate for Equal)
CMPHS	Compare for Higher or Same	CMPHS (Compare for Higher or Same)
CMPLT	Compare for Less Than	CMPLT (Compare for Less Than)
cpShReg	Update Context of PCU Registers and Flags	cpShReg (Update Context of PCU Registers and Flag)
DONE	DONE, Yield	DONE (DONE, Yield)
ILLEGAL	ILLEGAL Instruction	ILLEGAL (ILLEGAL Instruction)
JMP	Unconditional Jump Immediate	JMP (Unconditional Jump Immediate)
JMPR	Unconditional Jump	JMPR (Unconditional Jump)
JSR	Unconditional Jump to Subroutine Immediate	JSR (Unconditional Jump to Subroutine Immediate)
JSRR	Unconditional Jump to Subroutine	JSRR (Unconditional Jump to Subroutine)
LD	Load Register	LD (Load Register)
LDF	Load Register from Functional Unit	LDF (Load Register from Functional Unit)
LDI	Load Register with Immediate Value	LDI (Load Register with Immediate Value)
LDRPC	Load from RPC to Register	LDRPC (Load from RPC to Register)

Table continues on the next page...

**Table 7-45. SDMA Instruction List
(continued)**

Instruction	Description	Page
LOOP	Hardware Loop	LOOP (Hardware Loop)
LSL1	Logical Shift Left by 1 Bit	LSL1 (Logical Shift Left by 1 Bit)
LSR1	Logical Shift Right by 1 Bit	LSR1 (Logical Shift Right by 1 Bit)
MOV	Logical Move	MOV (Logical Move)
NOTIFY	Notify to Arm platform	NOTIFY (Notify to Arm platform)
OR	Logical OR	OR (Logical OR)
ORI	Logical OR with Immediate Value	ORI (Logical OR with Immediate Value)
RET	Return from Subroutine	RET (Return from Subroutine)
REVB	Reverse Byte Order	REVB (Reverse Byte Order)
REVBLO	Reverse Low Order Bytes	Reverse Low Order Bytes(REVBLO)
ROR1	Rotate Right by 1 Bit	ROR1 (Rotate Right by 1 Bit)
RORB	Rotate Right by 1 Byte	RORB (Rotate Right by 1 Byte)
SOFTBKPT	Software Breakpoint	SOFTBKPT (Software Breakpoint)
ST	Store Register	ST (Store Register)
STF	Store Register in Functional Unit	STF (Store Register in Functional Unit)
SUB	Subtract	SUB (Subtract)
SUBI	Subtract with Immediate	SUBI (Subtract with Immediate)
TST	Test with Zero	TST (Test with Zero)
TSTI	Test Immediate	TSTI (Test Immediate)
XOR	Logical Exclusive OR	XOR (Logical Exclusive OR)
XORI	Exclusive OR with Immediate	XORI (Exclusive OR with Immediate)

7.2.5.2.1 ADD (Addition)

Operation:

$$GReg[r] \leftarrow GReg[s] + GReg[r]$$

$$T \leftarrow (GReg[r] == 0)$$

Assembler:

Syntax: `add r,s`

Example: `add 0,3`

ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Cycles: 1

Description: Performs the ADDition of the source general register s and the destination general register r , and stores the result in the destination general register r . The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.2 ADDI (Add with Immediate Value)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] + \text{immediate}$

$T \leftarrow (\text{GReg}[r] == 0)$

Assembler:

Syntax: `addi r,immediate`

Example: `add 6,112`

ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Adds a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Smart Direct Memory Access Controller (SDMA)

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

7.2.5.2.3 AND (Logical AND)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s] \ \& \ \text{GReg}[r]$

Assembler:

Syntax: `and r,s`

Example: `and 1,2`

AND GReg[1] and GReg[2] and store the result in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register s and the destination general register r , and stores the result in the destination general register r .

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.4 ANDI (Logical AND with Immediate Value)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \& \text{immediate}$

Assembler:

Syntax: `andi r,immediate`

Example: `andi 7,45`

AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

- 000 - GReg[0]
- 001 - GReg[1]
- 010 - GReg[2]
- 011 - GReg[3]
- 100 - GReg[4]
- 101 - GReg[5]
- 110 - GReg[6]
- 111 - GReg[7]

iiiiiii - immediate value:

- 00000000 - 0
- 00000001 - 1
- ...
- 11111110 - 254
- 11111111 - 255

7.2.5.2.5 ANDN (Logical AND NOT)

Operation:

$GReg[r] \leftarrow \sim GReg[s] \ \& \ GReg[r]$

Assembler:

Syntax: `andn r,s`

Example: `andn 3,4`

AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

Table 7-46. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	0	s	s	s

Instruction Fields:

rrr /sss - destination register field:

- 000 - GReg[0]
- 001 - GReg[1]
- 010 - GReg[2]
- 011 - GReg[3]
- 100 - GReg[4]
- 101 - GReg[5]
- 110 - GReg[6]
- 111 - GReg[7]

7.2.5.2.6 ANDNI (Logical AND with Negated Immediate Value)**Operation:**

$GReg[r] \leftarrow GReg[r] \& \sim immediate$

Assembler:

Syntax: `andni r,immediate`

Example: `andni 0,2`

AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

- 000 - GReg[0]
- 001 - GReg[1]
- 010 - GReg[2]
- 011 - GReg[3]
- 100 - GReg[4]
- 101 - GReg[5]
- 110 - GReg[6]
- 111 - GReg[7]

iiiiiii - immediate value:

- 00000000 - 0
- 00000001 - 1
- ...
- 11111110 - 254
- 11111111 - 255

7.2.5.2.7 ASR1 (Arithmetic Shift Right by 1 Bit)

Operation:

$$\text{GReg}[r] : \{b_{31}, b_{30}, \dots, b_1, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, b_{31}, b_{30}, \dots, b_1\}$$

Assembler:

Syntax: asr1 r

Example: asr1 3

divide by 2 the signed value of GReg[3] and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

Table 7-47. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.8 BCLR1 (Bit Clear Immediate)

Operation:

$$\text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, 0, b_{(i-1)}, \dots, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, b_{(i)}, b_{(i-1)}, \dots, b_0\}$$

Assembler:

Syntax: `bclri r,i`

Example: `bclri 1,12`

clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	1	i	i	i	i	i

rrr - register field:

000 - GReg[0]

Smart Direct Memory Access Controller (SDMA)

001 - GReg [1]

010 - GReg [2]

011 - GReg [3]

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

iiii - immediate value:

00000 - 0

00001 - 1

...

11110 - 30

11111 - 31

7.2.5.2.9 BDF (Conditional Branch if Destination Fault)

Operation:

if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

Assembler:

Syntax: bdf label

Example: bdf LLL

Jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

7.2.5.2.10 BF (Conditional Branch if False)

Operation:

```
if (T == 0)
PC ← PC + 1 + displacement
else
PC ← PC + 1
```

Assembler:

Syntax: bf label

Example: bf LLL

Jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

- 00000000 - 0
- 00000001 - 1
- ...
- 01111110 - 126
- 01111111 - 127
- 10000000 - (-128)
- 10000001 - (-127)
- ...
- 11111110 - (-2)
- 11111111 - (-1)

7.2.5.2.11 BSETI (Bit Set Immediate)

Operation:

$$GReg[r] : \{b_{31}, \dots, b_{(i+1)}, 1, b_{(i-1)}, \dots, b_0\} \leftarrow GReg[r] : \{b_{31}, \dots, b_{(i+1)}, b_{(i)}, b_{(i-1)}, \dots, b_0\}$$

Assembler:

Syntax: bseti r,i

Example: bseti 6,5

Set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number i in the selected General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

Instruction Fields:

rrr - register field:

- 000 - GReg[0]
- 001 - GReg[1]

010 - GReg [2]
 011 - GReg [3]
 100 - GReg [4]
 101 - GReg [5]
 110 - GReg [6]
 111 - GReg [7]

iiii - bit number field:

00000 - 0
 00001 - 1
 ...
 11110 - 30
 11111 - 31

7.2.5.2.12 BSF (Conditional Branch if Source Fault)

Operation:

if (SF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

Assembler:

Syntax: bsf label

Example: bsf LLL

Jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

7.2.5.2.13 BT (Conditional Branch if True)

Operation

```
if (T == 1)
    PC ← PC + 1 + displacement
else
    PC ← PC + 1
```

Assembler

```
Syntax: bt label
bt LLL
```

Jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

7.2.5.2.14 BTSTI (Bit Test immediate)

Operation:

$T \leftarrow \text{GReg}[r]:b(i)$

Assembler:

Syntax: `btsti r,i`

Example: `btsti 2,29`

Test bit 29 in GReg[2] and copy its value in flag T

CPU flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

Instruction Format:

Table 7-48. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

Smart Direct Memory Access Controller (SDMA)

010 - GReg [2]

011 - GReg [3]

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

iiii - bit number field:

0000 - 0

0001 - 1

...

11110 - 30

11111 - 31

7.2.5.2.15 CLRF (Clear Arm platform flags)

Operation:

```
if (ff%2 == 0)
```

```
SF ← 0
```

```
if (ff/2 == 0)
```

```
DF ← 0
```

Assembler:

Syntax: `clrf ff`

Example: `clrf 2`

Clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the Arm platform fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

ff - flags field:

00 - clear SF and clear DF
 01 - clear DF
 10 - clear
 SF 11 - no clear

7.2.5.2.16 CMPEQ (Compare for Equal)

Operation:

$T \leftarrow (\text{GReg}[s] == \text{GReg}[r])$

Assembler:

Syntax: `cmpeq r,s`

Example: `cmpeq 7,5`

Compare GReg[7] and GReg[5] and set flag T if they are equal

CPU flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

7.2.5.2.17 CMPEQI (Compare with Immediate for Equal)

Operation:

$T \leftarrow (\text{GReg}[r] == \text{immediate})$

Assembler:

Syntax: `cmpeqi r,immediate`

Example: `cmpeqi 2,13`

Compare GReg[2] and decimal value 13 and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

7.2.5.2.18 CMPHS (Compare for Higher or Same)

Operation:

$$T \leftarrow (\text{GReg}[r] \geq \text{GReg}[s])$$

Assembler:

Syntax: `cmphs r,s`Example: `cmphs 0,1`

Compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.19 CMPLT (Compare for Less Than)

Operation:

Smart Direct Memory Access Controller (SDMA)

$T \leftarrow (\text{GReg}[r] < \text{GReg}[s])$

Assembler:

Syntax: `cmplt r,s`

Example: `cmplt 7,4`

Compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.20 cpShReg (Update Context of PCU Registers and Flag)

Assembler:

Syntax: `cpShReg`

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC, LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done 5 operation.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

7.2.5.2.21 DONE (DONE, Yield)**Operation:**

```

if (jjj&6 == 2) HE[CCR] ← 0
if (jjj == 3) HI[CCR] ← 1
if (jjj == 4) EP[CCR] ← 0

if ((jjj == 0) && (NCP > CCP)) CCR ← NCR
else if ((jjj == 1) && (NCP >= CCP))
CCR ← NCR
else
CCR ← NCR

```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

Assembler:

Syntax: done jjj

Example: done 3

Clear HE bit for the current channel, send an interrupt to the Arm platform for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding Arm platform by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched. If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending). If no flag is modified, the reschedule can allow the replacement of the current

channel by another channel with a priority strictly greater than the current channel priority (yield). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (yieldge). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

jjj - Channel Flags field:

000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)

001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)

010 - Clear HE for the current channel and reschedule
 011 - Clear HE, set HI for the current channel and reschedule

100 - Clear EP for the current channel and reschedule

101 - Reserved for debug to copy relevant registers into context memory

110 - RESERVED

111 - RESERVED

For the scheduling rules, refer to [Scheduler Functional Description](#). Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a Arm platform start via the [Channel Start \(SDMAARM_HSTART\)](#) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a Arm platform start via the [Channel Start \(SDMAARM_HSTART\)](#) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the Arm platform upon closure;

- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

7.2.5.2.22 ILLEGAL (ILLEGAL Instruction)

Operation:

PC ← 0001

Assembler:

Syntax: illegal

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format

Table 7-49. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

7.2.5.2.23 JMP (Unconditional Jump Immediate)

Operation:

PC ← absolute_address

Assembler:

Syntax: jmp label

Example: jmp LLL

The assembler translates the label to the exact address

CPU Flags: Unaffected

Cycles: 2

Smart Direct Memory Access Controller (SDMA)

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

0000000000000001 - 1

...

1111111111111110 - 16382

1111111111111111 - 16383

7.2.5.2.24 JMPR (Unconditional Jump)

Operation:

PC \leftarrow GReg[r]

Assembler:

Syntax: jmp r

Example: jmp 0

Jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg [2]
 011 - GReg [3]
 100 - GReg [4]
 101 - GReg [5]
 110 - GReg [6]
 111 - GReg [7]

7.2.5.2.25 JSR (Unconditional Jump to Subroutine Immediate)

Operation:

$RPC \leftarrow PC + 1$
 $PC \leftarrow \text{absolute_address}$

Assembler:

Syntax: jsr r
 Example: jsr LLL

Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

0000000000000000 - 0
 0000000000000001 - 1
 ...
 1111111111111110 - 16382
 1111111111111111 - 16383

7.2.5.2.26 JSRR (Unconditional Jump to Subroutine)

Operation:

Smart Direct Memory Access Controller (SDMA)

$RPC \leftarrow PC + 1$

$PC \leftarrow GReg[r]$

Assembler:

Syntax: `jsrr r`

Example: `jsrr 5`

Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.27 LD (Load Register)

Operation:

$GReg[r] \leftarrow [GReg[b] + displacement]$

if (transfer_error)

SF \leftarrow 1

else

SF \leftarrow 0

Assembler:

Syntax: `ld r, (b, displacement)`

Example: `ld 1, (2, 23)`

Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

rrr / bbb - register field:

000 - GReg[0]

001 - GReg[1]

...

111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1

...

11111 - 31

7.2.5.2.28 LDF (Load Register from Functional Unit)**Operation:**

$\text{GReg}[r] \leftarrow [\text{fu_address}]$

if (transfer_error)

SF \leftarrow 1

else

SF ←0

fu_address is an 8-bit field and depends on addressed functional unit

Assembler:

Syntax: ldf r, fu_address

Example: ldf 0, 13

Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- [Burst DMA Read \(ldf\)](#) for Burst DMA
- [Peripheral DMA Read \(ldf\)-Read Mode](#) for Peripheral DMA

Instruction Fields:

rrr - register field:

- 000 - GReg [0]
- 001 - GReg [1]
- 010 - GReg [2]
- 011 - GReg [3]
- 100 - GReg [4]
- 101 - GReg [5]
- 110 - GReg [6]
- 111 - GReg [7]

fffffff - functional unit source register and action (unspecified values are reserved):

```

00000000 - MSA
00000100 - MDA
00001001 - MD byte
00001010 - MD halfword
00001011 - MD word
00001100 - MS
00101001 - MD byte - prefetch
00101010 - MD halfword - prefetch
00101011 - MD word - prefetch
01000000 - DSA

11000000 - PSA
11001000 - PD
11010000 - PDA
11011000 - PD in copy mode (rrr contents are lost)
11101000 - PD - prefetch next data
11111111 - PS

```

7.2.5.2.29 LDI (Load Register with Immediate Value)

Operation:

$GReg[r] \leftarrow \text{immediate}$

Assembler:

Syntax: `ldi r,immediate`

Example: `ldi 6,1`

loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

Smart Direct Memory Access Controller (SDMA)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

7.2.5.2.30 LDRPC (Load from RPC to Register)

Operation:

GReg[r] ← RPC

Assembler:

Syntax: `ldrpc r`

Example: `ldrpc 3`

copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.31 LOOP (Hardware Loop)

Operation:

```

if (ff%2 == 0)
    SF ← 0
if (ff/2 == 0)
    DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
    PC ← PC + loop_size + 1
else
{
    SPC ← PC + 1
    EPC ← PC + loop_size + 1
    LM ← 1
    PC ← PC + 1
}

```

during every instruction execution in the loop:

```

if ((SF == 1) || (DF == 1))
{

```

Smart Direct Memory Access Controller (SDMA)

```
    LM ← 0
    PC ← EPC
}
else if ((PC + 1) == EPC)
{
    GReg[0] ← GReg[0] - 1
    if (GReg[0] == 0)
    {
        LM ← 0
        PC ← EPC
    }
    else
        PC ← SPC
}
else
    PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)
    T ← 1
else
    T ← 0
```

Assembler:

Syntax: loop n{,ff}

Example: loop 3,1

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the ff field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The loop instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times. The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body). The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

Limitations:

1. 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. 2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. 3. The empty loop (0 instruction in the body) is forbidden.
4. 4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

Instruction Fields:

ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear SF

Smart Direct Memory Access Controller (SDMA)

11 - no clear

nnnnnnnn - loop size

00000000 - empty loop: forbidden value

00000001 - 1 instruction in the loop

00000010 - 2 instructions in the loop

...

11111111 - 255 instructions in the loop

7.2.5.2.32 LSL1 (Logical Shift Left by 1 Bit)

Operation:

$GReg[r] : \{b30, \dots, b1, b0, 0\} \leftarrow GReg[r] : \{b31, b30, \dots, b1, b0\}$

Assembler:

Syntax: `lsl1 r`

Example: `lsl1 2`

multiplies by 2 the value in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.33 LSR1 (Logical Shift Right by 1 Bit)

Operation:

$$\text{GReg}[r] : \{0, b_{31}, b_{30}, \dots, b_1\} \leftarrow \text{GReg}[r] : \{b_{31}, b_{30}, \dots, b_1, b_0\}$$

Assembler:

Syntax: lsr1 r

Example: lsr1 4

divides by 2 the unsigned value contained in GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

rrr - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.34 MOV (Logical Move)

Operation:

$$\text{GReg}[r] \leftarrow \text{GReg}[s]$$

Assembler:

Smart Direct Memory Access Controller (SDMA)

Syntax: `mov r,s`

Example: `mov 4,0`

copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register *s* to the destination General Register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.35 NOTIFY (Notify to Arm platform)

Operation:

```
if (jjj & 4 == 0)
{
    if (jjj&2 == 2)
        HE[CCR] ← 0
    if (jjj&1== 1)
        HI[CCR] ← 1
}
else if (jjj == 4)
```

```
EP[CCR] ← 0
```

```
else
```

(CCR stands for Current Channel Register)

Assembler:

```
Syntax: notify jjj
```

```
Example: notify 3
```

clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding Arm platform by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

jjj - Channel Flags field:

000 - unused

001 - set HI for the current channel

010 - clear HE for the current channel

011 - clear HE, set HI for the current channel

100 - clear EP for the current channel

101 - RESERVED

110 - RESERVED

111 - RESERVED

7.2.5.2.36 OR (Logical OR)

Operation:

```
GReg[r] ← GReg[s] | GReg[r]
```

Assembler:

```
Syntax: or r,s
```

Smart Direct Memory Access Controller (SDMA)

Example: `ori 3,6`

ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the OR of the source General Register *s* and the destination General Register *r*, and stores the result in the destination General Register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.37 ORI (Logical OR with Immediate Value)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \mid \text{immediate}$

Assembler:

Syntax: `ori r,immediate`

Example: `ori 1,56`

ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

Description: Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

7.2.5.2.38 RET (Return from Subroutine)

Operation:

PC ← RPC

Assembler:

Syntax: ret

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

7.2.5.2.39 REVB (Reverse Byte Order)

Operation:

$GReg[r] : \{B3, B2, B1, B0\} \leftarrow GReg[r] : \{B0, B1, B2, B3\}$

Assembler:

Syntax: `revb r`

Example: `revb 5`

reverses bytes order in `GReg[5]`

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

Instruction Fields:

rrr - register field:

000 - `GReg[0]`

001 - `GReg[1]`

010 - `GReg[2]`

011 - `GReg[3]`

100 - `GReg[4]`

101 - `GReg[5]`

110 - `GReg[6]`

111 - `GReg[7]`

7.2.5.2.40 Reverse Low Order Bytes(REVBLO)

Operation:

$$\text{GReg}[r] : \{B3, B2, B0, B1\} \leftarrow \text{GReg}[r] : \{B3, B2, B1, B0\}$$

Assembler:

Syntax: revblo r

Example: revblo 0

reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.41 ROR1 (Rotate Right by 1 Bit)

Operation:

$$\text{GReg}[r] : \{b0, b31, b30, \dots, b1\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$$

Assembler:

Syntax: ror1 r

Example: ror1 3

rotates bits to the right in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.42 RORB (Rotate Right by 1 Byte)

Operation:

$GReg[r] : \{B0, B3, B2, B1\} \leftarrow GReg[r] : \{B3, B2, B1, B0\}$

Assembler:

Syntax: rorb r

Example: rorb 2

rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.43 SOFTBKPT (Software Breakpoint)

Operation:

Stops the current script and enters debug mode

Assembler:

```
softbkpt
```

CPU Flags: Unaffected

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in [OnCE and Real-Time Debug](#).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

7.2.5.2.44 ST (Store Register)

Operation:

$[GReg[b] + displacement] \leftarrow GReg[r]$

Smart Direct Memory Access Controller (SDMA)

```
if (transfer_error)
    DF ← 1
else
    DF ← 0
```

Assembler:

Syntax: `st r, (b, displacement)`

Example: `st 7, (0, 9)`

stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

rrr / bbb - register field:

000 - GReg[0]
001 - GReg[1]
010 - GReg[2]
011 - GReg[3]
100 - GReg[4]
101 - GReg[5]
110 - GReg[6]
111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1
 ...
 11111 - 31

7.2.5.2.45 STF (Store Register in Functional Unit)

Operation:

```
[fu_address] ← GReg[r] 0
if (transfer_error) 0
DF ← 1 0
else 0
DF ← 0
```

fu_address is an 8-bit field

Assembler:

Syntax: stf r, fu_address

Example: stf 3, 0x2B

stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Table 7-50. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	1	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the STF instruction usage with each functional unit:

- [Burst DMA Write \(stf\)](#) for Burst DMA
- [Peripheral DMA Write \(stf\)-Write Mode](#) for Peripheral DMA

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

fffffff - functional unit destination register and action (unspecified values are reserved):

00000000 - MSA in incremented mode

00000100 - MDA in incremented mode

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - clear MS error flag

00001111 - MS

00010000 - MSA in frozen mode

00010100 - MDA in frozen mode

00011000 - MD in copy mode - number of words in rrr

00100000 - MSA in incremented mode - start prefetch

00101000 - MD no data - flush

00101001 - MD byte - flush

00101010 - MD halfword - flush

00101011 - MD word - flush

00110000 - MSA in frozen mode - start prefetch

11000001 - PSA in frozen mode - 8-bit data width
11000010 - PSA in frozen mode - 16-bit data width
11000011 - PSA in frozen mode - 32-bit data width
11000101 - PSA in incremented mode - 8-bit data width
11000110 - PSA in incremented mode - 16-bit data width
11000111 - PSA in incremented mode - 32-bit data width
11001000 - PD
11001001 - PSA in decremented mode - 8-bit data width
11001010 - PSA in decremented mode - 16-bit data width
11001011 - PSA in decremented mode - 32-bit data width
11001100 - clear PS error flag
11001101 - PSA data width becomes 8-bit
11001110 - PSA data width becomes 16-bit
11001111 - PSA data width becomes 32-bit
11010001 - PDA in frozen mode - 8-bit data width
11010010 - PDA in frozen mode - 16-bit data width
11010011 - PDA in frozen mode - 32-bit data width
11010101 - PDA in incremented mode - 8-bit data width
11010110 - PDA in incremented mode - 16-bit data width
11010111 - PDA in incremented mode - 32-bit data width
11011001 - PDA in decremented mode - 8-bit data width
11011010 - PDA in decremented mode - 16-bit data width
11011011 - PDA in decremented mode - 32-bit data width
11011101 - PDA data width becomes 8-bit
11011110 - PDA data width becomes 16-bit
11011111 - PDA data width becomes 32-bit

11100001 - PSA in frozen mode - 8-bit data width - prefetch data
11100010 - PSA in frozen mode - 16-bit data width - prefetch data
11100011 - PSA in frozen mode - 32-bit data width - prefetch data
11100101 - PSA in incremented mode - 8-bit data width - prefetch data
11100110 - PSA in incremented mode - 16-bit data width - prefetch data
11100111 - PSA in incremented mode - 32-bit data width - prefetch data
11101001 - PSA in decremented mode - 8-bit data width - prefetch data
11101010 - PSA in decremented mode - 16-bit data width - prefetch data
11101011 - PSA in decremented mode - 32-bit data width - prefetch data
11101101 - PSA data width becomes 8-bit - prefetch data
11101110 - PSA data width becomes 16-bit - prefetch data
11101111 - PSA data width becomes 32-bit - prefetch data
11111111- PS

7.2.5.2.46 SUB (Subtract)

Operation:

$GReg[r] \leftarrow GReg[r] - GReg[s]$

$T \leftarrow (GReg[r] == 0)$

Assembler:

Syntax: `sub r,s`

Example: `sub 4,7`

SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register *s* from the destination General Register *r*, and stores the result in the destination General Register *r*. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

Instruction Fields:

rrr / sss - register fields:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

7.2.5.2.47 SUBI (Subtract with Immediate)

Operation:

$GReg[r] \leftarrow GReg[r] - \text{immediate}$

$T \leftarrow (GReg[r] == 0)$

Assembler:

Syntax: `sub r,immediate`

Example: `sub 1,255`

SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

- 000 - GReg[0]
- 001 - GReg[1]
- 010 - GReg[2]
- 011 - GReg[3]
- 100 - GReg[4]
- 101 - GReg[5]
- 110 - GReg[6]
- 111 - GReg[7]

iiiiiii - immediate value:

- 00000000 - 0
- 00000001 - 1
- ...
- 11111110 - 254
- 11111111 - 255

7.2.5.2.48 TST (Test with Zero)

Operation:

$$T \leftarrow ((\text{GReg}[s] \ \& \ \text{GReg}[r]) \ != \ 0)$$

Assembler:

Syntax: `tst r,s`

Example: `tst 2,3`

ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

Instruction Fields:**rrr / sss - register field:**

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

7.2.5.2.49 TSTI (Test Immediate)**Operation:**

$$T \leftarrow ((\text{GReg}[r] \ \& \ \text{immediate}) \neq 0)$$
Assembler:

Syntax: `tsti r,immediate`

Example: `tsti 5,13`

ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:**rrr - destination register field:**

000 - GReg[0]
 001 - GReg[1]

Smart Direct Memory Access Controller (SDMA)

010 - GReg [2]

011 - GReg [3]

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

7.2.5.2.50 XOR (Logical Exclusive OR)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s] \wedge \text{GReg}[r]$

Assembler:

Syntax: `xor r,s`

Example: `xor 0,3`

XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg [0]

001 - GReg [1]

010 - GReg [2]
 011 - GReg [3]
 100 - GReg [4]
 101 - GReg [5]
 110 - GReg [6]
 111 - GReg [7]

7.2.5.2.51 XORI (Exclusive OR with Immediate)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \wedge \text{immediate}$

Assembler:

Syntax: `xori r,immediate`

Example: `xor 7,5`

XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg [0]
 001 - GReg [1]
 010 - GReg [2]
 011 - GReg [3]
 100 - GReg [4]
 101 - GReg [5]
 110 - GReg [6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

7.2.5.2.52 YIELD, YIELDGE (DONE, Yield)

By default, unsupported assembler syntax. Can be aliased to the corresponding done instructions (yield = done 0; yieldge = done 1). Refer to the done instruction description [DONE \(DONE, Yield\)](#).

7.2.6 Software Restrictions

7.2.6.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior.

An example of the sequence which could result in undefined results is shown in the following example:

Instruction sequence not supported

```
stf r1, MSA|PF      ; Update source address, triggers data pre-fetch in the
                    ; background
mov R0,R0           ; Execute multiple assembly instructions, none of which
                    ; read
mov R0,R0           ; or write data to/from MD
stf MD|SZ0|FL      ; Flush FIFO without writing data. If the pre-fetch is still
                    ; in progress when this instruction is executed, there
                    ; could be undefined operation
```

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Work-Around to previous example

```
stf r1, MSA|PF      ; Update source address, triggers data pre-fetch.
```

```

mov R0,R0          ; Execute multiple assembly instructions, none of which
                  ; read
mov R0,R0          ; or write data to/from MD
ldf r2, MD         ; dummy read of MD to ensure pre-fetch is complete
                  ; before the next instruction
stf MD|SZ0|FL     ; Flush FIFO without writing data

```

7.2.7 Application Notes

7.2.7.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application.

The boot code is run after reset when channel 0 is started by the Arm platform. The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the Arm platform memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation (see [SDMA Scripts](#)).

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

Figure 7-15. Data Structures Layout

The previous figure shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MC0PTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described [Buffer Descriptor Format](#).

7.2.7.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as, shown in the figure found here.

A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the Arm platform processor memory. The CCB contains a pointer to the base BD as well as the current BD.

Table 7-51. Buffer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Command									-	-	L	R	I	C	W	D	Count														
Buffer Address																															
Extended Buffer Address																															

Table 7-52. Buffer Descriptor Field Descriptions

Field	Description
31-24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootload script are defined in Buffer Descriptor Commands for Bootload scripts . Refer to the individual script definition in script library documents in SDMA Scripts for command field definitions for other scripts.
23	Reserved
22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over. This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set. For example, when the DSP prepares a single buffer descriptor with count equals to 25 and Arm platform prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to Arm platform, the DSP buffer descriptor is normally closed while the Arm platform buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the Arm platform. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	Continuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers. The Continuous bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the Arm platform wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONtinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 Arm platform owns the buffer. 1 SDMA owns the buffer
15-0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31-0	Buffer address. Address pointer to the data buffer.
31-0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit $W=1$, the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the Arm platform with $D=0$, and the remainder owned by the SDMA with $D=1$. The count field of the buffer descriptor indicates how much data has been transmitted.

If Arm platform has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONTInous* bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3rd BD. The SDMA script opens and processes BD#1. Since *CONTInous* bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3rd BD, if *CONTInous* is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONTInous* bit and *Wrap* bits are both set in the 3rd BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONTInous* bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desires the SDMA to fill them again. Basically, if the Arm platform expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the Arm platform to set the *Done* bit of a buffer descriptor at an appropriate time.

Figure 7-16. Buffer Descriptor Flow

The previous figure shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the CONTinuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The Done bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the Arm platform because the Interrupt flag is set in the 3rd BD. The CONTinuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the Wrap flag was set in the 3rd BD. It is the Arm platform responsibility to set the Done bit of all the BD if it wants to use the same buffers.

7.2.7.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script.

The following table lists the buffer descriptor commands defined for the channel 0 bootload script.

Table 7-53. Channel Zero Buffer Descriptor Commands

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from Arm platform memory buffer	Arm platform memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to Arm platform memory buffer	Arm platform memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from Arm platform memory buffer	Arm platform memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to Arm platform memory buffer	Arm platform memory destination address	SDMA memory source address
cccc_c111 (0x07 CHN)	C0_SETCTX	Load Context for channel cccc into SDMA RAM from Arm platform memory buffer	Arm Platform memory source address	-
cccc_c011 (0x03 CHN)	C0_GETCTXT	Copy Context for channel cccc from SDMA RAM to Arm platform memory buffer	Arm platform memory destination address	-

The Channel 0 bootload commands are summarized as follows:

- **C0_SET_[PM-DM]**: load the buffer descriptor data in the SDMA local memory at the address pointed to by the "extended buffer address" field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0_SET_PM is used, the count field is expressed in "shorts" (16-bit half words), this command can be used to download scripts. When C0_SET_DM is

used, the count field is expressed in "long" (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.

- **C0_GET_[PM-DM]**: write to the buffer descriptor's data buffer the content of the SDMA local memory from the address pointed to by the "extended buffer address" field for the length defined by the count in the buffer descriptor. **C0_GET_PM** is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in "shorts"; while **C0_GET_DM** is used to dump to the buffer descriptor's data buffer, so the count field is in "longs."
- **C0_SETCTX**: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination address in SDMA memory. Then the **C0_SET_DM** command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.
- **Command value**: (in binary) `cccc c111`, where `cccc` is the channel number (5 bits). For instance, `0x0F` means set context for channel 1, `0xFF` means set context for channel 31.
- **C0_GETCTX**: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the **C0_GET_DM** command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.
- **Command value**: (in binary): `cccc c011`, where `cccc` is the channel number (5 bits). For instance, `0x03` means get context of channel 1, `0xFB` means get context of channel 31.

NOTE

To download channel context, **C0_SETDM** and **C0_SETCTX** command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the **C0_SETDM**, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

7.2.7.1.3 Example of Buffer Descriptors for Channel 0.

Figure 7-18 illustrates the buffer descriptors that must be set in Arm platform memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in the following figure.

Figure 7-17. Example of SDMA RAM After Boot Session

SDMA RAM

AP Memory Space

7.2.7.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed.

The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure below shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

The structure is divided in 4 areas:

- Channel status registers
- General purpose registers
- Functional units state registers reflecting the state of the Arm platform DMAs (Burst and Peripheral DMA).
- Scratch RAM

The details of the channel context status registers are described in the following figure.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0_SETPM command.

SF: Source fault while loading data
 RPC: Return program counter
 T: Test bit: status of arithmetic and test instructions
 PC: Program counter
 LM: Loop mode
 EPC: Loop end program counter
 DF: Destination fault while storing data
 SPC: Loop Start program counter

Figure 7-19. SDMA State Registers (ShPC, ShLoop)

7.2.7.2 Typical Data Transfer Supported by SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units.

The Arm platform memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See the following table for the summary.

Table 7-54. Typical Data Transfers Summary

Data Transfer	Peripheral DMA	Burst DMA	Comments
Arm platform External Memory ↔ Arm platform External Memory		3	Copy mode Script example, see Burst DMA Unit Copy Mode and External Memory to External Memory .
Arm platform Peripheral ↔ Arm platform Peripheral	3		Copy mode if same data path width Script example, see Peripheral to Peripheral Transfer .
Arm platform External Memory ↔ Arm platform Peripheral	3	3	Data transit through SDMA Script example, see Transfer Between Peripheral and External Memory .
Arm platform External Memory ↔ Arm platform Internal Memory		3	Copy mode Script example, see Transfer Between External Memory and Internal Memory .
Arm platform Internal Memory ↔ Arm platform Internal Memory		3	Copy mode Script example, see Internal Memory to Internal Memory .
Arm platform Internal memory ↔ Arm platform Peripheral	3		Data transit through SDMA Script example, see Transfer Between Peripheral and Internal Memory .

NOTE

These scripts are provided as examples of how to use DMA blocks to perform required data transfers: They are not "official" programs.

7.2.7.2.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory.

For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register.

The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

Data Moves in External Memory

```

1      stf r1,MSA                // Source address setup
2      stf r2,MDA                // Destination address setup
3      ldi r0,0x64              // 64 words must be transferred from MSA to
MDA
4      ldi r1,0x8
MAIN_XFER:
5      cmphs r0,r1              // Is r0 >= 0x8
6      bf LAST_XFER            // If not, jump to last transfer label
7      stf r1,MD|CPY           // Copy 8 words from MSA to MDA address.
8      subi r0,0x8             // Decrement counter
9      jmp MAIN_XFER           // return to main transfer loop
LAST_XFER:
10     stf r0,MD|CPY           // perform last transfer

```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN_XFER), r1 always equals 8, so burst lengths are 8 words. On the last ldf |CPY instruction (10), r1 equals the remainder of r0 divided by 8; therefore, the length of bursts triggered in copy mode equal r1 value, which is between 1 and 7.

7.2.7.2.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used.

It is programmed in copy mode, so no data will transmit through the SDMA general register used in the ldf instruction, but the contents of the general register are lost. The SDMA core only monitors the transfer.

7.2.7.2.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

Same Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ16|F           //r1=0x1002 Source address register setup
2      stf r2, PDA|SZ16|F           //r2=0x2006 Destination address register
setup
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                   //loop counter is 10
//MAIN LOOP TRANSFER
copy_loop:
5      loop 2,0
6      ldf r7,PD|CPY                //Reads 1 half-word from src and writes to
dest.
7      yield
8      bdf ERROR_DURING_XFER
ERROR_ADDR_SETUP:                //correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
//flag error is set,
//PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware loop instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute the next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction ldf is a multi-cycle instruction.

7.2.7.2.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag.

The following example shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

Different Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ32|F|PF                //r1=0x1000 and prefetch data
2      stf r2, PDA|SZ16|F                  //r2=0x2006
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                          //loop counter is 10
//MAIN LOOP TRANSFER
main_loop_xfer_16_16:
5      loop 6,0
6      ldf r7,PD                            //copy 32-bit of PD in r7
7      stf r7,PD                            //store 16 LSB of r7 in PD and a flush is
executed
8      rorb r7
9      rorb r7                            //16 MSB --> 16 LSB
10     stf r7,PD                            //store 16 LSB of r6 in PD and a flush.
11     yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the ldf will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

7.2.7.2.3 Transfer Between Peripheral and External Memory

7.2.7.2.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from word peripheral to the external memory would be as follows:

Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, PSA|SZ16|F|PF                //r1=0x1000 and prefetch 32-bit data
2      stf r2, MDA                          //r2=0x2000, setup burst DMA destination
address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64                          //loop counter is 100
5
//MAIN LOOP TRANSFER
6      loop 3,0
7      ldf r1,PD|PF                          // read 32 bits of PD and initiate a new read
```

Smart Direct Memory Access Controller (SDMA)

```

access.
8      stf r1,MD|32          // store 32 bits of r1 in the MD fifo.
9      yield
10     ldf r1,PD             // last word data is read
11     stf r1,MD|32|FL      // to flush all remaining bytes of MD
    
```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. The following figures show how the peripheral DMA and burst DMA work in parallel.

Figure 7-20. Peripheral to External Memory Example (1)

As seen in the figure above, the read access triggered by the `ldf PD` instruction is symbolized by the blue bar when in progress. After wait states, the read data (`data 0`, `data 1`) is stored in PD on the `clk` rising edge. On edge 2, `data 0` is available in PD so it can be transferred to the SDMA general register `r1`, and then stored in MD FIFO. On edge 3, `data 1` is not in PD; therefore, SDMA is stalled on the `ldf` instruction, which lasts two cycles. The figure below shows an example of when MD FIFO is full with data.

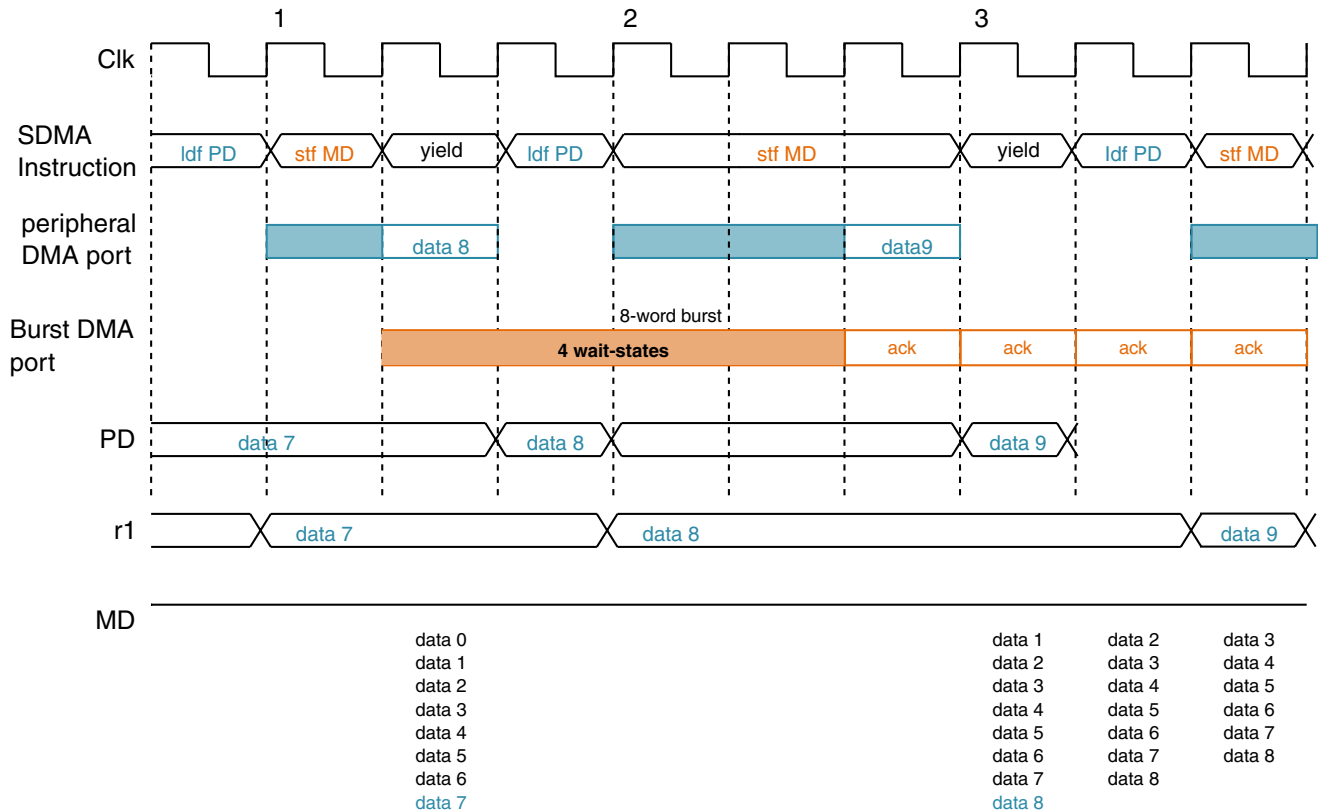

Figure 7-21. Peripheral to External Memory Example (2)

In the previous figure, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction stf because no acknowledge was received, MD FIFO is full, and there is no empty slot to store data 9. When an acknowledge is sampled by the burst DMA, FIFO is shifted and data 8 is written. As long as there is at least one empty slot in MD FIFO, the stf MD instruction lasts one cycle.

7.2.7.2.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from external memory to a word peripheral would be as follows:

External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, MSA|PF           //r1=0x1000 and starts a 8-word read burst
2      stf r2, PDA|SZ32|P      //r2=0x2010, setup peripheral DMA destination address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64             //loop counter is 100
//MAIN LOOP TRANSFER
```

Smart Direct Memory Access Controller (SDMA)

```
6      loop 3,0
7      ldf r1,MD|32|PF          // read 32 bits of MD and initiate a new read access
                                   // if MD is empty after this reading.
8      stf r1,PD              // store 32 bits of r1 in the PD.
9      yield
10     ldf r1,MD|32          // last word data is read
11     stf r1,PD            // last write access
```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

7.2.7.2.4 Transfer Between External Memory and Internal Memory

Since the internal memory (Arm platform RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in [Transfer Between Peripheral and External Memory](#) can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

7.2.7.2.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in [Peripheral to Peripheral Transfer](#) can be reused with a different programming of the peripheral DMA address registers.

7.2.7.2.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode.

The SDMA script is very similar to the one described in [Peripheral to Peripheral Transfer](#), except for the peripheral DMA address registers programming.

7.2.8 Arm Platform Memory Map and Control Register Definitions

The Arm platform controls the SDMA by means of several interface registers. Those registers are described in the current section.

All registers are clocked with the SDMA clock (which means the Arm platform must ensure that the SDMA clock is running when it wants to access any register).

7.2.8.1 Arm platform Channel 0 Pointer (SDMAARM_MC0PTR)

Address: 30BD_0000h base + 0h offset = 30BD_0000h

SDMAARM_MC0PTR field descriptions

Field	Description
MC0PTR	Channel 0 Pointer contains the 32-bit address, in Arm platform memory, of channel 0 control block (the boot channel). Appendix A fully describes the SDMA Application Programming Interface (API). The Arm platform has a read/write access and the SDMA has a read-only access.

7.2.8.2 Channel Interrupts (SDMAARM_INTR)

Address: 30BD_0000h base + 4h offset = 30BD_0004h

SDMAARM_INTR field descriptions

Field	Description
HI[31:0]	The Arm platform Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the Arm platform. This register is a "write-ones" register to the Arm platform. When the Arm platform sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding done instruction is executed.

7.2.8.3 Channel Stop/Channel Status (SDMAARM_STOP_STAT)

Address: 30BD_0000h base + 8h offset = 30BD_0008h

SDMAARM_STOP_STAT field descriptions

Field	Description
HE	This 32-bit register gives access to the Arm platform Enable bits. There is one bit for every channel. This register is a "write-ones" register to the Arm platform. When the Arm platform writes 1 in bit <i>i</i> of this register, it clears the HE[<i>i</i>] and HSTART[<i>i</i>] bits. Reading this register yields the current state of the HE[<i>i</i>] bits.

7.2.8.4 Channel Start (SDMAARM_HSTART)

Address: 30BD_0000h base + Ch offset = 30BD_000Ch

SDMAARM_HSTART field descriptions

Field	Description
HSTART_HE	<p>The HSTART_HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the Arm platform to trigger a channel a second time before the first trigger is processed.</p> <ul style="list-style-type: none"> This register is a "write-ones" register to the Arm platform. Neither HSTART[<i>i</i>] bit can be set while the corresponding HE[<i>i</i>] bit is cleared. When the Arm platform tries to set the HSTART[<i>i</i>] bit by writing a one (if the corresponding HE[<i>i</i>] bit is clear), the bit in the HSTART[<i>i</i>] register will remain cleared and the HE[<i>i</i>] bit will be set. If the corresponding HE[<i>i</i>] bit was already set, the HSTART[<i>i</i>] bit will be set. The next time the SDMA channel <i>i</i> attempts to clear the HE[<i>i</i>] bit by means of a <code>done</code> instruction, the bit in the HSTART[<i>i</i>] register will be cleared and the HE[<i>i</i>] bit will take the old value of the HSTART[<i>i</i>] bit. Reading this register yields the current state of the HSTART[<i>i</i>] bits. This mechanism enables the Arm platform to pipeline two HSTART commands per channel.

7.2.8.5 Channel Event Override (SDMAARM_EVTOVR)

Address: 30BD_0000h base + 10h offset = 30BD_0010h

SDMAARM_EVTOVR field descriptions

Field	Description
EO	The Channel Event Override register contains the 32 EO[i] bits. A bit set in this register causes the SDMA to ignore DMA requests when scheduling the corresponding channel.

7.2.8.6 Channel BP Override (SDMAARM_DSPOVR)

Address: 30BD_0000h base + 14h offset = 30BD_0014h

SDMAARM_DSPOVR field descriptions

Field	Description
DO	This register is reserved. All DO bits should be set to the reset value of 1. A setting of 0 will prevent SDMA channels from starting according to the condition described in Runnable Channels Evaluation . 0 - Reserved 1 - Reset value.

7.2.8.7 Channel Arm platform Override (SDMAARM_HOSTOVR)

Address: 30BD_0000h base + 18h offset = 30BD_0018h

SDMAARM_HOSTOVR field descriptions

Field	Description
HO	The Channel Arm platform Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the Arm platform enable bit (HE) when scheduling the corresponding channel.

7.2.8.8 Channel Event Pending (SDMAARM_EVTPEND)

Address: 30BD_0000h base + 1Ch offset = 30BD_001Ch

SDMAARM_EVTPEND field descriptions

Field	Description
EP	<p>The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the Arm platform to determine what channels are pending after the reception of a DMA request.</p> <ul style="list-style-type: none"> Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests. The EP[i] bit may be cleared by the <code>done</code> instruction when running the channel <i>i</i> script. This is a "write-ones" mechanism: Writing a '0' does not clear the corresponding bit.

7.2.8.9 Reset Register (SDMAARM_RESET)

Address: 30BD_0000h base + 24h offset = 30BD_0024h

SDMAARM_RESET field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a done instruction. This enables the Arm platform to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

7.2.8.10 DMA Request Error Register (SDMAARM_EVTERR)

Address: 30BD_0000h base + 28h offset = 30BD_0028h

SDMAARM_EVTERR field descriptions

Field	Description
CHNERR	<p>This register is used by the SDMA to warn the Arm platform when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel.</p> <ul style="list-style-type: none"> An interrupt is sent to the Arm platform if the corresponding channel bit is set in the INTRMASK register. This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the Arm platform or during SDMA reset. The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the Arm platform tries to set the EP[i] bit, whereas, that EP[i] bit is already set.

7.2.8.11 Channel Arm platform Interrupt Mask (SDMAARM_INTRMASK)

Address: 30BD_0000h base + 2Ch offset = 30BD_002Ch

SDMAARM_INTRMASK field descriptions

Field	Description
HIMASK	<p>The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit HIMASK[i] is set, the HI[i] bit is set and an interrupt is sent to the Arm platform when a DMA request error is detected on channel <i>i</i> (for example, EVTERR[i] is set).</p>

7.2.8.12 Schedule Status (SDMAARM_PSW)

Address: 30BD_0000h base + 30h offset = 30BD_0030h

SDMAARM_PSW field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning. 0 No running channel 1 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel. 0 No running channel 1 Active channel priority
CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA. SDMA. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

7.2.8.13 DMA Request Error Register (SDMAARM_EVERRDBG)

Address: 30BD_0000h base + 34h offset = 30BD_0034h

SDMAARM_EVERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVERR, except reading it does not clear its contents. This address is meant to be used in debug mode. The Arm platform OnCE may check this register value without modifying it.

7.2.8.14 Configuration Register (SDMAARM_CONFIG)

Address: 30BD_0000h base + 38h offset = 30BD_0038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	[Shaded]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		DSPDMA	RTDOBS	0				ACR	0		CSM				
W	[Shaded]		[Shaded]	[Shaded]	[Shaded]				[Shaded]	[Shaded]		[Shaded]				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

SDMAARM_CONFIG field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 DSPDMA	This bit's function is reserved and should be configured as zero. 0 - Reset Value 1 - Reserved
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–5 Reserved	This read-only field is reserved and always has the value 0.
4 ACR	Arm platform DMA / SDMA Core Clock Ratio. Selects the clock ratio between Arm platform DMA interfaces (burst DMA and peripheral DMA) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 Arm platform DMA interface frequency equals twice core frequency 1 Arm platform DMA interface frequency equals core frequency
3–2 Reserved	This read-only field is reserved and always has the value 0.
CSM	Selects the Context Switch Mode. The Arm platform has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase. NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used.

Table continues on the next page...

SDMAARM_CONFIG field descriptions (continued)

Field	Description
0	static
1	dynamic low power
2	dynamic with no loop
3	dynamic

7.2.8.15 SDMA LOCK (SDMAARM_SDMA_LOCK)

Address: 30BD_0000h base + 3Ch offset = 30BD_003Ch

SDMAARM_SDMA_LOCK field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.
1 SRESET_LOCK_ CLR	The SRESET_LOCK_CLR bit determine if the LOCK bit is cleared on a software reset triggered by writing to the RESET register. This bit cannot be changed if LOCK=1. SREST_LOCK_CLR is cleared by conditions that clear the LOCK bit. 0 Software Reset does not clear the LOCK bit. 1 Software Reset clears the LOCK bit.
0 LOCK	The LOCK bit is used to restrict access to update SDMA script memory through ROM channel zero scripts and through the OnCE interface under Arm platform control. The LOCK bit is set: <ul style="list-style-type: none"> The SDMA_LOCK, ONCE_ENB, CH0ADDR, and ILLINSTADDR registers cannot be written. These registers can be read, but writes are ignored. SDMA software executing out of ROM or RAM may check the LOCK bit in the LOCK register Lock Status Register (SDMACORE_SDMA_LOCK) to determine if certain operations are allowed, such as up-loading new scripts.

Table continues on the next page...

SDMAARM_SDMA_LOCK field descriptions (continued)

Field	Description
	Once the LOCK bit is set to 1, only a reset can clear it. The LOCK bit is cleared by a hardware reset. LOCK is cleared by a software reset only if SRESET_LOCK_CLR is set.
0	LOCK disengaged.
1	LOCK enabled.

7.2.8.16 OnCE Enable (SDMAARM_ONCE_ENB)

Address: 30BD_0000h base + 40h offset = 30BD_0040h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

SDMAARM_ONCE_STAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows: <ul style="list-style-type: none"> The "Program" state is the usual instruction execution cycle. The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st).

Table continues on the next page...

SDMAARM_ONCE_STAT field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. The "Debug" state means the SDMA is in debug mode. The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). The "in Sleep" states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore</p>
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the Arm platform peripheral interface. 0 The JTAG interface controls the OnCE. 1 The Arm platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value 0.
ECDR	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the <code>addrb_cond</code> , <code>addrb_cond</code> , and <code>data_cond</code> conditions. The value of those fields is given by the EDR bits.

Table continues on the next page...

SDMAARM_ONCE_STAT field descriptions (continued)

Field	Description
0	1 matched addra_cond
1	1 matched addrb_cond
2	1 matched data_cond

7.2.8.20 OnCE Command Register (SDMAARM_ONCE_CMD)

Address: 30BD_0000h base + 50h offset = 30BD_0050h

SDMAARM_ONCE_CMD field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
CMD	<p>Writing to this register will cause the OnCE to execute the command that is written. When needed, the ONCE_DATA and ONCE_INSTR registers should be loaded with the correct value before writing the command to that register. For a list of the OnCE commands and their usage, see OnCE and Real-Time Debug.</p> <p>NOTE: 7-15 reserved</p> <ul style="list-style-type: none"> 0 rstatus 1 dmov 2 exec_once 3 run_core 4 exec_core 5 debug_rqst 6 rbuffer

7.2.8.21 Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR)

Address: 30BD_0000h base + 58h offset = 30BD_0058h

SDMAARM_ILLINSTADDR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
ILLINSTADDR	The Illegal Instruction Trap Address is the address where the SDMA jumps when an illegal instruction is executed. It is 0x0001 after reset. The value of ILLINSTADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

7.2.8.22 Channel 0 Boot Address (SDMAARM_CHN0ADDR)

Address: 30BD_0000h base + 5Ch offset = 30BD_005Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	SMSZ	CHN0ADDR													
W																
Reset	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0

SDMAARM_CHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set. 0 24 words per context 1 32 words per context
CHN0ADDR	This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80). The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

7.2.8.23 DMA Requests (SDMAARM_EVT_MIRROR)

Address: 30BD_0000h base + 60h offset = 30BD_0060h

SDMAARM_EVT_MIRROR field descriptions

Field	Description
EVENTS	<p>This register reflects the DMA requests received by the SDMA for events 31-0. The Arm platform and the SDMA have a read-only access. There is one bit associated with each of 32 DMA request events. This information may be useful during debug of the blocks that generate the DMA requests. The EVT_MIRROR register is cleared following read access.</p> <p>0 DMA request event not pending 1 DMA request event pending</p>

7.2.8.24 DMA Requests 2 (SDMAARM_EVT_MIRROR2)

Address: 30BD_0000h base + 64h offset = 30BD_0064h

SDMAARM_EVT_MIRROR2 field descriptions

Field	Description
31-16 Reserved	This read-only field is reserved and always has the value 0.
EVENTS[47:32]	<p>This register reflects the DMA requests received by the SDMA for events 47-32. The Arm platform and the SDMA have a read-only access. There is one bit associated with each of DMA request events. This information may be useful during debug of the blocks that generate the DMA requests. The EVT_MIRROR2 register is cleared following read access.</p> <p>0 - DMA request event not pending 1- DMA request event pending</p>

7.2.8.25 Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1)

Address: 30BD_0000h base + 70h offset = 30BD_0070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	CNF3	NUM3[5:0]					0	CNF2	NUM2[5:0]

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_XTRIG_CONF1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 CNF3	Configuration of the SDMA event line number i that is connected to the cross-trigger. It determines whether the event line pulse is generated by the reception of a DMA request or by the starting of a channel script execution. 0 channel 1 DMA request
29–24 NUM3[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number i .
23 Reserved	This read-only field is reserved and always has the value 0.
22 CNF2	Configuration of the SDMA event line number i that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
21–16 NUM2[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number i .
15 Reserved	This read-only field is reserved and always has the value 0.
14 CNF1	Configuration of the SDMA event line number i that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution.

Table continues on the next page...

SDMAARM_XTRIG_CONF1 field descriptions (continued)

Field	Description
	0 channel 1 DMA request
13–8 NUM1[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
7 Reserved	This read-only field is reserved and always has the value 0.
6 CNF0	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
NUM0[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .

7.2.8.26 Cross-Trigger Events Configuration Register 2 (SDMAARM_XTRIG_CONF2)

Address: 30BD_0000h base + 74h offset = 30BD_0074h

SDMAARM_XTRIG_CONF2 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 CNF7	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request

Table continues on the next page...

SDMAARM_XTRIG_CONF2 field descriptions (continued)

Field	Description
29–24 NUM7[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
23 Reserved	This read-only field is reserved and always has the value 0.
22 CNF6	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
21–16 NUM6[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
15 Reserved	This read-only field is reserved and always has the value 0.
14 CNF5	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution 0 channel 1 DMA request
13–8 NUM5[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
7 Reserved	This read-only field is reserved and always has the value 0.
6 CNF4	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
NUM4[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .

7.2.8.27 Channel Priority Registers (SDMAARM_SDMA_CHNPRIn)

Address: 30BD_0000h base + 100h offset + (4d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W																	CHNPRIn															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_SDMA_CHNPRIn field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
CHNPRIn	This contains the priority of channel number <i>n</i> . Useful values are between 1 and 7; 0 is reserved by the SDMA hardware to determine when there is no pending channel. Reset value is 0, which prevents the channels from starting.

7.2.8.28 Channel Enable RAM (SDMAARM_CHNENBLn)

Address: 30BD_0000h base + 200h offset + (4d × i), where i=0d to 47d

SDMAARM_CHNENBLn field descriptions

Field	Description
ENBLn	This 32-bit value selects the channels that are triggered by the DMA request number <i>n</i> . If ENBLn[i] is set to 1, bit EP[i] will be set when the DMA request <i>n</i> is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the Arm platform to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

7.2.9 BP Memory Map and Control Register Definitions

The following section describes SDMA control registers available to the BP.

NOTE

These registers are physically implemented in all platforms, but are not accessible when the SDMA BP control port is not connected. Reset values are calculated to allow the system to work when those registers cannot be accessed.

All registers are clocked with the SDMA clock (which means the SDMA clock must be running when the BP wants to access any register).

SDMABP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
30BD_0000	Channel 0 Pointer (SDMABP_DC0PTR)	32	R/W	0000_0000h	7.2.9.1/1485
30BD_0004	Channel Interrupts (SDMABP_INTR)	32	w1c	0000_0000h	7.2.9.2/1485
30BD_0008	Channel Stop/Channel Status (SDMABP_STOP_STAT)	32	R/W	0000_0000h	7.2.9.3/1486
30BD_000C	Channel Start (SDMABP_DSTART)	32	R	0000_0000h	7.2.9.4/1486
30BD_0028	DMA Request Error Register (SDMABP_EVTERR)	32	R	0000_0000h	7.2.9.5/1487
30BD_002C	Channel DSP Interrupt Mask (SDMABP_INTRMASK)	32	R/W	0000_0000h	7.2.9.6/1487
30BD_0034	DMA Request Error Register (SDMABP_EVTERRDBG)	32	R	0000_0000h	7.2.9.7/1488

7.2.9.1 Channel 0 Pointer (SDMABP_DC0PTR)

Address: 30BD_0000h base + 0h offset = 30BD_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DC0PTR																															
W	DC0PTR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_DC0PTR field descriptions

Field	Description
DC0PTR	Channel 0 Pointer contains the 32-bit address, in BP memory, of the array of channel control blocks starting with the one for channel 0 (the control channel). This register should be initialized by the BP before it enables a channel (for example, channel 0). See the API document SDMA Scripts User Manual for the use of this register. The BP has a read/write access and the SDMA has a read-only access.

7.2.9.2 Channel Interrupts (SDMABP_INTR)

Address: 30BD_0000h base + 4h offset = 30BD_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_INTR field descriptions

Field	Description
DI	<p>The BP Interrupts register contains the 32 DI[i] bits. If any bit is set, it will cause an interrupt to the BP.</p> <ul style="list-style-type: none"> This register is a "write-ones" register to the BP. When the BP sets a bit in this register, the corresponding DI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced; failure to do so will cause continuous interrupts. The SDMA is responsible for setting the DI[i] bit corresponding to the current channel when the corresponding <code>done</code> instruction is executed.

7.2.9.3 Channel Stop/Channel Status (SDMABP_STOP_STAT)

Address: 30BD_0000h base + 8h offset = 30BD_0008h

SDMABP_STOP_STAT field descriptions

Field	Description
DE	<p>This 32-bit register gives access to the BP (DSP) Enable bits, DE. There is one bit for every channel.</p> <ul style="list-style-type: none"> This register is a "write-ones" register to the BP. When the BP writes 1 in bit <i>i</i> of this register, it clears the DE[i] and DSTART[i] bits. Reading this register yields the current state of the DE[i] bits.

7.2.9.4 Channel Start (SDMABP_DSTART)

Address: 30BD_0000h base + Ch offset = 30BD_000Ch

SDMABP_DSTART field descriptions

Field	Description
DSTART_DE	<p>The DSTART_DE registers are 32 bits wide with one bit for every channel.</p> <ul style="list-style-type: none"> When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (DSTART and DE), which enables the BP to trigger a channel a second time before the first trigger was processed. This register is a "write-ones" register to the BP. Neither DSTART[i] bit can be set while the corresponding DE[i] bit is cleared.

SDMABP_DSTART field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> When the BP tries to set the DSTART[i] bit by writing a one (if the corresponding DE[i] bit is clear), the bit in the DSTART[i] register will remain cleared and the DE[i] bit will be set. If the corresponding DE[i] bit was already set, the DSTART[i] bit will be set. The next time the SDMA channel <i>i</i> attempts to clear the DE[i] bit by means of a <code>done</code> instruction, the bit in the DSTART[i] register will be cleared and the DE[i] bit will take the old value of the DSTART[i] bit. Reading this register yields the current state of the DSTART[i] bits. This mechanism enables the BP to pipeline two DSTART commands per channel.

7.2.9.5 DMA Request Error Register (SDMABP_EVTERR)

Address: 30BD_0000h base + 28h offset = 30BD_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CHNERR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_EVTERR field descriptions

Field	Description
CHNERR	<p>This register is used by the SDMA to warn the BP when an incoming DMA request was detected; it then triggers a channel that is already pending or being serviced, which may mean there is an overflow of data for that channel. An interrupt is sent to the BP if the corresponding channel bit is set in the INTRMASK register.</p> <ul style="list-style-type: none"> This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the BP or during an SDMA reset. The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set. The EVTERR[i] bit is unaffected if the BP tries to set the EP[i] bit when that EP[i] bit is already set.

7.2.9.6 Channel DSP Interrupt Mask (SDMABP_INTRMASK)

Address: 30BD_0000h base + 2Ch offset = 30BD_002Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DIMASK																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_INTRMASK field descriptions

Field	Description
DIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit DIMASK[i] is set, the DI[i] bit is set and an interrupt is sent to the BP when a DMA request error is detected on channel <i>i</i> (for example, EVTERR[i] is set).

7.2.9.7 DMA Request Error Register (SDMABP_EVERRDBG)

Address: 30BD_0000h base + 34h offset = 30BD_0034h

SDMABP_EVERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVERR except reading it does not clear its contents. This address is meant to be used in debug mode. The BP OnCE may check this register value without modifying it.

7.2.10 SDMA Internal (Core) Memory Map and Internal Register Definitions

The actual SDMA memory mapped registers are summarized in the following sections; for peripherals' memory maps, refer to the respective chapters.

The following definitions serve as a key for the SDMA internal register summary.

SDMACORE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
30BD_0000	Arm platform Channel 0 Pointer (SDMACORE_MC0PTR)	32	R	0000_0000h	7.2.10.1/1489
30BD_0008	Current Channel Pointer (SDMACORE_CCPtr)	32	R	0000_0000h	7.2.10.2/1490
30BD_000C	Current Channel Register (SDMACORE_CCR)	32	R	0000_0000h	7.2.10.3/1490
30BD_0010	Highest Pending Channel Register (SDMACORE_NCR)	32	R	0000_0000h	7.2.10.4/1491
30BD_0014	External DMA Requests Mirror (SDMACORE_EVENTS)	32	R	0000_0000h	7.2.10.5/1492
30BD_0018	Current Channel Priority (SDMACORE_CCPRI)	32	R	0000_0000h	7.2.10.6/1493

30BD_003C	OnCE Real-Time Buffer (SDMACORE_RTB)	32	R/W	0000_0000h	7.2.10.15/1498
30BD_0040	OnCE Trace Buffer (SDMACORE_TB)	32	R	0000_0000h	7.2.10.16/1498
30BD_0044	OnCE Status (SDMACORE_OSTAT)	32	R	0000_0000h	7.2.10.17/1499
30BD_0048	Channel 0 Boot Address (SDMACORE_MCHN0ADDR)	32	R	0000_0000h	7.2.10.18/1501
30BD_004C	ENDIAN Status Register (SDMACORE_ENDIANNES)	32	R	0000_0001h	7.2.10.19/1502
30BD_0054	Lock Status Register (SDMACORE_SDMA_LOCK)	32	R	0000_0000h	7.2.10.20/1503
30BD_0058	External DMA Requests Mirror #2 (SDMACORE_EVENTS2)	32	R	0000_0000h	7.2.10.21/1503

7.2.10.1 Arm platform Channel 0 Pointer (SDMACORE_MCOPTR)

Address: 30BD_0000h base + 0h offset = 30BD_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	MCOPTR																																
W																																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACORE_MCOPTR field descriptions

Field	Description
MCOPTR	Contains the address-in the Arm platform memory space-of the initial SDMA context and scripts that are loaded by the SDMA boot script running on channel 0.

7.2.10.2 Current Channel Pointer (SDMACORE_CCPTR)

Address: 30BD_0000h base + 8h offset = 30BD_0008h

SDMACORE_CCPTR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
CCPTR	Contains the start address of the context data for the current channel: Its value is <i>CONTEXT_BASE</i> + 24* <i>CCR</i> or <i>CONTEXT_BASE</i> + 32* <i>CCR</i> where <i>CONTEXT_BASE</i> = 0x0800. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in Channel 0 Boot Address (SDMAARM_CHN0ADDR) .

7.2.10.3 Current Channel Register (SDMACORE_CCR)

Address: 30BD_0000h base + Ch offset = 30BD_000Ch

SDMACORE_CCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
CCR	Contains the number of the current running channel whose context is installed. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel. The PST bits in the OSTAT register indicate when the SDMA is in sleep state.

7.2.10.4 Highest Pending Channel Register (SDMACORE_NCR)

Address: 30BD_0000h base + 10h offset = 30BD_0010h

SDMACORE_NCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
NCR	Contains the number of the pending channel that the scheduler has selected to run next.

7.2.10.5 External DMA Requests Mirror (SDMACORE_EVENTS)

NOTE

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words).

If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.

The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the Arm platform programmed.

Address: 30BD_0000h base + 14h offset = 30BD_0014h

SDMACORE_EVENTS field descriptions

Field	Description
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 0-31. The EVENTS2 register displays events 32-47.

7.2.10.6 Current Channel Priority (SDMACORE_CCPRI)

Address: 30BD_0000h base + 18h offset = 30BD_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_CCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
CCPRI	Contains the 3-bit priority of the channel whose context is installed. It is 0 when no channel is running. NOTE: 1-7 current channel priority 0 no running channel

7.2.10.7 Next Channel Priority (SDMACORE_NCPRI)

Address: 30BD_0000h base + 1Ch offset = 30BD_001Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_NCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
NCPRI	Contains the 3-bit priority of the channel the scheduler has selected to run next. It is 0 when no other channel is pending.

7.2.10.8 OnCE Event Cell Counter (SDMACORE_ECOUNTER)

Address: 30BD_0000h base + 20h offset = 30BD_0020h

SDMACORE_ECOUNTER field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
ECOUNT	The event cell counter contains the number of times minus one that an event detection must occur before generating a debug request. <ul style="list-style-type: none"> This register should be written before any attempt to use the event detection counter during an event detection process. The counter is cleared on a JTAG reset.

7.2.10.9 OnCE Event Cell Control Register (SDMACORE_ECTL)

Address: 30BD_0000h base + 24h offset = 30BD_0024h

SDMACORE_ECTL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 EN	Event Cell Enable. If the EN bit is set, the event cell is allowed to generate debug requests (the cell is awakened). If it is cleared, the event detection unit is disabled and no hardware breakpoint is generated, but matching conditions are still reflected on the emulation pin. 0 Cell is disabled. 1 Cell is enabled.
12 CNT	Event Counter Enable. The event counter enable bit determines if the cell counter is used during the event detection. In order to use the event counter during an event detection process, the event cell counter register should be loaded with a value equal to the number of times minus one that an event occurs before a debug request is sent. After every event detection, the counter is decreased. When the counter reaches

Table continues on the next page...

SDMACORE_ECTL field descriptions (continued)

Field	Description
	<p>the value 0, the event detection cell sends a debug request to the core. The event counter register should be written and the EN bit should be set before each new event detection process uses the event counter.</p> <p>0 Counter is disabled. 1 Counter is enabled.</p>
11–10 ECTC[1:0]	<p>The event cell trigger condition bits select the combination of address and data matching conditions that generate the final address/data condition. During program execution, if this event cell trigger condition goes to 1, a debug request is sent to the SDMA. The EN bit must be set to enable the debug request generation.</p> <p>00 address ONLY 01 data ONLY 10 address AND data 11 address OR data</p>
9–8 DTC[1:0]	<p>The data trigger condition bits define when data is considered matching after comparison with the data register of the event detection unit. The operations are performed on unsigned values.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
7–6 ATC[1:0]	<p>The address trigger condition bits select how the two address conditions (addressA and addressB) are combined to define the global address matching condition. The supported combinations are described, as follows.</p> <p>00 addressA ONLY 01 addrA AND addrB 10 addrA OR addrB 11 reserved</p>
5–4 ABTC[1:0]	<p>The Address B Trigger Condition (ABTC) controls the operations performed by address comparator B. All operations are performed on unsigned values. This comparator B outputs the addressB condition.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
3–2 AATC[1:0]	<p>The Address A Trigger Condition (AATC) controls the operations performed by address comparator A. All operations are performed on unsigned values. This comparator A outputs the addressA condition.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
ATS[1:0]	<p>The access type select bits define the memory access type required on the SDMA memory bus.</p> <p>00 read ONLY 01 write ONLY 10 read or write 11 -</p>

7.2.10.10 OnCE Event Address Register A (SDMACORE_EAA)

Address: 30BD_0000h base + 28h offset = 30BD_0028h

SDMACORE_EAA field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EAA	Event Cell Address Register A computes an address A condition. It is cleared on a JTAG reset.

7.2.10.11 OnCE Event Cell Address Register B (SDMACORE_EAB)

Address: 30BD_0000h base + 2Ch offset = 30BD_002Ch

SDMACORE_EAB field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EAB	Event Cell Address Register B computes an address B condition. It is cleared on a JTAG reset.

7.2.10.12 OnCE Event Cell Address Mask (SDMACORE_EAM)

Address: 30BD_0000h base + 30h offset = 30BD_0030h

SDMACORE_EAM field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EAM	The Event Cell Address Mask contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before performing the address comparison. NOTE: There is a common address mask value for both address comparators. If bit <i>i</i> of this register is set, then bit <i>i</i> of the address value latched from the memory bus does not influence the result of the address comparison. The register is cleared on a JTAG reset.

7.2.10.13 OnCE Event Cell Data Register (SDMACORE_ED)

Address: 30BD_0000h base + 34h offset = 30BD_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_EDM field descriptions

Field	Description
EDM	The event cell data mask register contains the user-defined data mask value. <ul style="list-style-type: none"> This mask is applied to the data value latched from the memory bus before performing the data comparison. Setting bit <i>i</i> of the event cell data mask register means that bit <i>i</i> of the data value latched from the address bus does not influence the result of the data comparison. The data mask is cleared on a JTAG reset.

7.2.10.15 OnCE Real-Time Buffer (SDMACORE_RTB)

Address: 30BD_0000h base + 3Ch offset = 30BD_003Ch

SDMACORE_RTB field descriptions

Field	Description
RTB	<p>The Real Time Buffer register stores and retrieves run time information without putting the SDMA in debug mode. Writing to that register triggers a pulse on a specific real-time debug pin whose connection depends on the chip implementation.</p> <p>The RTB value can be accessed by the OnCE under Arm platform or JTAG control using the rbuffer command.</p>

7.2.10.16 OnCE Trace Buffer (SDMACORE_TB)

Address: 30BD_0000h base + 40h offset = 30BD_0040h

SDMACORE_TB field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 TBF	<p>The Trace Buffer Flag is set when the buffer contains the addresses of a valid change of flow. The contents of the buffer should be ignored otherwise.</p> <p>0 Invalid information 1 Valid information</p>
27–14 TADDR	The target address is the address taken after the execution of the change of flow instruction.
CHFADDR	The change of flow address is the address where the change of flow is taken when executing a change of flow instruction.

7.2.10.17 OnCE Status (SDMACORE_OSTAT)

Address: 30BD_0000h base + 44h offset = 30BD_0044h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

SDMACORE_OSTAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	<p>The Processor Status bits reflect the state of the SDMA RISC engine.</p> <ul style="list-style-type: none"> The "Program" state is the usual instruction execution cycle. The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel-switching instructions). The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. The "Debug" state means the SDMA is in debug mode. The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). The "in Sleep" states are the same as above except they do not have any corresponding channel. They are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow Loop Sleep 12 Debug in Sleep 13 Functional Unit in Sleep</p>

Table continues on the next page...

SDMACORE_OSTAT field descriptions (continued)

Field	Description
	14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the Arm platform peripheral interface. 0 JTAG interface controls the OnCE. 1 Arm platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value 0.
ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows: 0 1 matched addressA condition 1 1 matched addressB condition 2 1 matched data condition

7.2.10.18 Channel 0 Boot Address (SDMACORE_MCHN0ADDR)

Address: 30BD_0000h base + 48h offset = 30BD_0048h

SDMACORE_MCHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context
CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the Arm platform; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

7.2.10.19 ENDIAN Status Register (SDMACORE_ENDIANNES)

Address: 30BD_0000h base + 4Ch offset = 30BD_004Ch

SDMACORE_ENDIANNES field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 APEND	APEND indicates the endian mode of the Peripheral and Burst DMA interfaces. This bit is tied to logic '1' indicating little-endian mode. 0 - Arm platform is in big-endian mode 1 - Arm platform is in little-endian mode

7.2.10.20 Lock Status Register (SDMACORE_SDMA_LOCK)

Address: 30BD_0000h base + 54h offset = 30BD_0054h

SDMACORE_SDMA_LOCK field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 LOCK	The LOCK bit reports the value of the LOCK bit in the SDMA_LOCK status register. SDMA software may use this value to determine if certain operations such as loading of new scripts is allowed. 0 - LOCK bit clear 1 - LOCK bit set

7.2.10.21 External DMA Requests Mirror #2 (SDMACORE_EVENTS2)

Address: 30BD_0000h base + 58h offset = 30BD_0058h

SDMACORE_EVENTS2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 32-47. The separate EVENTS register displays events 0-31.

7.2.11 SDMA Peripheral Registers

Refer to the respective peripherals' chapters for more information.

Chapter 8

Chip IO and Pinmux

8.1 External Signals and Pin Multiplexing

8.1.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength, and hysteresis.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

8.1.1.1 Muxing Options

Instance	Port	Pad	Mode
ADC1	ADC1_IN0	ADC1_IN0	No muxing
	ADC1_IN1	ADC1_IN1	No muxing
	ADC1_IN2	ADC1_IN2	No muxing

8.2 IOMUX Controller (IOMUXC)

8.2.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

Figure 8-1 illustrates the IOMUX/IOMUXC connectivity in the system.

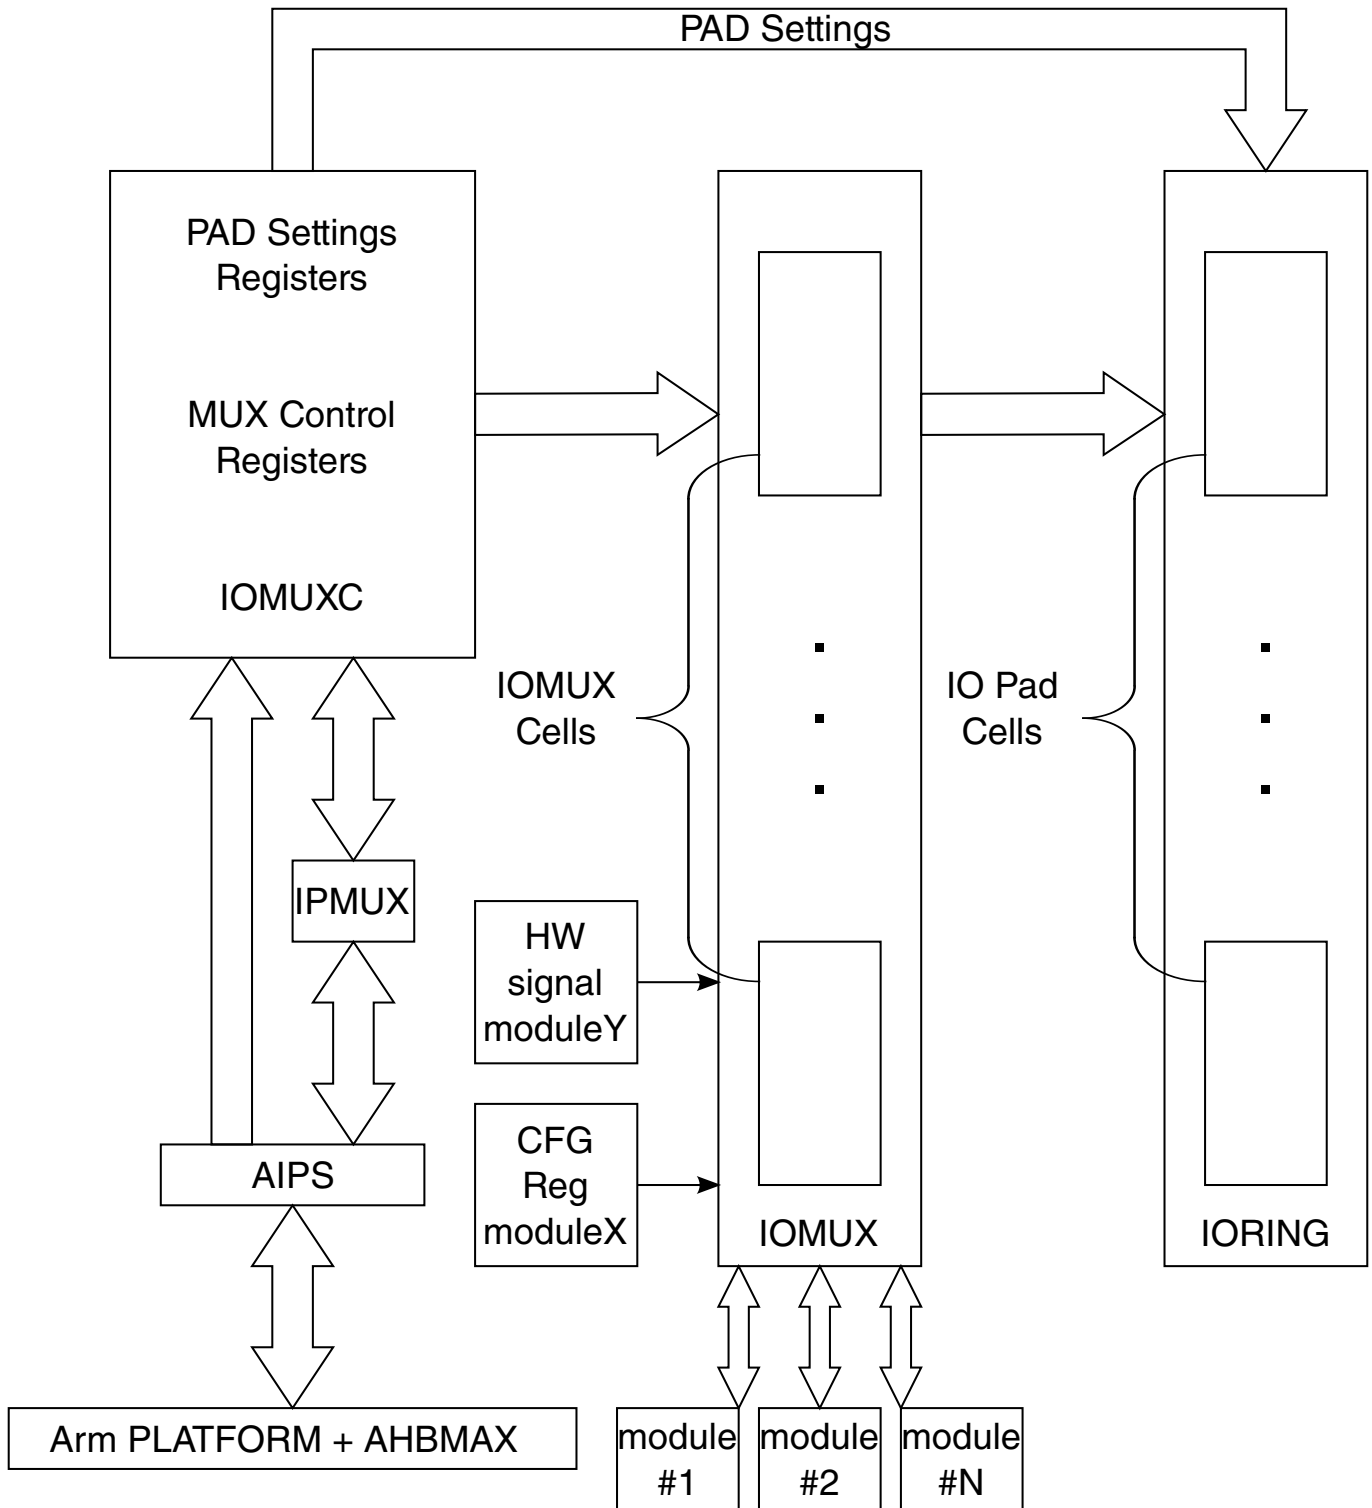

Figure 8-1. IOMUX SoC Level Block Diagram

8.2.1.1 Features

The IOMUXC features are:

- 32-bit software mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure 1 of 8 alternate (ALT) MUX_MODE fields of each pad or a predefined group of pads and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific pad settings of each pad, or a predefined group of pads.
- 32-bit general purpose registers - 14 (GPR0 to GPR13) 32-bit registers according to SoC requirements for any usage.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pad's group.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

8.2.2 Clocks

The table found here describes the clock sources for IOMUXC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 8-1. IOMUXC Clocks

Clock name	Clock Root	Description
ipt_clk_io		IO clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

8.2.3 Functional description

This section provides a complete functional description of the block.

The IOMUXC consists of two sub-blocks:

- IOMUXC_REGISTERS includes all of the IOMUXC registers (see [Features](#)).
- IOMUXC_LOGIC includes all of the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUX consists of a number (about the number of pads in the SoC) of basic iomux_cell units. If only one functional mode is required for a specific pad, there is no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

The basic iomux_cell design, which allows two levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in [Figure 8-2](#).

Figure 8-2. IOMUX Cell Block Diagram

8.2.3.1 ALT6 and ALT7 extended muxing modes

The ALT7 and ALT6 extended muxing modes allow any signal in the system (such as fuse, pad input, JTAG, or software register) to override any software configuration and to force the ALT6/ALT7 muxing mode.

It also allows an IOMUX software register to control a group of pads.

8.2.3.2 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active (`ipp_ibe==1'b1`) regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.
- GPIO Capture - Module x drives the pad and the value is captured by GPIO.

8.2.3.3 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programmable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers). The daisy chain is illustrated in the figure below.

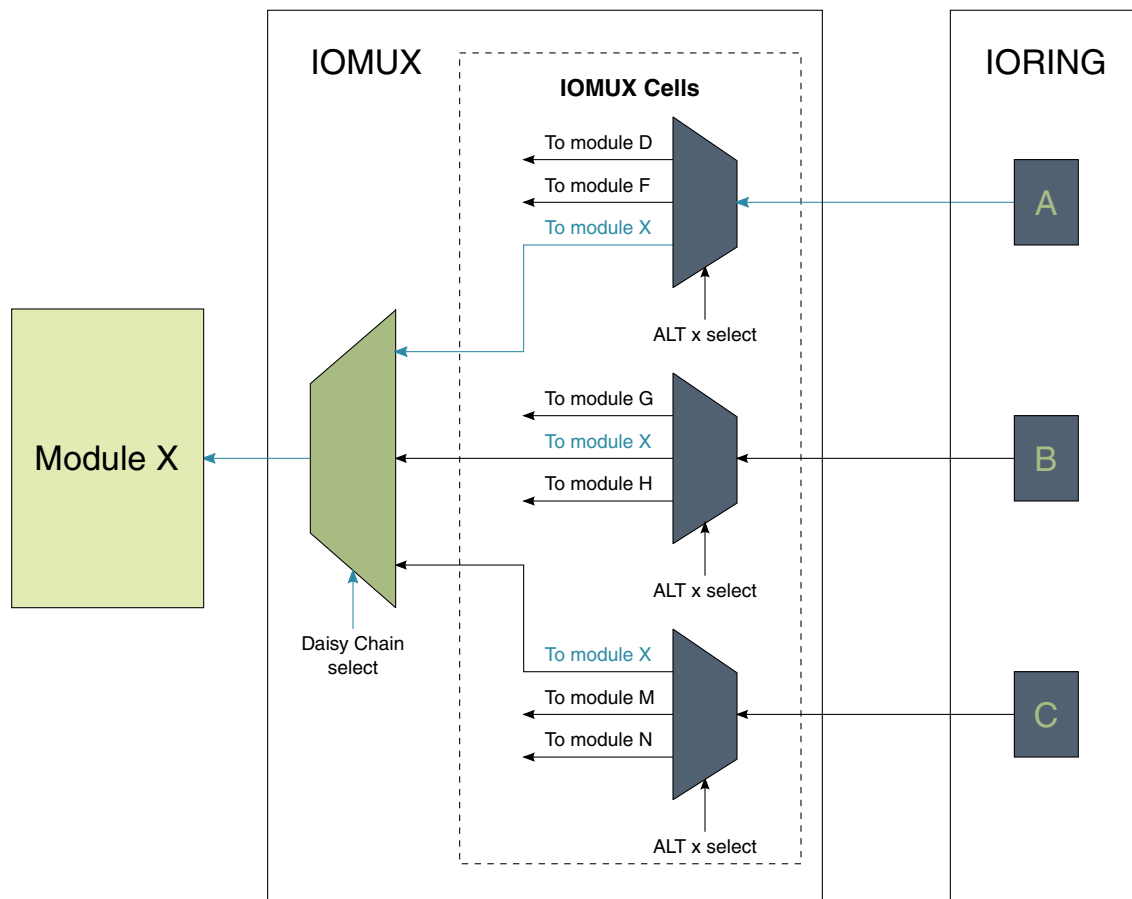

Figure 8-3. Daisy chain illustration

4 S_RDATA_WAIT_EN	State Retention On-chip RAM read data wait state control For description, please refer to RDATA_WAIT_EN bit
3 WADDR_PIPE_EN	On-chip RAM write address pipeline enable When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, i.e., at most 1 more clock cycle for each write burst with multiple beats of data. When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle). 0 write address pipeline is disabled 0 write address pipeline is disabled 1 write address pipeline is enabled
2 WDATA_PIPE_EN	On-chip RAM write data pipeline enable When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, i.e., at most 1 more clock cycle for each write burst with multiple beats of data. When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

Table continues on the next page...

IOMUXC_GPR_GPR3 field descriptions (continued)

Field	Description
	0 write data pipeline is disabled 1 write data pipeline is enabled
1 RADDR_PIPE_EN	<p>On-chip RAM read address pipeline enable</p> <p>When this feature is enabled, the read address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the read access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI read transaction, i.e., at most 1 more clock cycle for each read burst with multiple beats of data. When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).</p> 0 read address pipeline is disabled 1 read address pipeline is enabled
0 RDATA_WAIT_EN	<p>On-chip RAM read data wait state control</p> <p>When the read data wait state is enabled, it will cost 2 cycles for each read access, (each beat of a read burst). This can avoid the potential timing problem caused by the relatively longer memory access time at higher frequency. When this feature is disabled, it only costs 1 clock cycle to finish a read transaction, i.e., get read data back in the next cycle of read request becomes valid on the bus.</p> 0 read data wait state disabled 1 read data wait state enabled

IOMUXC_GPR_GPR10 field descriptions

Field	Description
31–10 GPR10_LOCK	Bits [25:18] are Lock Bits for bits [9:2] Other bits are Reserved
9–4 OCRAM_EPDC_TZ_ADDR	EPDC OCRAM TrustZone (TZ) start address. This is the start address of the secure memory region within the EPDC OCRAM memory space is 4KB granularity. The start address affects the EPDC OCRAM transactions only if OCRAM_EPDC_TZ_EN bit is set. The EPDC OCRAM TZ ENDADDR is not configurable and is set to the end of EPDC OCRAM memory space. These are "lock" type bits

Table continues on the next page...

IOMUXC_GPR_GPR10 field descriptions (continued)

Field	Description
3 OCRAM_EPDC_TZ_EN	EPDC OCRAM TrustZone (TZ) enable This is a "lock" type bit 0 The TrustZone feature is disabled. Entire EPDC OCRAM space is available for all access types (secure/non-secure/user/supervisor). 1 The TrustZone feature is enabled. Access to address in the range specified by [ENDADDR:STARTADDR] follows the execution mode access policy described in CSU chapter.
2 SEC_ERR_RESP_EN	Security error response enable for all security gaskets (on both AHB and AXI busses) This is a "lock" type bit 0 OKAY response 1 SLVERR response
-	This field is reserved. Reserved

IOMUXC_GPR_GPR11 field descriptions

Field	Description
31-14 GPR11_LOCK	Bits [29:16] are Lock Bits for bits [13:0] Other bits are Reserved

Table continues on the next page...

IOMUXC_GPR_GPR11 field descriptions (continued)

Field	Description
13–11 OCRAM_S_TZ_ADDR	State Retention OCRAM TrustZone (TZ) start address. This is the start address of the secure memory region within the State Retention OCRAM memory space is 4KB granularity. The start address affects the State Retention OCRAM transactions only if OCRAM_S_TZ_EN bit is set. The State Retention OCRAM TZ ENDADDR is not configurable and is set to the end of State Retention OCRAM memory space. These are "lock" type bits
10 OCRAM_S_TZ_EN	State Retention OCRAM TrustZone (TZ) enable This is a "lock" type bit 0 The TrustZone feature is disabled. Entire State Retention OCRAM space is available for all access types (secure/non-secure/user/supervisor). 1 The TrustZone feature is enabled. Access to address in the range specified by [ENDADDR:STARTADDR] follows the execution mode access policy described in CSU chapter.
9–7 OCRAM_PXP_TZ_ADDR	PXP OCRAM TrustZone (TZ) start address. This is the start address of the secure memory region within the PXP OCRAM memory space is 4KB granularity. The start address affects the PXP OCRAM transactions only if OCRAM_PXP_TZ_EN bit is set. The PXP OCRAM TZ ENDADDR is not configurable and is set to the end of PXP OCRAM memory space. These are "lock" type bits
6 OCRAM_PXP_TZ_EN	PXP OCRAM TrustZone (TZ) enable This is a "lock" type bit 0 The TrustZone feature is disabled. Entire PXP OCRAM space is available for all access types (secure/non-secure/user/supervisor). 1 The TrustZone feature is enabled. Access to address in the range specified by [ENDADDR:STARTADDR] follows the execution mode access policy described in CSU chapter.
5–1 OCRAM_TZ_ADDR	OCRAM TrustZone (TZ) start address. This is the start address of the secure memory region within the OCRAM memory space is 4KB granularity. The start address affects the OCRAM transactions only if OCRAM_TZ_EN bit is set. The OCRAM TZ ENDADDR is not configurable and is set to the end of OCRAM memory space. These are "lock" type bits
0 OCRAM_TZ_EN	OCRAM TrustZone (TZ) enable This is a "lock" type bit 0 The TrustZone feature is disabled. Entire OCRAM space is available for all access types (secure/non-secure/user/supervisor). 1 The TrustZone feature is enabled. Access to address in the range specified by [ENDADDR:STARTADDR] follows the execution mode access policy described in CSU chapter.

IOMUXC_GPR_GPR13 field descriptions

Field	Description
31 PCIE_PHY_PCS_REFCLK_DISABLE	PCS Clock Request. When high, indicates that PHY is ready for reference clock to be disabled. When MAC_CLKREQ_N goes high, PHY will assert this PCS_REFCLK_DISABLE if it's okay for the external reference clock to be disabled. This feature is not supported with internal reference clock, REFCLK_EXT. Timing: N/A
30 PCIE_PHY_CDR_VCO_MON_CH0	CDR VCO Monitor Channel 0
29 PCIE_PHY_PMA_RX_PRESENT_CH0	Receiver Detected Indication for PCIe Test. When receiver is detected in P1, this signal goes to high.
28 PCIE_PHY_PMA_CDR_LOCKED_CH0	PLL Lock Indication for PCIe Test. When CDR locking is done, this signal goes to high.
27-24 PCIE_PHY_VCO_BAND	Monitoring Code of VCO Calibration. This signal is the code of VCO calibration.

Table continues on the next page...

IOMUXC_GPR_GPR22 field descriptions

Field	Description
31 PCIE_PHY_PLL_LOCKED	PLL Lock Indication. When PLL locking is done, PLL_LOCKED goes to high.
30 Reserved	This read-only field is reserved and always has the value 1.
29 CHD1_ISO_ENA_1	USB OTG1 Auxiliary Charge Detector isolation control signal, high when dvdd_usb domain is unpowered and vdd_soc domain is powered. This signal is in the vdd_soc domain.
28 CHD1_DVDD_STABLE	USB OTG1 Auxiliary Charge Detector power stable signal for LDO_USB_1P0 to allow vdd_soc domain to monitor when dvdd_usb domain is valid. This signal is in the vdd_soc domain.
27 CHD2_ISO_ENA_1	USB OTG2 Auxiliary Charge Detector isolation control signal, high when dvdd_usb domain is unpowered and vdd_soc domain is powered. This signal is in the vdd_soc domain.
26 CHD2_DVDD_STABLE	USB OTG2 Auxiliary Charge Detector power stable signal for LDO_USB_1P0 to allow vdd_soc domain to monitor when dvdd_usb domain is valid. This signal is in the vdd_soc domain.
25 DFI_INIT_COMPLETE	DDR PHY initialization complete. This signal indicates that the PHY is able to respond to any proper stimulus on the DFI.
24 DDRC_MRR_VALID	DDR Controller Mode Register Read Data Valid
23–16 DDRC_MRR_DATA	DDR Controller Mode Register Read Data
Reserved	This read-only field is reserved and always has the value 0.

8.2.5 IOMUXC LPSR Memory Map/Register Definition

IOMUXC_LPSR memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
302C_0000	SW_MUX_CTL_PAD_GPIO1_IO00 SW MUX Control Register (IOMUXC_LPSR_SW_MUX_CTL_PAD_GPIO1_IO00)	32	R/W	0000_0000h	8.2.5.1/1588

Field	Description
31 GPIO1_IO15_MUX_CTL	Mux control for PAD 0 Pad control from SOC IOMUX 1 Pad control from LPSR GPR
30–29 GPIO1_IO15_PS	Pull Select Field Select one out of next values for pad: GPIO1_IO15 00 PS_0_100K_PD — 100K PD 01 PS_1_5K_PU — 5K PU 10 PS_2_47K_PU — 47K PU 11 PS_3_100K_PU — 100K PU
28 GPIO1_IO15_PE	Pull Enable Field Select one out of next values for pad: GPIO1_IO15 0 PE_0_Pull_Disabled — Pull Disabled 1 PE_1_Pull_Enabled — Pull Enabled
27 GPIO1_IO15_HYS	Hyst. Enable Field Select one out of next values for pad: GPIO1_IO15 0 HYS_0_Hysteresis_Disabled — Hysteresis Disabled 1 HYS_1_Hysteresis_Enabled — Hysteresis Enable

Table continues on the next page...

IOMUXC_LPSR_GPR_IOMUXC_LPSR_GPR21 field descriptions (continued)

Field	Description
26 GPIO1_IO15_ SRE	Slew Rate Field Select one out of next values for pad: GPIO1_IO15 0 SRE_0_Fast_Slew_Rate — Fast Slew Rate 1 SRE_1_Slow_Slew_Rate — Slow Slew Rate
25-24 GPIO1_IO15_ DSE	Drive Strength Field Select one out of next values for pad: GPIO1_IO15 00 DSE_0_X1 — X1 01 DSE_1_X1 — X2 10 DSE_2_X1 — X4 11 DSE_3_X1 — X6
23 GPIO1_IO14_ MUX_CTL	Mux control for PAD 0 Pad control from SOC IOMUX 1 Pad control from LPSR GPR
22-21 GPIO1_IO14_PS	Pull Select Field Select one out of next values for pad: GPIO1_IO14 00 PS_0_100K_PD — 100K PD 01 PS_1_5K_PU — 5K PU 10 PS_2_47K_PU — 47K PU 11 PS_3_100K_PU — 100K PU
20 GPIO1_IO14_PE	Pull Enable Field Select one out of next values for pad: GPIO1_IO14 0 PE_0_Pull_Disabled — Pull Disabled 1 PE_1_Pull_Enabled — Pull Enabled
19 GPIO1_IO14_ HYS	Hyst. Enable Field Select one out of next values for pad: GPIO1_IO14 0 HYS_0_Hysteresis_Disabled — Hysteresis Disabled 1 HYS_1_Hysteresis_Enabled — Hysteresis Enable
18 GPIO1_IO14_ SRE	Slew Rate Field Select one out of next values for pad: GPIO1_IO14 0 SRE_0_Fast_Slew_Rate — Fast Slew Rate 1 SRE_1_Slow_Slew_Rate — Slow Slew Rate
17-16 GPIO1_IO14_ DSE	Drive Strength Field Select one out of next values for pad: GPIO1_IO14 00 DSE_0_X1 — X1 01 DSE_1_X1 — X2 10 DSE_2_X1 — X4 11 DSE_3_X1 — X6
15 GPIO1_IO13_ MUX_CTL	Mux control for PAD 0 Pad control from SOC IOMUX 1 Pad control from LPSR GPR
14-13 GPIO1_IO13_PS	Pull Select Field Select one out of next values for pad: GPIO1_IO13 00 PS_0_100K_PD — 100K PD 01 PS_1_5K_PU — 5K PU 10 PS_2_47K_PU — 47K PU 11 PS_3_100K_PU — 100K PU

Table continues on the next page...

IOMUXC_LPSR_GPR_IOMUXC_LPSR_GPR21 field descriptions (continued)

Field	Description
12 GPIO1_IO13_PE	Pull Enable Field Select one out of next values for pad: GPIO1_IO13 0 PE_0_Pull_Disabled — Pull Disabled 1 PE_1_Pull_Enabled — Pull Enabled
11 GPIO1_IO13_HYS	Hyst. Enable Field Select one out of next values for pad: GPIO1_IO13 0 HYS_0_Hysteresis_Disabled — Hysteresis Disabled 1 HYS_1_Hysteresis_Enabled — Hysteresis Enable
10 GPIO1_IO13_SRE	Slew Rate Field Select one out of next values for pad: GPIO1_IO13 0 SRE_0_Fast_Slew_Rate — Fast Slew Rate 1 SRE_1_Slow_Slew_Rate — Slow Slew Rate
9–8 GPIO1_IO13_DSE	Drive Strength Field Select one out of next values for pad: GPIO1_IO13 00 DSE_0_X1 — X1 01 DSE_1_X1 — X2 10 DSE_2_X1 — X4 11 DSE_3_X1 — X6
7 GPIO1_IO12_MUX_CTL	Mux control for PAD 0 Pad control from SOC IOMUX 1 Pad control from LPSR GPR
6–5 GPIO1_IO12_PS	Pull Select Field Select one out of next values for pad: GPIO1_IO12 00 PS_0_100K_PD — 100K PD 01 PS_1_5K_PU — 5K PU 10 PS_2_47K_PU — 47K PU 11 PS_3_100K_PU — 100K PU
4 GPIO1_IO12_PE	Pull Enable Field Select one out of next values for pad: GPIO1_IO12 0 PE_0_Pull_Disabled — Pull Disabled 1 PE_1_Pull_Enabled — Pull Enabled
3 GPIO1_IO12_HYS	Hyst. Enable Field Select one out of next values for pad: GPIO1_IO12 0 HYS_0_Hysteresis_Disabled — Hysteresis Disabled 1 HYS_1_Hysteresis_Enabled — Hysteresis Enable
2 GPIO1_IO12_SRE	Slew Rate Field Select one out of next values for pad: GPIO1_IO12 0 SRE_0_Fast_Slew_Rate — Fast Slew Rate 1 SRE_1_Slow_Slew_Rate — Slow Slew Rate
GPIO1_IO12_DSE	Drive Strength Field Select one out of next values for pad: GPIO1_IO12 00 DSE_0_X1 — X1 01 DSE_1_X1 — X2 10 DSE_2_X1 — X4 11 DSE_3_X1 — X6

8.2.6.23 IOMUXC_LPSR General Purpose Register 22 (IOMUXC_LPSR_GPR_IOMUXC_LPSR_GPR22)

IOMUXC LPSR General Purpose Register

Address: 3027_0000h base + 58h offset = 3027_0058h

IOMUXC_LPSR_GPR_IOMUXC_LPSR_GPR22 field descriptions

Field	Description
31–16 RO	Read only bits, always 16'h0
GP	Common bits can be R/W freely

8.2.7 IOMUXC Memory Map/Register Definition

IOMUXC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
3033_0014	SW_MUX_CTL_PAD_GPIO1_IO08 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO08)	32	R/W	0000_0000h	8.2.7.1/1650
3033_0018	SW_MUX_CTL_PAD_GPIO1_IO09 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO09)	32	R/W	0000_0000h	8.2.7.2/1652
3033_001C	SW_MUX_CTL_PAD_GPIO1_IO10 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO10)	32	R/W	0000_0000h	8.2.7.3/1653

IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO08 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field. Force the selected mux mode Input path no matter of MUX_MODE functionality. 1 ENABLED — Force input path of pad GPIO1_IO08 0 DISABLED — Input Path is determined by functionality
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field. 8.3 General Purpose Input/Output (GPIO)

8.3.1 Overview

The GPIO general-purpose input/output peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs.

When configured as an output, it is possible to write to an internal register to control the state driven on the output pin. When configured as an input, it is possible to detect the state of the input by reading the state of an internal register. In addition, the GPIO peripheral can produce CORE interrupts.

The GPIO is one of the blocks controlling the IOMUX of the chip.

Figure 8-4. Chip IOMUX Scheme

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.

The eight registers are:

- Data register (GPIO_DR)
- GPIO direction register (GPIO_GDIR)
- Pad sample register (GPIO_PSR)
- Interrupt control registers (GPIO_ICR1, GPIO_ICR2)

General Purpose Input/Output (GPIO)

- Edge select register (GPIO_EDGE_SEL)
- Interrupt mask register (GPIO_IMR)
- Interrupt status register (GPIO_ISR)

These registers are described in detail in [GPIO Memory Map/Register Definition](#).

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (GPIO_IMR). These qualified outputs are OR'ed together to generate two one-bit interrupt lines:

- Combined interrupt indication for GPIOx signals 0 - 15
- Combined interrupt indication for GPIOx signals 16 - 31

In addition, GPIO1 provides visibility to each of its 8 low order interrupt sources (i.e. GPIO1 interrupt n, for n = 0 – 7). However, individual interrupt indications from other GPIOx are not available.

The GPIO edge detection is described further in [Interrupt Control Unit](#).

The GPIO's overall functionality is described further in [GPIO Functional Description](#).

8.3.1.1 Block Diagram

The GPIO subsystem contains multiple GPIO blocks, which can generate and control up to 32 signals for general purpose.

A block diagram of the GPIO is shown in [Figure 8-5](#)

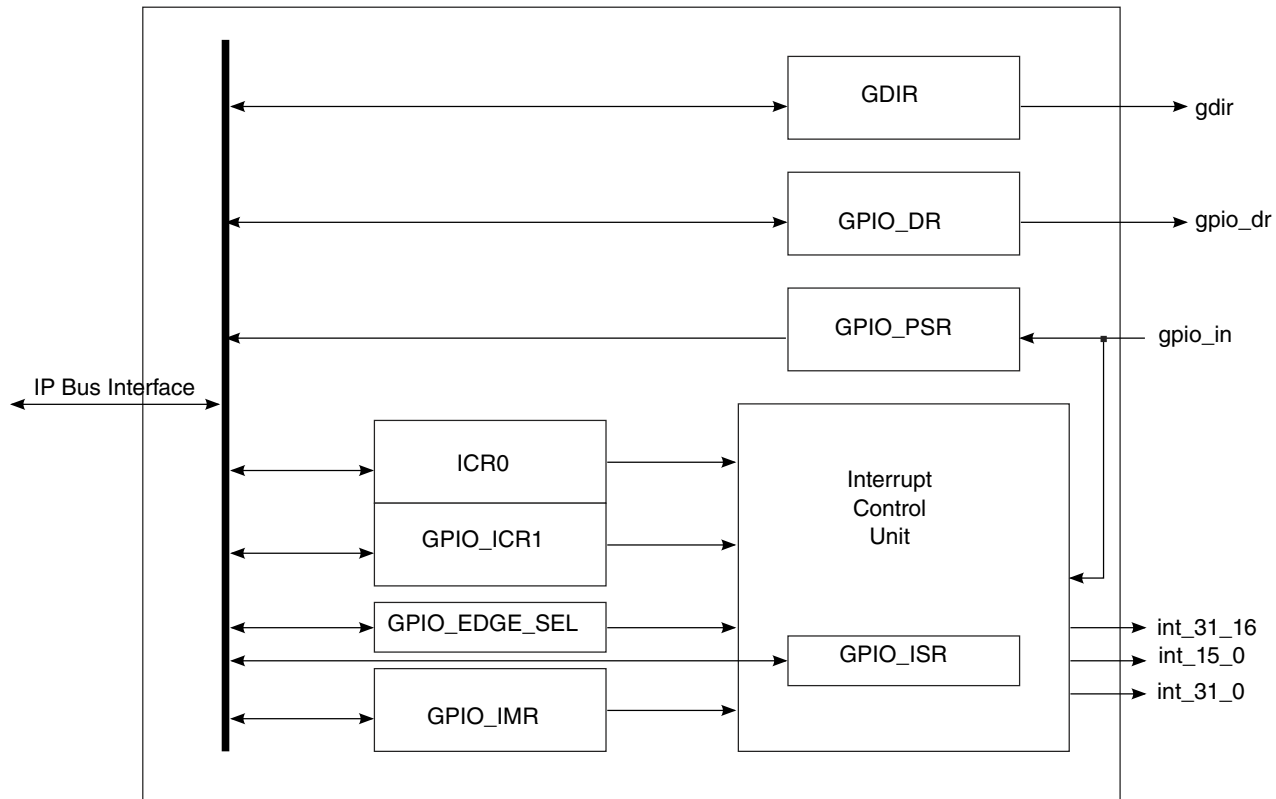

Figure 8-5. GPIO Block Diagram

8.3.1.2 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
 - Drives specific data to output using the data register (GPIO_DR)
 - Controls the direction of the signal using the GPIO direction register (GPIO_GDIR)
 - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (GPIO_PSR).
- GPIO interrupt capabilities:
 - Supports up to 32 interrupts
 - Identifies interrupt edges
 - Generates three active-high interrupts to the SoC interrupt controller

8.3.2 External Signals

The tables found here describe the external signals of GPIO.

Table 8-2. GPIO External Signals

8.3.3 Clocks

The table found here describes the clock sources for GPIO.

Please see the clock controller Module for clock setting, configuration and gating information.

Table 8-3. GPIO Clocks

Clock name	Clock Root	Description
ipg_clk_s	ipg_clk_root	Peripheral access clock

8.3.4 GPIO Functional Description

This section provides a complete functional description of the block.

8.3.4.1 GPIO Function

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal may be independently configured as either an input or an output using the GPIO direction register (GPIO_GDIR).

When configured as an output (GPIO_GDIR bit = 1), the value in the data bit in the GPIO data register (GPIO_DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GPIO_GDIR bit = 0), the state of the input can be read from the corresponding GPIO_PSR bit.

8.3.4.2 GPIO Programming

8.3.4.2.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUX Controller (IOMUXC)).
2. Configure GPIO direction register to input (GPIO_GDIR[GDIR] set to 0b).
3. Read value from data register/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
// SET INPUTS TO GPIO MODE.
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3>, 32'h00000000
// SET GDIR TO INPUT.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0
// READ INPUT VALUE FROM DR.
read DR
// READ INPUT VALUE FROM PSR.
read PSR
```

NOTE

While the GPIO direction is set to input (GPIO_GDIR = 0), a read access to GPIO_DR does not return GPIO_DR data. Instead, it returns the GPIO_PSR data, which is the corresponding input signal value.

8.3.4.2.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC), also enable SION if need to read loopback pad value through PSR
2. Configure GPIO direction register to output (GPIO_GDIR[GDIR] set to 1b).
3. Write value to data register (GPIO_DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
// SET PADS TO GPIO MODE VIA IOMUX.
write sw_mux_ctl_pad_<output[0-3]>.mux_mode, <GPIO_MUX_MODE>
// Enable loopback so we can capture pad value into PSR in output mode
write sw_mux_ctl_pad_<output[0-3]>.sion, 1
// SET GDIR=1 TO OUTPUT BITS.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF
// WRITE OUTPUT VALUE=4'b0101 TO DR.
write DR, 32'hxxxxxxx5
// READ OUTPUT VALUE FROM PSR ONLY.
read_cmp PSR, 32'hxxxxxxx5
```

8.3.4.3 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit = 0). The interrupt control registers (GPIO_ICR1 and GPIO_ICR2) may be used to independently configure the interrupt condition of each

General Purpose Input/Output (GPIO)

input signal (low-to-high transition, high-to-low transition, low, or high). For information about GPIO_ICR1 and GPIO_ICR2 settings, see [GPIO Memory Map/Register Definition](#).

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

8.3.5 GPIO Memory Map/Register Definition

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

The GPIO memory map is shown in the following table.

GPIO memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
3020_0000	GPIO data register (GPIO1_DR)	32	R/W	0000_0000h	8.3.5.1/2169

8.3.5.1 GPIO data register (GPIOx_DR)

The 32-bit GPIO_DR register stores data that is ready to be driven to the output lines. If the IOMUXC is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of GPIO_DR reflects the value of the corresponding signal. Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUXC input mode settings and the corresponding GDIR bit as follows:

- If GDIR[n] is set and IOMUXC input mode is GPIO, then reading DR[n] returns the contents of DR[n].
- If GDIR[n] is cleared and IOMUXC input mode is GPIO, then reading DR[n] returns the corresponding input signal's value.
- If GDIR[n] is set and IOMUXC input mode is not GPIO, then reading DR[n] returns the contents of DR[n].
- If GDIR[n] is cleared and IOMUXC input mode is not GPIO, then reading DR[n] always returns zero.

Address: Base address + 0h offset

GPIOx_DR field descriptions

Field	Description
DR	<p>Data bits. This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading GPIO_DR returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0).</p> <p>NOTE: The I/O multiplexer must be configured to GPIO mode for the GPIO_DR value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.</p>

8.3.5.2 GPIO direction register (GPIOx_GDIR)

GPIO_GDIR functions as direction control when the IOMUXC is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table. For more details consult the IOMUXC chapter.

Address: Base address + 4h offset

GPIOx_GDIR field descriptions

Field	Description
GDIR	<p>GPIO direction bits. Bit n of this register defines the direction of the GPIO[n] signal.</p> <p>NOTE: GPIO_GDIR affects only the direction of the I/O signal when the corresponding bit in the I/O MUX is configured for GPIO.</p> <p>0 INPUT — GPIO is configured as input.</p> <p>1 OUTPUT — GPIO is configured as output.</p>

8.3.5.3 GPIO pad status register (GPIOx_PSR)

GPIO_PSR is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

Address: Base address + 8h offset

GPIOx_PSR field descriptions

Field	Description
PSR	<p>GPIO pad status bits (status bits). Reading GPIO_PSR returns the state of the corresponding input signal.</p> <p>Settings:</p>

GPIOx_PSR field descriptions (continued)

Field	Description
	NOTE: The IOMUXC must be configured to GPIO mode for GPIO_PSR to reflect the state of the corresponding signal.

8.3.5.4 GPIO interrupt configuration register1 (GPIOx_ICR1)

GPIO_ICR1 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

Address: Base address + Ch offset

8.3.5.6 GPIO interrupt mask register (GPIOx_IMR)

GPIO_IMR contains masking bits for each interrupt line.

Address: Base address + 14h offset

GPIOx_IMR field descriptions

Field	Description
IMR	<p>Interrupt Mask bits. This register is used to enable or disable the interrupt function on each of the 32 GPIO signals.</p> <p>Settings:</p>

GPIOx_IMR field descriptions (continued)

Field	Description
	Bit IMR[n] (n=0...31) controls interrupt n as follows: 0 MASKED — Interrupt n is disabled. 1 UNMASKED — Interrupt n is enabled.

8.3.5.7 GPIO interrupt status register (GPIOx_ISR)

The GPIO_ISR functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ISR																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_ISR field descriptions

Field	Description
ISR	Interrupt status bits - Bit n of this register is asserted (active high) when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in GPIO_IMR. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

8.3.5.8 GPIO edge select register (GPIOx_EDGE_SEL)

GPIO_EDGE_SEL may be used to override the ICR registers' configuration. If the GPIO_EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared (ICR is not overridden).

Address: Base address + 1Ch offset

GPIOx_EDGE_SEL field descriptions

Field	Description
GPIO_EDGE_SEL	Edge select. When GPIO_EDGE_SEL[n] is set, the GPIO disregards the ICR[n] setting, and detects any edge on the corresponding input signal.

Chapter 9

External Memory

9.1 External Memory Controllers

9.1.1 Overview

This chip has these external memory interfaces and controllers:

- EIM-PSRAM/NOR flash controller

9.1.2 DDR controller (DDRC) overview and feature summary

The DDRC module is a DDR controller that supports several types of DDR memories.

Table 9-1. DDRC feature summary

Feature	Description
Supported standards	<ul style="list-style-type: none">• DDR3/LPDDR2/LPDDR3 1ch x32
DDR interface	<ul style="list-style-type: none">• Density of 256 MB - 2 GB<ul style="list-style-type: none">• Column size of 8-12 bits• Row size of 11-16 bits• Supports burst length of 8 (aligned) for DDR3 and burst lengths of 4 for LPDDR2.
DDR performance	<ul style="list-style-type: none">• Dynamic scheduling to optimize the bandwidth and latency.• Delayed writes for optimum bandwidth and latency.• For maximum SDRAM efficiency, commands are executed out of order.• Hardware configurable and software programmable QOS support.• Control options to avoid the starvation of lower priorities.• Write combine to allow multiple writes to the same address to be combined into a single write to the SDRAM.• Paging policy is selectable by the configuration registers.• Flexible address mapper logic to allow application-specific mapping of row, column, bank, and rank bits.• User-selectable refresh control options.
AXI interface	<ul style="list-style-type: none">• AXI bus compliant with a glueless interface to PL301 AXI network interconnect.

Table 9-1. DDRC feature summary (continued)

Feature	Description
DDR calibration and delay-lines	<ul style="list-style-type: none"> • All calibrations can be done automatically by hardware or manually by software. • ZQ calibration for external DDR device (in DDR3 through the ZQ calibration command and in LPDDR2 through the MRW command).
DDR general	<ul style="list-style-type: none"> • Configurable timing parameters. • Configurable refresh scheme. • Supports dynamic voltage, frequency change, and low-power mode entry through the hardware negotiation with the system (req/ack handshake). • Supports automatic self-refresh and power down entry and exit. • Supports fast and slow precharge power down in DDR3. • Supports various ODT control schemes. <ul style="list-style-type: none"> • Assertion/Deassertion of the ODT control per read or write accesses and for active or passive CS. • Supports MRW and MRR commands for LPDDR2. • Software control for moving to derated timing parameters and derated refresh rate according to the temperature variation.

9.2 DDR Controller (DDRC)

9.2.1 Introduction

The DDR Memory Controller (DDRMC) combined with DFI-compatible PHY is a complete memory interface solution for DDR memory subsystems. The DDRMC is a flexible and advanced solution for ASIC and System-on-Chip (SoC) designers who need very low power while achieving industry leading high-efficiency, low-latency and high-performance from their memory interface.

Supported SDRAM types include:

- DDR3
- LPDDR2
- LPDDR3

The DDRMC receives transactions from the SoC core. These transactions are queued internally and scheduled for access to the SDRAM while satisfying SDRAM protocol timing requirements, transaction priorities, and dependencies between the transactions. The DDRMC in turn issues commands on the DFI interface to the PHY module, which launches and captures data to and from the SDRAM.

9.2.2 General Overview

The DDRMC and the combine create a complete solution for connecting an SoC application bus to DDR memory devices. The combined DDRMC and solution enables the highest DDR performance and bandwidth, with the DDRMC initiating DDR commands to transfer data with the maximum efficiency.

The DDRMC SoC application bus interface supports an AMBA 3 AXI interface. The DDRMC has flexible address mapper logic to allow application-specific mapping of row, column, bank, bank group, and rank bits. The DDRMC includes a DFI interface that supports DDR3 (JEDEC JESD79-3*), LPDDR2 (JEDECJESD209-2*), and LPDDR3 (JEDEC 209-3*) standards.

9.2.2.1 Block diagram

The DDRMC converts system bus transactions into memory commands on the DFI interface that are compliant with the DDR protocols. The following figure is the block diagram of the DDRMC .

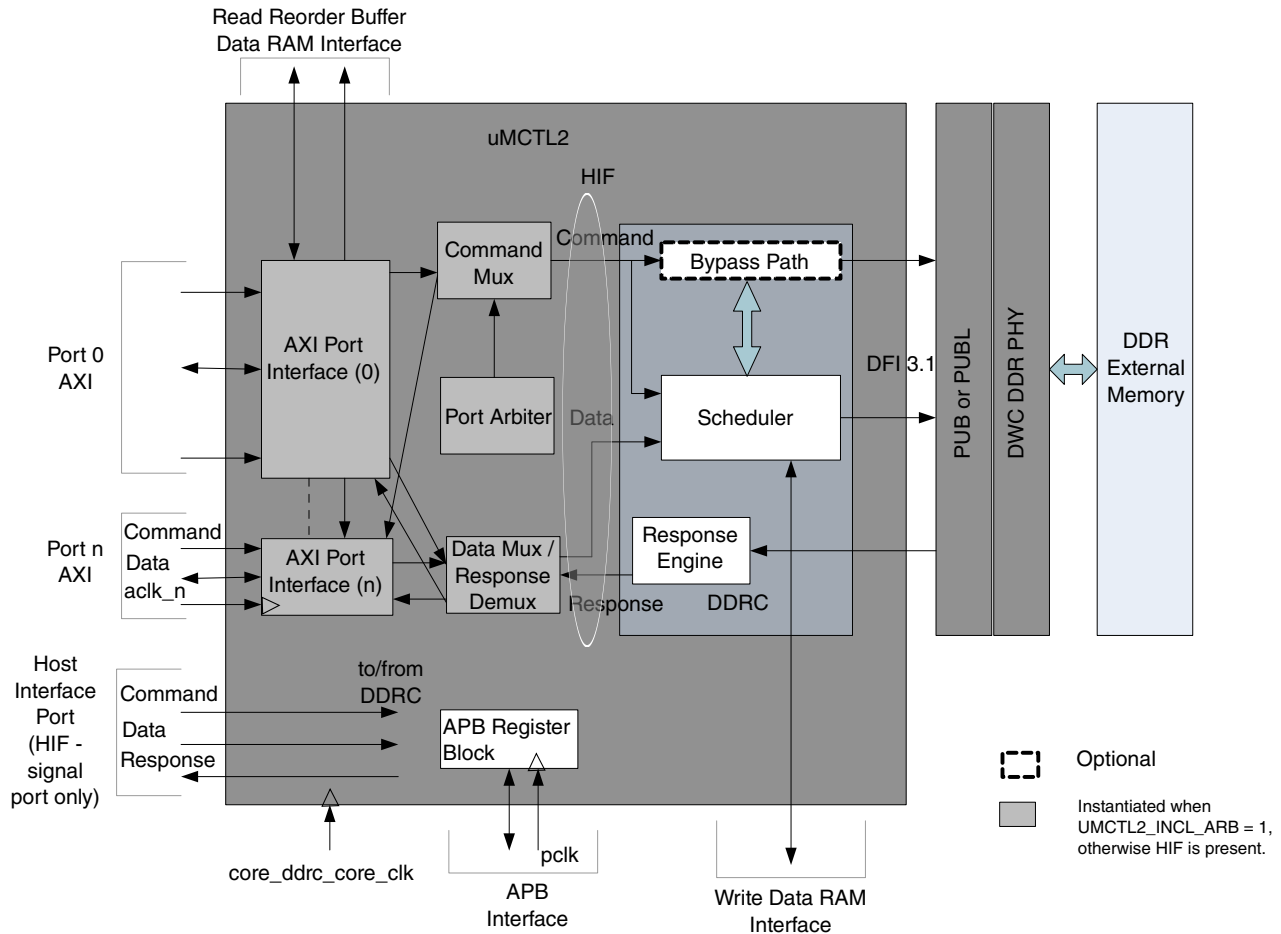

Figure 9-1. DDRMC Block Diagram

The DDRMC contains the following main architectural components:

- The AXI Port Interface (XPI) block: This block provides the interface to the application ports. It provides bus protocol handling, data buffering and reordering for read data, data bus size conversion (upsizing or downsizing), and memory burst address alignment.
- The Port Arbiter (PA) block: This block provides latency sensitive, priority based arbitration between the addresses issued by the XPIs (by the ports).
- The DDR Controller (DDRC) block: This block contains a logical CAM (Content Addressable Memory), which can be synthesized using standard cells. This holds information on the commands, which is used by the scheduling algorithms to optimally schedule commands to be sent to the PHY, based on priority, bank / rank status and DDR timing constraints. A bypass path is also provided (optionally).
- The APB Register Block: This block contains the software accessible registers.

9.2.2.2 Clocks

All application port clocks (ACLK_N) are independently configurable as asynchronous or synchronous with respect to the main DDRMC clock (CORE_DDRC_CORE_CLK). The APB interface clock (PCLK) is normally asynchronous to the CORE_DDRC_CORE_CLK. The interfaces that needs to be asynchronously configured, incur latency and area increase due to the additional clock domain crossing circuitry.

NOTE

PCLK frequency must be the same or less than CORE_DDRC_CORE_CLK frequency.

9.2.3 Features

The DDRMC supports the following features:

- Complete, integrated, single-vendor DDR3, LPDDR2, LPDDR3 solution
- DDR PHY Interface (DFI) support for easy integration with industry standard DFI 3.1-compliant PHYs
 - All signals supported on control, write data, and read data interfaces
 - Low Power Interface
- Scalable 1:2 frequency ratio architecture
- For DDR3, LPDDR2 and LPDDR3 configurations, direct software request control or programmable internal control for ZQ short calibration cycles
- For DDR3, LPDDR2 and LPDDR3 configurations, support for ZQ long calibration after self- refresh exit
- For LPDDR2 and LPDDR3 configurations, support for ZQ Reset feature through software
- Dynamic scheduling to optimize bandwidth and latency
- Read and write buffers in fully associative CAMs, configurable in powers of two, up to 64 reads and 64 writes
- Delayed writes for optimum performance on SDRAM data bus
- For maximum SDRAM efficiency, commands are executed out-of-order
- Hardware configurable and software programmable Quality of Service (QoS) support:
 - Support for three traffic classes on read commands—high priority reads, variable priority reads and low priority reads
 - Support for two traffic classes on write commands—normal priority writes and variable priority writes
 - Support for port urgent and port throttling control
- Configurable maximum SDRAM data-bus width (denoted “full data-bus width” below)

- Programmable support for all of the following SDRAM data-bus widths:
 - The full data-bus width or
 - Half of the full data-bus width or
- Two priorities for read transactions, and one for writes
- Control options to avoid starvation of lower priorities
- Guaranteed coherency for write-after-read (WAR) and read-after-write (RAW) hazards
- Write combine to allow multiple writes to the same address to be combined into a single write to SDRAM; supported for same starting address
- Paging policy selectable by configuration registers as any of the following:
 - Leave pages open after accesses
 - Close page when there are no further accesses available in the controller for that page, or
 - Auto-precharge with each access, with an optimization for page-close mode which leaves the page open after a flush for read-write and write-read collision cases
- Support automatic SDRAM power-down entry and exit caused by lack of transaction arrival for programmable time
- Support automatic Clock Stop (LPDDR2 / LPDDR3) entry and exit caused by lack of transaction arrival
- Support automatic power-down entry and exit caused by lack of transaction arrival for programmable time
- Support self-refresh entry and exit as follows:
 - Support automatic self-refresh entry and exit caused by lack of transaction arrival for programmable time
 - Support for self-refresh entry and exit under software control
 - Support for self-refresh entry and exit using dedicated DDRC hardware low power interface control (similar to the AMBA 3 AXI protocol low power control interface)
- Support for dynamically changing clock frequency while in self-refresh
 - DDR3 DLL-off mode supported
- Support for deep power-down entry and exit under software control (LPDDR2 / LPDDR3)
- Support for explicit SDRAM mode register updates under software control
- Flexible address mapper logic to allow application specific mapping of row, column, bank, and rank bits
- User-selectable refresh control options:
 - Controller-generated auto-refreshes at programmable average intervals
 - Ability to group up to 8 controller-generated refreshes together to be issued consecutively (this reduces the frequency of page closings, increasing overall efficiency)

- When controller-generated refreshes are grouped, some refreshes can be issued speculatively when the controller is idle for a programmable period of time
- Ability to disable controller-generated auto-refreshes
- Ability to issue a refresh through direct software request
- When LPDDR2 / LPDDR3 is used, user-selectable ability to perform per-bank refreshes rather than all-banks refreshes
- Advanced power-saving design includes no unnecessary toggling of command, address, and data pins (RAS / CAS / WE / BA / A hold last state after each command; DQ does not transition on writes when bytes are disabled)
- Low area, low power architecture
- 5-clock cycle typical command latency through the DDRMC (HIF interface)
 - Can be reduced to 4 cycles by choosing not to register DFI outputs (Configuration parameter)
 - 3-clock cycles for high priority read
- Leverages out of order requests with CAM to maximize throughput
- APB interface for the DDRMC software accessible registers

9.2.4 Functional Description

This chapter describes the functional about the DDRMC.

9.2.4.1 Functional overview

This section explains the functionality of the DDRMC. The DDRMC is composed of the following main architectural blocks:

- AXI Port Interface (XPI)
- DDR Controller (DDRC)
- Register Block

The DDRMC performs the following functions:

- Accepts requests from the SoC core with system addresses and associated data for writes.
- Performs address mapping from system addresses to SDRAM addresses (rank, bank, bank group, row).
- Prioritizes requests to minimize the latency of reads (especially high priority reads) and maximize page hits.
- Ensures that the SDRAM is properly initialized.
- Ensures that all requests made to the SDRAM are legal (accounting for associated SDRAM constraints).

- Ensures that refreshes and other SDRAM and PHY maintenance requests are inserted as required.
- Controls when the SDRAM enters and exits various power-saving modes appropriately.

9.2.4.2 Address mapper

Read and write requests are provided to the DDRMC with a system address. The system address is the command address of a transaction as presented on one of the data ports. The DDRMC converts this system address to a physical address. It maps the system address to the SDRAM rank, bank, row, and column addresses.

If the system address regions are enabled (`DDRMC_A_NSAR > 0`), the first part of the mapping is conversion of system address to AXI¹ byte address. The controller maps disjoint address regions to internal consecutive addresses. Otherwise, the controller assumes that the DRAM is always mapped as a monolithic block. For more information about this, see [System address regions](#).

The second part of this mapping is conversion of AXI/AHB byte address to HIF word address. This is performed in the XPI block, and is applicable to AXI/AHB configurations only. For more information about this, see [Application to HIF address mapping](#).

The last part is the conversion of HIF word address to SDRAM address. A flexible address mapper maps the HIF word address to the SDRAM rank / bank / bank group / row / column address. This address mapper is located within the DDRC.

The address mapping to be used depends on the use-case. The DDRMC provides a set of registers that allows flexible re-programming of logical to physical address mapping. For more information about this, see [HIF address to SDRAM address mapping](#).

The following figure explains the conversion of AXI to HIF to the SDRAM rank / bank / row / column / bank group addresses.

1. System Address Regions are only supported with AXI configurations.

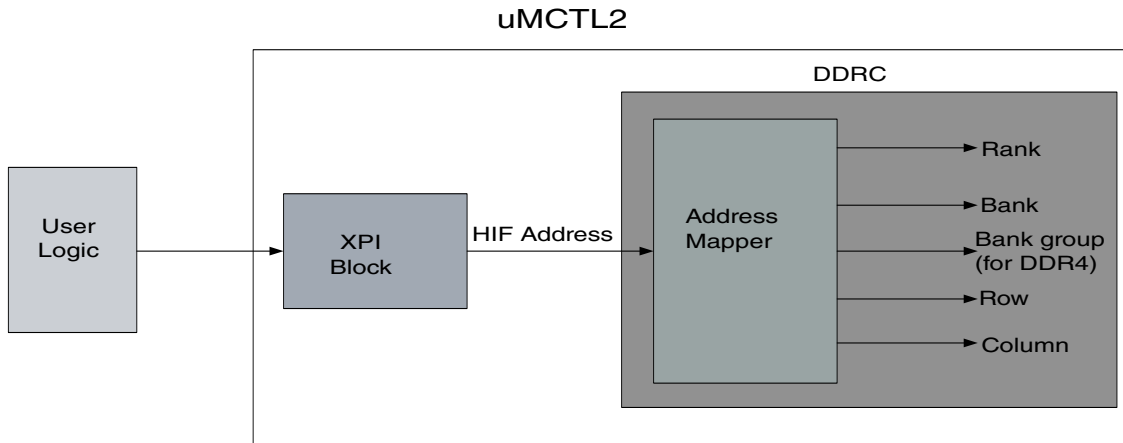

Figure 9-2. Conversion of AXI to HIF to SDRAM Rank / Bank / Row / Column / Bank Group Addresses

9.2.4.2.1 System address regions

The system address regions add the capability to define up to four disjoint memory regions mapping to the DRAM as consecutive addresses. The number of regions and minimum block size are determined by the hardware parameters `DDRMC_A_NSAR` and `DDRMC_SARMINSIZE`.

Each region is defined by:

- Base Address: Starting address of the region aligned to the minimum block size.
- Number of Blocks: Size of the region in multiples of minimum block size.

The base address of each region is specified by the register `SARBASEn.base_addr` and the total number of blocks is specified by the register `SARSIZEn.nblocks` (see [SAR Size Register n \(DDRC_MP_SARSIZEn\)](#)).

System address region specification is the same for all ports. Error response is not generated by the controller for addresses falling outside the specified address regions and the same address translation is applied from one base address to the next base address.

The base addresses must be specified so that they do not overlap. It is assumed that an outside agent can generate address decode errors if they happen to occur.

9.2.4.2.1.1 System address regions example

Consider the following example. The controller is set to have three system address regions (as specified on [Table 9-2](#)), with a minimum block size of 2 GB. Therefore, the `DDRC_SARMINSIZE` parameter must be set to 4.

The system address bits [`DDRC_A_ADDRW-1:31`] is used to represent the base addresses in the multiples of the minimum block size.

The registers must be programmed as follows:

- `SARBASE0.base_addr = 1` (see [SAR Base Address Register n \(DDRC_MP_SARBASEn\)](#))
- `SARBASE1.base_addr = 17`
- `SARBASE2.base_addr = 272`
- `SARSIZE0.nblocks = 0`
- `SARSIZE1.nblocks = 14`
- `SARSIZE2.nblocks = 15`

The specifications in [Table 9-2](#) translates to the register settings mentioned in [Table 9-3](#).

Table 9-2. Address Region Mapping Example - Specification

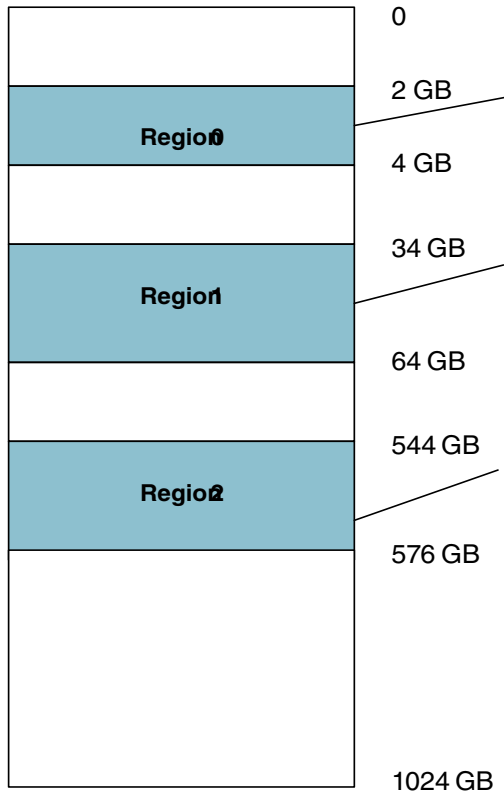

Region	System Address (40-bit)	Offset	Internal Controller Address (36-bit)
Region 0 (2 GB)	0x00 8000 0000–0x00 FFFF FFFF	0x00 8000 0000	0x00 0000 0000–0x00 7FFF FFFF
Region 1 (30 GB)	0x08 8000 0000–0x0F FFFF FFFF	0x08 80000 0000	0x00 8000 0000–0x07 FFFF FFFF
Region 2 (32 GB)	0x88 0000 0000–0x8F FFFF FFFF	0x80 0000 0000	0x08 0000 0000–0x0F FFFF FFFF

Table 9-3. Example Base Addresses, Number of Blocks and Offset

Region	Base Address (Binary)	Register Value (base_addr)	Register Value (n blocks)	Calculated Base Address	Calculated Offset (Decimal / GB)
Region 0	9'b0_0000_0001	1	1	2 GB	1 / 2GB
Region 1	9'b0_0001_0001	17	15	34 GB	16 / 32GB
Region 2	9'b1_0001_0000	272	16	544 GB	256 / 512GB

[Figure 9-3](#) shows the graphical illustration of the system address regions as specified in [Table 9-2](#).

System Address Map (40-bit)

Internal Controller Address Map (36-bit)

Figure 9-3. Address Region Mapping Example

NOTE

When $\text{DDRMC_AXI_BOUNDARY} > \text{DDRMC_SARMINSIZE} + 27$, portion of the address below the boundary can be changed by the conversion from system to AXI address. In this case, the user should ensure that the converted AXI address does not cross the boundary.

9.2.4.2.1.2 Application to HIF address mapping

The $\{\text{ARADDR} \mid \text{AWADDR} \mid \text{HADDR}\}$ is a byte address. Based on the MEMC_BURST_LENGTH , XPI maps the MSB bits of the application address to the HIF address (hif_cmd_addr) in the following ways:

- $\text{HIF_CMD_ADDR} [\text{36} : \text{LOG2}(\text{MEMC_BURST_LENGTH})] = \{\text{ARADDR} \mid \text{HADDR}\} [\text{DDRMC_A_ADDRW} - 1 : \text{LOG2}(\text{MEMC_BURST_LENGTH}) + \text{LOG2}(\text{MEMC_DRAM_DATA_WIDTH} / 8)]$

- HIF_CMD_ADDR [LOG2 (MEMC_BURST_LENGTH) - 1: MEMC_FREQ_RATIO] is internally generated by XPI.
- HIF_CMD_ADDR [MEMC_FREQ_RATIO-1: 0] = 0

For example, if memory data width is 16, frequency ratio is 1:1, and the application address width is 32:

- If MEMC_BURST_LENGTH = 8
 - HIF_CMD_ADDR [36:3] = {ARADDR | HADDR} [31:4]
 - HIF_CMD_ADDR [2:1] is internally generated by XPI.
 - HIF_CMD_ADDR [0] = 0
- If MEMC_BURST_LENGTH = 4
 - HIF_CMD_ADDR [36:2] = {ARADDR | AWADDR | HADDR} [31:3]
 - HIF_CMD_ADDR [1] is internally generated by XPI.
 - HIF_CMD_ADDR [0] = 0

9.2.4.2.1.3 HIF address to SDRAM address mapping

The address mapper maps HIF word addresses to SDRAM addresses by selecting the HIF address bit that maps to each and every applicable SDRAM address bit. While it is possible to map HIF address bits to a SDRAM address in any desired manner, the full available address space is accessible only when no two SDRAM address bits are determined by the same HIF address bit. Each SDRAM address bit has an associated register vector to determine its source.

Registers ADDRMAP_x (x = 0 to 8) are used to program the address mapper. For more information on ADDRMAP registers, see [DDRC](#).

The HIF address bit number is determined by adding the internal base of the ADDRMAP_x (x = 0 to 8) register to the programmed value for that register, as described in the following equation:

$$\text{HIF address bit number} = [\text{internal base}] + [\text{register value}]$$

For example, for ADDRMAP3.addrmap_col_b7, the internal base is 7. When full data bus is in use, column bit 7 is determined by the following equation:

$$7 + [\text{register value}]$$

If this register is programmed to 2, the HIF address bit can be calculated by using following equation:

$$[\text{HIF address bit number}] = 7 + 2 = 9$$

In other words, the column address bit 7 sent to SDRAM would always be equal to hif_cmd_addr[9] of the corresponding HIF source address.

NOTE

- All of the column bits shift up 1 bit when only half of the data bus is in use. In this case, you need to look at ADDRMAP3.addrmap_col_b6 instead to determine the value of column address bit 7.
- All of the column bits shift up 2 bits when only a quarter of the data bus is in use. In this case, you need to look at ADDRMAP2.addrmap_col_b5 instead to determine the value of column address bit 7.
- All of the column bits shift up an additional 1 bit when the DDRMC is configured for BL8 mode (MEMC_BURST_LENGTH = 8).
- For Arbiter configurations (DDRMC_UNCL_ARB = 1) with mEMC_BURST_LENGTH = 8, it is required to program ADDRMAP2.addrmap_col_b2 = 0, so that the Arbiter can generate HIF address that are column aligned.
- If LPDDR2 or LPDDR3, or if MEMC_BURST_LENGTH = 8, it is required that HIF_CMD_ADDR [0] = 0, If DDRMC_INCL_ARB = 1, this is automatically the case. Otherwise, it is required that the HIF master generates HIF_CMD_ADDR [0] = 0.
- The register ADDRMAP5.addrmap_row_b2_10 maps multiple HIF address bits.
- For any address bits which cannot be in use in all cases, all bits of the associated address map register must be set to 1 when the associated SDRAM address bit is not in use.

The system address to physical address mapping can be completed by choosing any one of the possible combinations from the following figure. It explains the different possible ways to map the HIF address bits to the SDRAM rank / bank/ bank group / row / column address.

Figure 9-4. System Address to Physical Address Mapping (Independent of MEMC_BURST_LENGTH)

NOTE

User should ensure that no two SDRAM address bits are determined by the same HIF address bit.

The following table shows some examples of address mapping schemes which might be used. This example assumes a full bus width, using an SDRAM with 10 column address bits (denoted “c” in the diagram), three bank address bits (denoted “b”) and 12 row address bits (denoted “r”). The non-interleaved example shows a simple address map where the lowest HIF address bits map to the SDRAM column addresses, the next three to the bank addresses, and the highest HIF address bits map to the row addresses. In the first interleaved example, the bank address bits are interleaved with the column address bits. In the last two examples, a more arbitrary mapping is shown. These examples are randomly selected to illustrate the flexibility of the DDRMC address mapper and they have no bearing on a typical system.

NOTE

The example "Non-Interleaved" and "Interleaved example1" are the same for both MEMC_BURST_LENGTH = 4 and MEMC_BURST_LENGTH = 8.

Table 9-4. Logical to Physical Address Mapping (Examples for DDR3)

	HIF Address Bits MEMC_BURST_LENGTH	2 4	2 3	2 2	2 1	2 0	1 9	1 8	1 7	1 6	1 5	1 4	1 3	1 2	1 1	1 0	9	8	7	6	5	4	3	2	1	0
Non-interleaved	8	r1 1	r1 0	r9	r8	r7	r6	r5	r4	r3	r2	r1	r0	b2	b1	b0	c9	c8	c7	c6	c5	c4	c3	c2	c1	c0
	4	r1 1	r1 0	r9	r8	r7	r6	r5	r4	r3	r2	r1	r0	b2	b1	b0	c9	c8	c7	c6	c5	c4	c3	c2	c1	c0
Interleaved - example 1	8	r1 1	r1 0	r9	r8	r7	r6	r5	r4	r3	r2	r1	r0	c9	c8	c7	c6	c5	c4	b2	b1	b0	c3	c2	c1	c0
	4	r1 1	r1 0	r9	r8	r7	r6	r5	r4	r3	r2	r1	r0	c9	c8	c7	c6	c5	c4	b2	b1	b0	c3	c2	c1	c0
Interleaved - example 2	8	r1 1	r1 0	r9	r8	r7	r6	r5	r4	r3	r2	c6	c7	b2	c8	c9	r0	r1	b1	c3	c5	c4	b0	c2	c1	c0
Interleaved - example 3	4	r1 1	r1 0	r9	r8	r7	r6	r5	r4	r3	r2	c9	r0	r1	b0	c7	c8	c5	b1	c6	b2	c4	c3	c2	c1	c0

The following table illustrates how the ADDRMAP* registers should be set to achieve a particular address mapping. The address mapping is chosen from the interleaved example 2 of [Table 9-4](#).

Table 9-5. Example of Register Programming to Implement a Desired Address Mapping Scheme (for DDR3)

HIF Address Bit	Desired SDRAM Address	Register Field to be Programmed	Internal Base	Value to Program
0	c0	None	—	—
1	c1	None	—	—
2	c2	ADDRMAP_MAP_COL_B2	2	0
3	b0	ADDRMAP_BANK_B0	2	0
4	c4	ADDRMAP_COL_B4	4	0
5	c5	ADDRMAP_COL_B5	5	0
6	c3	ADDRMAP_COL_B3	3	3
7	b1	ADDRMAP_BANK_B1	3	4
8	r1	ADDRMAP_ROW_B1	7	1
9	r0	ADDRMAP_ROW_B0	6	3
10	c9	ADDRMAP_COL_B8	8	2
11	c8	ADDRMAP_BANK_B7	7	4
12	b2	ADDRMAP_COL_B2	5	7

Table continues on the next page...

Table 9-5. Example of Register Programming to Implement a Desired Address Mapping Scheme (for DDR3) (continued)

HIF Address Bit	Desired SDRAM Address	Register Field to be Programmed	Internal Base	Value to Program
13	c7	ADDRMAP_COL_B6	6	7
14	c6	ADDRMAP_ROW_B5	5	9
15	r2	ADDRMAP_ROW_B2_10	8	7
...
23	r10	ADDRMAP_ROW_B2_10	16	7
24	r11	ADDRMAP_ROW_B11	17	7

9.2.4.2.1.4 LPDDR3 6-Gb and 12-Gb device densities

LPDDR3 6Gb and 12Gb device densities do not support addresses which have both row bits 13 and 14 high (row[14:13] = 2'b11). Any attempt to read or write to this address space could result in memory misbehavior or the system hangs. When such devices are used, the user must set register ADDRMAP6.lpddr3_6gb_12gb to 1 (see [Address Map Register 6 \(DDRC_ADDRMAP6\)](#)). This prevents the DDRMC from accessing this address space when there is a read or write request from the user / SoC core.

When ADDRMAP6.lpddr3_6gb_12gb is set to 1, any write or RMW request with row[14:13] = 2'b11 is discarded, while the HIF output HIF_WDATA_PTR_ADDR_ERR is asserted. Also, any read request with row[14:13] = 2'b11 is executed (dummy read), by changing row[14:13] from 2'b11 to 2'b10. The return data for such reads are masked to zeros, while the HIF output HIF_RDATA_ADDR_ERR is asserted.

For AXI / AHB configurations, any assertion of HIF_WDATA_PTR_ADDR_ERR or HIF_RDATA_ADDR_ERR results also in SLVERR / ERROR response.

9.2.4.3 Transaction service control

The transaction service control allows the user to carefully manage the following:

- Costly read / write bus turn-arounds
- Priorities of read requests to generally favor high priority traffic while also preventing starvation of low priority traffic

This functionality is implemented in a simple 2-state machine for each traffic type with completely configurable controls. The states of the 2-state machine determine when reads / writes are serviced and the relative priority (high priority versus low priority reads) at any given moment.

Following is the list of registers related to transaction service control:

- Low priority read transaction store
 - PERFLPR1.lpr_max_starve (see [Low Priority Read CAM Register 1 \(DDRC_PERFLPR1\)](#))
 - PERFLPR1.lpr_xact_run_length
- High priority read transaction store
 - PERFHPR1.hpr_max_starve
 - PERFHPR1.hpr_xact_run_length
- Write transaction store
 - PERFWR1.w_max_starve
 - PERFWR1.w_xact_run_length
- Bus turn-around control
 - SCHED.prefer_write
 - SCHED.rdwr_idle_gap
- Variable priority read transaction grouping
 - PERFVPR1.vpr_timeout_range
- Variable priority write transaction grouping
 - PERFVPW1.vpw_timeout_range

9.2.4.3.1 Transaction stores

Transactions in the DDRMC are separated into five categories:

- Low Priority Reads (LPR)
- Variable Priority Reads (VPR)
- High Priority Reads (HPR)
- Normal Priority Writes (NPW)
- Variable Priority Writes (VPW)

NOTE

VPR and VPW categories are only supported when the multi port arbiter is configured (`DDRMC_INC_ARB = 1`). Hardware parameters `DDRMC_INCL_ARB` and `DDRMC_VPRW_EN` should be defined to enable the VPR / VPW feature.

9.2.4.3.1.1 Read transaction store

This section describes how LPR, VPR and HPR traffic classes work inside the DDRC. See [Quality of service](#) for information on how to map the AXI `arqos` value to LPR, VPR, and HPR traffic queues.

SCHED.lpr_num_entries register splits the Read CAM in the controller into LPR and HPR sections. The LPR and VPR commands are sent to the LPR section of the CAM, and the HPR commands are sent to the HPR section. The VPR commands come in with an associated ‘timeout’ value. The LPR and HPR commands do not have ‘timeout’ value associated with them. The ‘timeout’ value of the VPR commands are counted down every cycle in which the commands are pending in the LPR store. If any VPR command has not been serviced and its ‘timeout’ value reaches 0, the command is considered as expired-VPR command. When there are any expired-VPR commands in the DDRC, those commands are given higher priority than HPR and LPR commands.

A register, PERFVPR1.vpr_timeout_range, is used to indicate the range of the ‘timeout’ counter value to be considered when the priority is switched from VPR to expired-VPR. This feature is used to execute a group of VPR commands that are in the temporal vicinity together, thereby possibly improving the bus utilization. For example, if the register value is set to 0xF, it indicates that the priorities of all the VPR entries whose timeout counters are 15 or below are promoted to expired-VPR when any of the VPR commands timeout.

The Read CAM handles three traffic classes - LPR, VPR and HPR. But the Scheduling Engine that gets its input from the Read CAM, handles only two traffic classes - LPR and HPR. When there are no expired-VPR commands, all the VPR commands are treated as LPR. When there are any expired-VPR commands in DDRC, all expired-VPR commands are treated as HPR commands.

9.2.4.3.1.2 Write transaction store

This section describes how NPW and VPW traffic classes work inside the DDRC. See [Quality of service](#) for information on how to map the AXI awqos value to NPW and VPW traffic queues.

The NPW and VPW commands are sent to the Write CAM. VPW commands do not have reserved space in the Write CAM. The VPW commands come in with an associated ‘timeout’ value. The NPW commands do not have ‘timeout’ value associated with them. The ‘timeout’ value of the VPW commands are counted down every cycle in which the commands are pending in the WR store. If any VPW command has not been serviced and its ‘timeout’ value reaches 0, the command is considered as expired-VPW command. When there are any expired-VPW commands in the DDRC, those commands are given higher priority than NPW commands.

A register, PERFVPW1.vpw_timeout_range, is used to indicate the range of the ‘timeout’ counter value to be considered when the priority is switched from VPW to expired-VPW. This feature is used to execute a group of VPW commands that are in the temporal vicinity together, thereby possibly improving the bus utilization. For example, if the

register value is set to 0xF, it indicates that the priorities of all the VPW entries whose timeout counters are 15 or below are promoted to expired-VPW when any of the VPW commands timeout.

The Write CAM handles two traffic classes - NPW and VPW. But the Scheduling Engine that gets its input from the Write CAM, handles only one traffic class - NPW. When there are no expired-VPW commands, all the VPW commands are treated as NPW. When there are any expired-VPW commands in DDRC, all expired-VPW commands are given higher preference over NPW commands.

9.2.4.3.1.3 Transaction store state transitions

Each class of transaction store (LPR, HPR, or WR) can be in any one of the following two states:

- Normal: It is the state where the transaction store starts.
- Critical: It indicates that the transaction store must be prioritized for service.

The transaction stores move between these two states under the control of *_MAX_STARVE and *_XACT_RUN_LENGTH registers.

The following table describes the transaction store state transitions.

Table 9-6. Transaction Store State Transitions

Current State	Next State	State Transition
Normal	Critical	This transaction store is not serviced for a count of *_MAX_STARVE clock cycles, or if an address collision happens.
Critical	Normal	*_XACT_RUN_LENGTH number of transactions is serviced from this transaction store.

Taking the low priority read transaction store as an example, it is expected that the transaction store generally functions independently based on the following registers (see [Low Priority Read CAM Register 1 \(DDRC_PERFLPR1\)](#)):

- PERFLPR1.lpr_max_starve
- PERFLPR1.lpr_xact_run_length

In the normal mode of operation, the FSM moves from normal to critical state when the starvation timer times out. The store remains in Critical state until the number of transactions equal to what is indicated in PERFLPR1.lpr_xact_run_length are serviced, or when there are no more commands available for that store, whichever happens first.

The presence of any expired-VPR command in the DDRC makes the HPR queue to be in Critical state regardless of the value of its starvation timer. The HPR queue stays in Critical state until all the expired-VPR commands are served.

Similarly, the presence of any expired-VPW command in DDRC makes the WR queue to be in Critical state regardless of the value of its starvation timer. The WR queue stays in Critical state until all the expired-VPW commands are served.

When the DDRMC is configured as HIF-only (DDRMC_INCL_ARB = 0), it provides a feature where the SoC core can force this state transition using external signals. It is useful in cases where the SoC core may have additional information that is helpful in determining state transitions. For example, if the data stream has real-time requirements and the SoC core has knowledge about FIFO depths or time-till-failure, it can use this information to explicitly request the DDRMC to prioritize a particular data stream when it is critical to do so. The signals associated with this feature are HIF_GO2CRITICAL_LPR and HIF_GO2CRITICAL_WR.

In case of multi port arbiter configuration (DDRMC_INCL_ARB = 1), the HIF_GO2CRITICAL_* SIGNALS are driven by the Port Arbiter. The generation of three signals involved in this case - HIF_GO2CRITICAL_WR, HIF_GO2CRITICAL_LPR and HIF_GO2CRITICAL_HPR is described in [VPR / VPW timeout](#) and [Urgent signalling](#).

The assertion of HIF_GO2CRITICAL_* SIGNALS cause their respective queue FSMs to go to Critical state. The change in Read / Write mode switching and the Read priority level selection based on the presence of the HIF_GO2CRITICAL_* SIGNALS is mentioned in the following section.

9.2.4.3.1.4 Read / Write turn-around

The following terminology is used to describe the Read / Write turn-around algorithm:

- Write / Read pending: A Write or a Read command is pending in the CAM.
- Write / Read collision: A Write collision indicates that a new Read command that arrived on the HIF bus is to the same address as a pending Write in the CAM and that the collided Write has to be now flushed before accepting the Read command into the CAM (vice versa for Read collision).
- Write / LPR / HPR critical: Indicates that the Write, LPR or HPR queue is in critical state due to starvation.
- Read / Write idle timeout: Read/Write idle timer based on the register SCHED.rdwr_idle_gap has expired.

The DDRC starts in the Read mode (servicing read requests) and then switches to Write mode (servicing write requests) in the following conditions:

- Write pending && (Write collision || Write critical) && ! Read collision && ! HPR critical && ! LPR critical, or

- No Read pending && (SCHED.prefer_write || (Write pending && Read/Write idle timeout)), or
- Expired-VPW pending and no Expired-VPR pending

The DDRC switches back to Read mode in the following conditions:

- Read pending && (hif_go2critical_hpr || hif_go2critical_lpr) && !Write collision
- Read pending && (Read collision || HPR critical || LPR critical) && ! Write collision && ! Write critical,
- No Write pending && (~SCHED.prefer_write || (Read pending && Read/Write idle timeout))
- Expired-VPR pending

The Read / Write idle timeout logic is as given below:

- If SCHED.prefer_write = 0, count down when Write pending and No Reads.
- If SCHED.prefer_write = 1, count down when Read pending and No Writes.

When both expired-VPR and expired-VPW are present at the same time, expired-VPR is given higher preference.

NOTE

- The normal programming is expected to be SCHED.prefer_write = 0. This implies that read requests are immediately serviced when the DDRMC is idle. Also, it is often desirable to set the SCHED.rdwr_idle_gap to a lower number (such as 0, 1, or 2). This ensures that writes do not go unserved in an otherwise-idle DDRMC for any length of time, wasting the bandwidth. The trade-off is that reads received on the HIF immediately after these writes may incur additional latency. This is because time is needed to turn the bus around, service the writes, and then turn the bus around again to service the reads.
- Ordering between reads and writes to the same address is guaranteed on all requests issued to the DDRMC. Therefore, write latency is not be a concern to system design. In the event that write data is required by a subsequent read, the DDRMC automatically forces the write data out to SDRAM before servicing the read.

9.2.4.3.1.5 Read priority management

In a read mode, high priority read requests are preferred for service over low priority read requests. However, if the low priority read transaction store is in Critical state due to a transaction that is pending for a long time (see [Transaction store state transitions](#)) and the high priority read transaction store is not, the low priority read requests are preferred over high priority read requests. This prevents starvation of low priority reads.

The exceptions to the above rule are as follows:

- When there are any expired-VPR commands in DDRC, the HPR queue is given priority over LPR queue, even if LPR queue is in Critical state.
- If HIF_GO2CRITICAL_HPR is high, the HPR queue is given priority over LPR queue, even if LPR queue is in Critical state.
- If HIF_GO2CRITICAL_LPR is high and HIF_GO2CRITICAL_HPR is low, the LPR queue is given priority over HPR queue, even if HPR queue is in Critical state

9.2.4.3.2 Address collision handling

The DDRC can execute transactions out-of-order while ensuring that all transactions appear as if they are executed in the order in which they are received. Every transaction that requires a response from the DDRC arrives with a token number which is provided back to the SoC core as part of the response. Since the DDRC queues transactions prior to execution, it is possible that multiple transactions to the same SDRAM address can arrive before the first transaction to that address is issued.

To enforce ordering of accesses to the same address, the DDRC uses the following algorithm:

1. **New read colliding with queued read:** This collision causes no problems. The two reads can end up being executed out-of-order.
2. **New write colliding with queued write:** If write combine is enabled, the DDRC overwrites the data for the old write with that from the new write and only performs one write transaction (write combine). For more information about this, see [Write combine](#).
3. **New read (or write) colliding with queued write (or read) respectively:** In this case, the DDRC performs the following sequence:
 - a. Holds the new transactions in a temporary buffer.
 - b. Applies flow control back to the SoC core to prevent more transactions from arriving.
 - c. Flushes the internal queue holding the colliding transaction until that transaction is serviced.
 - d. Accepts the new transaction and removes flow control.

4. **New read colliding with both read and write:** This can happen when a read collides with a RMW command. In this case, the reads are flushed until the read collision is cleared, then the writes are flushed in the same manner as described in the step3.
5. **New write colliding with both read and write:** This can happen when a write collides with a RMW command. In this case, the new write is held in a temporary buffer until the read is completed. Then, it is combined with the queued write (if write combine is enabled).
6. **New RMW colliding with queued write:** In this case, the new RMW is stored in a temporary buffer until the queued write is completed.

9.2.4.3.3 Write combine

The write combine feature can combine multiple writes to the same address into a single write to SDRAM.

When a new write collides with a queued write in the CAM

- If write combine is enabled, the DDRC overwrites the data for the old write with that from the new write and only performs one write transaction (write combine).
- If write combine is disabled, the DDRC performs the following sequence:
 - a. Holds the new write transaction in a temporary buffer.
 - b. Applies flow control back to the SoC core to prevent more transactions from arriving.
 - c. Flushes the internal queue holding the colliding transaction until that transaction is serviced.
 - d. Accepts the new transaction and removes flow control.

9.2.4.3.4 Page policy

9.2.4.3.4.1 Explicit auto-precharge (Per command)

The explicit auto-precharge feature can enable auto-precharge on a per-command basis. If the HIF signal HIF_CMD_AUTOPRE is set during a valid command, then the auto-precharge bit for that command is set when it is sent to the SDRAM.

If you do not want to use the per-command auto-precharge feature, then this bit can be tied to 1'b1 or 1'b0. Tying it to 1'b1 causes all the commands to be executed with auto-precharge, and tying it to 1'b0 causes no commands to be executed with auto-precharge. For AXI configurations, HIF_CMD_AUTOPRE is tied to 0 internally, and is not accessible to the user.

In cases where a HIF transaction is translated into multiple DFI transactions, only the last DFI transaction is executed with auto-precharge. The earlier ones keep the page open, to allow subsequent transactions to benefit from the page hit. Also, if `DBG0.dis_collision_page_opt` (see [Debug Register 0 \(DDRC_DBG0\)](#)) is set to 0, the auto-precharge is automatically disabled for the flushed command in a collision case.

9.2.4.3.4.2 Intelligent precharges

The `SCHED.pageclose` register (see [Scheduler Control Register \(DDRC_SCHED\)](#)) enables precharge commands to be issued smartly via auto-precharges or explicit precharges. The exact functionality depends on the value programmed in `SCHED1.pageclose_timer`:

- If `SCHED.pageclose` is set to 1 and `SCHED1.pageclose_timer = 0`, a bank is kept open until there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit is executed with auto-precharge. Even if this register is set to 1, explicit precharge (and not auto-precharge) can be issued in some cases where there is a mode switch between write and read or between LPR and HPR. The read and write commands that are executed as part of the ECC scrub requests are also executed with explicit precharge if the page needs to be closed.
- `SCHED.pageclose` is set to 1 and `SCHED1.pageclose_timer > 0`, a bank is kept open until there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit is not executed with auto-precharge. Instead, a timer is started with `pageclose_timer` as the initial value. There is a timer on a per bank basis. The timer decrements unless the next read or write in the CAM to a bank is a page hit. It resets to `pageclose_timer` value if the next read or write in the CAM to a bank is a page hit. Once the timer reaches zero, an explicit precharge is scheduled.
- If `SCHED.pageclose` is set to 0, the bank remains open only until there is a need to close it (to open a different page or for page timeout or refresh timeout). This is also known as open page policy. The open page policy can be overridden by setting the per command auto pre bit on the HIF interface (`HIF_CMD_AUTOPRE`) as described in [Explicit auto-precharge \(Per command\)](#). When the multi port arbiter is configured, the HIF signal `hif_cmd_autopre` is tied to 0 and the user has no control over it.

The intelligent precharge feature provides a midway between open and close page policies. `SCHED1.pageclose_timer` (see [Scheduler Control Register 1 \(DDRC_SCHED1\)](#)) gives user control over the time waited when there are no page hits to a bank in the CAM before auto-precharge or explicit precharge is scheduled. It is useful when the multi port arbiter is configured. This timer allows the page to be kept open for a configurable number of clock cycles after there are no commands pending in

the CAM to a bank. If there are pending commands higher up in the stream (for example, XPI / PA of multi port arbiter) to the same bank / page, it gives a chance to be scheduled by the DDRMC as an open page command.

The following table provides a summary of all paging policy options available in the DDRMC.

Table 9-7. Paging Policy Options

Paging Policy	Availability	Description
Open page policy	All configurations	Setting SCHED.pageclose to 0 enables the open page policy. In HIF configurations, the open page policy can be overridden by sending commands with HIF_CMD_AUTOPRE = 1.
Intelligent precharge(Midway between Closed page and Open page policy)	All configurations	Setting SCHED.pageclose to 1 enables this smart paging policy as described in Intelligent precharges . The exact functionality is dependent on SCHED1.pageclose_timer value. InHIF configurations, this paging policy can be overridden by sending commands with HIF_CMD_AUTOPRE = 1.
Closed page policy	Only in HIF configurations. Not in multi port configurations	Control the paging policy per-command by asserting or de-asserting the auto precharge signal on the HIF interface – HIF_CMD_AUTOPRE. If all commands are to be executed with auto-precharge, HIF_CMD_AUTOPRE can be tied to 1.

9.2.4.4 Quality of service

9.2.4.4.1 Traffic classes

The DDRMC supports different traffic classes that are distinguished from each other by the arqos signal:

9.2.4.4.1.1 Read classes

- **Low Priority Read (LPR):** It is also called as the best effort traffic. There is no resource allocation and it shares the resources with the other traffic types. LPR is always treated as low priority in the PA and in the DDRC. There are timeout mechanisms that can be used to prevent starvation for both the PA and the DDRC. When there is a timeout in the PA, that port becomes the highest priority (priority0). When there is a timeout in the LPR store in the DDRC (in other words, LPR store becomes critical), the LPR entries are served before HPR entries.
- **Variable Priority Read (VPR):** It is also called as the maximum latency bound traffic for meeting real time deadlines in video or audio applications. VPR traffic shares the same resources with LPR in the DDRC. But, based on the configuration, it may have a dedicated queue (red or blue) in the XPI. It has the same priority as LPR, but lower priority than HPR for the PA. For the DDRC, VPR has the same initial priority as

LPR. Each command tagged as VPR has an associated latency timer. When expired, VPR transactions have the highest priority in the controller, both in the PA and in the DDRC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.

- High Priority Read (HPR): It has allocated resources. If the XPIs are configured to have dual read address queues, then the red queue can be allocated to HPR. For DDRC, HPR traffic goes to its own dedicated store. HPR traffic has higher priority than LPR. HPR is meant for latency critical but not real time applications such as CPU.

9.2.4.4.1.2 Write classes

- Normal Priority Write (NPW): It is also called as the best effort traffic. There is no resource allocation and it shares the resources with the other traffic types. It is always treated as normal priority in the PA and DDRC. There are timeout mechanisms that can be used to prevent starvation for the PA. When there is a timeout in the PA, that port becomes the highest priority (priority0).
- Variable Priority Write (VPW): It is also called as the maximum latency bound traffic to meet real time deadlines in video or audio applications. VPW traffic shares the same resources with NPW in the DDRC. For the DDRC, VPW has the same initial priority as NPW. Each command tagged as VPW has an associated latency timer. When expired, VPW transactions have the highest priority in the controller, both in the PA and in the DDRC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.

9.2.4.4.1.3 QoS mapping

The priority of an initiator (master) is susceptible to change by the intermediate agents (for example, interconnect) before reaching the destination slave depending on the service levels provided with respect to the required targets. Therefore, the relationship between the IDs and their class representations must be dynamically determined.

Arqos / awqos signal determines both port priorities and DDRC priorities dynamically. 16 QoS levels are divided to three regions for reads, two regions for writes. Each region can be assigned to any of the following traffic class—LPR, VPR, and HPR for reads, NPW and VPW for writes.

Region 0 and 1 are assigned to the blue address queue (See [Dual read address queue](#)). Typically, LPR / NPW and VPR / VPW may share this resource.

Region 2 is assigned to the red read address queue, this is not present for writes. The red address queue can be mapped to the HPR or VPR traffic. In the DDRC, LPR and VPR share the same CAM store called LPR store. HPR has its own store in the DDRC.

The regions are mapped per port using PCFGQOS0_n and PCFGWQOS0_n registers (see [Port n Read QoS Configuration Register 0 \(DDRC_MP_PCFGQOS0_0\)](#) and [Port n Write QoS Configuration Register 0 \(DDRC_MP_PCFGWQOS0_0\)](#)).

Fields for PCFGQOS0_n register are as follows:

- RQOS_MAP_LEVEL<x> (where x is 1 to 2) indicates two separation levels for three regions. Possible values 0 to 14 correspond to an arqos value. These registers indicate the upper end of the region. For example, if RQOS_MAP_LEVEL2 is set to 14, then Region 2 is identified as all transactions with arqos value of 15.
- RQOS_MAP_REGION<y> (where y is 0 to 2) for region identifier. This register indicates the traffic class of each of the three regions. RQOS_MAP_REGION2 is present only in dual read queue configurations.

Valid values are:

- 0–LPR
- 1–VPR
- 2–HPR

Fields for PCFGWQOS0_n register are as follows:

- WQOS_MAP_LEVEL indicates the separation level for two regions. Possible values 0 to 14 correspond to an awqos value. These registers indicate the upper end of the region. For example, if WQOS_MAP_LEVEL is set to 14, then Region 1 is identified as all transactions with awqos value of 15.
- WQOS_MAP_REGION<y> (where y is 0 to 1) for region identifier. This register indicates the traffic class of each of the two regions.

Valid values are:

- 0–NPW
- 1–VPW

For dual read address queue configurations, Region 0 and Region 1 map to the blue queue, and Region 2 maps to the red queue. The blue queue can only be set to LPR, VPR or both. The red queue can only be set to VPR or HPR.

For single address queue configurations, Region 0 and Region 1 map to the blue queue. Being single queue, Region 2 is not present. In this case registers RQOS_MAP_LEVEL2 and RQOS_MAP_REGION2 don't exist. In this case Region 0 can be set to HPR or VPR, Region 1 to VPR or LPR.

The following figure shows an example dynamic mapping from AXI QoS input to internal controller traffic classes.

Figure 9-5. Example AxQoS Mapping to Traffic Classes

9.2.4.4.2 Dual read address queue

There are two separate read address queues in the XPI block—red and blue queue. They can be enabled by the parameter `DDRMC_XPI_USE2RAQ_n` for each port.

Both read queues request independently to the PA; therefore if enabled, maximum configurable number of XPI ports which is 16 is reduced. Each dual-queue XPI consumes two consecutive PA ports. The worst case is that there will be 8 ports where each XPI is configured to have dual read address queue.

Red queue can be used for one traffic class only and associated to Region 2 in the QoS mapper (HPR or VPR). Blue queue can be used for two traffic classes and associated to Region 0 and Region 1 in the QoS mapper (VPR and / or LPR).

There are separate time-outs for the blue and red queues. Timers are started to down count when the transaction is accepted in the XPI, which are then forwarded to DDRC together with the command (see [VPR / VPW timeout](#)).

Optional retiming block (register slice for pipelining) at the input of the XPI read address channel is enabled by `DDRMC_XPI_USE_INPUT_RAR`. Optional retiming block at the output of the XPI read address channel (enabled by `DDRMC_XPI_USE_RAR`) cannot be used if dual queue is enabled.

9.2.4.4.2.1 ID collisions

Due to the dynamic nature of the QoS with respect to the IDs, two transactions of the same ID can potentially exist in two queues. The collisions can be classified as:

- Blue after Red (BAR): A command with ID x is presented to the blue queue where a command with the same ID x is outstanding in the red queue.
- Red after Blue (RAB): A command with ID x is presented to the red queue where a command with same ID x is outstanding in the blue queue.

In the XPI, for both collision types, the ordering consistency within a given ID is preserved by stalling the incoming transaction to be pushed into the address queue it is mapped to until the colliding transaction in the opposite queue exists. This is required for functional correctness.

In case of any ID collision, the DDRMC does not speed up the drain of the stored transactions in the address queue causing collision even if the incoming transaction is HPR. In other words, address queues request arbitration to the Port Arbiter with their normal mapped priorities.

9.2.4.4.3 VPR / VPW timeout

There are separate timeouts for the blue and red queues for read transactions, and one timeout for write transactions. Timers are started to down count when the transaction is accepted in the XPI, which are then forwarded to DDRC together with the command.

Timeouts are set per port and queue using PCFGQOS1_n and PCFGWQOS1_n registers (see [Port n Read QoS Configuration Register 1 \(DDRC_MP_PCFGQOS1_0\)](#) and [Port n Write QoS Configuration Register 1 \(DDRC_MP_PCFGWQOS1_0\)](#)).

For PCFGQOS1_n register:

- RQOS_MAP_TIMEOUTB: Specifies the timeout value for transactions mapped to the blue queue.
- RQOS_MAP_TIMEOUTR: Specifies the timeout value for transactions mapped to the red queue.

For PCFGWQOS1_n register:

- WQOS_MAP_TIMEOUT: Specifies the timeout value for write transactions.

When expired, VPR/VPW transactions from XPI are tagged as expired-VPR or expired-VPW instead of LPR/NPW during normal priority transaction flow. The Port Arbiter treats these transactions with the highest priority (priority0). In addition, the Port Arbiter asserts hif_go2critical_lpr signal to the DDRC if there are no LPR credits available (LPR store of the read CAM is full) when an expired-VPR port is pending, and hif_go2critical_wr signal to the DDRC if there are no write credits available when an expired-VPW is pending. If an expired-VPW is issued as RMW at the HIF interface, the Port Arbiter asserts hif_go2critical_lpr signal to the DDRC if there are no LPR credits,

and / or `hif_go2critical_wr` signal if there are no write credits available. If both `hif_go2critical_lpr` and `hif_go2critical_wr` are asserted at the same time, priority in the DDRC is given to the read.

If VPR / VPW timeout registers are set to 0, the VPR / VPW transactions expire immediately as they enter the DDRMC, thereby making them the highest priority transaction class within the device. If multiple VPR / VPW transactions expire at the same time in the XPI, they are executed by the PA in round robin order.

To understand how the DDRC handles the VPR/VPW transactions, see [Transaction service control](#). In addition to the registers mentioned in this section, `PERFVPR1.vpr_timeout_range` and `PERFVPW1.vpw_timeout_range` registers are also used by the DDRC and are related to the QoS.

9.2.4.4.3.1 Head of line blocking

Blue queue can be assigned to LPR and / or VPR if single or dual queue is selected, HPR and / or VPR if single queue is selected. Head of line blocking can occur in the XPI if more than one traffic class is mapped to the same address queue.

If a VPR expires inside the read address queue there can be two scenarios:

- Expired-VPR is blocked by one or more LPR transactions (single or dual queue configuration)
- Expired-VPR is blocked by one or more HPR transactions (only single queue configuration)

In case an LPR is blocking, that port becomes the highest priority (priority0) and if there are no LPR credits available, `hif_go2critical_lpr` is asserted.

In case an HPR is blocking, that port becomes the highest priority (priority0) and if there are no HPR credits available, `hif_go2critical_hpr` is asserted.

If a VPW expires inside the write address queue, expired-VPW may be blocked by one or more NPW transactions.

In case an NPW is blocking, that port becomes the highest priority (priority0) and if there are no write credits available, `hif_go2critical_wr` is asserted.

This behavior allows the queue where the VPR / VPW is expired to be flushed as quickly as possible.

This mechanism is applied only for the expired-VPR and expired-VPW commands.

For single read address queue configurations, HPR commands may be blocked by LPR or VPR commands (not-expired); in this case, the port priority is not increased.

9.2.4.4.4 Urgent signalling

AXI sideband signals per port, `arurgent` (`arurgentb`, `arurgentr` when `DDRMC_XPI_USE2RAQ_n` is defined) and `awurgent`, when asserted (and as long as asserted), set a given port to the highest priority (`priority0`) and when applicable- cause the read/write direction to switch immediately in the Port Arbiter if enabled by `PCFGR_n.rd_port_urgent_en` and `PCFGW_n.wr_port_urgent_en` registers (see [Port n Configuration Read Register \(DDRC_MP_PCFGR_0\)](#) and [Port n Configuration Write Register \(DDRC_MP_PCFGW_0\)](#)).

Urgent signals also cause the `hif_go2critical_wr` / `hif_go2critical_lpr` / `hif_go2critical_hpr` signals to be asserted at the HIF interface, which in turn force the read/write direction switching in the DDRC, if enabled by the `PCFG.go2critical_en` register. Urgent signals are ignored by the PA if there are no requesters from the asserted address channel and port. Similarly, `hif_go2critical*` signals are ignored by the DDRC if the corresponding store is empty.

9.2.4.5 Refresh controls

Refresh can be issued using the auto-refresh feature in the DDRMC or using the direct software request of refresh command. The `RFSHCTL3.dis_auto_refresh` register bit selects the refresh method (see [Refresh Control Register 0 \(DDRC_RFSHCTL3\)](#)). When this bit is set to '1', the DDRMC uses direct software request of refresh command and when it is set to '0', the internal auto-refresh feature is used.

This section describes the following topics about refresh controls:

- [Refresh using direct software request of refresh command](#)
- [Refresh using auto refresh feature inside the DDRMC](#)

9.2.4.5.1 Refresh using direct software request of refresh command

Follow these steps to put the DDRMC in direct software request of refresh command mode:

1. Set the `RFSHCTL3.dis_auto_refresh` bit to 1. When the register bit set, the DDRMC checks for any pending refreshes. Any pending refreshes are issued right away using the 'critical refresh' feature inside the DDRMC. After these refreshes are issued, all the refresh timers inside the DDRMC are reset to 0. They are re-activated only when the auto-refresh feature is enabled.
2. The SoC core must keep track of the refresh requirements of the SDRAM.
3. The refresh command can be issued by setting the register bits `DBGCMD.rank*_refresh` to 1 (see [Command Debug Register \(DDRC_DBGCMD\)](#)). When the `rank*_refresh` request is stored in the DDRMC, the corresponding register

bit is automatically cleared. The SoC core can initiate a rank*_refresh operation only if DBGSTAT.rank*_refresh_busy is low. The DDRMC issues refresh to the SDRAM at the earliest.

4. Software-driven refresh commands for each rank are loaded into a 9-entry buffer, and are issued by the DDRMC on the DFI as soon as it is legal to do so (the DDRMC controller must wait tRFC(min) between each refresh request). If the buffer saturates, the DBGSTAT.rank*_refresh_busy remains asserted to prevent software from initiating further refreshes.
5. Refresh control through direct software request is not allowed when the controller is in DDR4 mode and Fine Granularity Refresh (FGR) operation is turned on. In this case, RFSHCTL3.dis_auto_refresh bit should be set to 0 and refresh control should be done using the auto-refresh feature.

NOTE

It is possible to give a burst of back-to-back refresh commands without polling the DBGSTAT.rank*_refresh_busy register field to reduce the time between the software refresh commands to a minimum with the following risk:

- If the refresh buffer is not empty when the burst starts or the burst is longer than 9 refresh commands, the buffer saturates (DBGSTAT.rank*_refresh_busy is asserted) and some APB writes given in the burst are not added to the buffer. This means that the number of APB writes do not reflect the number of REF commands sent out to the memory.

9.2.4.5.2 Refresh using auto refresh feature inside the DDRMC

The DDRMC provides advanced refresh controls. Besides fully-configurable refresh constraints (tRFC(min) and tREFI), the DDRMC can also be programmed to gather refreshes to each rank of SDRAM to reduce the bandwidth consumed by refreshes and to increase the likelihood that refreshes can be serviced during an idle period.

Fine-gain control of the refreshes ensures these benefits can be balanced against worst case latencies associated with servicing refreshes together. Staggered refresh timers for multi-rank configurations of the DDRMC allow transactions to continue to other ranks while refreshes are taking place to just one rank.

Following signals are related to refresh controls:

- RFSHCTL0.refresh_burst (see [Refresh Control Register 0 \(DDRC_RFSHCTL0\)](#))
- RFSHCTL0.per_bank_refresh (LPDDR2/LPDDR3 feature)
- RFSHCTL0.refresh_margin
- RFSHCTL0.refresh_to_x32.

- RFSHCTL1.refresh_timer0_start_value_x32
- RSHCTL1.refresh_timer1_start_value_x32
- RFSHCTL2.refresh_timer2_start_value_x32
- RFSHCTL2._refresh_timer3_start_value_x32
- RFSHCTL3.refresh_update_level
- RFSHCTL3.dis_auto_refresh

For more information on “x32” register fields, refer to [Computation for all the registers in units of 32, 1024, or 4096 clocks](#).

The purposes of refresh control are to:

- Reduce the bandwidth impact of refresh cycles
- Increase the likelihood of refreshes being serviced during idle periods
- Provide fine-gain control of the trading-off the above benefits (to gather refreshes) versus the increased worst case latencies associated with gathering refreshes
- Allow traffic to flow to other ranks while a given rank is being refreshed (for multi-rank configurations of the DDRMC only)

To minimize the worst case impact of a forced refresh cycle, the DDRMC can be programmed to issue single refreshes at a time by forcing RFSHCTL0.refresh_burst = 0 (see [Refresh Control Register 0 \(DDRC_RFSHCTL0\)](#)). It can be programmed to burst up to 8 refreshes (RFSHCTL0.refresh_burst = 7) in non-DDR4 modes. Burst refresh can be used to minimize the bandwidth lost to closing pages for refresh and to increase the likelihood that refreshes can be serviced during idle periods. It can also be programmed to any number in between to trade-off the benefits of each.

9.2.4.5.2.1 Single refresh

When using single refresh (RFSHCTL0.refresh_burst = 0), the DDRMC issues refreshes every time the refresh timer (t_{REFI}) expires. This is the optimal mode of operation for systems that minimize the maximum latency associated with refresh cycles.

9.2.4.5.2.2 Burst refresh

When burst refresh is enabled (RFSHCTL0.refresh_burst > 0), the DDRMC issues refreshes in bursts of (RFSHCTL0.refresh_burst + 1) refreshes at one time. Bursting refreshes reduces the total latency associated with those refreshes by reducing the number of pre-charges and activates required for refresh, as banks must be precharged only once to perform the entire group of refreshes, instead of once for each refresh.

9.2.4.5.2.2.1 Speculative refresh

When burst refresh is enabled (`RFSHCTL0.refresh_burst > 0`), the user can also make use of a feature called speculative refresh.

Burst refresh is implemented by counting the number of times t_{REFI} expires and issuing a group of refreshes when that number reaches the refresh burst number. Once t_{REFI} has expired at least once, the DDRMC can also perform speculative refreshes. This is done by automatically inserting refreshes when the DDRMC is idle.

The `RFSHCTL0.refresh_to_x32` register determines how long the DDRMC must be idle before considering inserting these speculative refreshes. Each time a speculative refresh is performed, the count of t_{REFI} expirations is decremented, and thereby increasing the time before a burst of refreshes is required. This also ensures that speculative refreshes never occur more often than is required to keep the SDRAM properly refreshed.

If a new read or write transaction is accepted by the DDRMC during speculative refresh, the DDRMC services it as soon as legally possible. Most often it entails waiting for the required NOP cycles after a refresh before performing an activate and then servicing the read or write. If the DDRMC has begun closing pages for a speculative refresh but has not yet issued the refresh when the new transaction arrives, the speculative refresh is cancelled.

9.2.4.5.2.3 Per-bank refresh (LPDDR2/LPDDR3 only)

If `RFSHCTL0.per_bank_refresh` is set to 1 (see [Refresh Control Register 0 \(DDRC_RFSHCTL0\)](#)), the DDRMC performs per-bank refreshes instead of all-bank refreshes. In this case, `RFSHTMG.t_rfc_nom_x32` and `RFSHTMG.t_rfc_min` should be set to the appropriate values for per-bank refresh (t_{REFIpb} and t_{RFCpb} respectively). In this mode, the DDRMC keeps track of which bank is being refreshed at any time, and is able to schedule commands to other banks immediately before and after the per-bank refresh commands, resulting in potential efficiency gains.

9.2.4.6 ZQ calibration

This feature is applicable for DDR3 and LPDDR2 / LPDDR3. The DDRMC uses ZQ calibration command to calibrate SDRAM R_{ON} (Resistor ON) and ODT (On-Die Termination) values over PVT (Process, Voltage, Temperature). DDR3 SDRAMs need more time to calibrate R_{ON} and ODT at initialization and relatively less time to perform periodic calibrations. For more information, refer to DDR3 (JEDEC JESD79-3*), LPDDR2 (JEDEC JESD209-2*) and LPDDR3 (JEDEC JESD209-3*) Specifications.

9.2.4.6.1 DDR3 devices

ZQCL (ZQ Calibration Long) command is used as follows:

- To perform the initial calibration during the power-up initialization sequence. This command is allowed a timing period of $tZQinit$ determined by `INIT5.dev_zqinit_x32` (see [SDRAM Initialization Register 5 \(DDRC_INIT5\)](#)) to perform full calibration and the transfer of values.
- To perform long ZQ Calibration after exiting from self-refresh. This command is allowed a timing period of $tZQOPER$, determined by `ZQCTL0._t_zq_long_nop`. This command is automatically issued when `ZQCTL0.dis_srx_zqcl` (`ZQCL0.dis_mpsmx_zqcl`) is set to 0. To disable issuing ZQCL after self-refresh exit, set `ZQCTL0.dis_srx_zqcl` (`ZQCTL0.dis_mpsmx_zqcl`) to 1.

ZQCS (ZQ Calibration Short) command is used to perform periodic calibration to account for VT (Voltage / Temperature) variations. A shorter timing window is provided to perform calibration and transfer of values as defined by the timing parameter $tZQCS$ (determined by `ZQCTL0._t_zq_short_nop`). ZQCS can be performed automatically on a regular interval or through direct software request. For more information about this, see [Automatic and software initiated ZQCs](#).

In DDR3 mode, the ZQ Calibration commands are sent out encoded on the DFI command bus as mentioned in the JEDEC Specification. The DDRMC performs no other activities for the duration of $tZQinit$, $tZQOPER$ and $tZQCS$. The quiet time on the SDRAM channel helps in accurate calibration of SDRAM R_{ON} and ODT. All banks are precharged and tRP met before the DDRMC issues the ZQ Calibration commands.

9.2.4.6.2 LPDDR2 / LPDDR3 devices

The DDRMC supports the ZQ Calibration commands that are supported by the JEDEC Specification.

ZQInit (ZQ Initial Calibration) command performs the initial calibration during the power-up initialization sequence. This command is allowed a time period of $tZQinit$ (determined by `INIT5.dev_zqinit_x32`).

ZQCL (ZQ Long Calibration) command performs long ZQ Calibration after exiting from self-refresh mode. This command is allowed a timing period of $tZQCL$ (determined by `ZQCTL0._t_zq_long_nop`). This command is issued automatically when `ZQCTL0.dis_srx_zqcl` is set to 0. To disable issuing of ZQCL after self-refresh exit, set `ZQCTL0.dis_srx_zqcl` to 1.

ZQCS (ZQ Short Calibration) command is used to perform periodic calibration to account for VT (Voltage/Temperature) variations. A shorter timing window is provided to perform calibration and transfer of values as defined by the timing parameter $tZQCS$

(determined by ZQCTL0.t_zq_short_nop). ZQCS can be performed automatically on a regular interval or through direct software request. For more information about this, see [Automatic and software initiated ZQCs](#).

ZQReset (ZQ Calibration Reset) command is used to reset the R_{ON} calibration to a default accuracy of $\pm 30\%$ across process, voltage and temperature. This command is used to ensure R_{ON} accuracy of $\pm 30\%$ when ZQCS and ZQCL are not used and is allowed a time period of $t_{ZQRESET}$, determined by ZQCTL1.t_zq_reset_nop. The command is issued by using the registers ZQCTL2.zq_reset and ZQSTAT.zq_reset_busy (see [ZQ Control Register 2 \(DDRC_ZQCTL2\)](#) and [ZQ Status Register \(DDRC_ZQSTAT\)](#)). For more information about this, see [LPDDR2 / LPDDR3 ZQ reset command](#).

In LPDDR2 / LPDDR3 mode, ZQ Calibration commands are sent out as Mode Register Write commands to the DRAM. The MRW is done to MR10 and the calibration codes for the different commands are as follows: ZQInit – 0xFF, ZQCL – 0xAB, ZQCS – 0x56, and ZQRest – 0xC3.

NOTE

For LPDDR2 / LPDDR3, it is possible to perform ZQ commands from software using the mode register interface (see [Mode register reads and writes](#)). However, the DDRMC does not implement the correct timing for such a command, so it is recommended not to do this, and instead to use either of the two methods mentioned below.

9.2.4.6.3 Automatic and software initiated ZQCs

The DDRMC issues a ZQCS command in the following two ways:

- **Automatic ZQCS by the DDRMC** : In this case, the DDRMC sends ZQCS commands to the SDRAM periodically. The interval is determined by ZQCTL1.t_zq_short_interval_x1024. This method is used if ZQCTL0.dis_auto_zq is set to 0 (see [ZQ Control Register 0 \(DDRC_ZQCTL0\)](#)).
- **ZQCS using direct software request**: In this case, the SoC core sends a ZQCS command through software by setting DBGCMD.zq_calib_short to 1. When the ZQCS request is stored in the DDRMC, the register bit is automatically cleared. It is recommended not to set DBGCMD.zq_calib_short signal in init, self-refresh, deep power-down operating modes or maximum power saving mode (MPSM). The SoC core can initiate a ZQCS operation only if DBGSTAT.zq_calib_short_busy is low. The DBGSTAT.zq_calib_short_busy signal goes high in the clock after the DDRMC accepts a ZQCS request. It goes low when the ZQCS operation is initiated in the DDRMC. For proper SDRAM operation, user/SoC core should schedule this command frequently. This method is used if ZQCTL0.dis_auto_zq is set to 1.

9.2.4.6.4 LPDDR2 / LPDDR3 ZQ reset command

In LPDDR2/LPDDR3 mode, ZQ Reset command is issued by setting ZQCTL2.zq_reset to 1 (see [ZQ Control Register 2 \(DDRC_ZQCTL2\)](#)). When the ZQ Reset operation is complete, the DDRMC automatically clears this register bit. It is recommended not to set this signal in init, self-refresh or deep power-down operating modes. The SoC core can initiate a ZQ Reset operation only if ZQSTAT.zq_reset_busy is low. This signal goes high in the clock after the DDRMC accepts a ZQ Reset request. It goes low when the ZQ reset command is issued to the SDRAM and the associated NOP period is completed. It is recommended not to perform ZQ Reset command when the ZQSTAT.zq_reset_busy signal is high.

9.2.4.7 SDRAM initialization sequence

A specific command sequence must be followed to properly initialize SDRAM modules. Much of the sequence is standard, but parts of it must be controlled differently according to the system configuration, clock speeds, and specific SDRAM parts in use. For this reason, the DDRMC provides a great deal of flexibility in how the initialization sequence is performed.

This section describes the initialization sequence and programmability provided by the DDRMC.

The list of registers associated with SDRAM initialization sequence are as follows:

- MSTR. ddr3
- MSTR. lpddr2
- MSTR. lpddr3
- INIT0.skip_dram_init
- INIT0.pre_cke_x1024
- INIT0.post_cke_x1024
- DRAMTMG3.t_mrd
- DRAMTMG3.t_mod (This is only used for DDR3 SDRAMs)
- INIT1.reg_ddrc_pre_ocrd_x32
- INIT1.final_wait_x32
- INIT3.mr
- INIT3.emr
- INIT4.emr2
- INIT4.emr3
- INIT5.dev_zqinit_x32. This is used for DDR3 and LPDDR2/LPDDR3 SDRAMs.

For LPDDR2 / LPDDR3 configurations, the following registers are used for the SDRAM initialization sequence:

- INIT2.min_stable_clock_x1
- INIT2.idle_after_reset_x32
- INIT5.max_auto_init_x1024
- DRAMTMG3.t_mrw

When user / SoC core appropriately sets the inputs listed above, the DDRMC automatically performs the necessary sequence to properly initialize the DDR SDRAM devices. These registers must be set before bringing the DDRMC out of reset.

NOTE

In addition to initializing the SDRAM after a hard reset, the initialization sequence can also be used to bring the SDRAM out of self-refresh mode (see [Self-refresh](#)).

9.2.4.7.1 DDR3 initialization sequence

For DDR3, the DDRMC initialization state machine executes the following initialization sequence:

1. Power-up.
2. Maintain dfi_reset_n low for duration specified by INIT1.dram_rstn_x1024. Specification requires at least 200 us with stable power.
3. Issue NOP / deselect for duration specified by INIT0.pre_cke_x1024. Specification requires at least 500 μ s.
4. Assert CKE and issue NOP/deselect for INIT0.post_cke_x1024 (specification requires at least t_{XPR}).
5. Issue MRS (mode register set) command to load MR2 with INIT4.emr2 value followed by NOP/deselect for duration of DRAMTMG3.t_mrd.
6. Issue MRS command to load MR3 with INIT4.emr3 followed by NOP/deselect for duration of DRAMTMG3.t_mrd.
7. Issue MRS command to load MR1 with INIT4.emr followed by NOP/deselect for duration of DRAMTMG3.t_mrd.
8. Issue MRS command to load MR0 with INIT3.mr followed by NOP/deselect for duration of DRAMTMG3.t_mod.
9. Issue ZQCL command to start ZQ calibration and wait for INIT5.dev_zqinit_x32.
10. Wait for INIT5.dev_zqinit_x32 counting to finish. Ensure wait from Step 8 is larger than t_{DLLK} .
11. DDR3 SDRAM is now ready for normal operation.

9.2.4.7.2 LPDDR2 / LPDDR3 initialization sequence

For LPDDR2 / LPDDR3, the DDRMC initialization state machine executes the following initialization sequence:

1. Power-up.
2. CKE is held low for a duration specified by INIT0.pre_cke_x1024. The clock is checked to be stable for duration specified by INIT2.min_stable_clock_x1 (minimum of 5 clock cycles) prior to the first low to high transition of CKE.
3. Assert CKE for INIT0.post_cke_x1024 (specification requires at least 200 μ s).
4. A MRW (Reset) command is issued to MRW63 register. Values of MA<7:0> = 3FH and OP<7:0> = 00H is used for this command. The MRW reset command brings the device to the device auto-initialization (resetting) state in the power-on initialization sequence.
5. Issue NOP / deselect for duration specified by INIT2.idle_after_reset_x32 (specification requires 1 μ s minimum) and INIT5.max_auto_init_x1024 (specification requires maximum time of 10 μ s).
6. An MRW ZQ initialization calibration command is issued to the memory to register MR10 to initiate the ZQ calibration. Values of MA<7:0> = 0AH and OP<7:0> = FFH is used for this command.
7. Issue NOP / deselect for duration specified by INIT5.dev_zqinit_x32 (specification requires a minimum time of 1 μ s).
8. Program MR2 register by setting MR2 register to INIT3.emr followed by a NOP / deselect for a duration specified by DRAMTMG3.t_mrw (typical value of 5 clock cycles).
9. Program MR1 register by setting MR1 register to INIT5.mr followed by a NOP / deselect for a duration specified by DRAMTMG3.t_mrw (typical value of 5 clock cycles).
10. Program MR3 register by setting MR3 register to INIT4.emr2 followed by a NOP / deselect for a duration specified by DRAMTMG3.t_mrw (typical value of 5 clock cycles).
11. Schedule multiple all bank refresh.
12. Begin normal operation.

9.2.4.8 ODT control

By default, ODT to memories (dfi_odt) is driven to all zeroes. [Figure 9-6](#) shows the timing diagram for ODT writes.

The register inputs control the following:

- **ODTMAP.rank*_wr_odt**: The value desired for ODT following a write command (see [ODT / Rank Map Register \(DDRC_ODTMAP\)](#)).

- **ODTCFG.wr_odt_delay**: The number of cycles to delay following a write command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- **ODTCFG.wr_odt_hold**: The number of cycles to hold the programmed write value after it is first driven.
- **ODTMAP.rank*_rd_odt**: The value desired for ODT following a read command.
- **ODTCFG.rd_odt_delay**: The number of cycles to delay following a read command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- **ODTCFG.rd_odt_hold**: The number of cycles to hold the programmed read value after it is first driven.

NOTE

- ODT for memories is not required for mDDR / LPDDR2. It is a DDR2/DDR3 specific feature. For mDDR/LPDDR2, set ODTMAP.rank*_wr_odt to all zeroes.

All of these must be set by the SoC core before taking the DDRMC out of reset. They are then applied to every read or write issued by the DDRMC.

The recommended settings for ODT related registers in each protocol are given in [ODT Configuration Register \(DDRC_ODTCFG\)](#).

To avoid overlap of ODT for reads and writes, the following constraints must be enforced:

- $ODTCFG.wr_odt_hold \leq MEMC_FREQ_RATIO * RANKCTL.diff_rank_wr_gap + MSTR.burst_rdwr$
 - If burst chop is enabled ($MSTR.burstchop = 1$), use $burst_rdwr / 2$ in the above equation
- $ODTCFG.rd_odt_hold \leq MEMC_FREQ_RATIO * RANKCTL.diff_rank_rd_gap + MSTR.burst_rdwr$
 - If burst chop is enabled ($MSTR.burstchop = 1$), use $burst_rdwr / 2$ in the above equation
- $ODTCFG.wr_odt_delay + ODTCFG.wr_odt_hold \leq ODTCFG.rd_odt_delay + MEMC_FREQ_RATIO * DRAMTMG2.wr2rd$
- $ODTCFG.rd_odt_delay + ODTCFG.rd_odt_hold \leq ODTCFG.wr_odt_delay + MEMC_FREQ_RATIO * DRAMTMG2.rd2wr$

Figure 9-7. RD ODT Timing Diagram

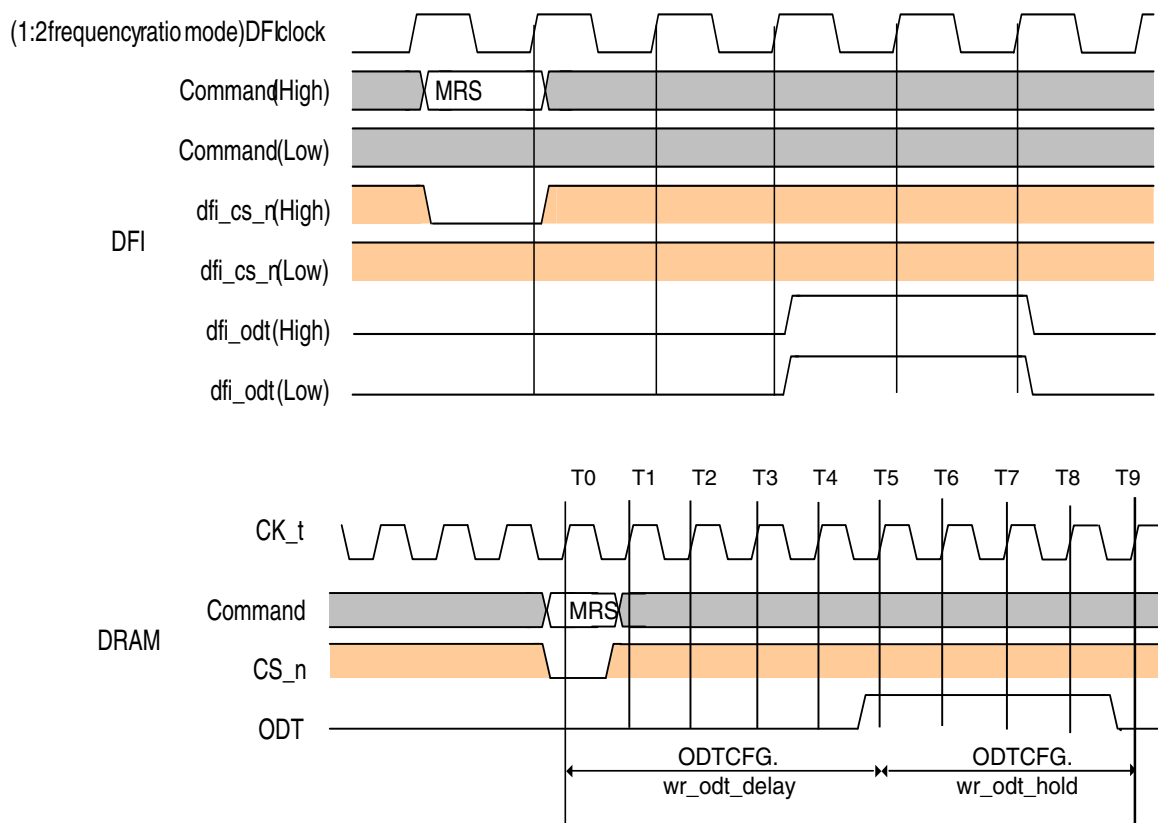

Figure 9-8. PDA ODT Timing Diagram

9.2.4.9 Power saving features

The DDRMC supports various methods to save power within the system:

- Power saving opportunities within the SDRAM. For more information about this, see [SDRAM power saving features](#).

9.2.4.9.1 SDRAM power saving features

The DDRMC supports various SDRAM power-saving modes—precharge power-down, self-refresh, deep power-down, maximum power saving mode, and support for disabling clock to the DRAM via DFI_DRAM_CLK_DISABLE.

This section describes the following power-saving modes:

- [Precharge power-down](#)
- [Self-refresh](#)

- [Deep power-down](#)
- [Assertion of dfi_dram_clk_disable](#)

In multi-rank systems, these power-saving modes cannot be applied on a per-rank basis. If applied, they are always applied globally.

When enabled, the DDRMC automatically enters and exits precharge power-down mode based on a programmable idle timeout period.

Self-refresh can be entered/exited via three ways:

- Based on a programmable idle timeout period (similar to precharge power-down idle timeout)
- Explicitly controlled by the user via software
- Via the hardware low power interface(s)

In addition, DFI_DRAM_CLK_DISABLE can be asserted to disable the clocks to the DRAM. This can be done in self-refresh, power-down, deep power-down, and maximum power saving mode. It also includes clock stop if mDDR / LPDDR2 / LPDDR3 is used.

In relation to the hardware low power interface, optional support is provided to drive `cactive_ddrc` low under idle conditions in normal or power-down or automatic self-refresh modes. Optional support for power-down, self-refresh, and clock stop to be forcefully exited via `CACTIVE_IN_DDRC = 1` is also provided.

Following registers are related to power saving features:

- DRAMTMG5.t_cke
- Precharge power-down controls:
 - PWRCTL.powerdown_en
 - PWRTMG.powerdown_to_x32
 - DRAMTMG1.t_xp
- Self-refresh controls:
 - PWRCTL.selfref_sw
 - PWRCTL.selfref_en
 - HWLPCTL.hw_lp_en
 - Hardware low power interface: `csysreq_*` / `csysack_*` / `cactive_*`
 - PWRTMG.selfref_to_x32
 - STAT.selfref_type
- Hardware low power interface:
 - HWLPCTL.hw_lp_exit_idle_en
 - HWLPCTL.hw_lp_idle_x32
- Deep power-down controls:
 - PWRCTL.deeppowerdown_en
 - PWRTMG.t_dpd_x4096
- Maximum power saving mode controls:

- PWRCTL.mpsm_en
- DRAMTMG11.t_mpx_lh
- DRAMTMG11.t_mpx_s
- DRAMTMG11.t_ckmpe
- Assertion of dfi_dram_clk_disable to disable the clocks to the DRAM controls:
 - PWRCTL.en_dfi_dram_clk_disable
 - DFITMG1.dfi_t_dram_clk_disable
 - DFITMG1.dfi_t_dram_clk_enable
 - DRAMTMG5.t_cksre
 - DRAMTMG5.t_cksrx
 - DRAMTMG6.t_ckpde
 - DRAMTMG6.t_ckpdx
 - DRAMTMG6.t_ckdpde
 - DRAMTMG6.t_ckdpdx
 - DRAMTMG6.t_ckcsx

For all the above power saving features, STAT.operating_mode signal can be used to monitor the current operating mode of the DDRMC.

NOTE

For more information on “x32 and x1024” register fields, refer to [Computation for all the registers in units of 32, 1024, or 4096 clocks](#).

9.2.4.9.1.1 Precharge power-down

This section explains the following topics:

- [Entering precharge power-down](#)
- [Exiting precharge power-down](#)

9.2.4.9.1.1.1 Entering precharge power-down

When PWRCTL.powerdown_en = 1 (see [Low Power Control Register \(DDRC_PWRCTL\)](#)), the DDRMC automatically enters precharge power-down when the period specified by PWRTMG.powerdown_to_x32 has passed while the DDRMC is idle (except for issuing refreshes).

Entering precharge power-down mode involves the following steps:

1. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
2. Waiting for tRP (row precharge) idle period.

3. Issuing the command to enter precharge power-down (NOP / deselect with CKE = 0).
4. This step occurs only if DFI low power interface for power-down is enabled (DFILPCFG0.dfi_lp_en_pd). Attempts an entry to low power mode via DFI low power interface with dfi_lp_wakeup set by DFILPCFG0.dfi_lp_wakeup_pd.

If the DDRMC receives a read or write request from the SoC core during Step 1 or Step 2 above, the power-down entry is immediately aborted. The same is true if PWRCTL.powerdown_en is driven to '0' during Step 1 or Step 2. Once the power-down entry command is issued then proper power-down exit is required, as described in [Exiting precharge power-down](#).

9.2.4.9.1.1.2 *Exiting precharge power-down*

Once the DDRMC has put the DDR SDRAM device(s) in precharge power-down mode, the DDRMC automatically performs the precharge power-down exit sequence for any of the following reasons:

- A refresh cycle is required to any rank in the system.
- The DDRMC receives a new request from the SoC core.
- A self-refresh entry is requested.
- PWRCTL.powerdown_en is set to '0' (see [Low Power Control Register \(DDRC_PWRCTL\)](#))

The DDRMC follows these steps when exiting precharge power-down mode:

1. Inserting any NOP / deselect commands required to satisfy the t_{CKE} requirement after entering precharge power-down.
2. This step occurs only if DFI low power mode entry during power-down entry is successful. Performs an exit from DFI low power mode.
3. Issuing the power-down exit command (NOP/deselect with CKE = 1). For multi-rank systems, all chip-selects are asserted so that all ranks exit precharge power-down simultaneously.
4. Issuing NOP/deselect for the period defined by t_{XP} .

NOTE

- **DDR2: Fast Exit versus Slow Exit Active Power-down** The DDR2 Specification describes two different variations on active power-down exit, depending on the programmed value of MR bit 12. As the DDRMC uses precharge power-down rather than active power-down, this programming has no effect on the DDRMC or the SDRAM devices.
- **DDR3: Fast Exit versus Slow Exit Precharge Power-down** The DDR3 Specification describes two different variations on precharge power-down exit, depending on the

programmed value of MR0 bit 12. If slow precharge power-down is used (MR0[12] = 0), DRAMTMG1.t_xp should be set to tXPDLL. If fast precharge power-down is used (MR0[12] = 1), DRAMTMG1.t_xp should be set to tXP.

- Other supported DDR protocols do not specify the difference between fast and slow power-down exit.

9.2.4.9.1.2 Self-refresh

This section explains the following topics:

- [Entering self-refresh](#)
- [Exiting self-refresh](#)

9.2.4.9.1.2.1 Entering self-refresh

The DDRMC puts the DDR SDRAM device(s) into self-refresh mode in the following cases:

- When the PWRCTL.selfref_en bit is set (see [Low Power Control Register \(DDRC_PWRCTL\)](#)) and no reads or writes are pending in the DDRMC for the period specified by PWRTMG.selfref_to_x32. This is referred to as automatic self-refresh. Dynamic changing of the PWRTMG.selfref_to_x32 register field is not allowed except when the DDRC is in reset (core_ddrc_rstn = 0).
- When the PWRCTL.selfref_sw bit is set. This is referred to as software self-refresh entry. The DDRC's hif_cmd_stall is driven high to stop new HIF commands from being accepted and existing core commands in DDRC are performed before sequence below. Note that, for arbiter configurations (MEMC_INCL_ARB = 1), commands may occur be accepted by the AXI/AHB interface, but they do not enter the DDRC via the HIF as hif_cmd_stall = 1.
- When a hardware low power entry request occurs (on csysreq_ddrc / csysack_ddrc) with cactive_in_ddrc = 0, no outstanding commands, and as long as the DDRMC is in not in init or deep power-down or maximum power saving mode. This is referred to as an accepted hardware low power self-refresh entry. When accepted, the DDRC's hif_cmd_stall is driven high to stop new commands from being accepted and existing core commands in the DDRC are performed before the sequence mentioned below occurs.

Entering self-refresh mode involves the following steps:

1. If there is a self-refresh exit previously, wait for at least one refresh command (or 8 per-bank refresh commands if LPDDR2 / LPDDR3 per-bank refresh is enabled) to all active ranks. Auto-refresh logic must be enabled, or refresh should be issued using direct software requests of refresh command via `DBGCMD.rank*_refresh`.
2. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
3. Waiting for t_{RP} (row precharge) idle period. If a new command is received on the HIF during this time, the self-refresh entry is aborted.
4. Issuing the command to enter self-refresh mode
5. This step occurs only if DFI low power interface for self-refresh is enabled (`DFILPCFG0.dfi_lp_en_sr`). Attempts an entry to low power mode via DFI low power interface with `dfi_lp_wakeup` set by `DFILPCFG0.dfi_lp_wakeup_sr`.

NOTE

`STAT.selfref_type` register field is `2'b11` if automatic self-refresh feature is the only cause of self-refresh. If software self-refresh or hardware low power self-refresh occurs, `STAT.selfref_type = 2'b10`.

Automatic self-refresh has lowest priority and is superseded by both software and hardware low power self-refresh. A software self-refresh entry means that a self-refresh exit occurs only if a software self-refresh exit occurs. Similarly, a hardware low power self-refresh entry means a self-refresh exit occurs only if a hardware low power self-refresh exit occurs. If both software and hardware low power self-refresh entry occurs, self-refresh exit occurs only if both software and hardware low power self-refresh exits occur.

9.2.4.9.1.2.2 *Exiting self-refresh*

The DDRMC takes the DDR SDRAM out of self-refresh mode under the following conditions:

- Whenever the `PWRCTL.selfref_en` input is de-asserted (see [Low Power Control Register \(DDRC_PWRCTL\)](#)), or new commands are received by the DDRMC, as long as automatic self-refresh is only cause for self-refresh entry (`STAT.selfref_auto_flag = 1`).
- Whenever the `PWRCTL.selfref_sw` bit is de-asserted. This is referred to as software self-refresh exit.
- When a hardware low power exit request occurs (on `csysreq_ddrc / csysack_ddrc`). This is referred to as hardware low power self-refresh exit.

Exiting self-refresh mode involves the following steps:

1. Inserting any NOP / deselect commands required to satisfy the t_{CKE} / t_{CKERSR} requirements after entering self-refresh.

2. This step occurs only if DFI low power mode entry during self-refresh entry is successful. Performs an exit from DFI low power mode.
3. Issuing the self-refresh exit command (refresh with CKE = 1).
4. Issuing NOP / deselect for the period defined by t_{XSDLL} / t_{XSNR} / t_{XSRD} .

9.2.4.9.1.3 Deep power-down

This power saving mode is applicable for LPDDR and LPDDR2 devices only. This section explains the following topics:

- [Entering deep power-down](#)
- [Exiting deep power-down](#)

9.2.4.9.1.3.1 Entering deep power-down

By setting the PWRCTL.deeppowerdown_en bit (see [Low Power Control Register \(DDRC_PWRCTL\)](#)), the user can put the SDRAM device(s) into deep power-down mode, if all the following conditions are true:

- The period specified by PWRTMG.powerdown_to_x32 has passed while the DDRMC is idle (except for issuing refreshes)
- PWRCTL.selfref_sw = 0
- PWRCTL.selfref_en = 0
- If HWLPCTL.hw_lp_en = 1, DPD is entered only when the hardware low power interface has completed a self-refresh exit. (This can be checked by observing STAT.operating_mode and STAT.selfref_type).
- If HWLPCTL.hw_lp_exit_idle_en = 1, DPD is entered only when all bits of

cactive_in_ddrc = 0 Entering Deep power-down involves the following steps:

1. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
2. Waiting for tRP (row precharge) idle period.
3. Issuing the command to enter deep power-down. For multi-rank systems, all chip-selects are asserted so that all ranks enter deep power-down simultaneously. The deep power-down entry commands are as follows:

Command for mDDR: CKE = 0, CSN = 0, RAS = 1, CAS = 1, WE = 0

Command for LPDDR2 / LPDDR3: CKE = 0, CSN = 0, CA0 = 1, CA1 = 1, CA2 = 0

4. This step occurs only if DFI low power interface for deep power-down is enabled (DFILPCFG0.dfi_lp_en_dpd). It attempts an entry to low power mode via DFI low power interface with dfi_lp_wakeup set by DFILPCFG0.dfi_lp_wakeup_dpd.

If the DDRMC receives a read or write request from the SoC core during Step 1 or Step 2 above, the deep power-down entry is immediately aborted. The same is true if PWRCTL.deep_powerdown_en is driven to '0' during Step 1 or Step 2. Once the deep power-down entry command is issued, proper deep power-down exit is required, as described in the following section.

NOTE

Contents of SDRAM may be lost upon entry into deep power-down mode.

9.2.4.9.1.3.2 *Exiting deep power-down*

Once the DDRMC puts the DDR SDRAM device(s) in deep power-down mode, the DDRMC automatically exits deep power-down and re-runs the initialization sequence when PWRCTL.deeppowerdown_en is reset to '0' (see [Low Power Control Register \(DDRC_PWRCTL\)](#)). An exit from DFI low power mode is performed prior to exiting deep power-down (this occurs only if DFI low power mode entry during deep power-down entry is successful).

9.2.4.9.1.4 Assertion of dfi_dram_clk_disable

Assertion of dfi_dram_clk_disable occurs only if PWRTL.en_dfi_dram_clk_disable = 1. dfi_dram_clk_disable is also dependent on the operating mode:

- In DDR2 / DDR3, dfi_dram_clk_disable can be asserted only in self-refresh mode.
- In mDDR / LPDDR2 / LPDDR3, dfi_dram_clk_disable can be asserted in the following modes:
 - In Self-refresh
 - In Power-down
 - In Deep power-down
 - In Normal mode. This is “Clock Stop” feature.

The timing of the assertion and de-assertion of dfi_dram_clk_disable in various modes is as follows:

- In Self-refresh:
 - Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG5.t_cksre - DFITMG1.dfi_t_dram_clk_disable cycles after SRE command.
 - Deasserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG5.t_cksrx - DFITMG0.dfi_t_ctrl_delay cycles before SRX command.
- In Power-down:

- Asserted at least $DFITMG0.dfi_t_ctrl_delay + DRAMTMG7.t_ckpde - DFITMG1.dfi_t_dram_clk_disable$ cycles after PDE command.
- Deasserted at least $DFITMG1.dfi_t_dram_clk_enable + DRAMTMG7.t_ckpdx - DFITMG0.dfi_t_ctrl_delay$ cycles before PDX command.
- In Deep power-down:
 - Asserted at least $DFITMG0.dfi_t_ctrl_delay + DRAMTMG6.t_ckdpde - DFITMG1.dfi_t_dram_clk_disable$ cycles after DPDE command.
 - Deasserted at least $DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckdpdx - DFITMG0.dfi_t_ctrl_delay$ cycles before DPDX command.
- In Normal mode (Clock Stop):
 - Asserted at least $DFITMG0.dfi_t_ctrl_delay - DFITMG0.dfi_t_dram_clk_disable$ cycles after any command other than SRE / PDE / DPDE.
 - Deasserted at least $DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckcsx - DFITMG0.dfi_t_ctrl_delay$ cycles before any command other than SRX / PDX / DPDX.
- In Maximum power saving mode:
 - Asserted at least $DFITMG0.dfi_t_ctrl_delay + DRAMTMG11.t_ckmpe - DFITMG1.dfi_t_dram_clk_disable$ cycles after MPSME.
 - Deasserted at least $DFITMG1.dfi_t_dram_clk_enable + DRAMTMG5.t_cksrx - DFITMG0.dfi_t_ctrl_delay$ cycles before MPSMX.

9.2.4.9.1.5 DLL-off mode (DDR3)

DLL-off mode enables DDR3 SDRAMs to be operated at low frequencies. The DDRMC supports DLL-off mode, and transitions between DLL-on and DLL-off mode, under software control. To enable DLL-off mode from initialization, the following register fields must be set:

- $INIT3.emr[0]$, so that the SDRAM mode register is set for DLL-off mode
- $MSTR.dll_off_mode = 1$
- If using the Synopsys DWC DDR PHY, it should be put in PLL-bypass mode

To perform a transition between DLL-off and DLL-on modes, the software must implement the sequence specified in the JEDEC specification. Full details of the software sequence is provided in the User Guide.

NOTE

DBI, geardown and programmable preamble are not supported in DLL-off mode. Also, geardown, C/A parity and CAL mode must be disabled when moving from DLL-off to DLL-on.

9.2.4.9.2 Software sequence for removal of clocks

Software can be used to keep the SDRAM in self-refresh. The AXI and DDRC clocks can be removed when in self-refresh by following the sequence described in the [Table 9-8](#).

Table 9-8. Software Clock Removal Sequence

Step	Description	Comment
1	Write 0 to PCTRL_n.port_en	Blocks AXI port(s) from taking anymore transactions
2	Poll PSTAT.rd_port_busy_n = 0 Poll PSTAT.wr_port_busy_n = 0	Wait unit all AXI ports are idle
3	Write 0 to SBRCTL.scrub_en	Disable SBR, only required if SBR instantiated
4	Poll SBRSTAT.scrub_busy=0	Indicates that there are no outstanding SBR read commands, only required if SBR instantiated
5	Write 1 to PWRCTL.selfref_sw	Cause system to move to self-refresh state
6	Poll STAT.selfref_type= 2'b10	Wait until self-refresh state entered
7	Remove AXI clock(s)	
8 ¹	Remove DDRC core clock	

1. Prior to this step, if PHY allows, it is recommended to disable generation of PHY initiated Update requests (dfi_phyupd_req). This avoids the possibility of the DDRMC missing dfi_phyupd_req assertions while its clock has been removed. The DDRMC cannot respond via dfi_phyupd_ack as its clock has been removed. If using a Synopsys PHY, this can be done via the PUB's DSGCR.PUREN.

The clocks should be re-enabled by following the sequence described in [Table 9-9](#).

Table 9-9. Re-enabling the Clocks

Step	Description	Comment
1	Enable AXI clock(s)	
2 ¹	Enable DDRC core clock	
3	Write 0 to PWRCTL.selfref_sw	Cause system to exit from self-refresh state
4	Poll STAT.selfref_type = 2'b00	Wait until self-refresh state is exited
5	Write 1 to PCTRL_n.port_en	AXI port(s) are no longer blocked from taking transactions
6	Write 1 to SBRCTL.scrub_en	Enable SBR if desired, only required if SBR instantiated

1. After this step, it is recommended to re-enable generation of PHY initiated Update requests (dfi_phyupd_req). If using a Synopsys PHY, this can be done via the PUB's DSGCR.PUREN.

9.2.4.9.3 Power removal flow

Table 9-10. Power Removal

Step	Description	Comment
1	Write 0 to PCTRL_n.port_en	Blocks AXI port(s) from taking anymore transactions

Table continues on the next page...

Table 9-10. Power Removal (continued)

Step	Description	Comment
2	Poll PSTAT.rd_port_busy_n = 0 Poll PSTAT.wr_port_busy_n = 0	Wait until all AXI ports are idle
3	Write 0 to SBRCTL.scrub_en	Disable SBR, only required if SBR instantiated
4	Poll SBRSTAT.scrub_busy = 0	Indicates that there are no outstanding SBR read commands, only required if SBR instantiated
5	Write 1 to PWRCTL.selfref_sw	Cause system to move to self-refresh state
6	Poll STAT.selfref_type= 2'b10	Wait until self-refresh state entered
7	Place IOs in retention mode	Refer to relevant PHY databook for more information
8	Remove power	

Table 9-11. Re-enabling the power

Step	Description	Comment
1	Enable Power	
2	Reset controller / PHY by driving core_ddrc_rstn = 1'b0, aresetn_n = 1'b0, presetn = 'b0	
3	Remove APB reset, presetn = 1'b1, and re-program the registers to pre-power removal values	
4	Program INIT0.skip_dram_init = 2'b11	Skips the DRAM init routine and starts up in self-refresh mode
5	Programs PWRCTL.selfref_sw = 1'b1	Keeps the controller in self-refresh mode
6	Program DFIMISC.dfi_init_complete_en to 1'b0	PHY initialization needs to be rerun so set to 0 until initialization complete
7	Remove the core reset core_ddrc_rstn = 1'b1 aresetn_n = 1'b1	
8	Remove IOs from retention mode	Refer to relevant PHY databook for more information
9	Run PHY initialization / training as required	Refer to relevant PHY databook for more information
10	Program DFIMISC.dfi_init_complete_en to 1'b1	Indicates to controller that PHY has completed re-training / initialization
11	Program PWRCTL.selfref_sw = 1'b0	trigger self-refresh exit
12	Poll STAT.selfref_type = 2'b00	Wait until self-refresh state is exited
13	Poll STAT.operating_mode for Normal Mode entry	
14	Write PCTRL.port_en = 1	AXI port(s) are no longer blocked from taking transactions
15	Write 1 to SBRCTL.scrub_en	Enable SBR if desired, only required if SBR instantiated

9.2.4.10 Mode register reads and writes

This section explains how to perform mode register reads and writes via software. Mode Register Reads (MRR) are applicable only to LPDDR2 / LPDDR3, and are used to read configuration and status data from mode registers in the SDRAM. Mode Register Writes (MRW or MRS) are applicable to all supported DDR protocols, and are used to write configuration data to mode registers in the SDRAM.

Access to the mode register is initiated by programming the MRCTRL0 and MRCTRL1 registers (see [Mode Register Read / Write Control Register 0 \(DDRC_MRCTRL0\)](#) and [Mode Register Read / Write Control Register 1 \(DDRC_MRCTRL1\)](#)). This must be done in three steps:

1. Poll MRSTAT.mr_wr_busy until it is '0'. This checks that there is no outstanding MR transaction. No writes should be performed to MRCTRL0 and MRCTRL1 if MRSTAT.mr_wr_busy = 1.
2. Write the MRCTRL0.mr_type, MRCTRL0.mr_addr, MRCTRL0.mr_rank and (for MRWs) MRCTRL1.mr_data to define the MR transaction.
3. In a separate APB transaction, write the MRCTRL0.mr_wr to 1. This bit is self-clearing, and triggers the MR transaction. The DDRMC then asserts the MRSTAT.mr_wr_busy while it performs the MR transaction to SDRAM, and no further accesses can be initiated until it is deasserted.

Some additional notes on mode register transactions are as follows:

- MRW transactions can be specified for either any single rank, or any combination of several ranks, by programming MRCTRL1.mr_rank.
- MRR transactions should only be performed to one rank at a time, to avoid bus contention.
- When a MRR is performed, the mode register contents are available on hif_mrr_data[7:0], qualified by hif_mrr_data_valid, after the mode register read command is issued by the DDRMC to the SDRAM.

9.2.4.10.1 Mode register write

The Mode Register Write (MRW) command is used to write configuration data to mode registers.

For non-LPDDR2 / non-LPDDR3 SDRAMs, MRW on <MR addr> with <MR Data> is triggered by writing MRCTRL0.mr_wr = '1', MRCTRL0.mr_type = '0', MRCTRL0.mr_addr = <MR addr>, MRCTRL1.mr_data = <MR Data> and MRCTRL0.mr_rank = <MR rank> for one clock.

For LPDDR2 / LPDDR3 SDRAMs, MRW on <MR addr> with <MR Data> is triggered by writing MRCTRL0.mr_wr = '1', MRCTRL0.mr_type = '0', MRCTRL1.mr_data[15:8] = <MR addr>, MRCTRL1.mr_data[7:0] = <MR Data> and MRCTRL0.mr_rank = <MR rank> for one clock.

In both the cases, the signal MRSTAT.mr_wr_busy is asserted by the DDRMC while the mode register access is performed, and no further accesses can be initiated until it is deasserted.

For user-initiated MR writes, the user can request mode registers programming operation for either any single rank / all even ranks / all odd ranks only. To implement this, a NUM_RANKS bits wide register is provided to indicate the rank of mode registers programming operation (MRCTRL1.mr_rank [NUM_RANKS - 1: 0]).

9.2.5 Register Descriptions

9.2.5.1 Description introduction

All registers are addressable on 32-bit boundaries; each unused bit or address location is reserved for future use and read back as 0. The register access abbreviations are as follows:

- R – Read only
- W – Write only
- R/W – Read / Write
- R/W1C - Read / Write 1 to clear
- R/WSC – Read / Write Self Clear. When a R/WSC bit is set to 1, the bit remains set until it is cleared by hardware after an internal event.

Some register fields might use the following optional attribute.

Table 9-12. Optional Attributes

Attribute	Description
Testable	As defined by the IP-XACT specification. Possible values are unconstrained, untestable, read only, write as read, restore. Untestable means that this field is untestable by a simple automated register test. For example, the read-write access of the register is controlled by a pin or another register. Read only means that you should not write to this register; only read from it. This might apply for a register that modifies the contents of another register.

NOTE

Computation for all the registers in units of 32, 1024, or 4096 clocks

This note refers to register fields whose names include “x32”, “x1024”, or “x4096”.

The DDRMC contains a timer which issues a pulse once every 32 clock cycles, another which issues a pulse once every 1024 clock cycles and another which issues a pulse once every 4096 clock cycles. “x32” register fields count pulses of the 32-cycle timer, “x1024” register fields count pulses of the 1024-cycle timer, and “x4096” register fields count pulses of the 4096-cycle timer. These timers are shared by the logic for all of these register fields, and the various periods start without any guaranteed relation to the phase of this timer.

Therefore for “x32” register fields:

- A programmed value of 0 gives 0 clock cycles
- A programmed value of 1 gives a 1 to 32 cycle delay
- A programmed value of 2 gives a 33 to 64 cycle delay and so on

For “x1024” register fields:

- A programmed value of 0 gives no delay
- A programmed value of 1 gives a 1 to 1,024 cycle delay
- A programmed value of 2 gives a 1,025 to 2,048 cycle delay and so on

For “x4096” register fields:

- A programmed value of 0 gives no delay
- A programmed value of 1 gives a 1 to 4,096 cycle delay
- A programmed value of 2 gives a 4,097 to 8,192 cycle delay and so on

For minimum delays, the control signal must be set to the smallest number for which the resulting delay is ALWAYS \geq the required delay; for maximum delays or nominal refresh, this must be set such that the delay is ALWAYS \leq the required delay.

This scheme is used to reduce the gate count that would be required to enforce these constraints more precisely.

NOTE

Most of the SDRAM timing registers are in terms of clock cycles. But the value given in an SDRAM datasheet may be in terms of ns / ps. These are primarily minimum timings. Before

using them to calculate value to program in the register, it is expected that these are divided by tCK (SDRAM clock period) and rounded up to the next integer value if division does not result in a whole integer value.

Exceptions to this rule are related to maximum timings, where these should be rounded down rather than rounded up, if division does not result in a whole integer value.

These include:

- RFSHTMG.t_rfc_nom_x32
- DRAMTMG0.t_ras_max

Certain SDRAM timing registers clarify this by using the following functions in their descriptions:

- RoundUp (X / Y) means that if X divided by Y does not result in a whole integer value, the result should be rounded up to the next integer value. For example, RoundUp ($1000 / 150$) = 7, RoundUp ($1050 / 150$) = 7.
- RoundDown (X / Y) means that if X divided by Y does not result in a whole integer value, the result should be rounded down to the next integer value. For example, RoundDown ($1000 / 150$) = 6, RoundDown ($1050 / 150$) = 7.

9.2.5.2 DDRC Registers

DDRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

9 BURSTCHOP	<p>When set, enable burst-chop in DDR3. This is only supported in HIF configurations (DDRC_INCL_ARB not set) using full bus width mode (MSTR.data_bus_width = 00). Value After Reset: 0x0</p>

Table continues on the next page...

DDRC_MSTR field descriptions (continued)

Field	Description
	Exists: MEMC_DDR3 == 1
8 BURST_MODE	Indicates Burst Mode Value After Reset: 0x0 Exists: DDRC_INCL_ARB == 0 0 Sequential burst mode 1 Interleaved burst mode
7–5 Reserved	This field is reserved. Reserved for future use
4 Reserved	This field is reserved.
3 LPDDR3	Select LPDDR3 SDRAM Present only in designs configured to support LPDDR3. Value After Reset: 0x0 Exists: MEMC_LPDDR3 == 1 1 LPDDR3 SDRAM device in use 0 Non-LPDDR3 device in use
2 LPDDR2	Select LPDDR2 SDRAM Present only in designs configured to support LPDDR2. Value After Reset: 0x0 Exists: MEMC_LPDDR2 == 1 1 LPDDR2 SDRAM device in use 0 Non-LPDDR2 device in use
1 Reserved	This field is reserved. Reserved for future use
0 DDR3	Only present in design that support DDR3. Value After Reset: "(MEMC_DDR3 == 1) ? 0x1 : 0x0" Exists: MEMC_DDR3 == 1 Select DDR3 SDRAM 1 DDR3 SDRAM device in use 0 Non-DDR3 device in use

9.2.5.2.2 Operating Mode Status Register (DDRC_STAT)

Address: 307A_0000h base + 4h offset = 307A_0004h

DDRC_STAT field descriptions

Field	Description
31–10 Reserved	This field is reserved. Reserved for future use
9–8 Reserved	This field is reserved.
7–6 Reserved	This field is reserved. Reserved for future use
5–4 SELFREF_TYPE	Flags if self-refresh is entered. If it is under automatic, it is self-refresh control only or not. Value After Reset: 0x0 Exists: Always 00 SDRAM is not in self-refresh. If retry is enabled by CRCPARCTRL1.crc_parity_retry_enable, this also indicates SRE command is still in parity error window or retry is in-progress.

Table continues on the next page...

DDRC_STAT field descriptions (continued)

Field	Description
	11 SDRAM is in self-refresh and self-refresh is caused by automatic self-refresh only. If retry is enabled, this guarantees SRE command is executed correctly without parity error. 10 SDRAM is in self-refresh and self-refresh is not caused solely under automatic self-refresh control. It could have been caused by Hardware Low Power Interface and/or Software (reg_ddrc_selfref_sw). If retry is enabled, this guarantees SRE command is executed correctly without parity error.
3 Reserved	This field is reserved. Reserved for future use
OPERATING_MODE	Operating Mode This is 3-bits wide in configurations with LPDDR2 / LPDDR3 support and 2-bits in all other configurations. Non-mDDR / LPDDR2 / LPDDR3 and non-DDR4 designs: <ul style="list-style-type: none"> • 00 - Init • 01 - Normal • 10 - Power-down • 11 - Self-refresh LPDDR2 / LPDDR3 designs: <ul style="list-style-type: none"> • 000 - Init • 001 - Normal • 010 - Power-down • 011 - Self-refresh • 1XX - Deep power-down / Maximum Power Saving Mode Value After Reset: 0x0 Exists: Always

9.2.5.2.3 Mode Register Read / Write Control Register 0 (DDRC_MRCTRL0)

NOTE

Do not enable more than one of the following fields simultaneously:

- RCD_INIT_EN
- PDA_EN
- MPR_EN

Address: 307A_0000h base + 10h offset = 307A_0010h

DDR Controller (DDRC)

DDRC_MRCTRL0 field descriptions

Field	Description
31 MR_WR	Setting this register bit to 1 triggers a mode register read or write operation. When the MR operation is complete, the DDRC automatically clears this bit. The other register fields of this register must be written in a separate APB transaction, before setting this mr_wr bit. It is recommended NOT to set this signal if in Init, Deep power-down or MPSM operating modes. Value After Reset: 0x0 Exists: Always
30–16 Reserved	This field is reserved. Reserved for future use
15–12 MR_ADDR	Address of the mode register that is to be written to Do not Care for LPDDR2 / LPDDR3 (see MRCTRL1.mr_data for mode register addressing in LPDDR2 / LPDDR3). This signal is also used for writing to control words of RDIMMs. In that case, it corresponds to the bank address bits sent to the RDIMM Value After Reset: 0x0 Exists: Always 0000 MR0 0001 MR1 0010 MR2 0011 MR3 0100 MR4 0101 MR5 0110 MR6 0111 MR7
11–8 Reserved	This field is reserved. Reserved for future use
7–4 MR_RANK	Controls which rank is accessed by MRCTRL0.mr_wr. Normally, it is desired to access all ranks, so all bits should be set to 1. However, for multi-rank UDIMMs / RDIMMs which implement address mirroring, it may be necessary to access ranks individually. Examples (assume DDRC is configured for 4 ranks): <ul style="list-style-type: none"> • 0x1 - select rank 0 only • 0x2 - select rank 1 only • 0x5 - select ranks 0 and 2 • 0xA - select ranks 1 and 3 • 0xF - select ranks 0, 1, 2 and 3 Value After Reset: "(MEMC_NUM_RANKS == 4) ? 0xF : ((MEMC_NUM_RANKS == 2) ? 0x3 : 0x1)" Exists: Always

Table continues on the next page...

DDRC_MRCTRL0 field descriptions (continued)

Field	Description
3–1 Reserved	This field is reserved.
0 MR_TYPE	Indicates whether the mode register operation is read or write. Only used for LPDDR2 / LPDDR3. Value After Reset: 0x0 Exists: MEMC_LPDDR2 == 1 0 Write 1 Read

9.2.5.2.4 Mode Register Read / Write Control Register 1 (DDRC_MRCTRL1)

Address: 307A_0000h base + 14h offset = 307A_0014h

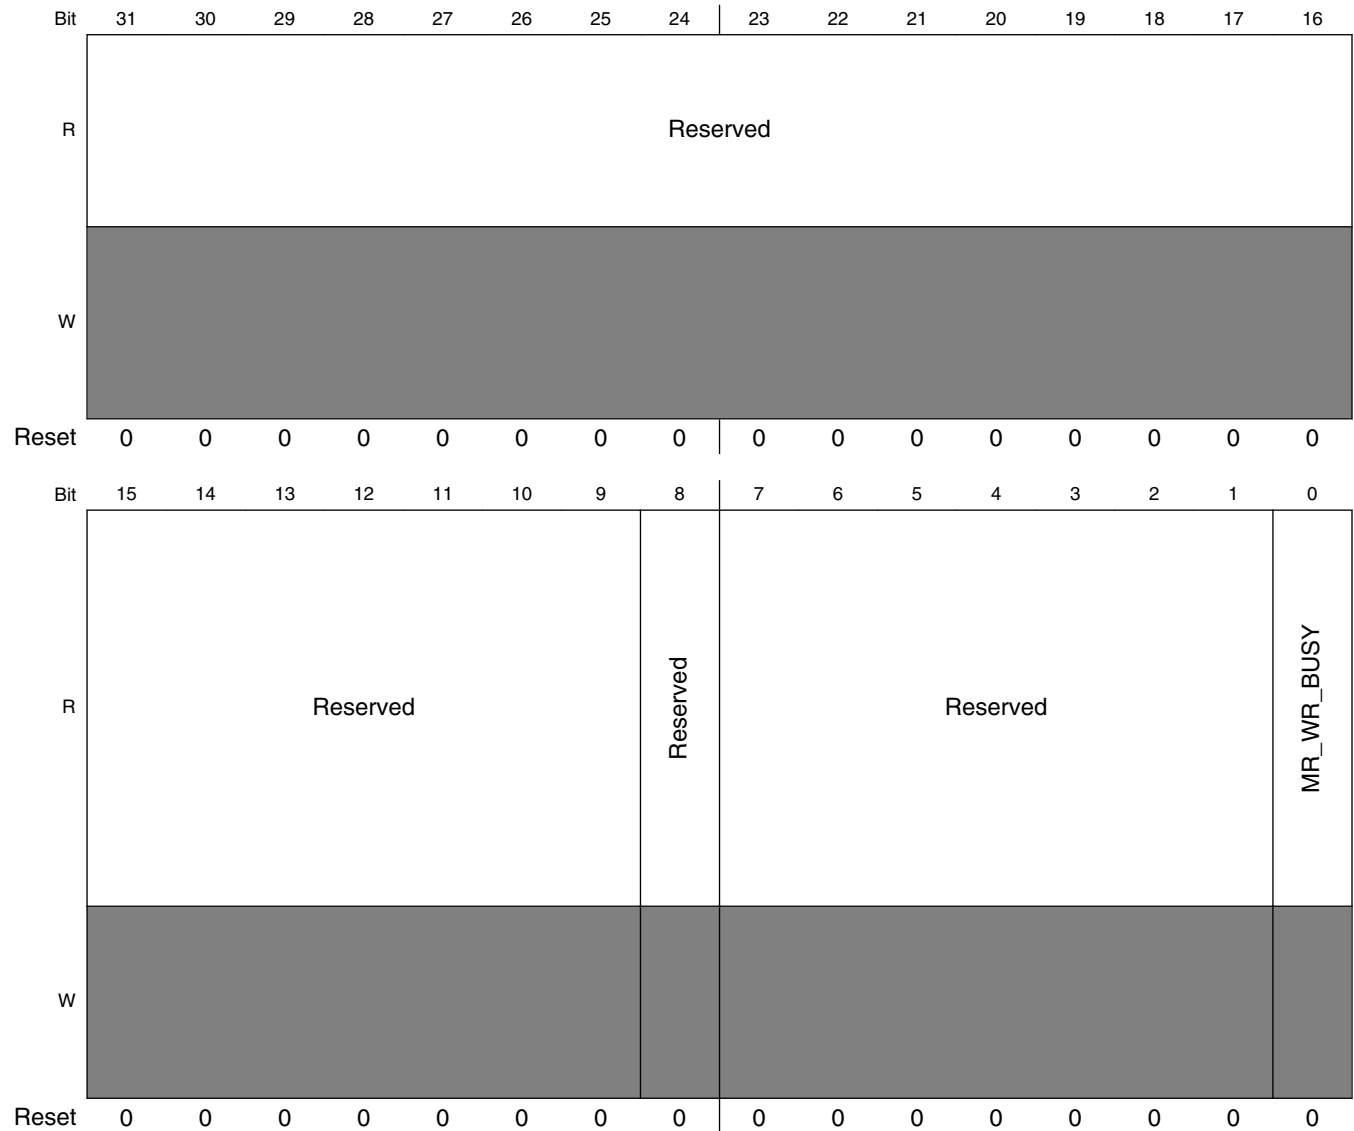

DDRC_MRCTRL1 field descriptions

Field	Description
31–18 Reserved	This field is reserved. Reserved for future use
MR_DATA	Mode register write data for all non- LPDDR2 / non-LPDDR3 modes. For LPDDR2 / LPDDR3, MRCTRL1 [15:0] are interpreted as [15:8] MR Address. [7:0] MR data for writes, do not care for reads. This is 18-bit wide in configurations with support and 16-bit in all other configurations. Value After Reset: 0x0 Exists: Always

9.2.5.2.5 Mode Register Read / Write Status Register (DDRC_MRSTAT)

Address: 307A_0000h base + 18h offset = 307A_0018h

DDRC_MRSTAT field descriptions

Field	Description
31–9 Reserved	This field is reserved. Reserved for future use
8 Reserved	This field is reserved.
7–1 Reserved	This field is reserved. Reserved for future use
0 MR_WR_BUSY	The SoC core may initiate a MR write operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the MRW / MRR request. It goes low when the MRW / MRR command is issued

Table continues on the next page...

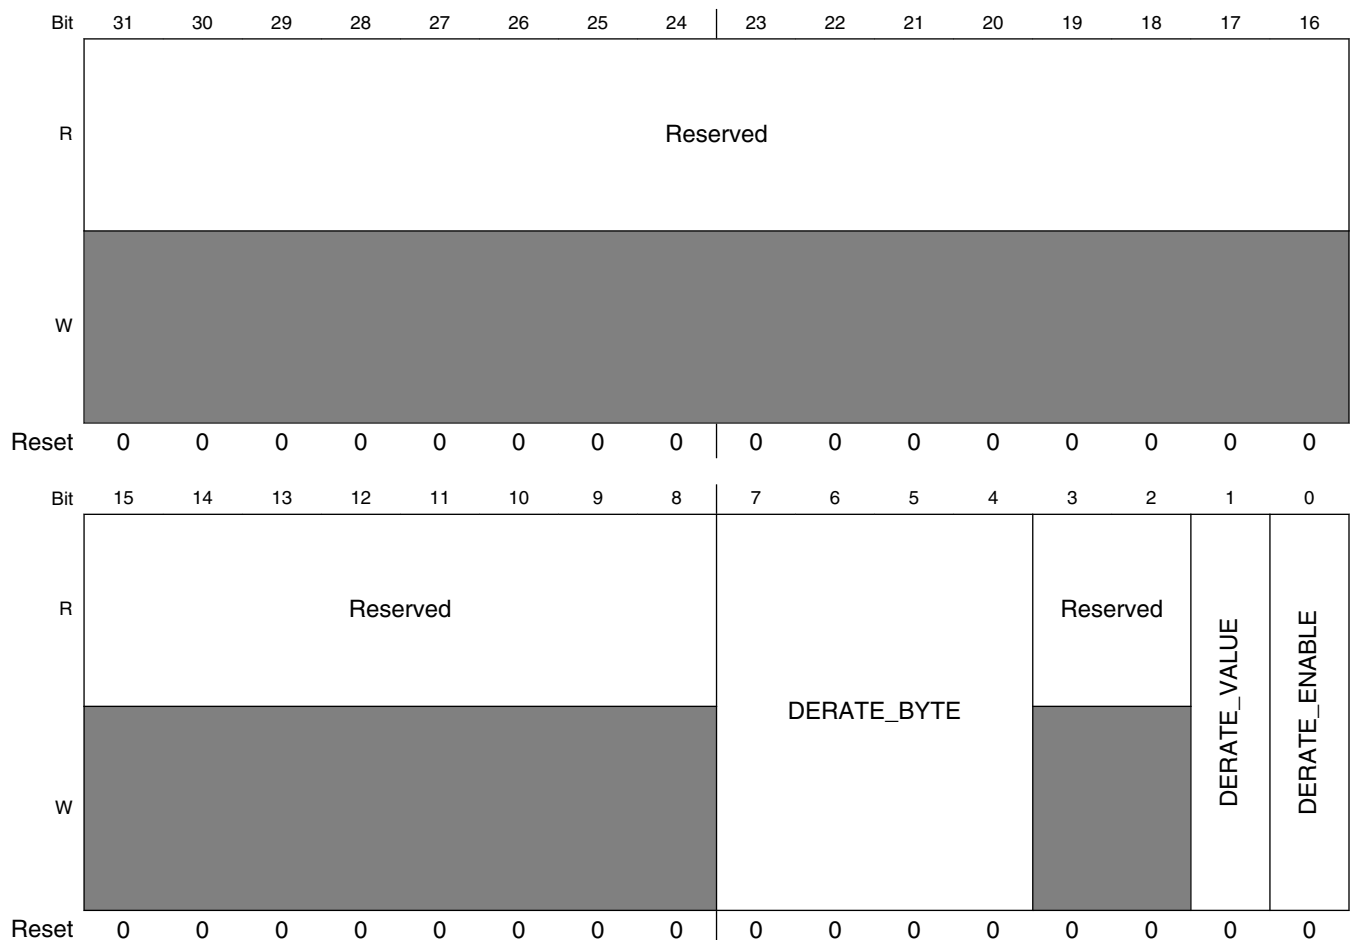

DDRC_MRSTAT field descriptions (continued)

Field	Description
	to the SDRAM. It is recommended not to perform MRW / MRR commands when 'MRSTAT.mr_wr_busy' is high. Value After Reset: 0x0 Exists: Always 0 Indicates that the SoC core can initiate a mode register write operation 1 Indicates that mode register write operation is in progress

9.2.5.2.6 Temperature Derate Enable Register (DDRC_DERATEEN)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + 20h offset = 307A_0020h

DDRC_DERATEEN field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved for future use.
7–4 DERATE_BYTE	Derate byte present only in designs configured to support LPDDR2 or LPDDR3 indicates which byte of the MRR data is used for derating. The maximum valid value depends on MEMC_DRAM_TOTAL_DATA_WIDTH. Value After Reset: 0x0 Exists: MEMC_LPDDR2==1
3–2 Reserved	This field is reserved. Reserved for future use.
1 DERATE_VALUE	Derate Value Present only in designs configured to support LPDDR2 or LPDDR3 Set to 0 for all LPDDR2 speed grades as derating value of +1.875 ns is less than a core_ddrc_core_clk period. It can be 0 or 1 for LPDDR3, depending if +1.875 ns is less than a core_ddrc_core_clk period or not. Value After Reset: 0x0 Exists: MEMC_LPDDR2==1 0 Derating uses + 1 1 Derating uses + 2
0 DERATE_ENABLE	Enable Derating Present only in designs configured to support LPDDR2 / LPDDR3. This field must be set to '0' for non-LPDDR2 / LPDDR3 mode. Value After Reset: 0x0 Exists: MEMC_LPDDR2==1 0 Timing parameter derating is disabled 1 Timing parameter derating is enabled using MR4 read value

9.2.5.2.7 Temperature Derate Interval Register (DDRC_DERATEINT)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + 24h offset = 307A_0024h

DDRC_DERATEINT field descriptions

Field	Description
MR4_READ_INTERVAL	Interval between two MR4 reads, used to derate the timing parameters. Present only in designs configured to support LPDDR2 / LPDDR3. This register cannot not be set to zero. Value After Reset: 0x800000 Exists: MEMC_LPDDR2 == 1

9.2.5.2.8 Low Power Control Register (DDRC_PWRCTL)

Address: 307A_0000h base + 30h offset = 307A_0030h

DDRC_PWRCTL field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_PWRCTL field descriptions (continued)

Field	Description
5 SELFREF_SW	A value 0 of 1 to this register causes system to move to self-refresh state immediately, as long as it is not in INIT or DPD / MPSM operating_mode. This is referred to as Software Entry / Exit to Self-refresh. Value After Reset: 0x0 Exists: Always 1 Software Entry to Self-refresh 0 Software Exit from Self-refresh
4 Reserved	This field is reserved.
3 EN_DFI_DRAM_CLK_DISABLE	Enable the assertion of dfi_dram_clk_disable whenever a clock is not required by the SDRAM. If set to 0, dfi_dram_clk_disable is never asserted. Assertion of dfi_dram_clk_disable is as follows: In DDR3, can only be asserted in self-refresh. Value After Reset: 0x0 Exists: Always
2 DEEPPowerdown_EN	When this is 1, DDRC puts the SDRAM into deep power-down mode when the transaction store is empty. This register must be reset to '0' to bring DDRC out of deep power-down mode. Controller performs automatic SDRAM initialization on deep power-down exit. Present only in designs configured to support LPDDR2 or LPDDR3. FOR PERFORMANCE ONLY. Value After Reset: 0x0 Exists: MEMC_LPDDR2 == 1
1 POWERDOWN_EN	If true then the DDRC goes into power-down after a programmable number of cycles "maximum idle clocks before power down" (PWRTMG.powerdown_to_x32). This register bit may be re-programmed during the course of normal operation. Value After Reset: 0x0 Exists: Always
0 SELFREF_EN	If true then the DDRC puts the SDRAM into Self Refresh after a programmable number of cycles "maximum idle clocks before Self Refresh (PWRTMG.selfref_to_x32)". This register bit may be re-programmed during the course of normal operation. Value After Reset: 0x0 Exists: Always

9.2.5.2.9 Low Power Timing Register (DDRC_PWRTMG)

Address: 307A_0000h base + 34h offset = 307A_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRC_PWRTMG field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_PWRTMG field descriptions (continued)

Field	Description
23–16 SELFREF_TO_ X32	<p>After this many clocks of NOP or deselect the DDRC automatically puts the SDRAM into Self Refresh. This must be enabled in the PWRCTL.selfref_en. Unit: Multiples of 32 clocks.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0x40</p> <p>Exists: Always</p>
15–8 T_DPD_X4096	<p>For LPDDR2 / LPDDR3, value from the JEDEC specification is 500 μs.</p> <p>Unit: Multiples of 4096 clocks.</p> <p>Present only in designs configured to support LPDDR2 or LPDDR3.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: "(MEMC_MOBILE_OR_LPDDR2_EN) ? 0x20 : 0x0"</p> <p>Exists: MEMC_LPDDR2 == 1</p>
7–5 Reserved	<p>This field is reserved.</p> <p>Reserved for future use</p>
POWERDOWN_ TO_X32	<p>After this many clocks of NOP or deselect the DDRC automatically puts the SDRAM into power-down. This must be enabled in the PWRCTL.powerdown_en. Unit: Multiples of 32 clocks</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0x10</p> <p>Exists: Always</p>

9.2.5.2.10 Hardware Low Power Control Register (DDRC_HWLPCTL)

Address: 307A_0000h base + 38h offset = 307A_0038h

DDRC_HWLPCTL field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–16 HW_LP_IDLE_X32	Hardware idle period. The cactive_ddrc output is driven low if the system is idle for hw_lp_idle * 32 cycles if not in INIT or DPD / MPSM operating_mode. The hardware idle function is disabled when hw_lp_idle_x32 = 0. Unit: Multiples of 32 clocks. FOR PERFORMANCE ONLY. Value After Reset: 0x0 Exists: Always
15–2 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_HWLPCTL field descriptions (continued)

Field	Description
1 HW_LP_EXIT_ IDLE_EN	When this bit is programmed to 1 the cactive_in_ddrc pin of the DDRC can be used to exit from the automatic clock stop, automatic power down or automatic self-refreshmodes. NOTE: It will not cause exit of Self-Refresh that is caused by Hardware Low Power Interface and / or Software (PWRCTL.selfref_sw). Value After Reset: 0x1 Exists: Always
0 HW_LP_EN	Enable for Hardware Low Power Interface Value After Reset: 0x1 Exists: Always

9.2.5.2.11 Refresh Control Register 0 (DDRC_RFSHCTL0)

Address: 307A_0000h base + 50h offset = 307A_0050h

DDRC_RFSHCTL0 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use
23–20 REFRESH_MARGIN	Threshold value in number of clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t _{rfc_nom_x32} . Note that, in LPDDR2 / LPDDR3, internally used t _{rfc_nom_x32} may be equal to RFSHTMG.t _{rfc_nom_x32} >> 2 if derating is enabled (DERATEEN.derate_enable = 1). Otherwise, internally used t _{rfc_nom_x32} will be equal to RFSHTMG.t _{rfc_nom_x32} . Unit: Multiples of 32 clocks. Value After Reset: 0x2

Table continues on the next page...

DDRC_RFSHCTL0 field descriptions (continued)

Field	Description
	Exists: Always
19–17 Reserved	This field is reserved. Reserved for future use
16–12 REFRESH_TO_ X32	If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, but it has not expired (RFSHCTL0.refresh_burst + 1) times yet, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful, but before it is absolutely required. When the SDRAM bus is idle for a period of time determined by thisRFSHCTL0.refresh_to_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed. Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the DDRC. FOR PERFORMANCE ONLY. Value After Reset: 0x10 Exists: Always
11–9 Reserved	This field is reserved. Reserved for future use
8–4 REFRESH_ BURST	The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly increases utilization; lower numbers decreases the worst-case latency associated with refreshes. For DDR3, the refresh is always per-rank and not per-bank. The rank refresh can be accumulated over $8 * t_{REFI}$ cycles using the burst refresh feature. Value After Reset: 0x0 Exists: Always 0 Single refresh 1 Burst-of-2 refresh 7 Burst-of-8 refresh
3 Reserved	This field is reserved. Reserved for future use
2 PER_BANK_ REFRESH	Per bank refresh allows traffic to flow to other banks. Per bank refresh is not supported by all LPDDR2 devices but should be supported by all LPDDR3 devices. Present only in designs configured to support LPDDR2 / LPDDR3. Value After Reset: 0x0 Exists: MEMC_LPDDR2 == 1 1 Per bank refresh 0 All bank refresh
Reserved	This field is reserved. Reserved for future use

9.2.5.2.12 Refresh Control Register 1 (DDRC_RFSHCTL1)

Exists: MEMC_NUM_RANKS > 1

Address: 307A_0000h base + 54h offset = 307A_0054h

DDRC_RFSHCTL1 field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–16 REFRESH_TIMER1_START_VALUE_X32	Refresh timer start for rank 1 (only present in multi-rank configurations). This is useful in staggering the refreshes to multiple ranks to help traffic to proceed. This is explained in Refresh Controls section of architecture chapter. Unit: Multiples of 32 clocks. FOR PERFORMANCE ONLY. Value After Reset: 0x0 Exists: MEMC_NUM_RANKS > 1
15–12 Reserved	This field is reserved. Reserved for future use
REFRESH_TIMER0_START_VALUE_X32	Refresh timer start for rank 0 (only present in multi-rank configurations). This is useful in staggering the refreshes to multiple ranks to help traffic to proceed. This is explained in Refresh Controls section of architecture chapter. Unit: Multiples of 32 clocks. FOR PERFORMANCE ONLY. Value After Reset: 0x0 Exists: MEMC_NUM_RANKS > 1

9.2.5.2.13 Refresh Control Register 0 (DDRC_RFSHCTL3)

Address: 307A_0000h base + 60h offset = 307A_0060h

DDRC_RFSHCTL3 field descriptions

Field	Description
31–7 Reserved	This field is reserved. Reserved for future use
6–4 Reserved	This field is reserved.
3–2 Reserved	This field is reserved. Reserved for future use
1 REFRESH_UPDATE_LEVEL	Toggle this signal (either from 0 to 1 or from 1 to 0) to indicate that the refresh register(s) have been updated. The value is automatically updated when exiting reset, so it does not need to be toggled initially. Value After Reset: 0x0 Exists: Always

Table continues on the next page...

DDRC_RFSHCTL3 field descriptions (continued)

Field	Description
0 DIS_AUTO_REFRESH	<p>When '1', disable auto-refresh generated by the DDRC. When auto-refresh is disabled, the SoC core must generate refreshes using the registers reg_ddrc_rank0_refresh, reg_ddrc_rank1_refresh, reg_ddrc_rank2_refresh and reg_ddrc_rank3_refresh. When dis_auto_refresh transitions from 0 to 1, any pending refreshes are immediately scheduled by the DDRC.</p> <p>This register field is changeable on the fly.</p> <p>Value After Reset: 0x0</p> <p>Exists: Always</p>

9.2.5.2.14 Refresh Timing Register (DDRC_RFSHTMG)

Address: 307A_0000h base + 64h offset = 307A_0064h

DDRC_RFSHTMG field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–16 T_RFC_NOM_X32	<p>tREFI: Average time interval between refreshes per rank (Specification: 7.8us for DDR3. See JEDEC specification for LPDDR2 and LPDDR3). For LPDDR2 / LPDDR3:</p> <ul style="list-style-type: none"> • If using all-bank refreshes (RFSHCTL0.per_bank_refresh = 0), this register should be set to tREFIab • If using per-bank refreshes (RFSHCTL0.per_bank_refresh = 1), this register should be set to tREFIpb <p>For configurations with MEMC_FREQ_RATIO = 2, program this to (tREFI / 2), no rounding up.</p> <p>Note that RFSHTMG.t_rfc_nom_x32 * 32 must be greater than RFSHTMG.t_rfc_min.</p> <p>Unit: Multiples of 32 clocks.</p> <p>Value After Reset: 0x62</p> <p>Exists: Always</p>
15–10 Reserved	This field is reserved. Reserved for future use
T_RFC_MIN	<p>tRFC (min): Minimum time from refresh to refresh or activate.</p> <p>For MEMC_FREQ_RATIO = 1 configurations, t_rfc_min should be set to RoundUp (tRFCmin / tCK).</p> <p>For MEMC_FREQ_RATIO = 2 configurations, t_rfc_min should be set to RoundUp (RoundUp (tRFCmin / tCK) / 2).</p> <p>In LPDDR2 / LPDDR3 mode:</p> <ul style="list-style-type: none"> • If using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab • If using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb <p>Unit: Clocks.</p>

Address: 307A_0000h base + D0h offset = 307A_00D0h

DDRC_INIT0 field descriptions

Field	Description
31–30 SKIP_DRAM_INIT	If lower bit is enabled the SDRAM initialization routine is skipped. The upper bit decides what state the controller starts up in when reset is removed. Value After Reset: 0x0 Exists: Always 00 SDRAM Initialization routine is run after power-up. 01 SDRAM Initialization routine is skipped after power-up. Controller starts up in Normal Mode. 11 SDRAM Initialization routine is skipped after power-up. Controller starts up in Self-refresh Mode. 10 SDRAM Initialization routine is run after power-up.
29–26 Reserved	This field is reserved. Reserved for future use
25–16 POST_CKE_X1024	Cycles to wait after driving CKE high to start the SDRAM initialization sequence. Unit: 1024 clocks. LPDDR2 / LPDDR3 typically requires this to be programmed for a delay of 200 us. For configurations with MEMC_FREQ_RATIO = 2, program this to JEDEC spec value divided by 2, and round it up to next integer value. Value After Reset: 0x2

Table continues on the next page...

DDRC_INIT0 field descriptions (continued)

Field	Description
	Exists: Always
15–11 Reserved	This field is reserved. Reserved for future use
PRE_CKE_ X1024	Cycles to wait after reset before driving CKE high to start the SDRAM initialization sequence. Unit: 1024 clock cycles. LPDDR2 / LPDDR3: tINIT1 of 100 ns (min) For configurations with MEMC_FREQ_RATIO = 2, program this to JEDEC spec value divided by 2, and round it up to next integer value. Value After Reset: 0x4e Exists: Always

9.2.5.2.16 SDRAM Initialization Register 1 (DDRC_INIT1)

Address: 307A_0000h base + D4h offset = 307A_00D4h

DDRC_INIT1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use
23–16 DRAM_RSTN_ X1024	Number of cycles to assert SDRAM reset signal during init sequence. This is only present for designs supporting DDR3 devices. Value After Reset: 0x0 Exists: MEMC_DDR3 == 1
15 Reserved	This field is reserved. Reserved for future use
14–8 FINAL_WAIT_ X32	Cycles to wait after completing the SDRAM initialization sequence before starting the dynamic scheduler. Unit: Counts of a global timer that pulses every 32 clock cycles. There is no known specific requirement for this; it may be set to zero. Value After Reset: 0x0 Exists: Always
7–4 Reserved	This field is reserved. Reserved for future use
PRE_OCD_X32	Wait period before driving the OCD complete command to SDRAM. Unit: Counts of a global timer that pulses every 32 clock cycles. There is no known specific requirement for this; it may be set to zero. Value After Reset: 0x0 Exists: Always

9.2.5.2.17 SDRAM Initialization Register 2 (DDRC_INIT2)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + D8h offset = 307A_00D8h

Table continues on the next page...

DDRC_ZQSTAT field descriptions (continued)

Field	Description
0 ZQ_RESET_ BUSY	<p>SoC core may initiate a ZQ Reset operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ZQ Reset request. It goes low when the ZQ Reset command is issued to the SDRAM and the associated NOP period is over. It is recommended not to perform ZQ Reset commands when this signal is high.</p> <p>Value After Reset: 0x0</p> <p>Exists: Always</p> <p>0 Indicates that the SoC core can initiate a ZQ Reset operation. 1 Indicates that ZQ Reset operation is in progress.</p>

9.2.5.2.35 DFI Timing Register 0 (DDRC_DFITMG0)

Address: 307A_0000h base + 190h offset = 307A_0190h

DDRC_DFITMG0 field descriptions

Field	Description
31–29 Reserved	This field is reserved. Reserved for future use
28–24 DFI_T_CTRL_ DELAY	Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or deassertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value Value After Reset: 0x7. Exists: Always
23 DFI_RDDATA_ USE_SDR	Defines whether dfi_rddata_en / dfi_rddata / dfi_rddata_valid is generated using HDR or SDR values Selects whether value in DFITMG0.dfi_t_rddata_en is in terms of SDR or HDR clock cycles. Value After Reset: 0x0 Exists: MEMC_FREQ_RATIO == 2 0 In terms of HDR clock cycles 1 In terms of SDR clock cycles Refer to PHY specification for correct value.
22 Reserved	This field is reserved. Reserved for future use
21–16 DFI_T_ RDDATA_EN	Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal. Refer to PHY specification for correct value. This corresponds to the DFI parameter trddata_en. Note that, depending on the PHY, if using RDIMM, it may be necessary to use the value (CL + 1) in the calculation of trddata_en. This is to compensate for the extra cycle of latency through the RDIMM. Unit: Clocks Value After Reset: 0x2 Exists: Always
15 DFI_WRDATA_ USE_SDR	Defines whether dfi_wrdata_en / dfi_wrdata / dfi_wrdata_mask is generated using HDR or SDR values Selects whether value in DFITMG0.dfi_tphy_wrlat is in terms of SDR or HDR clock cycles Selects whether value in DFITMG0.dfi_tphy_wrdata is in terms of SDR or HDR clock cycles. Refer to PHY specification for correct value. Value After Reset: 0x0 Exists: MEMC_FREQ_RATIO==2 0 In terms of HDR clock cycles 1 In terms of SDR clock cycles
14 Reserved	This field is reserved. Reserved for future use
13–8 DFI_TPHY_ WRDATA	Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. NOTE: The max supported value is 8. Unit: Clocks Value After Reset: 0x0 Exists: Always
7–6 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_DFITMG0 field descriptions (continued)

Field	Description
DFI_TPHY_WRLAT	<p>Write latency</p> <p>Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat.</p> <p>Refer to PHY specification for correct value. Note that, depending on the PHY, if using RDIMM, it may be necessary to use the value (CL + 1) in the calculation of tphy_wrlat. This is to compensate for the extra cycle of latency through the RDIMM.</p> <p>Value After Reset: 0x2</p> <p>Exists: Always</p>

9.2.5.2.36 DFI Timing Register 1 (DDRC_DFITMG1)

Address: 307A_0000h base + 194h offset = 307A_0194h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–26 Reserved	This field is reserved. Reserved for future use
25–24 Reserved	This field is reserved.
23–21 Reserved	This field is reserved. Reserved for future use
20–16 DFI_T_WRDATA_DELAY	<p>Specifies the number of DFI clocks between when the dfi_wrdata_en signal is asserted and when the corresponding write data transfer is completed on the DRAM bus. This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value. For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0. For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM). Value to be programmed is in terms of DFI clocks, not PHY clocks. In $FREQ_RATIO = 2$, divide PHY's value by 2 and round up to next integer. If using $DFITMG0.dfi_wrdata_use_sdr = 1$, add 1 to the value.</p> <p>Unit: Clocks</p> <p>Value After Reset: 0x0</p> <p>Exists: Always</p>
15–12 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_DFITMG1 field descriptions (continued)

Field	Description
11–8 DFI_T_DRAM_CLK_DISABLE	Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value. Value After Reset: 0x4 Exists: Always
7–4 Reserved	This field is reserved. Reserved for future use
DFI_T_DRAM_CLK_ENABLE	Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value. Value After Reset: 0x4 Exists: Always

9.2.5.2.37 DFI Low Power Configuration Register 0 (DDRC_DFILPCFG0)

Address: 307A_0000h base + 198h offset = 307A_0198h

DDRC_DFILPCFG0 field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–24 DFI_TLP_RESP	Setting for DFI's tlp_resp time. Same value is used for both Power Down, Self Refresh, Deep Power Down and Maximum Power Saving modes. DFI 2.1 specification onwards, recommends using a fixed value of 7 always. Value After Reset: 0x7 Exists: Always
23–20 DFI_LP_WAKEUP_DPD	Value to drive on dfi_lp_wakeup signal when Deep Power Down mode is entered. Determines the DFI's tlp_wakeup time. This is only present for designs supporting LPDDR2 / LPDDR3 devices. Value After Reset: 0x0 Exists: MEMC_LPDDR2 == 1 0x0 16 cycles 0x1 32 cycles 0x2 64 cycles 0x3 128 cycles 0x4 256 cycles 0x5 512 cycles 0x6 1024 cycles 0x7 2948 cycles 0x8 4096 cycles 0x9 8192 cycles 0xA 16384 cycles 0xB 32768 cycles 0xC 65536 cycles 0xD 131072 cycles 0xE 262144 cycles 0xF Unlimited
19–17 Reserved	This field is reserved. Reserved for future use
16 DFI_LP_EN_DPD	Enables DFI Low Power interface handshaking during Deep Power Down Entry / Exit. This is only present for designs supporting LPDDR2 / LPDDR3 devices. Value After Reset: 0x0 Exists: MEMC_LPDDR2 == 1 0 Disabled 1 Enabled
15–12 DFI_LP_WAKEUP_SR	Value to drive on dfi_lp_wakeup signal when Self Refresh mode is entered. Determines the DFI's tlp_wakeup time. Value After Reset: 0x0 Exists: Always

Table continues on the next page...

0 DFI_LP_EN_PD	Enables DFI Low Power interface handshaking during Power Down Entry / Exit. Value After Reset: 0x0 Exists: Always 0 Disabled 1 Enabled

9.2.5.2.38 DFI Update Register 0 (DDRC_DFIUPD0)

Address: 307A_0000h base + 1A0h offset = 307A_01A0h

DDRC_DFIUPD0 field descriptions

Field	Description
31 DIS_AUTO_CTRLUPD	When '1', disable the automatic dfi_ctrlupd_req generation by the DDRC NOTE: It is recommended to set this register to 1 when the PHY-Initiated Update is enabled in the DDR PHY. Value After Reset: 0x0 Exists: Always
30 DIS_AUTO_CTRLUPD_SRX	When '1', disable the automatic dfi_ctrlupd_req generation by the DDRC following a self-refresh exit. The core must issue the dfi_ctrlupd_req signal using register reg_ddrc_ctrlupd. This register field is changeable on the fly. When '0', DDRC issues a dfi_ctrlupd_req after exiting self- refresh. Value After Reset: 0x0 Exists: Always
29–26 Reserved	This field is reserved. Reserved for future use
25–16 DFI_T_CTRLUPD_MAX	Specifies the maximum number of clock cycles that the dfi_ctrlupd_req signal can assert. The lowest value to assign to this variable is 0x40. Unit: Clocks Value After Reset: 0x40 Exists: Always
15–10 Reserved	This field is reserved. Reserved for future use
DFI_T_CTRLUPD_MIN	Specifies the minimum number of clock cycles that the dfi_ctrlupd_req signal must be asserted. The DDRC expects the PHY to respond within this time. If the PHY does not respond, the DDRC will de-assert dfi_ctrlupd_req after dfi_t_ctrlupd_min + 2 cycles. Lowest value to assign to this variable is 0x3. Unit: Clocks Value After Reset: 0x3 Exists: Always

9.2.5.2.39 DFI Update Register 1 (DDRC_DFIUPD1)

Address: 307A_0000h base + 1A4h offset = 307A_01A4h

DDRC_DFIUPD1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use
23–16 DFI_T_CTRLUPD_	This is the minimum amount of time between DDRC initiated DFI update requests (which is executed whenever the DDRC is idle). Set this number higher to reduce the frequency of update requests, which can have a small impact on the latency of the first read request when the DDRC is idle.

Table continues on the next page...

DDRC_DFIUPD1 field descriptions (continued)

Field	Description
INTERVAL_MIN_X1024	Unit: 1024 clocks Value After Reset: 0x0 Exists: Always
15–8 Reserved	This field is reserved. Reserved for future use
DFI_T_CTRLUPD_INTERVAL_MAX_X1024	This is the maximum amount of time between DDRC initiated DFI update requests. This timer resets with each update request; when the timer expires dfi_ctrlupd_req is sent and traffic is blocked until the dfi_ctrlupd_ackx is received. PHY can use this idle time to recalibrate the delay lines to the DLLs. The DFI controller update is also used to reset PHY FIFO pointers in case of data capture errors. Updates are required to maintain calibration over PVT, but frequent updates may impact performance. NOTE: Value programmed for DFIUPD1.dfi_t_ctrlupd_interval_max_x1024 must be greater than DFIUPD1.dfi_t_ctrlupd_interval_min_x1024. Unit: 1024 clocks Value After Reset: 0x0 Exists: Always

9.2.5.2.40 DFI Update Register 2 (DDRC_DFIUPD2)

Address: 307A_0000h base + 1A8h offset = 307A_01A8h

DDRC_DFIUPD3 field descriptions (continued)

Field	Description
15–12 Reserved	This field is reserved. Reserved for future use
DFI_PHYUPD_ TYPE2	Specifies the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type = 2'b10. Is used in conjunction with value defined via DFIUPD4.dfi_phyupd_type2_mult. The dfi_phyupd_req signal may de-assert at any cycle after the assertion of the dfi_phyupd_ack signal. Value After Reset: 0x10 Exists: Always

9.2.5.2.42 DFI Miscellaneous Control Register (DDRC_DFIMISC)

Address: 307A_0000h base + 1B0h offset = 307A_01B0h

DDRC_DFIMISC field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved for future use
0 DFL_INIT_COMPLETE_EN	PHY initialization complete enable signal. When asserted the dfi_init_complete signal can be used to trigger SDRAM initialisation Value After Reset: 0x1 Exists: Always

9.2.5.2.43 Address Map Register 0 (DDRC_ADDRMAP0)

Exists: (MEMC_NUM_RANKS>1)

Address: 307A_0000h base + 200h offset = 307A_0200h

DDRC_ADDRMAP0 field descriptions

Field	Description
31–13 Reserved	This field is reserved. Reserved for future use
12–8 ADDRMAP_CS_BIT1	Selects the HIF address bit used as rank address bit 1. Valid Range: 0 to 26, and 31 Internal Base: 7 The selected HIF address bit is determined by adding the internal base to the value of this field. If set to 31, rank address bit 1 is set to 0. Value After Reset: 0x0 Exists: MEMC_NUM_RANKS == 4
7–5 Reserved	This field is reserved. Reserved for future use
ADDRMAP_CS_BIT0	Selects the HIF address bit used as rank address bit 0. Valid Range: 0 to 27, and 31 Internal Base: 6 The selected HIF address bit is determined by adding the internal base to the value of this field. If set to 31, rank address bit 0 is set to 0. Value After Reset: 0x0 Exists: MEMC_NUM_RANKS > 1

9.2.5.2.44 Address Map Register 1 (DDRC_ADDRMAP1)

9.2.5.2.52 Scheduler Control Register (DDRC_SCHED)

Address: 307A_0000h base + 250h offset = 307A_0250h

DDRC_SCHED field descriptions

Field	Description
31 Reserved	This field is reserved. Reserved for future use
30–24 RDWR_IDLE_ GAP	When the preferred transaction store is empty for these many clock cycles, switch to the alternate transaction store if it is non-empty. The read transaction store (both high and low priority) is the default preferred transaction store and the write transaction store is the alternative store. When prefer write over read is set this is reversed. 0x0 is a legal value for this register. When set to 0x0, the transaction store switching will happen immediately when the switching conditions become true.

Table continues on the next page...

DDRC_SCHED field descriptions (continued)

Field	Description
	FOR PERFORMANCE ONLY Value After Reset: 0x0 Exists: Always
23–14 Reserved	This field is reserved. Reserved for future use
13–8 LPR_NUM_ ENTRIES	Number of entries in the low priority transaction store is this value + 1. (MEMC_NO_OF_ENTRY - (SCHED.lpr_num_entries + 1)) is the number of entries available for the high priority transaction store. Setting this to maximum value allocates all entries to low priority transaction store. Setting this to 0 allocates 1 entry to low priority transaction store and the rest to high priority transaction store. Value After Reset: "MEMC_NO_OF_ENTRY / 2" Exists: Always
7–3 Reserved	This field is reserved. Reserved for future use
2 PAGECLOSE	If true, bank is kept open only until there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit will be executed with auto-precharge if SCHED1.pageclose_timer = 0. Even if this register set to 1 and SCHED1.pageclose_timer is set to 0, explicit precharge (and not auto-precharge) may be issued in some cases where there is a mode switch between Write and Read or between LPR and HPR. The Read and Write commands that are executed as part of the ECC scrub requests are also executed without auto-precharge. If false, the bank remains open until there is a need to close it (to open a different page, or for page timeout or refresh timeout) - also known as open page policy. The open page policy can be overridden by setting the per-command- autopre bit on the HIF interface (hif_cmd_autopre). The pageclose feature provides a midway between Open and Close page policies. FOR PERFORMANCE ONLY. Value After Reset: 0x1 Exists: Always
1 PREFER_WRITE	If set then the bank selector prefers writes over reads. FOR DEBUG ONLY. Value After Reset: 0x0 Exists: Always
0 FORCE_LOW_ PRI_N	Active low signal. When asserted ('0'), all incoming transactions are forced to low priority. This implies that all High Priority Read (HPR) and Variable Priority Read commands (VPR) will be treated as Low Priority Read (LPR) commands. On the write side, all Variable Priority Write (VPW) commands will be treated as Normal Priority Write (NPW) commands. Forcing the incoming transactions to low priority implicitly turns off Bypass path for read commands. FOR PERFORMANCE ONLY. Value After Reset: 0x1 Exists: Always

9.2.5.2.53 Scheduler Control Register 1 (DDRC_SCHED1)

Address: 307A_0000h base + 254h offset = 307A_0254h

DDRC_SCHED1 field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved for future use
PAGECLOSE_TIMER	<p>This field works in conjunction with SCHED.pageclose. It only has meaning if SCHED.pageclose == 1.</p> <p>If SCHED.pageclose == 1 and pageclose_timer == 0, then an auto-precharge may be scheduled for last read or write command in the CAM with a bank and page hit. Note, sometimes an explicit precharge is scheduled instead of the auto-precharge. See SCHED.pageclose for details of when this may happen.</p> <p>If SCHED.pageclose == 1 and pageclose_timer > 0, then an auto-precharge is not scheduled for last read or write command in the CAM with a bank and page hit. Instead, a timer is started, with pageclose_timer as the initial value.</p> <p>There is a timer on a per bank basis. The timer decrements unless the next read or write in the CAM to a bank is a page hit. It gets reset to pageclose_timer value if the next read or write in the CAM to a bank is a page hit. Once the timer has reached zero, an explicit precharge will be attempted to be scheduled.</p> <p>Value After Reset: 0x0</p> <p>Exists: Always</p>

9.2.5.2.54 High Priority Read CAM Register 1 (DDRC_PERFHPR1)

Address: 307A_0000h base + 25Ch offset = 307A_025Ch

DDRC_PERFHPR1 field descriptions

Field	Description
31–24 HPR_XACT_RUN_LENGTH	<p>Number of transactions that are serviced once the HPR queue goes critical is the smaller of:</p> <ul style="list-style-type: none"> This number Number of transactions available. <p>Unit: Transaction</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0xf</p>

Table continues on the next page...

DDRC_PERFHPR1 field descriptions (continued)

Field	Description
	Exists: Always
23–16 Reserved	This field is reserved.
HPR_MAX_STARVE	<p>Number of clocks that the HPR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies.</p> <p>Unit: Clock cycles.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0x1</p> <p>Exists: Always</p>

9.2.5.2.55 Low Priority Read CAM Register 1 (DDRC_PERFLPR1)

Address: 307A_0000h base + 264h offset = 307A_0264h

DDRC_PERFLPR1 field descriptions

Field	Description
31–24 LPR_XACT_RUN_LENGTH	<p>Number of transactions that are serviced once the LPR queue goes critical is the smaller of:</p> <ol style="list-style-type: none"> This number Number of transactions available <p>Unit: Transaction.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0xf</p> <p>Exists: Always</p>
23–16 Reserved	This field is reserved. Reserved for future use
LPR_MAX_STARVE	<p>Number of clocks that the LPR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies.</p> <p>Unit: Clock cycles.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0x7f</p> <p>Exists: Always</p>

9.2.5.2.56 Write CAM Register 1 (DDRC_PERFWR1)

Address: 307A_0000h base + 26Ch offset = 307A_026Ch

DDRC_PERFWR1 field descriptions

Field	Description
31–24 W_XACT_RUN_LENGTH	<p>Number of transactions that are serviced once the WR queue goes critical is the smaller of:</p> <ol style="list-style-type: none"> 1. This number 2. Number of transactions available <p>Unit: Transaction.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0xf</p> <p>Exists: Always</p>
23–16 Reserved	<p>This field is reserved.</p> <p>Reserved for future use</p>
W_MAX_STARVE	<p>Number of clocks that the WR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies.</p> <p>Unit: Clock cycles.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0x7f</p> <p>Exists: Always</p>

9.2.5.2.57 Variable Priority Read CAM Register 1 (DDRC_PERFVPR1)

Exists: DDRC_VPR_EN==1

Address: 307A_0000h base + 274h offset = 307A_0274h

DDRC_PERFVPR1 field descriptions

Field	Description
31–11 Reserved	This field is reserved. Reserved for future use
VPR_TIMEOUT_RANGE	<p>Indicates the range of the timeout value that is used for grouping the expired VPR commands in the CAM in DDRC. For example, if the register value is set to 0xF, then the priorities of all the VPR commands whose timeout counters are 15 or below will be considered as expired-VPR commands when the timeout value of any of the VPR commands reach 0. The expired-VPR commands, when present, are given higher priority than HPR commands. The VPR commands are expected to consist of largely page hit traffic and by grouping them together the bus utilization is expected to increase. This register applies to transactions inside the DDRC only.</p> <p>The Max value for this register is 0x7FF and the Min value is 0x0.</p> <p>When programmed to the Max value of 0x7FF, all the VPR commands that come in to DDRC will time-out right-away and will be considered as expired-VPR.</p> <p>When programmed to the Min value of 0x0, the timer of each command would have to reach a value of 0 before it will be considered as expired-VPR.</p> <p>Unit: Clock cycles.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0x0</p> <p>Exists: DDRC_VPR_EN == 1</p>

9.2.5.2.58 Variable Priority Write CAM Register 1 (DDRC_PERFVPW1)

Exists: DDRC_VPW_EN==1

Address: 307A_0000h base + 278h offset = 307A_0278h

DDRC_PERFVPW1 field descriptions

Field	Description
31–11 Reserved	This field is reserved. Reserved for future use
VPW_TIMEOUT_RANGE	<p>Indicates the range of the timeout value that is used for grouping the expired VPW commands in the CAM in DDRC. For example, if the register value is set to 0xF, then the priorities of all the VPW commands whose timeout counters are 15 or below will be considered as expired-VPW commands when the timeout value of any of the VPW commands reach 0. The expired-VPW commands, when present, are given higher priority than normalWrite commands. The VPW commands are expected to consist of largely page hit traffic and by grouping them together the bus utilization is expected to increase. This register applies to transactions inside the DDRC only.</p> <p>The Max value for this register is 0x7FF and the Min value is 0x0.</p>

Table continues on the next page...

DDRC_PERFVPW1 field descriptions (continued)

Field	Description
	<p>When programmed to the Max value of 0x7FF, all the VPW commands that come in to DDRC will time-out right-away and will be considered as expired-VPW.</p> <p>When programmed to the Min value of 0x0, the timer of each command would have to reach a value of 0 before it will be considered as expired-VPW.</p> <p>Unit: Clock cycles.</p> <p>FOR PERFORMANCE ONLY.</p> <p>Value After Reset: 0x0</p> <p>Exists: DDRC_VPW_EN == 1</p>

9.2.5.2.59 Debug Register 0 (DDRC_DBG0)

Address: 307A_0000h base + 300h offset = 307A_0300h

DDRC_DBG0 field descriptions

Field	Description
31–5 Reserved	This field is reserved. Reserved for future use
4 DIS_COLLISION_PAGE_OPT	When this is set to '0', auto-precharge is disabled for the flushed command in a collision case. Collision cases are write followed by read to same address, read followed by write to same address, or write followed by write to same address with DBG0.dis_wc bit = 1 (where same address comparisons exclude the two address bits representing critical word). FOR DEBUG ONLY. Value After Reset: 0x0 Exists: Always
3–1 Reserved	This field is reserved. Reserved for future use
0 DIS_WC	When the value is 1, disable write combine. FOR DEBUG ONLY Value After Reset: 0x0 Exists: Always

9.2.5.2.60 Debug Register 1 (DDRC_DBG1)

Address: 307A_0000h base + 304h offset = 307A_0304h

DDRC_DBG1 field descriptions

Field	Description
31–2 Reserved	This field is reserved. Reserved for future use
1 DIS_HIF	When 1, the DDRC asserts the HIF command signal hif_cmd_stall. The DDRC will ignore the hif_cmd_valid and all other associated request signals. This bit is intended to be switched on-the-fly. Value After Reset: 0x0 Exists: Always
0 DIS_DQ	When 1, DDRC will not de-queue any transactions from the CAM. Bypass is also disabled. All transactions are queued in the CAM. No reads or writes are issued to SDRAM as long as this is asserted. This bit may be used to prevent reads or writes being issued by the DDRC, which makes it safe to modify certain register fields associated with reads and writes (see User Guide for details). After setting this bit, it is strongly recommended to poll DBGCAM.wr_data_pipeline_empty and DBGCAM.rd_data_pipeline_empty, before making changes to any registers which affect reads and writes. This will ensure that the relevant logic in the DDRC is idle. This bit is intended to be switched on-the-fly. Value After Reset: 0x0 Exists: Always

9.2.5.2.61 CAM Debug Register (DDRC_DBGCAM)

Address: 307A_0000h base + 308h offset = 307A_0308h

DDRC_DBGCAM field descriptions

Field	Description
31 DBG_STALL_RD	Stall for Read channel FOR DEBUG ONLY Value After Reset: 0x0 Exists: DDRC_DUAL_PA_1 == 1
30 DBG_STALL_WR	Stall for Write channel FOR DEBUG ONLY Value After Reset: 0x0 Exists: DDRC_DUAL_PA_1 == 1
29 WR_DATA_PIPELINE_EMPTY	This bit indicates that the write data pipeline on the DFI interface is empty. This register is intended to be polled after setting DBG1.dis_dq, to ensure that all remaining commands / data have completed. Value After Reset: 0x0 Exists: Always

Table continues on the next page...

DDRC_DBGCAM field descriptions (continued)

Field	Description
28 RD_DATA_ PIPELINE_ EMPTY	This bit indicates that the read data pipeline on the DFI interface is empty. This register is intended to be polled after setting DBG1.dis_dq, to ensure that all remaining commands / data have completed. Value After Reset: 0x0 Exists: Always
27 Reserved	This field is reserved. Reserved for future use
26 DBG_WR_Q_ EMPTY	When 1, all the Write command queues and Write data buffers inside DDRC are empty. This register is to be used for debug purpose. An example use-case scenario: When Controller enters Self-Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time. FOR DEBUG ONLY Value After Reset: 0x0 Exists: Always
25 DBG_RD_Q_ EMPTY	When 1, all the Read command queues and Read data buffers inside DDRC are empty. This register is to be used for debug purpose. An example use-case scenario: When Controller enters Self-Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time. FOR DEBUG ONLY Value After Reset: 0x0 Exists: Always
24 DBG_STALL	Stall FOR DEBUG ONLY Value After Reset: 0x0 Exists: Always
23 Reserved	This field is reserved. Reserved for future use
22–16 DBG_W_Q_ DEPTH	Write Queue Depth FOR DEBUG ONLY Value After Reset: 0x0 Exists: Always
15 Reserved	This field is reserved. Reserved for future use
14–8 DBG_LPR_Q_ DEPTH	Low Priority Read Queue Depth FOR DEBUG ONLY Value After Reset: 0x0 Exists: Always
7 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_DBGCAM field descriptions (continued)

Field	Description
DBG_HPR_Q_DEPTH	High Priority Read Queue Depth FOR DEBUG ONLY Value After Reset: 0x0 Exists: Always

9.2.5.2.62 Command Debug Register (DDRC_DBGCMD)

Address: 307A_0000h base + 30Ch offset = 307A_030Ch

DDRC_DBGCMD field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved for future use
5 CTRLUPD	Setting this register bit to 1 indicates to the DDRC to issue a dfi_ctrlupd_req to the PHY. When this request is stored in the DDRC, the bit is automatically cleared. This operation must only be performed when DFIUPD0.dis_auto_ctrlupd = 1.

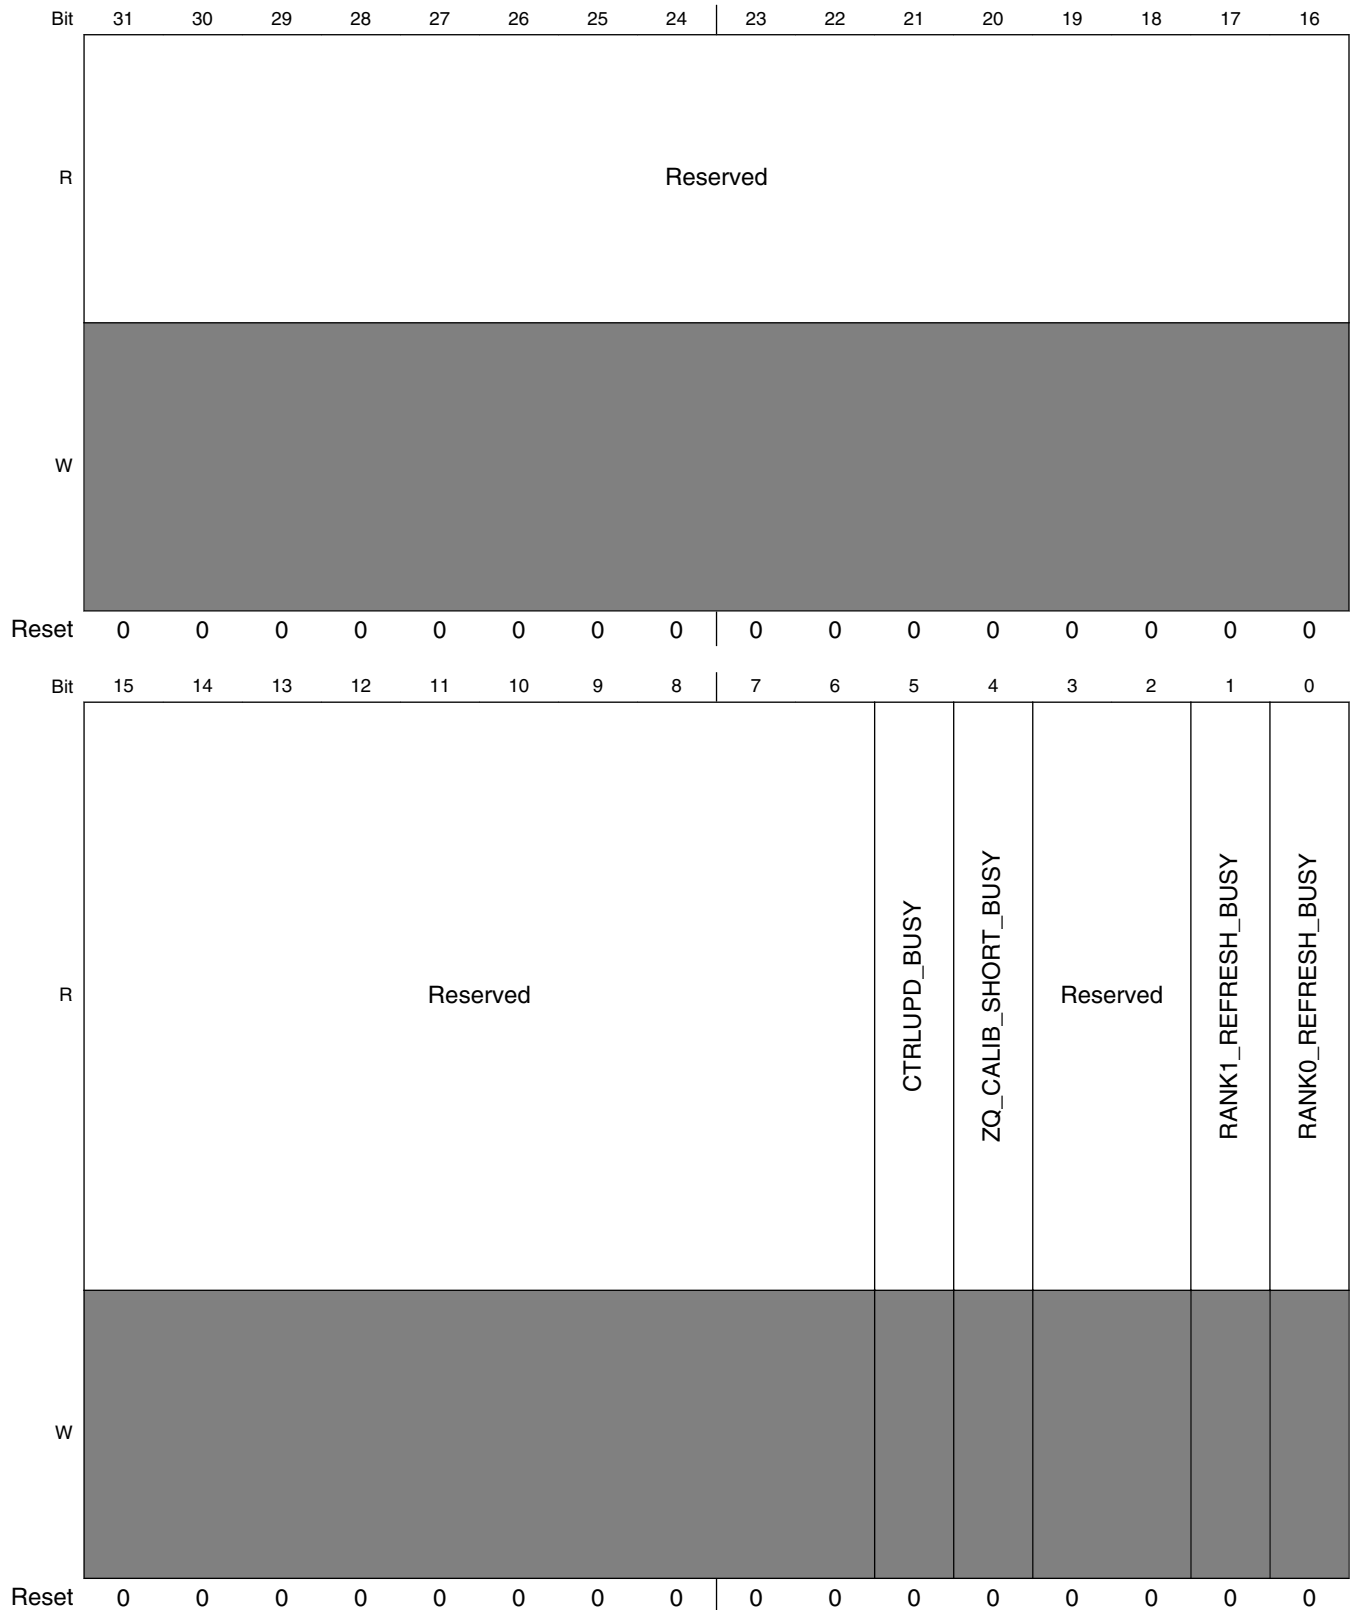

Table continues on the next page...

DDRC_DBGCMD field descriptions (continued)

Field	Description
	<p>Value After Reset: 0x0</p> <p>Exists: Always</p> <p>Testable: Read only</p>
4 ZQ_CALIB_SHORT	<p>Setting this register bit to 1 indicates to the DDRC to issue a ZQCS (ZQ calibration short) command to the SDRAM. When this request is stored in the DDRC, the bit is automatically cleared. This operation can be performed only when ZQCTL0.dis_auto_zq = 1. It is recommended NOT to set this register bit if in Init operating mode. This register bit is ignored when in Self-Refresh and Deep power-down operating modes and Maximum Power Saving Mode.</p> <p>Value After Reset: 0x0</p> <p>Exists: MEMC_DDR3_OR_LPDDR2 == 1</p> <p>Testable: Read only</p>
3-2 Reserved	<p>This field is reserved. Reserved for future use</p>
1 RANK1_REFRESH	<p>Setting this register bit to 1 indicates to the DDRC to issue a refresh to rank 1. Writing to this bit causes DBGSTAT.rank1_refresh_busy to be set. When DBGSTAT.rank1_refresh_busy is cleared, the command has been stored in the DDRC. This operation can be performed only when RFSHCTL3.dis_auto_refresh = 1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.</p> <p>Value After Reset: 0x0 Exists: MEMC_NUM_RANKS > 1</p> <p>Testable: Read only</p>
0 RANK0_REFRESH	<p>Setting this register bit to 1 indicates to the DDRC to issue a refresh to rank 0. Writing to this bit causes DBGSTAT.rank0_refresh_busy to be set. When DBGSTAT.rank0_refresh_busy is cleared, the command has been stored in the DDRC. This operation can be performed only when RFSHCTL3.dis_auto_refresh = 1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.</p> <p>Value After Reset: 0x0</p> <p>Exists: Always</p> <p>Testable: Read only</p>

9.2.5.2.63 Status Debug Register (DDRC_DBGSTAT)

Address: 307A_0000h base + 310h offset = 307A_0310h

DDRC_DBGSTAT field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved for future use
5 CTRLUPD_ BUSY	SoC core may initiate a ctrlupd operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ctrlupd request. It goes low when the ctrlupd operation is initiated in the DDRC. It is recommended not to perform ctrlupd operations when this signal is high. Value After Reset: 0x0 Exists: Always 0 Indicates that the SoC core can initiate a ctrlupd operation 1 Indicates that ctrlupd operation has not been initiated yet in the DDRC
4 ZQ_CALIB_ SHORT_BUSY	SoC core may initiate a ZQCS (ZQ calibration short) operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ZQCS request. It goes low when the ZQCS operation is initiated in the DDRC. It is recommended not to perform ZQCS operations when this signal is high. Value After Reset: 0x0 Exists: MEMC_DDR3_OR_LPDDR2 == 1
3–2 Reserved	This field is reserved. Reserved for future use
1 RANK1_ REFRESH_ BUSY	SoC core may initiate a rank1_refresh operation (refresh operation to rank 1) only if this signal is low. This signal goes high in the clock after DBGCMD.rank1_refresh is set to one. It goes low when the rank1_refresh operation is stored in the DDRC. It is recommended not to perform rank1_refresh operations when this signal is high. Value After Reset: 0x0 Exists: MEMC_NUM_RANKS > 1 0 Indicates that the SoC core can initiate a rank1_refresh operation 1 Indicates that rank1_refresh operation has not been stored yet in the DDRC
0 RANK0_ REFRESH_ BUSY	SoC core may initiate a rank0_refresh operation (refresh operation to rank 0) only if this signal is low. This signal goes high in the clock after DBGCMD.rank0_refresh is set to one. It goes low when the rank0_refresh operation is stored in the DDRC. It is recommended not to perform rank0_refresh operations when this signal is high. Value After Reset: 0x0 Exists: Always 0 Indicates that the SoC core can initiate a rank0_refresh operation 1 Indicates that rank0_refresh operation has not been stored yet in the DDRC

9.2.5.2.64 Software Register Programming Control Enable (DDRC_SWCTL)

Address: 307A_0000h base + 320h offset = 307A_0320h

DDRC_SWCTL field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved for future use
0 SW_DONE	Enable quasi dynamic register programming outside reset. Program register to 0 to enable quasi dynamic programming. Set back register to 1 once programming is done. Value After Reset: 0x1 Exists: Always

9.2.5.2.65 Software Register Programming Control Status (DDRC_SWSTAT)

Address: 307A_0000h base + 324h offset = 307A_0324h

DDRC_SWSTAT field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved for future use
0 SW_DONE_ACK	Register programming done

Table continues on the next page...

DDRC_SWSTAT field descriptions (continued)

Field	Description
	<p>This register is the echo of SWCTL.sw_done.Wait for sw_done value 1 to propagate to sw_done_ack at the end of the programming sequence to ensure that the correct registers values are propagated to the destination clock domains.</p> <p>Value After Reset: 0x0</p> <p>Exists: Always</p>

9.2.5.3 DDRMC multi port registers

The following n and m is always 0 in the register.

0 GO2CRITICAL_ EN	<p>If set to 1 (enabled), sets hif_go2critical_wr and hif_go2critical_lpr / hif_go2critical_hpr signals going to DDRC based on urgent input (awurgent, arurgent) coming from AXI master.</p> <p>If set to 0 (disabled), hif_go2critical_wr and hif_go2critical_lpr / hif_go2critical_hpr signals at DDRC are driven to 1b'0.</p> <p>Value After Reset: 0x0</p> <p>Exists: Always</p>

9.2.5.3.3 Port n Configuration Read Register (DDRC_MP_PCFGR_0)

Exists: DDRC_INCL_ARB==1 && DDRC_PORT_n==1

Address: 307A_0000h base + 404h offset = 307A_0404h

DDRC_MP_PCFG0 field descriptions

Field	Description
31–17 Reserved	This field is reserved. Reserved for future use
16 RDWR_ORDERED_EN	Enable ordered read / writes. If set to 1, preserves the ordering between read transaction and write transaction issued to the same address, on a given port. In other words, the controller ensures that all same address read and write commands from the application port interface are transported to the DFI interface in the order of acceptance. This feature is useful in cases where software coherency is desired for masters issuing back-to-back read / write transactions without waiting for write/read responses. NOTE: This register has an effect only if necessary logic is instantiated via the DDRC_RDWR_ORDERED_0 parameter. Value After Reset: 0x0 Exists: DDRC_A_RDWR_ORDERED_0 == 1 && DDRC_A_AXI_0 == 1
15 Reserved	This field is reserved. Reserved for future use
14 RD_PORT_PAGEMATCH_EN	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register. Value After Reset: 0x1 Exists: Always
13 RD_PORT_URGENT_EN	If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the master, that port becomes the highest priority and hif_go2critical_lpr / hif_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. NOTE: Arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command). Value After Reset: 0x0 Exists: Always
12 RD_PORT_AGING_EN	If set to 1, enables aging function for the read channel of the port. Value After Reset: 0x0 Exists: Always
11 READ_REORDER_BYPASS_EN	If set to 1, read transactions with ID not covered by any of the virtual channel ID mapping registers are not reordered. Value After Reset: 0x0 Exists: DDRC_PORT_CHm_0 == 1
10 Reserved	This field is reserved. Reserved for future use
RD_PORT_PRIORITY	Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bit of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bit of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this

31–15 Reserved	This field is reserved. Reserved for future use
14 WR_PORT_PAGEMATCH_EN	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register. Value After Reset: 0x1 Exists: Always
13 WR_PORT_URGENT_EN	If set to 1, enables the AXI urgent sideband signal (awurgent). When enabled and awurgent is asserted by the master, that port becomes the highest priority and hif_go2critical_wr signal to DDRC is asserted if enabled in PCCFG.go2critical_enregister. NOTE: Awurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command). Value After Reset: 0x0 Exists: Always
12 WR_PORT_AGING_EN	If set to 1, enables aging function for the write channel of the port. Value After Reset: 0x0 Exists: Always
11–10 Reserved	This field is reserved. Reserved for future use
WR_PORT_PRIORITY	Determines the initial load value of write aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bit of the write aging counter sets the initial priority of the write channel of a given port. Port's priority will increase as the higher significant 5-bit of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level. For multi port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (awqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. NOTE: Two LSBs of this register field are tied internally to 2'b00. Value After Reset: 0x0 Exists: Always

9.2.5.3.5 Port n Channel m Configuration ID Mask Register (DDRC_MP_PCFGIDMASKCH_n0)

M signifies the number of the virtual channel for the Port n where m = 0 to 15.

Exists: DDRC_PORT_CH m_0==1

9.3 DDR PHY (DDRP)

9.3.1 Overview

Figure 9-9. LPDDR3 HPHY

9.3.1.1 Features

The DDR3 PHY (V6R0) provides the following features:

- Fully supports DDR3, LPDDR2, LPDDR3 memory types.
- Fully digital DLL for 90° phase shift of strobe signal.
- FIFO (width:16-bit / depth:16 per 8-bit data slice) for programmable read timing.
- Provide feedback loop-back test scheme for at-speed data and control channel test.

NOTE

- RL should be greater than 4. If PHY is used with the dual-rank configurations, RL (Read Latency) and BL (Burst Length) should be used as the same value for those two ranks.
- ODT is not supported for LPDDR3.

9.3.2 Block diagram description

9.3.2.1 DLL and CONTROL I/F

9.3.2.1.1 DLL

DLL detects one clock period and generates delay line control signal. Delay line consists of 128 delay cells and is controlled by control logic. Delay line delays input clock and phase detector compares input clock and delayed clock. After phase comparison, phase detector detects whether delayed clock is lag or lead and generates INC / DEC signals to increase or decrease the delay amount of the delay line.

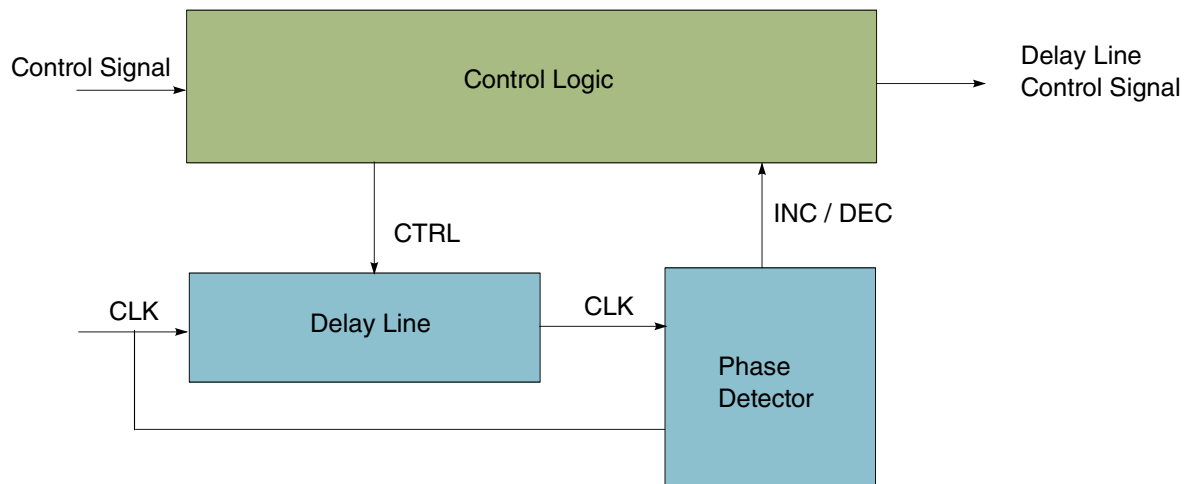

Figure 9-10. Block Diagram of DLL

9.3.2.1.2 Control

Figure 9-11. Block Diagram of the Control Path

The control block generates address, control, and clock signals that are sent to the I/O pads. ADCT[24:0] are the address traces that consist of Reset (RSN), ODT, Address[15:0], Bank Address[2:0], and Chip Selects[1:0] (chip selects [3:2] are not used in this implementation). Command signals consist of RAS, CAS, and WE. CK and CKB are differential clock signals. Address and control signals are center aligned at rising CK edge to maximize address / control signal setup / hold timing.

9.3.2.2 DATA I/F

9.3.2.2.1 Write path

Data I/F block generates data, mask and strobe signals to interface memory for memory write transaction. DQs are 8-bit width data signals, DM is data mask signal and DQS is strobe signal. Therefore, to interface 32-bit memory, 4 data slices are required.

DQS is edge-aligned signal to CK / CKB and DQs / DM are center-aligned signals to the edge of CK / CKB.

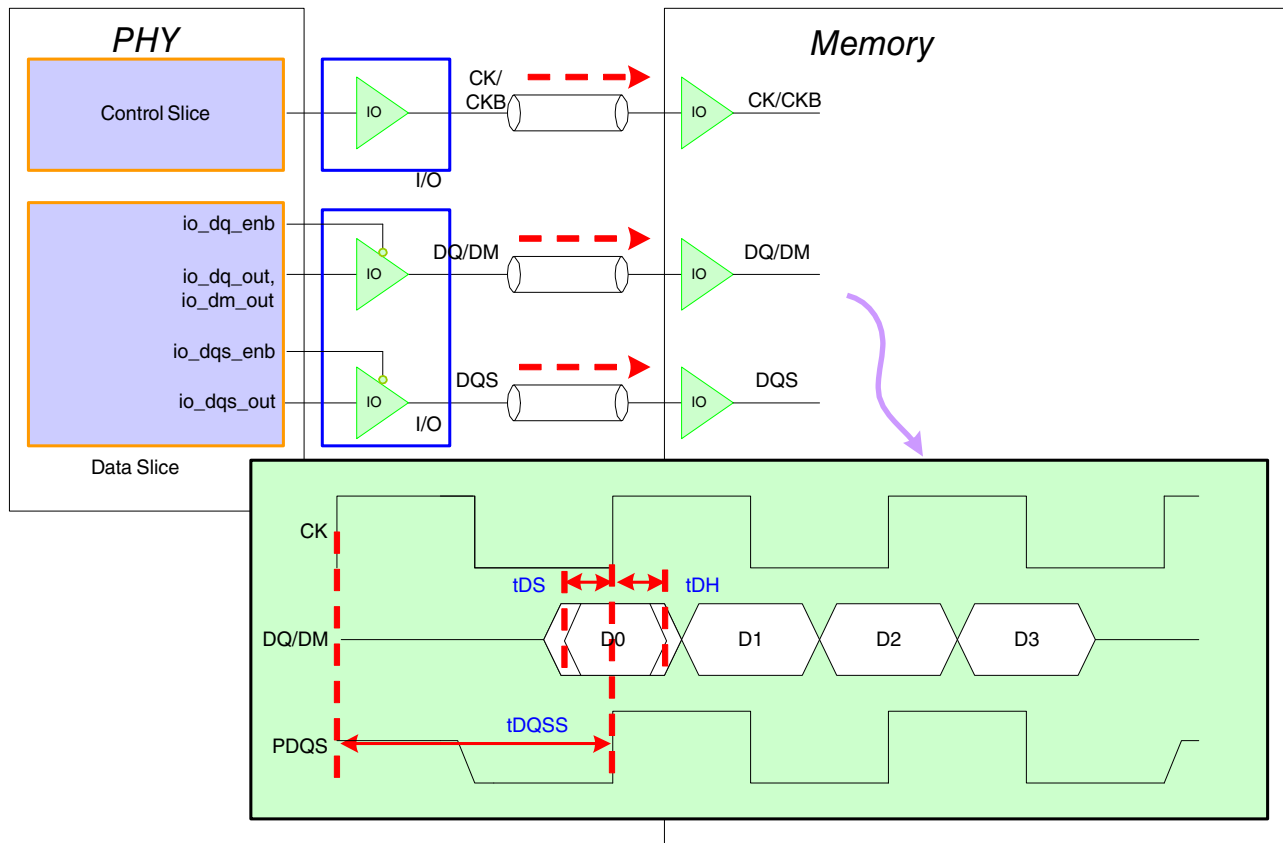

Figure 9-12. Block Diagram of the Write Path

9.3.2.2.2 Read path

Read blocks capture valid data using strobe signal which come from memory for read transaction. DQs are 8-bit width data signals, DQS is strobe signal.

DQs and DQS from memory are edge aligned to CK edge. Therefore, to capture DQs using DQS, DQS should be delayed to make 90° phase shifted DQS, i.e. DQs should be center aligned to the edge of delayed DQS and captured DQs are stored in the FIFO.

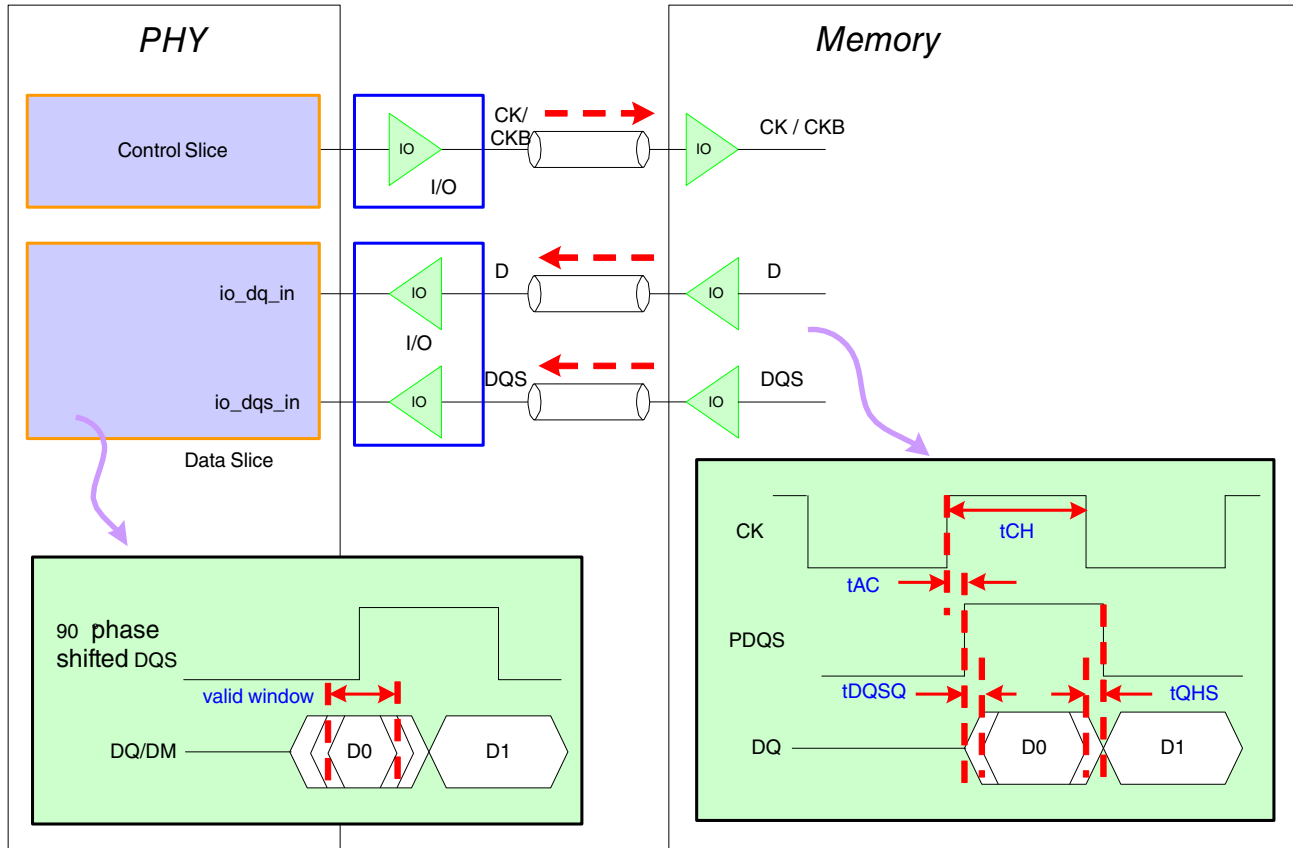

Figure 9-13. Block Diagram of the Read Path

9.3.2.2.3 ZQ CALIBRATION I/O

ZQ_IO calibrates the output and termination impedance and passes through impedance control signals to each I/O cells. RZQ should be 240 ohm.

Figure 9-14. Connectivity Between ZQ I/O and the other I/Os

9.3.3 Functional description

9.3.3.1 DATAPATH

The timing parameters t_{phy_wrlat} and t_{phy_wrdata} define the delay from the write command to the $dfi_wrdata_en_pN$ signal, and from the $dfi_wrdata_en_pN$ signal to when data will be driven on the dfi_wrdata_pN signal respectively. These timing parameters are defined in terms of DFI PHY clocks.

- $t_{phy_wrlat} = WL - 1$, $t_{phy_wrdata} = 2$, for example if $WL = 4$, $t_{phy_wrlat} = 3$, $t_{phy_wrdata} = 2$ (LPDDR3)
- $t_{phy_wrlat} = WL - 2$, $t_{phy_wrdata} = 2$, for example if $WL = 8$, $t_{phy_wrlat} = 6$, $t_{phy_wrdata} = 2$ (DDR3)

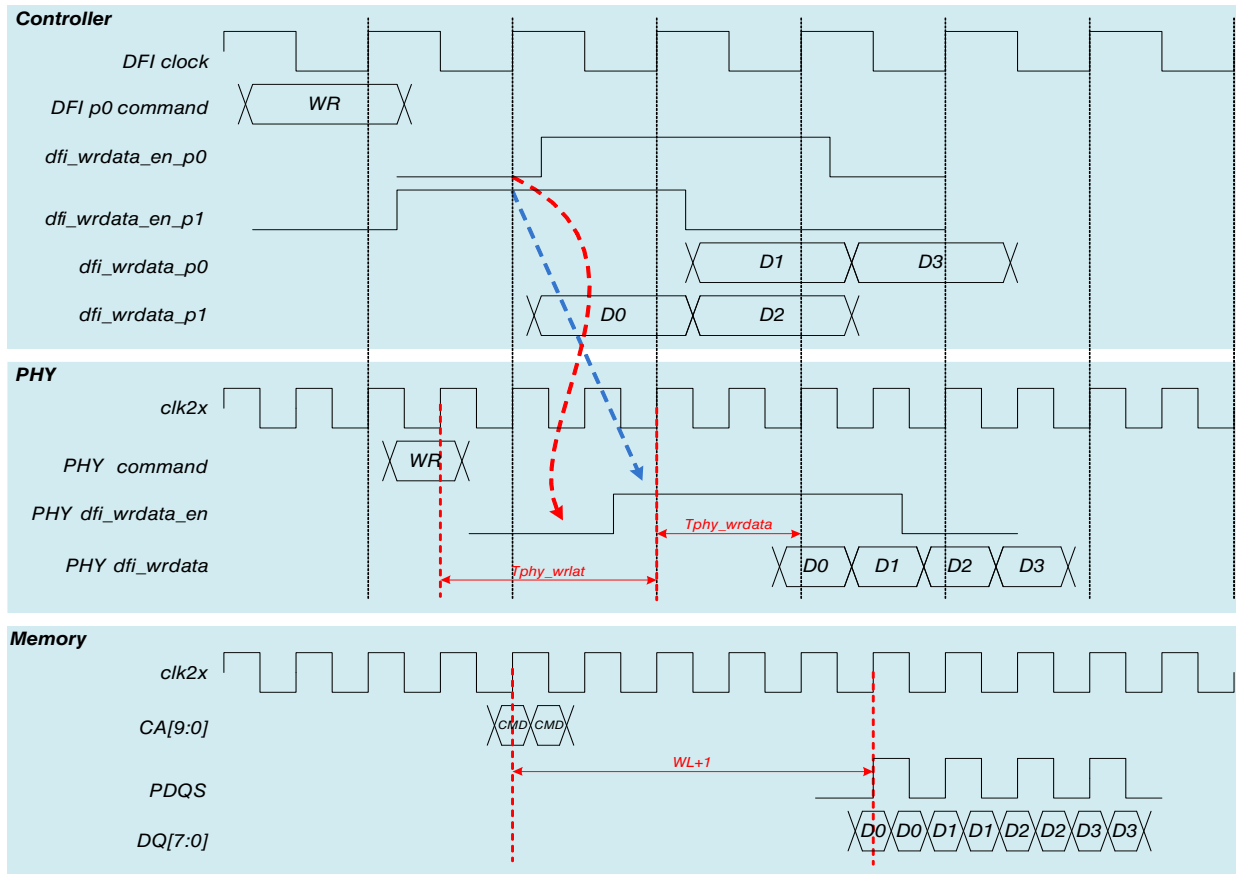

Figure 9-15. Data write Timing Diagram with phase 0 command (1:2 frequency ratio, LPDDR3)

Signal interface timing for data write is shown in the following figure.

dfi_wrddata_en_p0/p1 is enable signal to indicate dfi_wrddata_p0/p1 and dfi_mask_p0/p1 are valid.

Figure 9-16. Data write Timing Diagram with phase 1 command (1:2 frequency ratio, LPDDR3)

The timing parameters `trddata_en` and `tphy_rldat` define the delay from the read command to the `dfi_rddata_en_pN` signal, and from the `dfi_rddata_en_pN` signal to when data will be returned on the `dfi_rddata_wN` bus, respectively. These timing parameters are defined in terms of DFI PHY clocks and are measured relative to how the PHY interprets the data.

Signal interface timing for data read is shown in the following figure. After read command is issued, `DQ` and `PDQS/NDQS` are driven by the memory and `DQ` is stored in FIFO in read data path. After read data is stored in FIFO, when `dfi_rddate_en_p0/p1` is issued from controller, the valid read data is driven during HIGH `dfi_rddata_valid_w0/w1` signal at the rising edge of the `clk` signal.

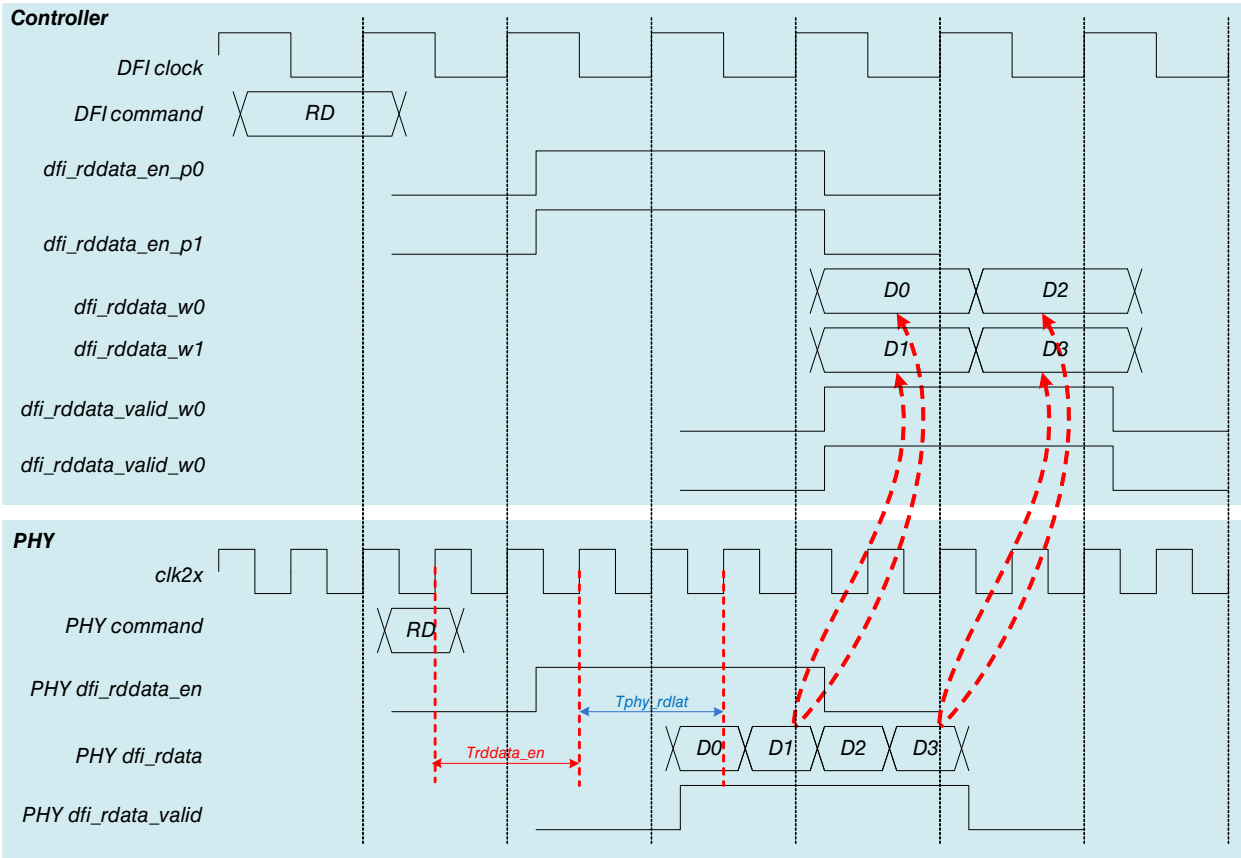

Figure 9-17. Data Read Timing Diagram (1:2 frequency ratio)

The following figure illustrates control signal and data read path. At the read path, DQS clean block is used to clean DQS signal and Delay line is used for 90° phase shift of DQS. If read command is issued at A point, read command is driven and memory drives DQ and DQS after CL(CAS Latency) at B point. DQ and DQS experience board and IO input delay and arrive at C point. Delay line execute 90° phase shift of DQS and shifted DQS is used as a clock signal to capture DQ in FIFO. After that dfi_rddata_en_p0/p1 is driven HIGH by the controller, the FIFO outputs valid read data at E point.

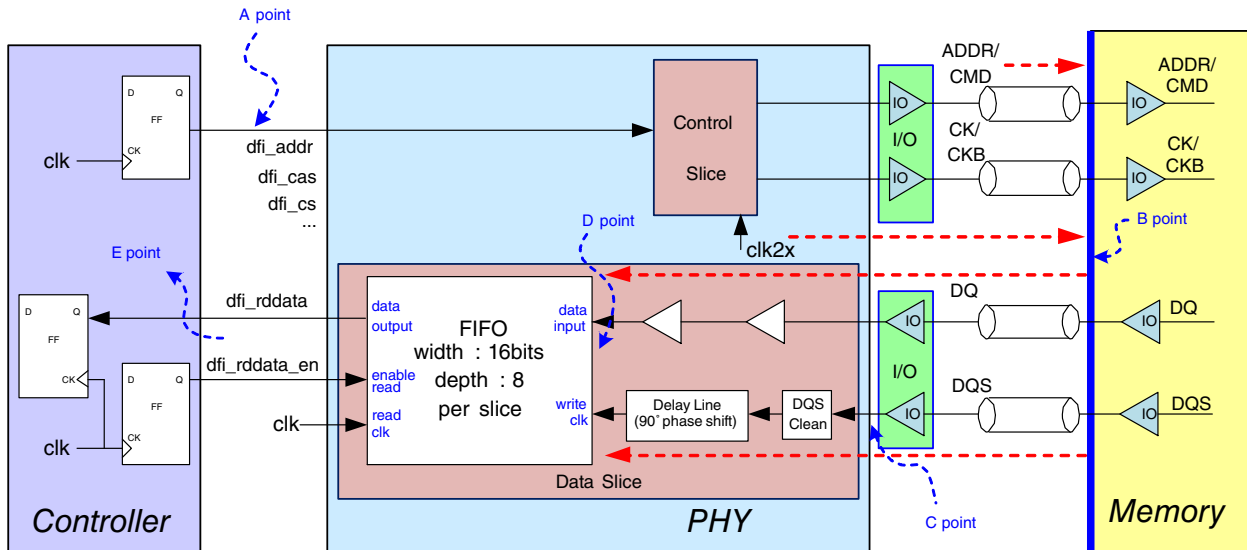

Figure 9-18. Read Data Path

The following figure illustrates the full timing diagram of command and data path for memory read. The deterministic timing values for the read path are latency to generate command (1 clock cycle), CL (CAS Latency) and data write time in FIFO (1 clock cycle). But the propagation delay of command (from PHY to memory) and DQ / DQS (from memory to PHY) varies according to the board designs and operating condition. And also internal logic delay in the following figure, is also different according to operating condition. For this reason, read data arrival time is quite different according to designs and environment and deterministic read timing calculation is difficult. To overcome this issue, FIFO of 8-depth is used in read path and data read timing can be programmed.

DQS cleaning is needed to remove high-Z state of DQS during read, but there is a lot of variation in DQS. We recommended that the pull-down mode in DQS (LP_CON0[NS-1:0]) should be used to remove high-Z state of DQS.

When it is in the pull-down mode, the duration of HIGH in "ctrl_gate_p0 /p1" should be extended to compensate the variation of DQS with ctrl_shgate = 0

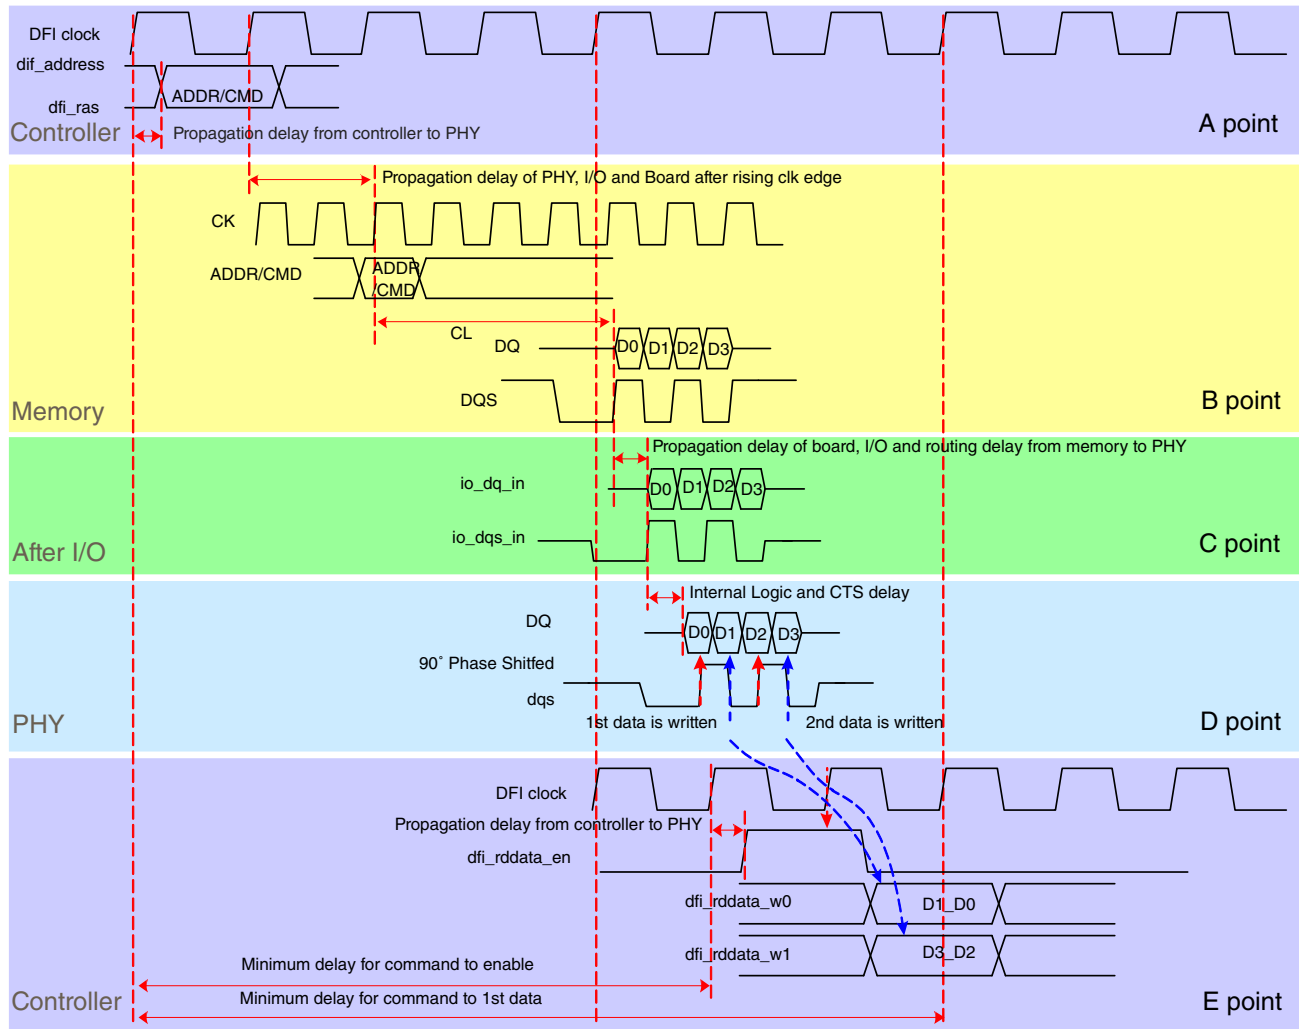

Figure 9-19. Full Read Path Timing Diagram

9.3.3.2 Package and board guide

In the following table, Skew in picoseconds is translated to physical length on the PCB.

Table 9-13. Skew Including Package and Board

Group	Signals	Skew	From	To
G0_1	CK / CKB	±10ps	Pad	Memory Pin
G0_2	PDQS[N] / NDQS[N]	±10ps	Pad	Memory Pin

Table continues on the next page...

Table 9-13. Skew Including Package and Board (continued)

Group	Signals	Skew	From	To
G1	PDQS[N] / NDQS[N] DQ[(N + 1) * 8 - 1:N * 8] DM[N]	±25ps from PDQS[N] / NDQS[N]	Pad	Memory Pin
G2	CK / CKB, RESET, ADCT[15:0], CS, RAS, CAS, BANK, CKE, WEN, ODT	±25ps from CK / CKB	Pad	Memory Pin
G3 (LPDDR2/LPDDR3)	CK / CKB, ADCT[9:0]	±25ps from CK / CKB	Pad	Memory Pin
G4	CK / CKB, P / NDQS[NS-1:0]	-100ps from CK / CKB	Pad	Memory Pin

NOTE

- Recommend that CK / CKB should be delayed than P/ NDQS[NS-1:0] (G4)
- When CK / CKB is connected to two rank, the skew of CK / CKB between two ranks should follow "G0_1" in.
- If using Write Leveling to support DIMM, The skew of "-100ps" for G4 can be changed by "-2500ps" which came from 2 cycles at 800 MHz.
- N means 0,1... NS-1.

9.3.3.3 Initialization

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Select Memory Type (= PHY_CON0[12:11]).
 - ctrl_dds_mode = 2'b11 (LPDDR3)
 - ctrl_dds_mode = 2'b10 (LDDR2)
 - ctrl_dds_mode = 2'b01 (DDR3)
- GATE default settings for DQS Cleaning
 - Set "ctrl_gateadj = 1, ctrl_gateduradj = 2, ctrl_shgate = 0, ctrl_pulld_dqs = 0xF, ctrl_shiftc = 0x0" (ctrl_atgate = 1)
- Set Read Latency (RL), Burst Length (BL) and Write Latency (WL)
 - SetRL (= PHY_CON4[4:0]), BL (= PHY_CON4[12:8]),WL (= PHY_CON4[20:16])
- ZQ Calibration (Please refer to [ZQ I/O control procedure](#) for more details)
 - Enable and Disable "zq_clk_div_en" in ZQ_CON0[18]
 - Enable "zq_manual_str" in ZQ_CON0[1]
 - Wait until "zq_cal_done" (ZQ_CON1[0]) is enabled.
 - Disable "zq_manual_str" in ZQ_CON0[1]

- Memory Controller should assert "dfi_init_start" from LOW to HIGH.
- Memory Controller should wait until "dfi_init_complete" is set to finish DLL lock.
- Enable DQS pull down mode
 - Please be careful that DQS pull down can be disabled only after Gate Leveling is done.
- Memory Controller should assert "dfi_ctrlupd_req" after "dfi_init_complete" is set.
- Start Memory Initialization by memory controller.

NOTE

Recommend to set "upd_mode = 0" (= OFFSETD_CON0[28])
for PHY-Initiated Update

Caution: Please do not change the frequency of "clkm" or voltage during operation. Those conditions should be changed without memory access. After changing, "ctrl_start" should be clear and set to lock again.

9.3.3.4 Training Procedure

9.3.3.4.1 WRITE LEVELING

Write Leveling compensates for the additional flight time skew delay introduced by the package, board and on-chip with respect to strobe(= DQS) and clock. Write Leveling can support 1 rank only (CS[0] or CS[1]), so CK and DQS delay at each rank should be same as possible to support two ranks. For example, CK delay at rank0 and rank1 should be designed to be same on package / board.

9.3.3.4.1.1 H/W write leveling

- Memory Controller should configure Memory (DDR3, LPDDR3) in Write Level mode.
 - Set "cmd_default[8:7] = 2'b11" (LPDDR_CON4[8:7]) to enable "ODT[1:0]" signals during Write Leveling.
- Configure PHY in Write Level mode.
 - Enable "wrlvl_mode" in PHY_CON0[16].
- Start Write Leveling by setting "wrlvl_start = 1'b1" (= PHY_CON3[16])
- Wait until "wrlvl_resp = 1'b1" (= PHY_CON3[24])
- Finish Write Leveling by setting "wrlvl_start = 1'b0" (= PHY_CON3[16])
- Configure PHY in normal mode.

- Disable "wrlvl_mode" in PHY_CON0[16].
- Set "cmd_default[8:7] = 2'b00" (LPDDR_CON4[8:7]) to disable "ODT[1:0]" signals.
- Set "reg_mode[0] = 1'b1" (= PHY_CON3[0]).
- Memory Controller should configure Memory (DDR3, LPDDR3) in normal mode.
- Enable and Disable "ctrl_resync" (= OFFSETD_CON0[24]) to make sure All SDLL is updated.
- Recommend to set "ctrl_readduradj = 1"

9.3.3.4.1.2 Write leveling dll manual setting

After knowing the board and package delay exactly, you can use the following manual setting instead of Write Leveling.

- Set WR_LVL_CON0 for Data Slices 0-3.
 - For example, suppose the following conditions
 - "ctrl_lock_value[8:0] = 0x7F(= 127)"
 - The delay of CK is about 118ps, 295ps, 512ns, and 704ps for Data Slices 0-3.
 - Fine step delay will be about 9.84ps by calculating "1250 / 127" at 800 MHz.
 - The delay of CK can be represented by 0x0C, 0x1E, 0x34, and 0x47 with Fine step delay unit.
 - If the delay of CK at DRAM is greater than 1 or 2 cycle, please ignore that cycle delay when setting "WR_LVL_CON0". For example, the delay of CK for Data Slice0 is 1329ns and the fine step delay should be 0x85, but after ignoring 0x7F (= 1250ns), the setting value will be 0x08.
 - Please set "WR_LVL_CON0 = 0x47341E0C"
- Set "wrlvl_mode = 1" (= PHY_CON0[16])
- Set "wrlvl_mode = 0" (= PHY_CON0[16])
- Enable and Disable "ctrl_resync" (= OFFSETD_CON0[24]) to make sure All SDLL is updated.

9.3.3.4.2 GATE LEVELING

NOTE

Gate Leveling is a feature used for DDR3 mode only. Do not use Gate Leveling for LPDDR2/LPDDR3.

The goal of gate training is to locate the delay at which the initial read DQS rising edge aligns with the rising edge of the read DQS gate (= ctrl_gate_p0 / p1). Once this point is identified, the read DQS gate can be adjusted prior to the DQS, to the approximate midpoint of the read DQS preamble.

- Controller should configure Memory (DDR3) in MPR mode.
- Set Gate Leveling Mode.(1)
 - Enable "gate_cal_mode" (= PHY_CON2[24])
 - Enable "ctrl_shgate" (= PHY_CON0[8])
 - Set "ctrl_gateduradj[3:0]" (= PHY_CON1[23:20]) in the following way:
 - Set "4'b0000" (DDR3)
- Enable "gate_lvl_start (= PHY_CON3[18])" to do read leveling.(2)
- Wait until "rd_wr_cal_resp" (= PHY_CON3[26]) is set.(3)
 - The maximum waiting time will be 20µs. If the any command (the refresh or pre-charge command) is required within 20µs, please issue those commands before "(1)".
- Disable "gate_lvl_start (= PHY_CON3[18])" after "rd_wr_cal_resp"(= PHY_CON3[26]) is disabled.
- Disable DQS pull down mode.(4)
- Memory Controller should configure Memory (DDR3) in normal mode.

9.3.3.5 Low frequency operation

Even if the operation frequency of "clk2x" is out of the range of MDLL Input frequency (400 ~ 800 MHz), DDR PHY can operate at the low frequency because MDLL Input clock is separated from PHY Input clock. It is recommended that Read Leveling should be done in the normal operation. The following sequence is how to operate PHY at low frequency with the different MDLL clock.

- If "dfi_init_start" = 0, Controller should assert "dfi_init_start" from LOW to HIGH.
- After "dfi_init_complete" is checked by controller, read the value of "ctrl_lock_value".
- Enter Self-Refresh (CKE = 0)
- Go to the low frequency.
 - Change "clk2x" to the low frequency, but do not change the frequency of "clkm"(400 ~ 800 MHz).
- Write the multiplied value of ctrl_lock_value[8:0] to ctrl_force[8:0].
 - Enter DLL OFF mode before Leveling.
 - Set "ctrl_dll_on = 0" (= MDLL_CON0[5])
 - Read "ctrl_lock_value[8:0]" (= MDLL_CON1[16:8]) after setting "ctrl_dll_on = 0"
 - For example, if the operation frequency will be the half of MDLL clock, two multiplied value of ctrl_lock_value should be written to "ctrl_force".
 - If "the multiplied value" is more than 0x1FF, "ctrl_force" will be "0x1FF".
- The low frequency is under 100 MHz,
 - Enter DLL OFF mode by setting "ctrl_dll_on = 0".

- Set "ctrl_force" = 0x1FF, "ctrl_offsetd" = 0x7F, ctrl_offsetr* = 0x7F, ctrl_offsetw* = 0x7F (*means 0 ~ 3)
- Set CA0DeSkewCode = 0x60, CA1DeSkewCode = 0x60, ~ CA9DeSkewCode = 0x60.
- "dfi_ctrlupd_req" should be issued more than 10 cycles after ctrl_dll_on is disabled.
- Exit Self-Refresh (CKE = 1).
- Operate in the low frequency.

Caution: If using RL = 3 or 4, "ctrl_atgate" (= PHY_CON0[6]) should be set as "0", and "ctrl_gate_p0 / p1" and "ctrl_read_p0 / p1" should be generated from controller.

If it goes back to the original high frequency again, please refer to the following procedures.

- Enter Self-Refresh (CKE = 0)
- If "ctrl_dll_on = 0", turn on "ctrl_dll_on".
- "ctrl_offsetd" = 0x08, ctrl_offsetr* = 0x08, ctrl_offsetw* = 0x08 (*means 0 ~ 3)
- CA0DeSkewCode ~ CA9DeSkewCode = 0x8.
- Wait until "ctrl_clock = 1".
- Controller should assert "dfi_ctrlupd_req" to apply the new "ctrl_lock_value" after "ctrl_clock = 1".
- Exit Self-Refresh (CKE = 1)

9.3.3.6 Offset control

ctrl_offset0 ~ 3 control the offset of 90° phase shift of DQS or 270° clock.

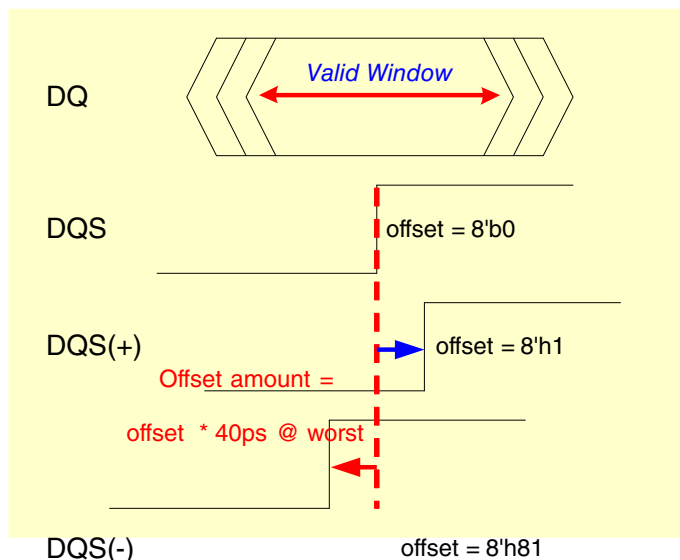

Figure 9-20. Offset Control Example for ctrl_offset0 ~ ctrl_offset3

9.3.3.7 DLL lock procedure

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Assert "dfi_init_start" from LOW to HIGH.
- When DLL lock is finished, "dfi_init_complete" is set.
- Before memory access, "dfi_ctrlupd_req" should be applied. It is recommended that "dfi_ctrlupd_req" should be set and clear at the start of refresh cycle automatically by the memory controller to update DLL lock information periodically.

DLL is used to compensate PVT condition. Therefore DLL should not be turned-off for reliable operation except for the case of frequency scaling.(only to lower frequency scaling is permitted).

To turn-off the DLL, follow the next steps.

- After DLL locking, Enter DLL OFF mode by clearing ctrl_dll_on.
- CPU reads ctrl_lock_value and write ctrl_lock_value[8:0] to ctrl_force.
- "dfi_ctrlupd_req" should be issued 6 cycles after ctrl_dll_on was set and cleared.

9.3.3.8 ZQ I/O control procedure

ZQ I/O calibrates the I/Os to match the driving and termination impedance by referencing resistor value of resistor (RZQ) connected externally from ZQ pin to ground. For DDR3, RZQ should be 240ohm. One-time calibration is provided for ZQ I/O control procedure. There are two modes for one-time calibration. One is “Long calibration mode” and the other is “Short calibration mode”.

9.3.3.8.1 One-time calibration

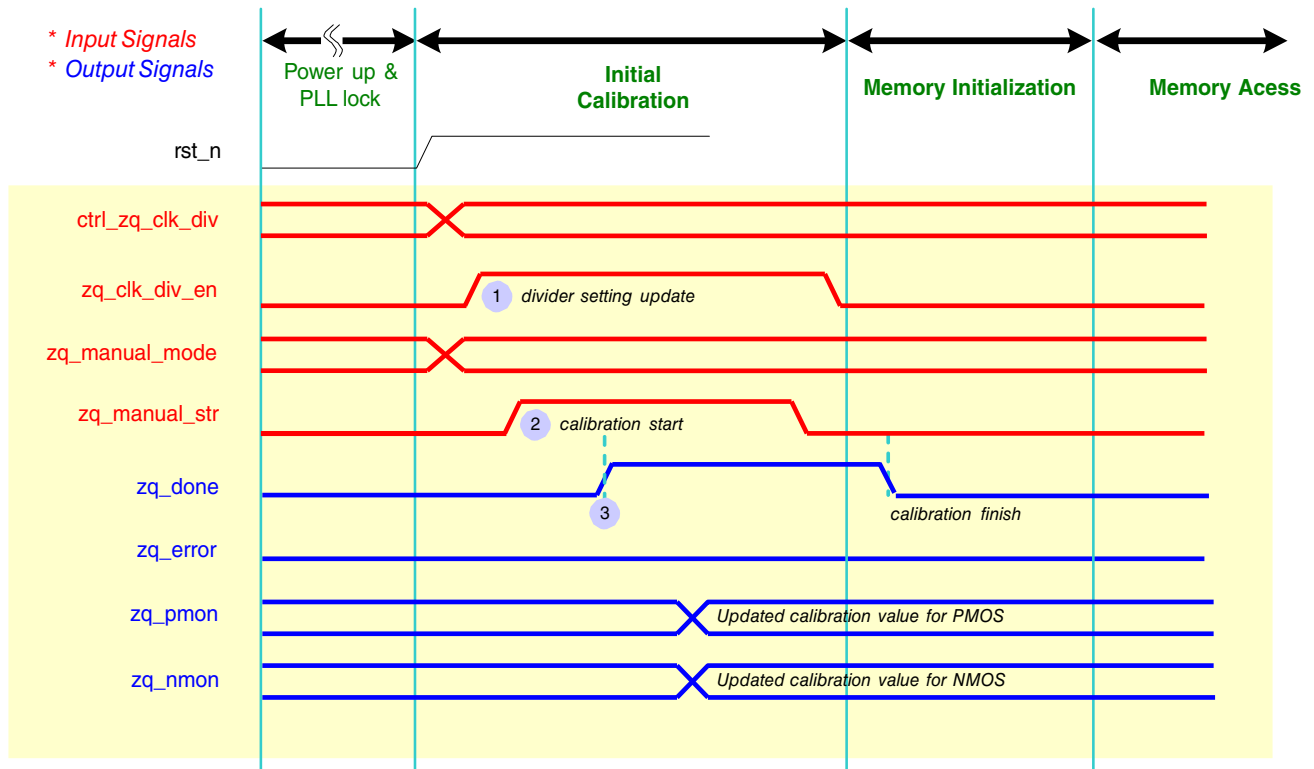

Figure 9-21. One-time Calibration Procedure

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Set ctrl_zq_clk_div[31:0] to proper value (= 0x7)
- Set zq_clk_div_en from 1'b0 to 1'b1 to update divider settings (ctrl_zq_clk_div[31:0] = 0x7).
- Set zq_manual_mode
 - Long calibration mode: 2'b01
 - Short calibration mode: 2'b10
- Start ZQ I/O calibration by setting zq_manual_str from 1'b0 to 1'b1
- When calibration is done, zq_done (= PHY_CON1[0]) will be set.

- After zq_done (= PHY_CON1[0]) is asserted, clear zq_manual_str
- Clear zq_clk_div_en

9.3.3.8.2 Manual setting

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Set ctrl_zq_clk_div[31:0] to proper value (= 0x7)
- Set zq_clk_div_en from 1'b0 to 1'b1 to update divider settings (ctrl_zq_clk_div[31:0] = 0x7).
- Set zq_manual_mode=2'b00 (= Force calibration mode).
- Start ZQ I/O calibration by setting zq_manual_str from 1'b0 to 1'b1
- After zq_done (= PHY_CON1[0]) is asserted, clear zq_manual_str.

9.3.3.9 DLL code update

Assertion of the "dfi_ctrlupd_ack" or "dfi_phyupd_ack" signal indicates the control, read and write interfaces on the DFI should be idle. While the "dfi_ctrlupd_ack" or "dfi_phyupd_ack" signal is asserted, the DFI bus may only be used for commands related to the update process.

The MC guarantees that dfi_ctrlupd_req signal will be asserted for at least tctrlupd_min cycles, allowing the PHY time to respond. To acknowledge the request, the dfi_ctrlupd_ack signal must be asserted while the dfi_ctrlupd_req signal is asserted. The dfi_ctrlupd_ack signal must de-assert at least one cycle before tctrlupd_max expires (Tctrlupd_min = 2, Tctrlupd_max = 21). Please use "MC-Initiated Update" until initialization including all calibrations is finished.

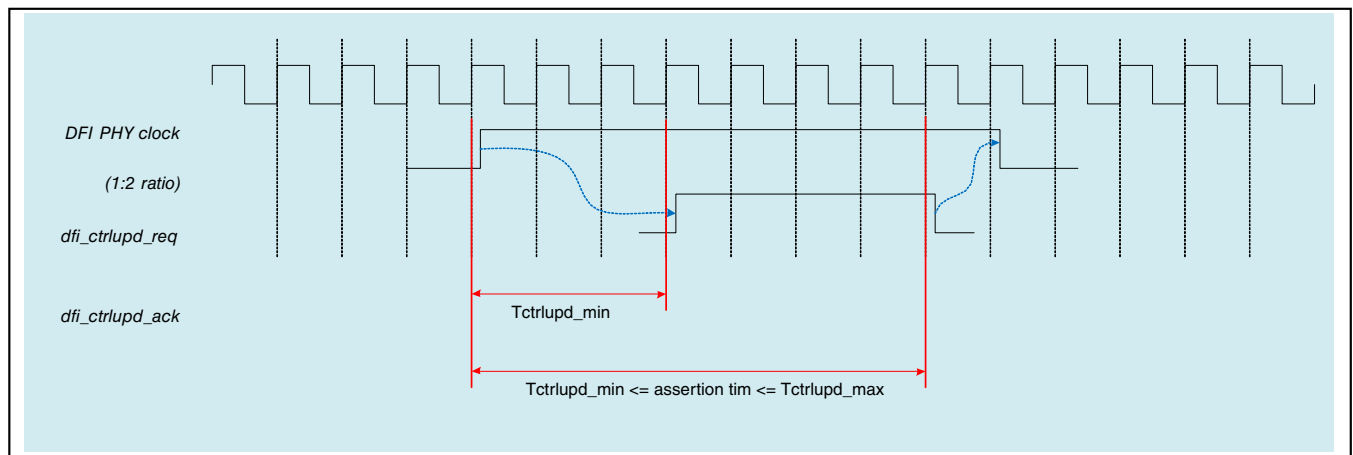

Figure 9-22. MC-Initiated Update Timing Diagram

Assertion of the `dfi_phyupd_req` signal indicates the control, read and write interfaces on the DFI are required. While the `dfi_phyupd_ack` signal is asserted, the DFI bus should be idle.

The `Tphyupd_typeX` parameters indicate the number of cycles of idle time on the DFI control, read and write data interfaces being requested. The `dfi_phyupd_ack` signal must assert within `Tphyupd_resp` cycles after the assertion of the `dfi_phyupd_req` signal (`Tphyupd_resp = 64`, `Tphyupd_typeX = 4`).

If MC (Memory Controller) does not assert `dfi_phyupd_ack` within `Tphyupd_resp`, PHY will keep `dfi_phyupd_req` asserting until `dfi_phyupd_ack` is asserted and `Tphyupd_typeX` will be changed up to "21".

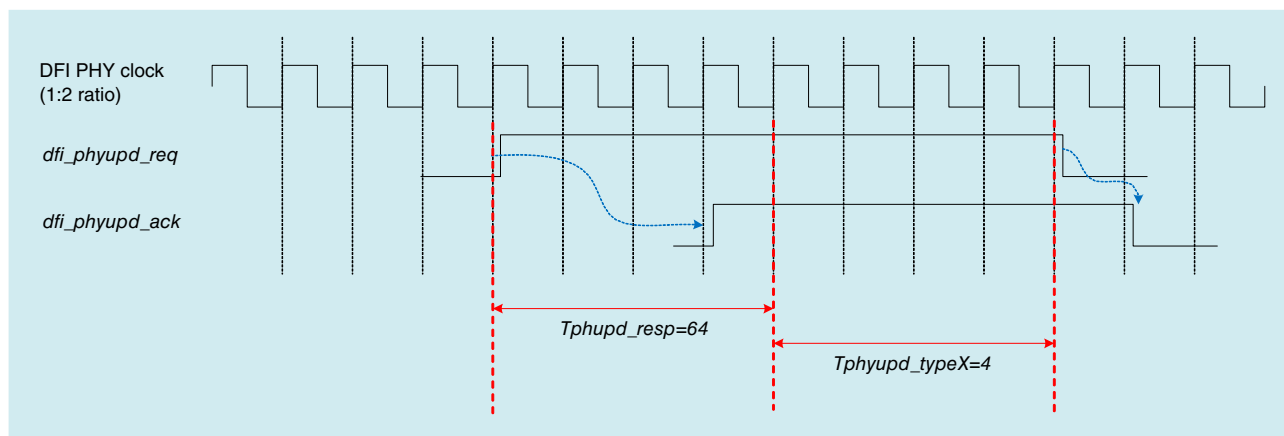

Figure 9-23. PHY-Initiated Update Timing Diagram

In case of LPDDR2 / LPDDR3, The PHY is expected to drive values on `dfi_address[9:0]` to `ADCT[9:0]` on the rising edge of clock and value on `dfi_address[19:10]` to `ADCT[9:0]` on falling edge of memory clock. But PHY will drive value on `dfi_address[19:10]` of controller to `ADCT[9:0]` during 4 clock cycles after "`dfi_phyupd_ack`" is issued.

When CPU or MC change the code value in SDLL or De-skew DLL by using APB Interface, "`ctrl_resync`" (`PHY_CON[24]`) or "`wrlvl_resync`" (= `WR_LVL_CON3[0]`) should be high and then low to apply the updated code values. And the following conditions should be met during the assertion of "`dfi_ctrlupd_req`", "`ctrl_resync`" or "`wrlvl_resync`".

- `CS = 1` or `CKE = 0` if any CA SDLL (`LP_DDR_CON2`) or DeSkew (`WR_LVL_CON*`) Code is changed.
- Any Write operation should not be permitted if Write SDLL (`OFFSETW_CON*`) Code is changed.

DDR PHY (DDRP)

Caution: If the DeSkew Code for CKE[1:0], CS[1:0], CK, RESET is changed, CKE should be always "LOW" during the assertion of "dfi_ctrlupd_req", "ctrl_resync" or "wrlvl_resync".

9.3.3.10 Clock control

dfi_dram_clk_disable controls CK / CKB signals.

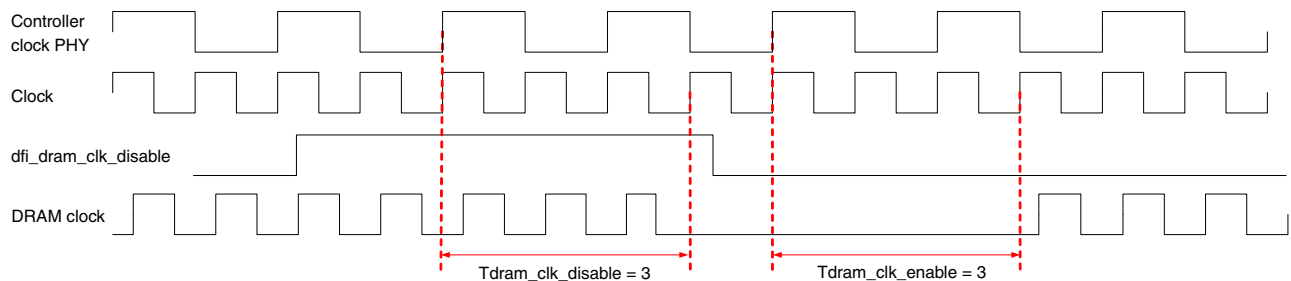

Figure 9-24. Clock Control Timing

Field	Description
14 WRDESKEW_ CLEAR	Write "ctrl_offsetw*" to WrDeSkewCode Initial Value = 1'b0
13 RDDESKEW_ CLEAR	Clear "ctrl_offsetr*" to RdDeSkewCode Initial Value = 1'b0
Reserved	This field is reserved. Initial Value = 13'h4

9.3.4.4 DDR_PHY_PHY_CON3

Address: 3079_0000h base + Ch offset = 3079_000Ch

DDR_PHY_PHY_CON3 field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27 WL_CAL_RESP	Response after Write Leveling Calibration Initial Value = 0x0

Table continues on the next page...

DDR_PHY_PHY_CON3 field descriptions (continued)

Field	Description
26–25 Reserved	This field is reserved.
24 WRLVL_RESP	Response after Write Leveling Initial Value = 0x0
23–22 Reserved	This field is reserved.
21 WL_CAL_START	Start Write Leveling Calibration Initial Value = 0x0
20 WL_CAL_MODE	Write Leveling Calibration mode Enable Initial Value = 0x0
19–17 Reserved	This field is reserved.
16 WRLVL_START	Start Write Leveling signal. It can be enabled when wrlvl_mode = 1. It should be disabled after Write Leveling Response is asserted. Initial Value = 0x0
15–8 Reserved	This field is reserved.
REG_MODE	Register mode control to write the information at each data Initial Value = 0x0

9.3.4.5 DDR_PHY_PHY_CON4

PHY Control Register

Address: 3079_0000h base + 10h offset = 3079_0010h

DDR_PHY_PHY_CON4 field descriptions

Field	Description
31–21 Reserved	This field is reserved.
20–16 CTRL_WRLAT	Clock cycles between write command and the first edge of DQS which can capture the first valid DQ. For example, if WL is 6, It should be set as 7(= WL + 1) in LPDDR3, 6(= WL) in DDR3. Initial Value = 5'h8
15–13 Reserved	This field is reserved.

Table continues on the next page...

DDR_PHY_PHY_CON4 field descriptions (continued)

Field	Description
12–8 CTRL_BSTLEN	Burst Length (BL) Initial Value = 5'h0
7–5 Reserved	This field is reserved.
CTRL_RDLAT	Read Latency (RL) Initial Value = 5'h0

9.3.4.6 DDR_PHY_PHY_CON5

NOTE

When "wl_cal_mode" = 1'b1, "PHY_CON5" will show the results of HW Write Latency Calibration. Please do not change "PHY_CON5" during "wl_cal_mode" = 1'b1.

Address: 3079_0000h base + 14h offset = 3079_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDR_PHY_LP_CON0 field descriptions

Field	Description
31-25 Reserved	This field is reserved.
24-16 CTRL_PULLD_ DQ	Active HIGH signal to down DQ signals. For normal operation this field should be zero. When bus is idle, it can be set to pull-down or up the bus not to make bus high-z state. Initial Value = 4'h0
15-9 Reserved	This field is reserved.
CTRL_PULLD_ DQS	Active HIGH signal to pull-up or down PDQS / NDQS signals. When using Gate Leveling in DDR3, this field can be zero. When bus is idle, it can be set to pull-down or up the bus not to make bus high-z state (PDQS / NDQS is pulled-down / up). For LPDDR2 / LPDDR3 mode, this field should be always set for normal operation to make P / NDQS signals pull-down / up. Initial Value = 4'h0

9.3.4.8 DDR_PHY_RODT_CON0

Address: 3079_0000h base + 1Ch offset = 3079_001Ch

DDR_PHY_RODT_CON0 field descriptions

Field	Description
31–17 Reserved	This field is reserved. Initial Value = 15'h80
16 CTRL_READ_DIS	Read ODT (On-Die-Termination) Disable Signal. This signal should be one in LPDDR2 or LPDDR3 mode. Initial Value = 4'h0 1'b1 Drive ctrl_read_p* to 0 (If using LPDDR2 or LPDDR3, ctrl_read_p* will be always 0 by enabling this field). 1'b0 Drive ctrl_read_p* normally.
Reserved	This field is reserved. Initial Value = 16'h0

9.3.4.9 DDR_PHY_OFFSET_RD_CON0

To capture the DQs with DQS in read operation, DQS is shifted by 90° and this makes rising edge of DQS be located in the center of valid window of DQs. But according to the channel condition, i.e. PCB or SSN, rising edge of DQS could be biased from the center of valid window of DQs. ctrl_offset* is used to compensate the biased DQS and make it be placed in the center of DQs. If ctrl_offset*[7] is 0, ctrl_offset*[6:0] x tFS (tFS: fine step delay) is added to the 90° delay amount and if ctrl_offset*[7] is 1, ctrl_offset*[6:0] x tFS is subtracted from the 90° delay amount. ctrl_offset*[6:0] means the number of delay cells of the "delay line". Generally, ctrl_offset*[6:0] would be zero.

dfi_ctrlupd_req signal is required to update delay line control signals before the first normal operation after checking whether dfi_init_complete is set and at every memory refresh cycle. Before set and clear this signal during initialization, dfi_init_complete signal should be checked whether it's HIGH to confirm that DLL is locked.

Be careful that "ctrl_offsetr*" can be used for the other purpose (= Read Deskew Code Register). Please refer to mode (= PHY_CON3[7:0]).

Address: 3079_0000h base + 20h offset = 3079_0020h

Field	Description
31 Reserved	This field is reserved. Initial Value = 1'b0
30–24 CTRL_START_POINT	Initial DLL lock start point. This is the number of delay cells and is the start point where "DLL" start tracing to be locked. Initial delay time is calculated by multiplying the unit delay of delay cell and this value. Initial Value = 7'h10
23 Reserved	This field is reserved. Initial Value = 1'b0
22–16 CTRL_INC	Increase amount of start point Initial Value = 7'h10
15–7 CTRL_FORCE	This field is used instead of ctrl_lock_value[8:0] found by the DLL only when ctrl_dll_on is LOW, i.e. If the DLL is off, this field is used to generate 270° clock and shift DQS by 90°. Initial Value = 9'h00
6 CTRL_START	This field is used to start DLL locking. Initial Value = 1'b1
5 CTRL_DLL_ON	HIGH active start signal to turn on the DLL. This signal should be kept HIGH for normal operation. If this signal becomes LOW, DLL is turned off. This bit should be kept set before ctrl_start is set to turn on the DLL. HIGH active start signal to turn on the DLL. This signal should be kept HIGH for normal operation. If this signal becomes LOW, DLL is turned off. This bit should be kept set before ctrl_start is set to turn on the DLL. Initial Value = 1'b1
4–1 CTRL_REF	This field determines the period of time when ctrl_locked is cleared. Initial Value = 4'h8 4'b0000 Do not use. 4'b0001 ctrl_flock is de-asserted during 16 clock cycles, ctrl_locked is deasserted. 4'b0010 ctrl_flock is de-asserted during 24 clock cycles, ctrl_locked is deasserted. 4'b1110 ctrl_flock is de-asserted during 120 clock cycles, ctrl_locked is deasserted. 4'b1111 Once ctrl_locked and dfi_init_complete are asserted, those won't be deasserted until rst_n is asserted.
0 Reserved	This field is reserved. Initial Value = 1'b0

9.3.4.23 DDR_PHY_MDLL_CON1

"DLL" is used to get how many delay cells should be passed through the "delay line" to delay a signal to an amount of one clock period and is controlled by ctrl_start, ctrl_start_point and ctrl_inc.

ctrl_start should be set and kept high to make "DLL" keep tracing one clock period after clock(PHY clock) becomes stable. If ctrl_start becomes LOW, "DLL" stops tracing one clock period.

ctrl_clock and ctrl_flock are status fields indicating whether "DLL" is locked. After ctrl_start becomes HIGH, DLL starts tracing one clock period and controls (increases or decreases) the number of delay cells for the clock to pass through. And if ctrl_clock is set ("DLL" is locked), "DLL" changes step delays of the "delay line" and controls the "delay line" in fine resolution to reduce the "phase offset error". When ctrl_flock is set, "DLL" is locked with fine resolution. ctrl_lock_value is information field to indicate the number of delay cells to delay a signal to one clock period through the "delay line".

- {ctrl_clock, ctrl_flock = 2'b00} : DLL is not locked.
- {ctrl_clock, ctrl_flock = 2'b01} : Impossible value.
- {ctrl_clock, ctrl_flock = 2'b10} : Locked.
- {ctrl_clock, ctrl_flock = 2'b11} : Locked.

NOTE

Recommended value for ctrl_start_point[7:0] and ctrl_inc[7:0] are 8'h10.

Address: 3079_0000h base + B4h offset = 3079_00B4h

DDR_PHY_MDLL_CON1 field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16–8 CTRL_LOCK_ VALUE	Locked delay line encoding value. Defines the number of Fine Steps to be used for one clock period. From ctrl_lock_value[8:0], tFS (fine step delay) can be calculated. $tFS = tCK / ctrl_lock_value[8:0]$.
7–3 Reserved	This field is reserved.
2 CTRL_CLOCK	Coarse lock information. According to clock jitter, ctrl_clock can be de-asserted.
1 CTRL_FLOCK	Fine lock information. According to clock jitter, ctrl_flock can be de-asserted.
0 CTRL_LOCKED	DLL stable lock information. This field is set after ctrl_flock is set. This field is cleared when ctrl_flock is de-asserted for some period of time specified by ctrl_ref[3:0] value. This field is required for stable lock status check.

9.3.4.24 DDR_PHY_ZQ_CON0

NOTE

"zq_manual_str" (= ZQ_CON0[1]) should be toggled after ZQ_CON0[17:2] or ZQ_CON0[26:19] is changed. For example, if zq_mode_dds is written by 3'b111, "zq_manual_str" should be set and cleared to apply this new strength value (3'b111).

Field	Description
VERSION_INFO	Version Information

9.4 AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA)

9.4.1 Overview

The AHB-to-APBH bridge provides the chip with an inexpensive peripheral attachment bus running on the AHB's HCLK. (The H in APBH denotes that the APBH is synchronous to HCLK.)

As shown in the figure below, the AHB-to-APBH bridge includes the AHB-to-APB PIO bridge for a memory-mapped I/O to the APB devices, as well as a central DMA facility for devices on this bus and a vectored interrupt controller for the Arm core. Each one of the APB peripherals, including the vectored interrupt controller, is documented in their respective chapters.

Figure 9-25. AHB-to-APBH Bridge DMA Block Diagram

The DMA controller uses the APBH bus to transfer read and write data to and from each peripheral. There is no separate DMA bus for these devices. Contention between the DMA's use of the APBH bus and the AHB-to-APBH bridge functions' use of the APBH is mediated by an internal arbitration logic. For contention between these two units, the DMA is favored and the AHB slave will report "not ready" through its HREADY output until the bridge transfer can complete. The arbiter tracks repeated lockouts and inverts the priority, guaranteeing the Arm platform every fourth transfer on the APB.

9.4.2 Clocks

The table found here describes the clock sources for APBH. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 9-14. APBH Clocks

Clock name	Clock Root	Description
hclk	usdhc_clk_root	Module clock

9.4.3 APBH DMA

The DMA supports four channels of DMA services, as shown in the following table. The shared DMA resource allows each independent channel to follow a simple chained command list. Command chains are built up using the general structure, as shown in [Figure 9-26](#).

Table 9-15. APBH DMA channel assignments

APBH DMA Channel #	Usage
0	GPMI0
1	GPMI1
2	GPMI2
3	GPMI3

A single command structure or channel command word specifies a number of operations to be performed by the DMA in support of a given device. Thus, the Arm platform can set up large units of work, chaining together many DMA channel command words, pass them off to the DMA, and have no further concern for the device until the DMA completion interrupt occurs. The goal is to have enough intelligence in the DMA and the devices to keep the interrupt frequency from any device below 1 KHz (arrival intervals longer than 1 ms).

A single command structure can issue 32-bit PIO write operations to key registers in the associated device using the same APB bus and controls that it uses to write DMA data bytes to the device. For example, this allows a chain of operations to be issued to the GPMI controller to send NAND command bytes, address bytes, and data transfers where the command and the address structure is completely under software control, but the administration of that transfer is handled autonomously by the DMA. Each DMA structure can have 0–15 PIO words appended to it. The CMDPIOWORDS field, if non-zero, instructs the DMA engine to copy these words to the APB, beginning at the first register address offset for the peripheral and incrementing the register offset each cycle.

The DMA master generates only normal read/write transfers to the APBH. It does *not* generate set, clear, or toggle (SCT) transfers.

After any requested PIO words have been transferred to the peripheral, the DMA examines the two-bit command field in the channel command structure. [Table 9-16](#) shows the four commands implemented by the DMA.

Figure 9-26. AHB-to-APBH Bridge DMA channel command structure

Table 9-16. APBH DMA commands

DMA Command	Usage
00	NO_DMA_XFER. Perform any requested PIO word transfers, but terminate the command before any DMA transfer.
01	DMA_WRITE. Perform any requested PIO word transfers, then perform a DMA transfer from the peripheral for the specified number of bytes.
10	DMA_READ. Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes.
11	DMA_SENSE. Perform any requested PIO word transfers, then perform a conditional branch to the next chained device. Follow the NEXTCMD_ADDR pointer if the peripheral sense is false. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is true. This command becomes a no-operation for any channel other than a GPMI channel.

DMA_WRITE operations copy data bytes to the system memory (on-chip RAM or SDRAM) from the associated peripheral.

DMA_READ operations copy data bytes to the APB peripheral from the system memory. The DMA engine contains a shared byte aligner that aligns bytes from system memory to or from the peripherals. Peripherals always assume little-endian-aligned data arrives or departs on their 32-bit APB. The DMA_READ transfer uses the BUFFER_ADDRESS word in the command structure to point to the DMA data buffer to be read by the DMA_READ command.

The NO_DMA_XFER command is used to write PIO words to a device without performing any DMA data byte transfers. This command is useful in such applications as activating the NAND devices CHECKSTATUS operation. The check status command reads a status byte from the NAND device, performs an XOR and MASK against an expected value supplied as part of the PIO transfer. Once the read check completes (see [NAND Read Status Polling Example](#)), the NO_DMA_XFER command completes. The result in the peripheral is that its sense line is driven by the results of the comparison. The sense flip-flop is only updated by CHECKSTATUS for the device that is executed. At some future point, the chain contains a DMA command structure with the fourth and final command value, that is, the DMA_SENSE command.

As each DMA command completes, it triggers the DMA to load the next DMA command structure in the chain. The normal flow list of DMA commands is found by following the NEXTCMD_ADDR pointer in the DMA command structure. The DMA_SENSE command uses the DMA buffer pointer word of the command structure to point to an alternate DMA command structure chain or list. The DMA_SENSE command examines the sense line of the associated peripheral. If the sense line is false, then the DMA follows the standard list found whose next command is found from the pointer in the NEXTCMD_ADDR word of the command structure. If the sense line is true, then the DMA follows the alternate list whose next command is found from the pointer in the DMA Buffer Pointer word of the DMA_SENSE command structure (see [Figure 9-26](#)). The sense command ignores the CHAIN bit, so that both pointers must be valid when the DMA comes to a sense command.

If the wait-for-end-command bit (WAIT4ENDCMD) is set in a command structure, the DMA channel waits for the device to signal completion of a command by toggling the endcmd signal before proceeding to load and execute the next command structure. Then, if DECREMENT_SEMAPHORE is set, the semaphore is decremented after the end command is seen.

A detailed bit-field view of the DMA command structure is shown in the following table, which shows a field that specifies the number of bytes to be transferred by this DMA command. The transfer-count mechanism is duplicated in the associated peripheral, either as an implied or as a specified count in the peripheral.

Table 9-17. DMA channel command word in system memory

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
NEXT_COMMAND_ADDRESS																															

Table continues on the next page...

Table 9-17. DMA channel command word in system memory (continued)

Number DMA Bytes to Transfer	Number PIO Words to Write					HALTONTERMINATE	WAIT4ENDCMD	DECREMENT SEMAPHORE	NANDWAIT4READY	NANDLOCK	IRQ_COMPLETE	CHAIN	COMMAND
DMA Buffer or Alternate CCW													
Zero or More PIO Words to Write to the Associated Peripheral Starting at its Base Address on the APBH Bus													

Figure 9-26 also shows the CHAIN bit in bit 2 of the second word of the command structure. This bit is set to 1, if the NEXT_COMMAND_ADDRESS contains a pointer to another DMA command structure. If a null pointer (0) is loaded into the NEXT_COMMAND_ADDRESS, it is not detected by the DMA hardware. Only the CHAIN bit indicates whether a valid list exists beyond the current structure.

If the IRQ_COMPLETE bit is set in the command structure, then the last act of the DMA before loading the next command is to set the interrupt-status bit corresponding to the current channel. The sticky interrupt request bit in the DMA CSR remains set until cleared by the software. It can be used to interrupt the Arm platform.

The NAND_LOCK bit is monitored by the DMA channel arbiter. Once a NAND channel (from channel 0 to channel 3) succeeds in the arbiter with its NAND_LOCK bit set, then the arbiter ignores the other NAND channels until a command is completed in which the NAND_LOCK is not set. Notice that the semantic here is that the NAND_LOCK state is to limit scheduling of a non-locked DMA. A DMA channel can go from unlocked to locked in the arbiter at the beginning of a command when the NAND_LOCK bit is set. When the last DMA command of an atomic sequence is completed, the lock should be removed. To accomplish this, the last command does not have the NAND_LOCK bit. It is still locked in the atomic state within the arbiter when the command starts, so that it is the only NAND command that can be executed. At the end, it drops from the atomic state within the arbiter.

The NAND_WAIT4READY bit also has a special use for GPMI channels (from channel 0 to channel 3), i.e., the NAND device channels. The GPMI peripheral supplies a sample of the ready line from the NAND device. This ready value is used to hold off of a command with this bit set until the ready line is asserted to 1. Once the arbiter sees a command with a wait-for-ready set, it holds off that channel until ready is asserted.

Receiving an IRQ for HALTONTERMINATE (HOT) is a feature in the APBH DMA descriptor that allows GPMI to signal to the DMA engine that an error has occurred. If a command is stalled due to an error, a HOT signal is sent from the peripheral to the DMA engine and causes an IRQ after terminating the DMA descriptor being executed.

Therefore, it is recommended that software use this signal as follows:

- Always set HALTONTERMINATE to 1 in a DMA descriptor. That way, if a peripheral signals HOT, the transfer will end, leaving the peripheral block and the DMA engine synchronized (but at the end of a command).
- When an IRQ from an APBH channel is received, and the IRQ is determined to be due to an error (as opposed to an IRQONCOMPLETE interrupt) the software should:
 - Reset the channel.
 - Determine the error from error reporting in the peripheral block, then manage the error in the peripheral that is attached to that channel in whatever appropriate way exists for that device (software recovery, device reset, block reset, etc).

Each channel has an eight-bit counting semaphore that controls whether it is in the idle state. When the semaphore is non-zero, the channel is ready to run, process commands and perform DMA transfers. Whenever a command finishes its DMA transfer, it checks the DECREMENT_SEMAPHORE bit. If set, it decrements the counting semaphore. If the semaphore goes to 0 as a result, then the channel enters the idle state and remains there until the semaphore is incremented by the software. When the semaphore goes to non-zero and the channel is in its idle state, then it uses the value in the APBH_CHn_NXTCMDAR register (next command address register) to fetch a pointer to the next command to process.

NOTE

This is a double indirect case. This method allows the software to append to a running command list under the protection of the counting semaphore.

To start processing the first time, software creates the command list to be processed. It writes the address of the first command into the APBH_CHn_NXTCMDAR register, and then writes 1 to the counting semaphore in APBH_CHn_SEMA. The DMA channel loads APBH_CHn_CURCMDAR register and then enters the normal state machine processing for the next command. When the software writes a value to the counting semaphore, it is added to the semaphore count by hardware, protecting the case where both hardware and software are trying to change the semaphore on the same clock edge.

Software can examine the value of APBH_CHn_CURCMDAR at any time to determine the location of the command structure currently being processed.

9.4.4 NAND Read Status Polling Example

The following figure shows a more complicated scenario.

This subset of a NAND device workload shows that the first two command structures are used during the data-write phase of an NAND device write operation (CLE and ALE transfers omitted for clarity).

- After writing the data, one must wait until the NAND device status register indicates that the write charge has been transferred. This is built into the workload using a check status command in the NAND in a loop created from the next two DMA command structures.
- The NO_DMA_TRANSFER command is shown here performing the read check, followed by a DMA_SENSE command to branch the DMA command structure list, based on the status of a bit in the external NAND device.

Figure 9-27. AHB-to-APBH Bridge DMA NAND Read Status Polling with DMA Sense Command

The example in the above figure shows the workload continuing immediately to the next NAND page transfer. However, one could perform a second sense operation to see if an error has occurred after the write. One could then point the sense command alternate branch at a NO_DMA_XFER command with the interrupt bit set. If the CHAIN bit is not

set on this failure branch, then the Arm platform is interrupted immediately, and the channel process is also immediately terminated in the presence of a workload-detected NAND error bit.

Note that each word of the three-word DMA command structure corresponds to a PIO register of the DMA that is accessible on the APBH bus. Normally, the DMA copies the next command structure onto these registers for processing at the start of each command by following the value of the pointer previously loaded into the NEXTCMD_ADDR register.

To start DMA processing for the first command, initialize the PIO registers of the desired channel, as follows:

- First, load the next command address register with a pointer to the first command to be loaded.
- Then, write 1 to the counting semaphore register. This causes the DMA to schedule the targeted channel for the DMA command structure load, just as if it had finished its previous command.

9.4.5 APBH Memory Map/Register Definition

APBH Hardware Register Format Summary

APBH memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
3300_0000	AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0)	32	R/W	E000_0000h	9.4.5.1/2421
3300_0004	AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0_SET)	32	R/W	E000_0000h	9.4.5.1/2421

9.4.5.1 AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0n)

The APBH CTRL 0 provides overall control of the AHB to APBH bridge and DMA.

This register contains module softreset, clock gating, channel clock gating/freeze bits.

AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA)

Address: 3300_0000h base + 0h offset + (4d × i), where i=0d to 3d

APBH_CTRL0n field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal APBH DMA operation. Set this bit to one (default) to disable clocking with the APBH DMA and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the APBH DMA block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 AHB_BURST8_EN	Set this bit to one (default) to enable AHB 8-beat burst. Set to zero to disable 8-beat burst on AHB interface.
28 APB_BURST_EN	Set this bit to one to enable apb master do a continous transfers when a device request a burst dma. Set to zero will treat a burst dma request as 4/8 individual requests.
27–16 RSVD0	This field is reserved. Reserved, always set to zero.
CLKGATE_CHANNEL	These bits must be set to zero for normal operation of each channel. When set to one they gate off the individual clocks to the channels. 0x0001 NAND0 — 0x0002 NAND1 — 0x0004 NAND2 — 0x0008 NAND3 — 0x0010 NAND4 — 0x0020 NAND5 — 0x0040 NAND6 — 0x0080 NAND7 — 0x0100 SSP —

9.4.5.2 AHB to APBH Bridge Control and Status Register 1 (APBH_CTRL1n)

The APBH CTRL one provides overall control of the interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0); // use bitfield write macro
BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0; // or, assign to register

struct's bitfield
```

APBH_CTRL1n field descriptions (continued)

Field	Description
17 CH1_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 1.
16 CH0_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 0.
15 CH15_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 15. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
14 CH14_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 14. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
13 CH13_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 13. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
12 CH12_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 12. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
11 CH11_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 11. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
10 CH10_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 10. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
9 CH9_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 9. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
8 CH8_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 8. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
7 CH7_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 7. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
6 CH6_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 6. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

Table continues on the next page...

APBH_CTRL1n field descriptions (continued)

Field	Description
5 CH5_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 5. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
4 CH4_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 4. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
3 CH3_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 3. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
2 CH2_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 2. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
1 CH1_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 1. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
0 CH0_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 0. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

9.4.5.3 AHB to APBH Bridge Control and Status Register 2 (APBH_CTRL2n)

The APBH CTRL 2 provides channel error interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```

BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0); // use bitfield write macro
BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;    // or, assign to register

struct's bitfield

9.4.5.6 AHB to APBH DMA burst size (APBH_DMA_BURST_SIZE)

This register programs the apbh burst size of the APBH DMA devices when a DMA burst request is issued.

This register provides a mechanism for assigning the device.

Address: 3300_0000h base + 50h offset = 3300_0050h

9.4.5.7 AHB to APBH DMA Debug Register (APBH_DEBUG)

This register is for debug purpose.

The debug register is for internal use only. Not recommend for customer usage.

Address: 3300_0000h base + 60h offset = 3300_0060h

APBH_DEBUG field descriptions

Field	Description
31–1 -	This field is reserved. Reserved, always set to zero.
0 GPMI_ONE_ FIF0	Set to One and the 8 GPMI channels will share the DMA FIFO, and when set to zero, the 8 GPMI channels will use its own DMA FIFO.

9.4.5.8 APBH DMA Channel n Current Command Address Register (APBH_CHn_CURCMDAR)

The APBH DMA channel n current command address register points to the multiword command that is currently being executed. Commands are threaded on the command address.

APBH DMA Channel n is controlled by a variable sized command structure. This register points to the command structure currently being executed.

EXAMPLE

```
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR_RD(0);           // read the whole
register, since there is only one field
pCurCmd = (apbh_chn_cmd_t *) BF_RDn(APBH_CHn_CURCMDAR, 0, CMD_ADDR); // or, use multi-
register bitfield read macro
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR(0).CMD_ADDR;    // or, assign from
bitfield of indexed register's struct
```

Address: 3300_0000h base + 100h offset + (112d × i), where i=0d to 15d

APBH_CHn_CURCMDAR field descriptions

Field	Description
CMD_ADDR	Pointer to command structure currently being processed for channel n.

9.4.5.9 APBH DMA Channel n Next Command Address Register (APBH_CHn_NXTCMDAR)

The APBH DMA Channel n Next Command Address register contains the address of the next multiword command to be executed. Commands are threaded on the command address. Set CHAIN to 1 in the DMA command word to process command lists.

APBH DMA Channel n is controlled by a variable sized command structure. Software loads this register with the address of the first command structure to process and increments the Channel n semaphore to start processing. This register points to the next command structure to be executed when the current command is completed.

EXAMPLE

```

APBH_CHn_NXTCMDAR_WR(0, (reg32_t) pCommandTwoStructure);           // write the entire
register, since there is only one field
BF_WRn(APBH_CHn_NXTCMDAR, 0, (reg32_t) pCommandTwoStructure);     // or, use multi-
register bitfield write macro
APBH_CHn_NXTCMDAR(0).CMD_ADDR = (reg32_t) pCommandTwoStructure;   // or, assign to bitfield
of indexed register's struct
    
```

Address: 3300_0000h base + 110h offset + (112d × i), where i=0d to 15d

APBH_CHn_NXTCMDAR field descriptions

Field	Description
CMD_ADDR	Pointer to next command structure for channel n.

9.4.5.10 APBH DMA Channel n Command Register (APBH_CHn_CMD)

The APBH DMA Channel n command register specifies the DMA transaction to perform for the current command chain item.

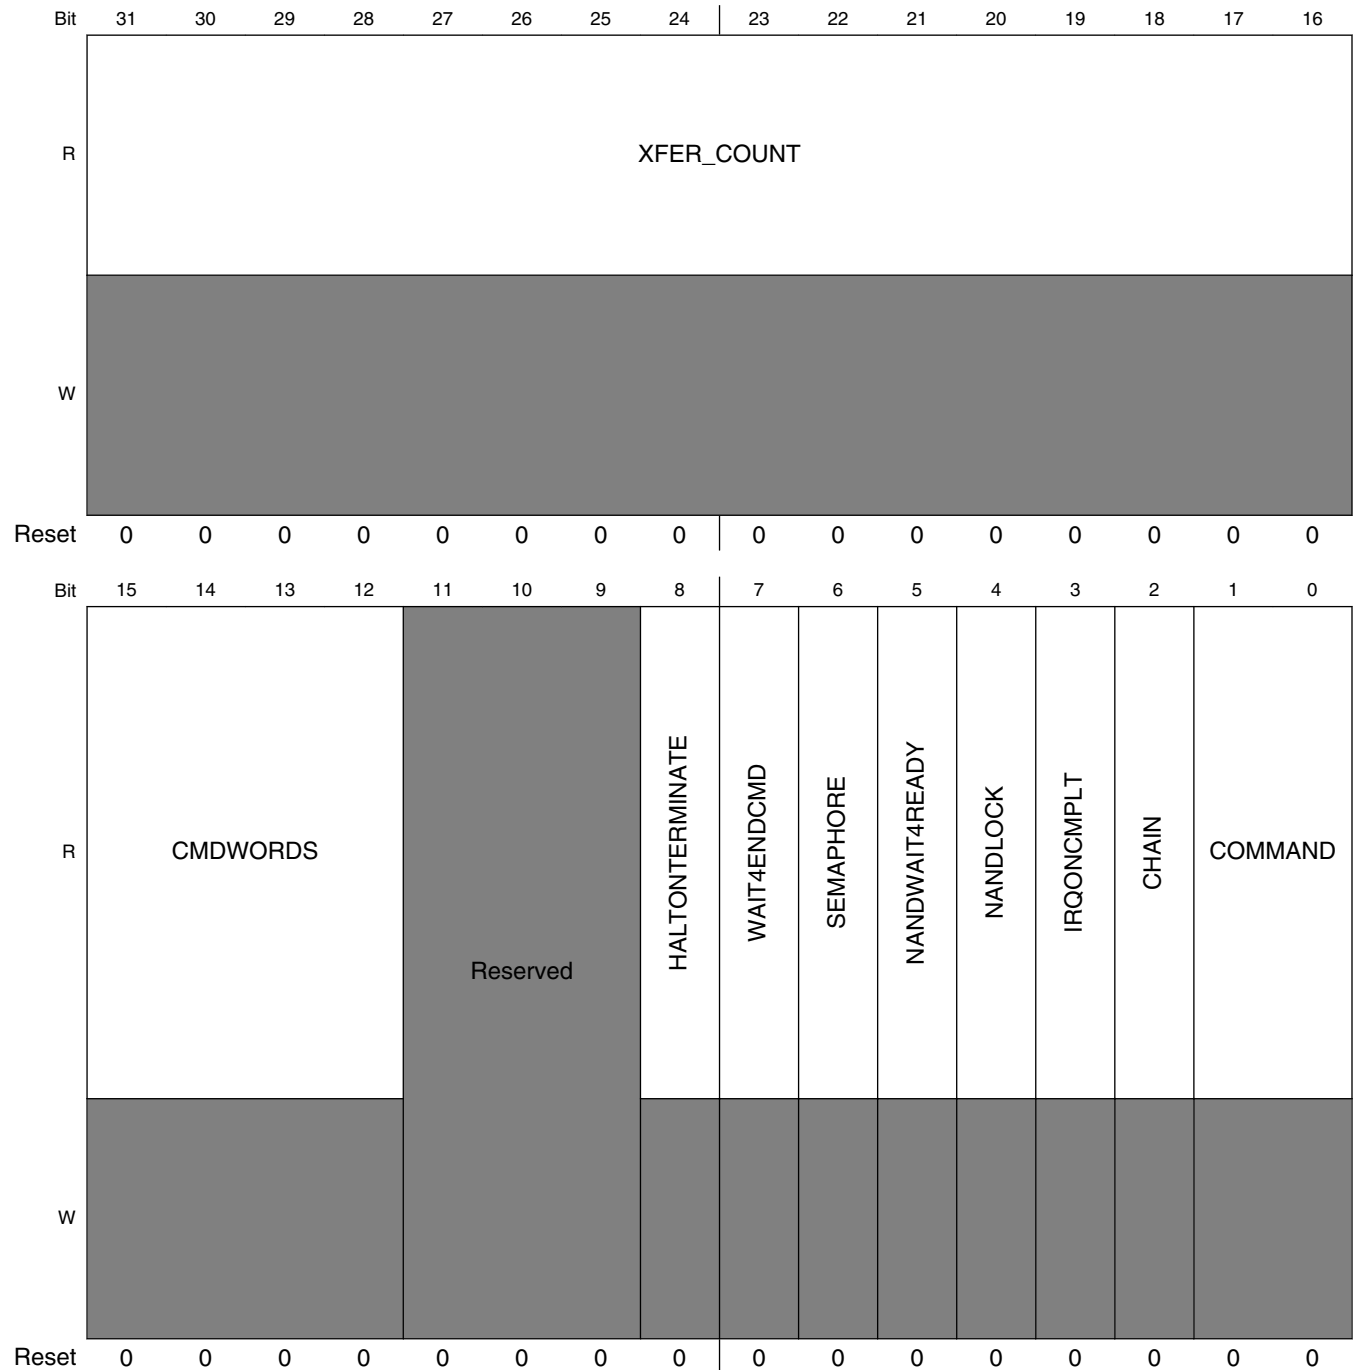

The command register controls the overall operation of each DMA command for this channel. It includes the number of bytes to transfer to or from the device, the number of APB PIO command words included with this command structure, whether to interrupt at command completion, whether to chain an additional command to the end of this one and whether this transfer is a read or write DMA transfer.

EXAMPLE

```

apbh_chn_cmd_t dma_cmd;
dma_cmd.XFER_COUNT = 512; // transfer 512 bytes
dma_cmd.COMMAND = BV_APBH_CHn_CMD_COMMAND_DMA_WRITE; // transfer to system memory from
peripheral device
dma_cmd.CHAIN = 1; // chain an additional command
structure on to the list
dma_cmd.IRQONCMPLT = 1; // generate an interrupt on
completion of this command structure
    
```

Address: 3300_0000h base + 120h offset + (112d × i), where i=0d to 15d

APBH_CHn_CMD field descriptions

Field	Description
31–16 XFER_COUNT	This field indicates the number of bytes to transfer to or from the appropriate PIO register in the GPMIO device. A value of 0 indicates a 64 KBytes transfer.
15–12 CMDWORDS	This field indicates the number of command words to send to the GPMIO, starting with the base PIO address of the GPMIO control register and incrementing from there. Zero means transfer NO command words
11–9 -	This field is reserved. Reserved, always set to zero.
8 HALTONTERMINATE	A value of one indicates that the channel will immediately terminate the current descriptor and halt the DMA channel if a terminate signal is set. A value of 0 will still cause an immediate terminate of the channel if the terminate signal is set, but the channel will continue as if the count had been exhausted, meaning it will honor IRQONCMPLT, CHAIN, SEMAPHORE, and WAIT4ENDCMD.
7 WAIT4ENDCMD	A value of one indicates that the channel will wait for the end of command signal to be sent from the APBH device to the DMA before starting the next DMA command.
6 SEMAPHORE	A value of one indicates that the channel will decrement its semaphore at the completion of the current command structure. If the semaphore decrements to zero, then this channel stalls until software increments it again.
5 NANDWAIT4READY	A value of one indicates that the NAND DMA channel will wait until the NAND device reports "ready" before executing the command. It is ignored for non-NAND DMA channels.
4 NANDLOCK	A value of one indicates that the NAND DMA channel will remain "locked" in the arbiter at the expense of other NAND DMA channels. It is ignored for non-NAND DMA channels.
3 IRQONCMPLT	A value of one indicates that the channel will cause the interrupt status bit to be set upon completion of the current command, i.e. after the DMA transfer is complete.
2 CHAIN	A value of one indicates that another command is chained onto the end of the current command structure. At the completion of the current command, this channel will follow the pointer in APBH_CHn_CMDAR to find the next command.
COMMAND	This bitfield indicates the type of current command: 0x0 NO_DMA_XFER — Perform any requested PIO word transfers but terminate command before any DMA transfer. 0x1 DMA_WRITE — Perform any requested PIO word transfers and then perform a DMA transfer from the peripheral for the specified number of bytes. 0x2 DMA_READ — Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes. 0x3 DMA_SENSE — Perform any requested PIO word transfers and then perform a conditional branch to the next chained device. Follow the NEXCMD_ADDR pointer if the peripheral sense is true. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is false.

9.4.5.11 APBH DMA Channel n Buffer Address Register (APBH_CHn_BAR)

The APBH DMA Channel n buffer address register contains a pointer to the data buffer for the transfer. For immediate forms, the data is taken from this register. This is a byte address which means transfers can start on any byte boundary.

This register holds a pointer to the data buffer in system memory. After the command values have been read into the DMA controller and the device controlled by this channel, then the DMA transfer will begin, to or from the buffer pointed to by this register.

EXAMPLE

```
apbh_chn_bar_t dma_data;
dma_data.ADDRESS = (reg32_t) pDataBuffer;
```

Address: 3300_0000h base + 130h offset + (112d × i), where i=0d to 15d

APBH_CHn_BAR field descriptions

Field	Description
ADDRESS	Address of system memory buffer to be read or written over the AHB bus.

9.4.5.12 APBH DMA Channel n Semaphore Register (APBH_CHn_SEMA)

The APBH DMA Channel n semaphore register is used to synchronize the Arm platform instruction stream and the DMA chain processing state.

Each DMA channel has an 8 bit counting semaphore that is used to synchronize between the program stream and the DMA chain processing. DMA processing continues until the DMA attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DMA channel is stalled until software increments the semaphore count.

EXAMPLE

```
BF_WR(APBH_CHn_SEMA, 0, INCREMENT_SEMA, 2); // increment semaphore by two
current_sema = BF_RD(APBH_CHn_SEMA, 0, PHORE); // get instantaneous value
```

Address: 3300_0000h base + 140h offset + (112d × i), where i=0d to 15d

APBH_CHn_SEMA field descriptions

Field	Description
31–24 -	This field is reserved. Reserved, always set to zero.
23–16 PHORE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	This field is reserved. Reserved, always set to zero.
INCREMENT_ SEMA	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DMA hardware subtracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the DMA channel decrements the count on the same clock, then the count is incremented by a net one.

9.4.5.13 AHB to APBH DMA Channel n Debug Information (APBH_CHn_DEBUG1)

This register gives debug visibility into the APBH DMA Channel n state machine and controls.

This register allows debug visibility of the APBH DMA Channel n.

Address: 3300_0000h base + 150h offset + (112d × i), where i=0d to 15d

APBH_CHn_DEBUG1 field descriptions

Field	Description
31 REQ	This bit reflects the current state of the DMA Request Signal from the APB device
30 BURST	This bit reflects the current state of the DMA Burst Signal from the APB device
29 KICK	This bit reflects the current state of the DMA Kick Signal sent to the APB Device
28 END	This bit reflects the current state of the DMA End Command Signal sent from the APB Device
27 SENSE	This field is reserved. This bit is reserved for this DMA Channel and always reads 0.
26 READY	This bit is reserved for this DMA Channel and always reads 0.
25 LOCK	This field is reserved. This bit is reserved for this Channel and always reads 0.
24 NEXTCMDADDRVALID	This bit reflects the internal bit which indicates whether the channel's next command address is valid.
23 RD_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Read FIFO Empty signal.
22 RD_FIFO_FULL	This bit reflects the current state of the DMA Channel's Read FIFO Full signal.
21 WR_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Write FIFO Empty signal.
20 WR_FIFO_FULL	This bit reflects the current state of the DMA Channel's Write FIFO Full signal.
19–5 RSVD1	This field is reserved. Reserved
STATEMACHINE	<p>PIO Display of the DMA Channel n state machine state.</p> <p>0x00 IDLE — This is the idle state of the DMA state machine.</p> <p>0x01 REQ_CMD1 — State in which the DMA is waiting to receive the first word of a command.</p> <p>0x02 REQ_CMD3 — State in which the DMA is waiting to receive the third word of a command.</p> <p>0x03 REQ_CMD2 — State in which the DMA is waiting to receive the second word of a command.</p> <p>0x04 XFER_DECODE — The state machine processes the descriptor command field in this state and branches accordingly.</p> <p>0x05 REQ_WAIT — The state machine waits in this state for the PIO APB cycles to complete.</p> <p>0x06 REQ_CMD4 — State in which the DMA is waiting to receive the fourth word of a command, or waiting to receive the PIO words when PIO count is greater than 1.</p> <p>0x07 PIO_REQ — This state determines whether another PIO cycle needs to occur before starting DMA transfers.</p> <p>0x08 READ_FLUSH — During a read transfers, the state machine enters this state waiting for the last bytes to be pushed out on the APB.</p> <p>0x09 READ_WAIT — When an AHB read request occurs, the state machine waits in this state for the AHB transfer to complete.</p> <p>0x0C WRITE — During DMA Write transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel.</p> <p>0x0D READ_REQ — During DMA Read transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel.</p>

Table continues on the next page...

APBH_CHn_DEBUG1 field descriptions (continued)

Field	Description
0x0E	CHECK_CHAIN — Upon completion of the DMA transfers, this state checks the value of the Chain bit and branches accordingly.
0x0F	XFER_COMPLETE — The state machine goes to this state after the DMA transfers are complete, and determines what step to take next.
0x14	TERMINATE — When a terminate signal is set, the state machine enters this state until the current AHB transfer is completed.
0x15	WAIT_END — When the Wait for Command End bit is set, the state machine enters this state until the DMA device indicates that the command is complete.
0x1C	WRITE_WAIT — During DMA Write transfers, the state machine waits in this state until the AHB master completes the write to the AHB memory space.
0x1D	HALT_AFTER_TERM — If HALTONTERMINATE is set and a terminate signal is set, the state machine enters this state and effectively halts. A channel reset is required to exit this state
0x1E	CHECK_WAIT — If the Chain bit is a 0, the state machine enters this state and effectively halts.
0x1F	WAIT_READY — When the NAND Wait for Ready bit is set, the state machine enters this state until the GPMI device indicates that the external device is ready.

9.4.5.14 AHB to APBH DMA Channel n Debug Information (APBH_CHn_DEBUG2)

This register gives debug visibility for the APB and AHB byte counts for DMA Channel n.

This register allows debug visibility of the APBH DMA Channel n.

Address: 3300_0000h base + 160h offset + (112d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

APBH_CHn_DEBUG2 field descriptions

Field	Description
31–16 APB_BYTES	This value reflects the current number of APB bytes remaining to be transferred in the current transfer.
AHB_BYTES	This value reflects the current number of AHB bytes remaining to be transferred in the current transfer.

9.4.5.15 APBH Bridge Version Register (APBH_VERSION)

This register always returns a known read value for debug purposes it indicates the version of the block.

62BIT Correcting ECC Accelerator (BCH)

This register indicates the RTL version in use.

EXAMPLE

```
if (APBH_VERSION.B.MAJOR != 3)
    Error();
```

Address: 3300_0000h base + 800h offset = 3300_0800h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

APBH_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

9.5 62BIT Correcting ECC Accelerator (BCH)

9.5.1 Overview

The hardware ECC accelerator provides a forward error-correction function for improving the reliability of various storage media that may be attached to the device.

For example, NAND flash devices use a spare area to store ecc codes to correct some hard bit errors in data stored within the device, allowing higher device yields and, therefore, lower NAND device costs.

The Bose, Ray-Chaudhuri, Hocquenghem (BCH) Encoder and Decoder module is capable of correcting from 2 to 62 single bit errors within a block of data no larger than about 1900 bytes (512 bytes or 1024 bytes are typical) in applications such as protecting data and resources stored on modern NAND flash devices. The correction level in the BCH block is programmable to provide flexibility for varying applications and configurations of flash page size. The design can be programmed to encode protection of 2 to 62 bit errors when writing flash and to correct the corresponding number of errors on decode. The correction level when decoding MUST be programmed to the same correction level as was used during the encode phase.

BCH-codes are a type of block-code, which implies that all error-correction is performed over a block of N -symbols. The BCH operation will be performed over $GF(2^{13} = 8192)$ or $GF(2^{14} = 16384)$, which is the Galois Field consisting of 8191 or 16383 one-bit symbols. BCH-encoding (or encode for any block-code) can be performed by two algorithms: systematic encoding or multiplicative encoding. Systematic encoding is the process of reading all the symbols which constitute a block, dividing continuously these symbols by the generator polynomial for the $GF(8192)$ or $GF(16384)$ and appending the resulting t parity symbols to the block to create a BCH codeword (where t is the number of correctable bits).

The BCH encode process creates $t*13$ (or $t*14$)-bit parity symbols for each data block when the data is written to the flash device. The parity symbols are written to the flash device after the corresponding data block, and together these are collectively called the codeword. The codeword can be used during the decode process to correct errors that occur in either the data or parity blocks.

The BCH decoder processes code words in a 4-step fashion:

1. Syndrome Calculation (SC): This is the process of reading in all of the symbols of the codeword and continuously dividing by the generator polynomial for the field. $2*t$ syndromes must be calculated for each codeword and inspection of the syndromes determines if there are errors: a non-zero set of syndromes indicates one or more errors. This process is implemented parallel hardware to minimize processing time since it must be done every time the decode is performed.
2. Key Equation Solver (KES): The syndromes represent $2t$ -linear equations with $2t$ -unknown variables. The process of solving these equations and selecting from the numerous solutions constitutes the KES module. When the KES block completes its operations, it generates an error locator polynomial (σ) that is used in the proceeding block to determine the locations and values of the errors.
3. Chien Search (CS): This block takes input from the KES block and uses the Chien Algorithm for finding the locations of the errors based on the error locator polynomial. The method basically involves substituting all 8191 symbols from the $GF(8192)$ or 16383 symbols from the $GF(16383)$ into the locator polynomial. All evaluations that produce a zero solution indicate locations of the various errors. Since each located error corresponds to a single bit, the bit in the original data may be corrected by simply flipping the polarity of the incorrect location.
4. Correction: this block has to convert the symbol index and mask information to memory byte indexes and masks.

The BCH block, shown in the figure, was designed to operate in a pipelined fashion to maximize throughput. Aside from the initial latency to fill the pipeline stages, the BCH throughput is about 7/4 cycles/byte. Thus, the bottleneck in performing NAND reads and error corrections is the BCH rate. Current GPMI read rates are approximately 1/2 cycles/byte maximally for the current generation of NAND flash. Fortunately, BCH has a different master clock from GPMI, this gives some flexibility to match the throughput rate. The CPU is not directly involved in generating parity symbols, checking for errors, or correcting them.

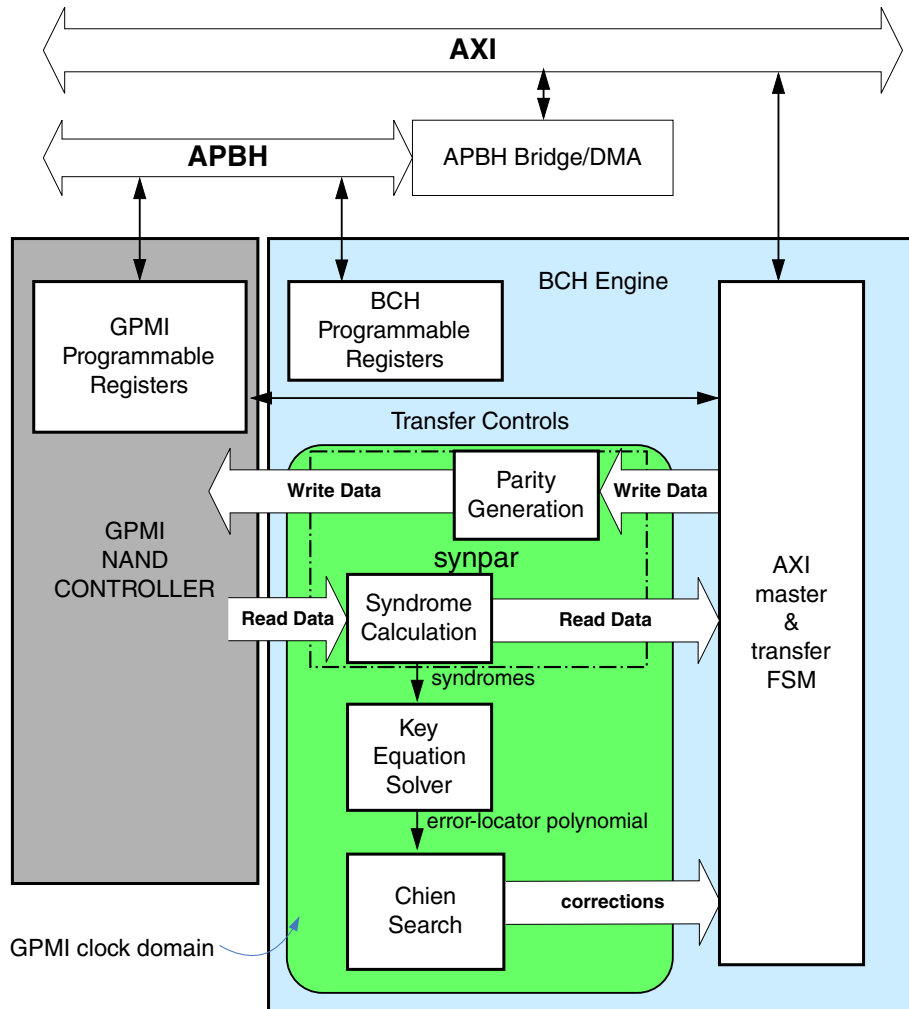

Figure 9-28. Hardware BCH Accelerator

9.5.2 Operation

Before performing any NAND flash read or write operations, software should first program the BCH's flash layout registers (see [Flash Page Layout](#)) to specify how data is to be formatted on the flash device. The BCH hardware allows full programmability over the flash page layout to enable users flexibility in balancing ECC correction levels and ever-changing flash page sizes.

To initiate a NAND Flash write, software will program a GPMI DMA operation. The DMA need only program the GPMI control registers (and handle the requisite flash addressing handshakes) since the BCH will handle all data operations using its AXI bus interface. The BCH will then send the data to the GPMI controller to be written to flash as it computes the parity symbols. At the end of each data block the BCH will insert the parity symbols into the data stream so that the GPMI sees only a continuous stream of data to be written.

NAND Flash read operations operate in a similar manner. As the GPMI controller reads the device, all data is sent to the BCH hardware for error detection/correction. The BCH controller writes all incoming read data to system memory and in parallel computes the syndromes used to detect bit errors. If errors are detected within a block, the BCH hardware activates the error correction logic to determine where bit errors have occurred and ultimately correct them in the data buffer in system memory. After an entire flash page has been read and corrected, the BCH will signal an interrupt to the CPU.

The figure below indicates how data read from the GPMI is operated on within the BCH hardware. As the BCH receives data from the GPMI (top row), it is written to memory by the BCH's Bus Interface Unit (BIU) (second row). For blocks requiring correction, the KES logic will be activated after the entire block has been received. Once the error locator polynomial has been computed, the corrections are determined by the Chien Search and fed back to the BIU, which performs a read, modify, write operation on the buffer in memory to correct the data.

62BIT Correcting ECC Accelerator (BCH)

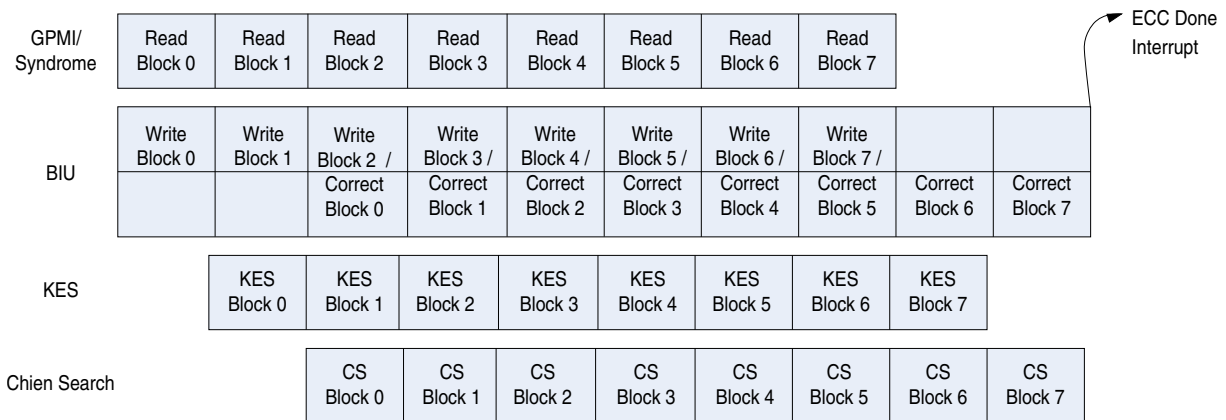

Figure 9-29. Block Pipeline while Reading Flash

9.5.2.1 BCH Limitations and Assumptions

- The BCH is programmable to support 2 to 62 bit error correction. ECC0 is supported as a pass-through, non-correcting mode.
- Data block sizes must be a multiple of 4 bytes and be aligned in system memory.
- The BCH supports a programmable number of metadata/auxiliary data bytes, from 0 to 255.
- Metadata will be written at the beginning of the flash page to facilitate fast access for filesystem operations.
- Metadata may be treated as an independent block for ECC purposes or combined with the first data block to conserve bits in the flash.
- The BCH does not support a partial page write (this can be accomplished by programming the BCH layout registers such that the BCH only sees a portion of the page).
- Flash read operations can read the entire page or the first block on the page.
- The BCH also supports a memory-to-memory mode of operation that does not require the use of DMA or the GPMI.

9.5.2.2 Flash Page Layout

The BCH supports a fully programmable flash page layout. The BCH maintains four independent layout registers that can describe four completely different NAND devices or layouts.

When the BCH initiates an operation, it selects one of the layouts by using the chip select as an index into the BCH_LAYOUTSELECT register that determines which layout should be used for the operation.

Three possible (generic) flash layout schemes are supported, as indicated in the figure below. (In each case, the metadata size may also be programmed to 0 bytes). Metadata may either be combined with the first block of data or the size of the first data block can be programmed to 0 to allow the metadata to be protected by its own ECC parity bits.

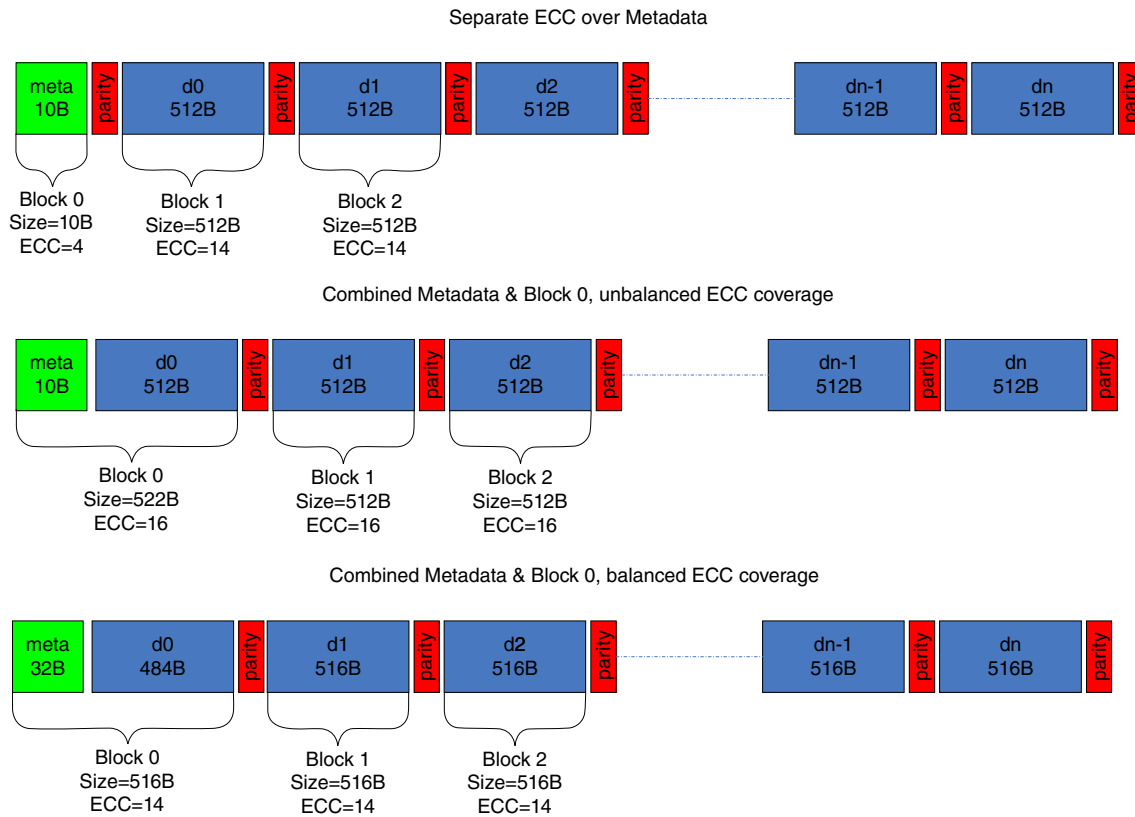

Figure 9-30. FLASH Page Layout Options

Each layout is determined by a pair of registers that define the following parameters:

- **DATA0_SIZE:** Indicates the number of data bytes in the first block on the page (this should not include parity or metadata bytes). This should be set to 0 when the metadata is to be covered separately with its own ECC. This must be a multiple of 4 bytes.
- **ECC0:** Indicates the ECC level to be used for the first block on the flash (data0+metadata).
- **META_SIZE:** Indicates the number of bytes (from 0-255) that are stored as metadata.

- NBLOCKS: Indicates the number of subsequent DATAN blocks on the flash, or the number of blocks following the DATA0 block.
- DATAN_SIZE: Indicates the number of data bytes in all subsequent data blocks. This MUST be a multiple of 4 bytes.
- ECCN: Indicates the ECC level to be used for the subsequent data blocks.
- GF0 or GFN: Indicates the Galois field the meta / data blocks are using
- PAGE_SIZE: Indicates the total number of bytes available per page on the physical flash device. This includes the spare area and is typically 4096+128, 4096+218, or 2048+64 bytes.

9.5.2.3 Determining the ECC layout for a device

Since the BCH is programmable, a system can trade off ECC levels for flash size and layout configurations.

The following examples indicate how to determine a valid layout based on the required storage space and flash size. For all cases, the size of the parity will be 13 (or 14 for GF(2¹⁴))*ECC level *bits*-- so for ECC8, 13 (or 14) bytes are required (per block).

9.5.2.3.1 4K+218 flash, 10 bytes metadata, 512 byte data blocks, separate metadata, Assuming GF(2¹³)

In this case, we have 8 data blocks each consisting of 512 bytes. Since the flash has 218 spare bytes (1744 bits), first estimate an ECC level for the data blocks by first subtracting the number of metadata bytes from the spare bytes (218 – 10 = 208 bytes = 1664 bits) then dividing the number of bits by 8 (number of blocks) and then by 13 (bits per ECC level).

$$(218 - 10) \times 8 = 1664 / 13(8) = 16$$

Therefore all the data blocks could be covered by ECC16 if the metadata had no parity. This isn't acceptable, so assume ECC14 for all the data blocks. Now calculate the number of free bits for the metadata parity as

$$1664 - (14) \times 13 \times 8 = 208$$

Therefore, 208 bits remain for metadata parity. Dividing by 13 (bits/ECC) gives 16, so the metadata can be covered with ECC16. The settings for this device would then be

Table 9-18. Settings for 4K+218 FLASH

Setting	Value
PAGE_SIZE	4096+218=4314=0x10DA
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	16=0x10
GF0	GF(2 ¹³)
DATAN_SIZE	512=0x200 (in register interface, assigned as 0x80)
ECCN	14=0x0E
GFN	GF(2 ¹³)
NBLOCKS	8

9.5.2.3.2 4K+128 flash, 10 bytes metadata, 1024 byte data blocks, separate metadata, assuming GF(2¹³) for data and GF(2¹⁴) for metadata

This flash will have 118 bytes available for ECC (after subtracting the metadata size), therefore, 994 bits.

Dividing by 4*14 (number of blocks * ECC level) we get 17.75, therefore we can support ECC16 on the data blocks. The number of free spare bits becomes 944 - 16 * 4 * 14 = 944 - 896 = 48, divided by 13 = 3.69, therefore the metadata can be also covered by ECC2.

Table 9-19. Settings for 4K+128 FLASH

Setting	Value
PAGE_SIZE	4096+128=4224=0x1080
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	2
GF0	GF(2 ¹³)
DATAN_SIZE	1024=0x400 (in register interface, assigned as 0x100)
ECCN	16
GFN	GF(2 ¹⁴)
NBLOCKS	4

In this case, there will be additional unused spare bits, with the BCH will pad out with zeros.

9.5.2.4 Data Buffers in System Memory

While the data on the flash is interleaved with parity symbols, the BCH assumes that the data buffers in memory are contiguous.

Metadata read from the flash will be stored to the location pointed to by the `GPMI_AUXILIARY` register and data will be written to the address specified in the `GPMI_PAYLOAD` register as is shown in the following figure where the block length is 512 bytes for example. Since the number of blocks on a flash page is programmable, the BCH also writes individual block correction status to the auxiliary pointer at the word-aligned address following the end of the metadata. Optionally, the computed syndromes may also be written to the auxiliary area if the `DEBUGSYNDROME` bit is set in the control register.

As blocks complete processing, the bus master will accumulate the status for each block and write it to the auxiliary data buffer following the metadata. The metadata area will be padded with 0's until the next word boundary and the status for blocks 0-3 will be written to the next word. The status for subsequent blocks will then be written to the buffer. The status for the first block (metadata block) is also stored in the `STATUS_BLK0` register in the `BCH_STATUS` register. The completion codes for the blocks are indicated in the [Table 9-20](#). Note that the definition of the bytes and their ordering in the auxiliary and payload storage areas are user defined. When this data is read back from the flash and put into memory, it will resemble the original buffer that was written out to the flash.

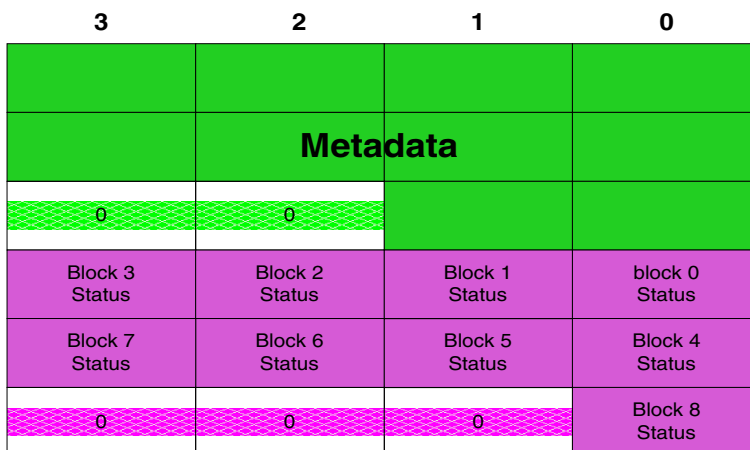

Figure 9-31. BCH Data Buffers in Memory

Table 9-20. Status Block Completion Codes

Code	Description
0xFF	Block is erased
0xFE	Block is uncorrectable
0x00	No errors found
0x01-0x3E	Number of errors corrected

The following figure shows the layout of the bytes within the status field.

Status bytes are allocated based on the NBLOCKS programmed into the flash format register. The number of status bytes are computed by NBLOCK+1. The status area will be padded with zeros to the next word boundary.

Syndrome data written for debug purposes follows the end of the status block.

Figure 9-32. Memory-to-Memory Operations

9.5.3 Memory to Memory (Loopback) Operation

The BCH supports a memory-to-memory mode of operation where both the encoded and decoded buffers reside in system memory.

This can be useful for applications where data must be protected by ECC, but the storage device does not reside on the GPMI bus.

The BCH operation in memory to memory mode is much simpler than in GPMI mode since DMAs are not required to manage the operation. Instead, software simply writes the BCH_DATAPTR and BCH_METAPTR with the addresses of the data and metadata (auxiliary) buffers and the BCH_ENCODEPTR with the address of the buffer for encoded data. To initiate the operation, software simply sets the M2M_ENCODE and M2M_ENABLE bits in the control register. The BCH can be programmed to either issue an interrupt at the end of the operation or software may poll the status bits for completion.

Memory to memory decode operations work in a similar manner. The encoded data address is written to the BCH_ENCODEPTR and the data and meta pointers are written to buffers that correspond to the desired decoded data addresses. To initiate a decode, software must set the M2M_ENCODE bit to 0 while writing the M2M_ENABLE bit. Note that the addresses written to the BCH_DATAPTR, BCH_METAPTR and BCH_ENCODEPTR registers should always be aligned on a 4 byte boundary. In other words, the 2 lower bits of the address should always be written with zeros.

9.5.4 Programming the BCH/GPMI Interfaces

Programming the BCH for NAND operations consists largely of disabling the soft reset and clock bits (SFTRST and CLKGATE) from the BCH_CTRL register and then programming the flash layout registers to correspond to the format of the attached NAND device(s).

The BCH_LAYOUTSELECT register should also be programmed to map the chip select of each attached device into one of the four layout registers.

The bulk of the programming is actually applied to the GPMI through PIO operations embedded in DMA command structures. The DMA will perform all the requisite handshaking with the GPMI interface to negotiate the address portion of the transfer, then the BCH will handle all the movement of data from memory to the GPMI (writes) or the GPMI to memory (reads). The BCH will direct all data blocks to the buffer pointed to by the PAYLOAD_BUFFER and the metadata will be written to the AUXILIARY_BUFFER. Both of these registers are located in the GPMI PIO data space and are communicated to the BCH hardware at the beginning of the transfer. Thus, the normal multi-NAND DMA based device interleaving is preserved, that is, four NANDs on four separate chip selects can be scheduled for read or write operations using the BCH. Whichever channel finishes its ready wait first and enters the DMA arbiter with its lock bit set owns the GPMI command interface and through it owns the BCH resources for the duration of its processing.

9.5.4.1 BCH Encoding for NAND Writes

The BCH encoder flowchart in [Figure 9-33](#) shows the detailed steps involved in programming and using the BCH encoder. This flowchart shows how to use the BCH block with the GPMI.

To use the BCH encoder with the GPMI's DMA, create a DMA command chain containing ten descriptor structures, as shown in [Figure 9-35](#) and detailed in the DMA structure code example that follows it in [DMA Structure Code Example](#). The ten descriptors perform the following tasks:

1. Disable the BCH block (in case it was enabled) and issue NAND write setup command byte (under CLE) and address bytes (under ALE).
2. Configure and enable the BCH and GPMI blocks to perform the NAND write.
3. Disable the BCH block and issue NAND write execute command byte (under CLE).

4. Wait for the NAND device to finish writing the data by watching the ready signal.
5. Check for NAND timeout through PSENSE.
6. Issue NAND status command byte (under CLE).
7. Read the status and compare against expected.
8. If status is incorrect or incomplete, branch to error handling descriptor chain.
9. Otherwise, write is complete and emit GPMI interrupt.

processing
                  BV_FLD(APBH_CHn_CMD, COMMAND, NO_DMA_XFER); // no dma transfer

```

9.5.4.1.2 Using the BCH Encoder

To use the BCH encoder, first turn off the module-wide soft reset bit in both the GPMI and BCH blocks before starting any DMA activity.

Turning off the soft reset must take place by itself, prior to programming the rest of the control registers. Turn off the BCH bus master soft reset bit. Turn off the clock gate bits.

Program the remainder of the GPMI, BCH and APBH DMA as follows:

```

// bring APBH out of reset
APBH_CTRL0_CLR(BM_APBH_CTRL0_SFRST);
APBH_CTRL0_CLR(BM_APBH_CTRL0_CLKGATE);

// bring BCH out of reset
BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);

// bring gpmi out of reset
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_SFTRST);
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_CLKGATE);
GPMI_CTRL1_SET(BM_GPMI_CTRL1_DEV_RESET | // deassert reset
               BM_GPMI_CTRL1_BCH_MODE ); // enable BCH mode

// enable pinctrl
PINCTRL_CTRL_WR(0x00000000);

// enable gpmi pins
PINCTRL_MUXSEL0_CLR(0x0000ffff); // data bits
PINCTRL_MUXSEL1_CLR(0x03ffffff); // control bits
PINCTRL_MUXSEL8_CLR(0x0003f3ff); // control bits
PINCTRL_MUXSEL8_SET(0x00015155); // control bits

```

Note that for writing NANDs (ECC encoding), only GPMI DMA command complete interrupts are used. The BCH engine is used for writing to the NAND but may optionally produce an interrupt. From the sample code in [DMA Structure Code Example](#) :

- DMA descriptor 1 prepares the NAND for data write by using the GPMI to issue a write setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is disabled and not used for these commands.
- DMA descriptor 2 enables the BCH engine for encoding to begin the initial writing of the NAND data by specifying where the data and auxiliary payload are coming from in system memory.

- DMA descriptor 3 issues the write commit command byte under CLE to the NAND.
- DMA descriptor 4 waits for the NAND to complete the write commit/transfer by watching the NAND's ready line status. This descriptor relinquishes the NANDLOCK on the GPMI to enable the other DMA channels to initiate NAND transactions on different NAND CS lines.
- DMA descriptor 6 issues a NAND status command byte under "CLE" to check the status of the NAND device following the page write.
- DMA descriptor 7 reads back the NAND status and compares the status with an expected value. If there are differences, then the DMA processing engine follows an error-handling DMA descriptor path.
- DMA descriptor 8 disables the BCH engine and emits a GPMI interrupt to indicate that the NAND write has been completed.

9.5.4.2 BCH Decoding for NAND Reads

When a page is read from NAND flash, BCH syndromes will be computed and, if correctable errors are found, they will be corrected on a per block basis within the NAND page. This decoding process is fully overlapped with other NAND data reads and with CPU execution. The BCH decoder flowchart in the figure below shows the steps involved in programming the decoder. The hardware flow of reading and decoding a 4096-byte page is shown in [Figure 9-37](#).

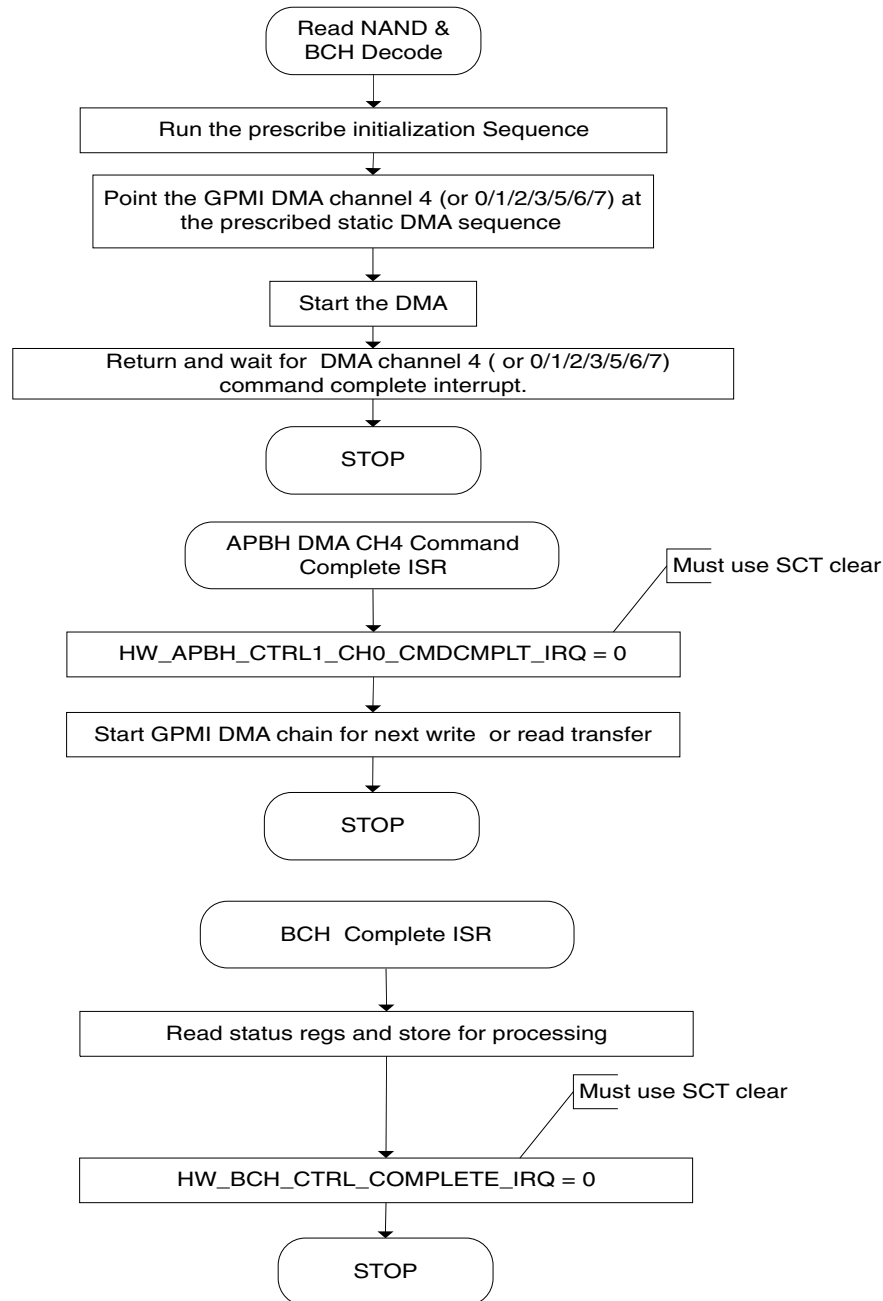

Figure 9-36. BCH Decode Flowchart

Conceptually, an APBH DMA Channel (0,1,2 or 3) command chain with seven command structures linked together is used to perform the BCH decode operation (as shown in [Figure 9-37](#)).

Note

The GPMI's DMA command structures controls the BCH decode operation.

To use the BCH decoder with the GPMI's DMA, create a DMA command chain containing seven descriptor structures, as shown in the figure below and detailed in the DMA structure code example that follows it in [DMA Structure Code Example](#). The seven DMA descriptors perform the following tasks:

1. Issue NAND read setup command byte (under "CLE") and address bytes (under "ALE").
2. Issue NAND read execute command byte (under "CLE").
3. Wait for the NAND device to complete accessing the block data by watching the ready signal.
4. Check for NAND timeout through "PSENSE".
5. Configure and enable the BCH block and read the NAND block data.
6. Disable the BCH block.
7. Descriptor NOP to allow NANDLOCK in the previous descriptor to the thread-safe.

Descriptor 1: Disable BCH engine and issue NAND read set-up command and address (CLE/ALE).

Descriptor 2: NAND read execute command (CLE).

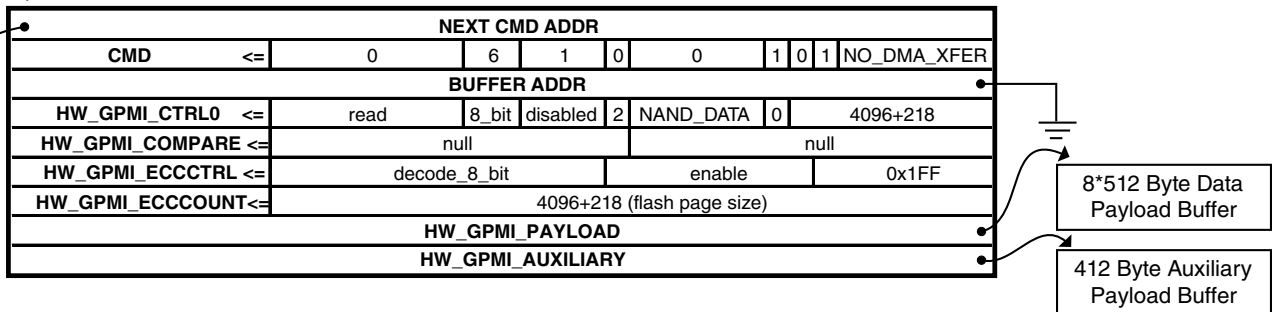

Descriptor 3: Wait for NAND ready.

Descriptor 4: PSENSE compare for time-out.

Descriptor 5: Enable BCH engine and read NAND data.

Descriptor 6: Disable BCH engine (wait for ready is a NOP here).

Descriptor 7: NOP to ensure NANDLOCK in previous descriptor .

Figure 9-37. BCH Decode DMA Descriptor Chain

9.5.4.2.1 DMA Structure Code Example

The following sample code illustrates the coding for one read transaction, consisting of a seven DMA command structure chain for reading all 4096 bytes of payload data (eight 512-byte blocks) and 65 bytes of metadata with the associative parity bytes ($8 * (18) + 9$) from a 4K NAND page sitting on GPMI CS2.

```

```

9.5.4.2.2 Using the Decoder

As illustrated in [Figure 9-37](#) and the sample code in [DMA Structure Code Example](#) :

- DMA descriptor 1 prepares the NAND for data read by using the GPMI to issue a NAND read setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is not used for these commands.
- DMA descriptor 2 issues a one-byte read execute command to the NAND device that triggers its read access. The NAND then goes not ready.
- DMA descriptor 3 performs a wait for ready operation allowing the DMA chain to remain dormant until the NAND device completes its read access time.

- DMA descriptor 5 handles the reading and error correction of the NAND data. This command's PIOs activate the BCH engine to write the read NAND data to system memory and to process it for any errors that need to be corrected. This DMA descriptor contains two PIO values that are system memory addresses pointing to the PAYLOAD data area and to the AUXILIARY data area. These addresses are used by the BCH engine's AHB master to move data into system memory and to correct it. While this example is reading an entire 4K page—payload plus metadata—it is equally possible to read just one 512-byte payload block or just the uniquely protected metadata block in a single 7 DMA structure transfer.
- DMA descriptor 6 disables the BCH engine with the NANDLOCK asserted. This is necessary to ensure that the GPMI resource is not arbitrated to another DMA channel when multiple DMA channels are active concurrently.
- DMA descriptor 7 de-asserts the NANDLOCK to free up the GPMI resource to another channel.

As the BCH block receives data from the GPMI:

- The decoder transforms the read NAND data block into a BCH code word and computes the codeword syndrome.
- If no errors are present, then the BCH block can immediately report back to firmware. This report is passed as the BCH_CTRL_COMPLETE_IRQ interrupt status bit and the associated status registers in BCH_STATUS0/1 registers.
- If an error is present, then the BCH block corrects the necessary data block or parity block bytes, if possible (not all errors are correctable).

As the BCH decoder reads the data and parity blocks, it records a special condition, i.e., that all of the bits of a payload data block or metadata block are one, including any associated parity bytes. The all-ones case for both parity and data indicates an erased block in the NAND device.

The BCH_STATUS0 register contains a 4-bit field that indicates the final status of the auxiliary block. A value of 0x0 indicates no errors found for a block.

- A value of 1 to 20 inclusive indicates that many correctable errors were found and fixed.
- A value of 0xFE indicates uncorrectable errors detected on the block.

- A value of 0xFF indicates that the block was in the special ALL ONES state and is therefore considered to be an ERASED block.
- All other values are disallowed by the hardware design.

Recall that up to eight NAND devices can have DMA chains in-flight at once, i.e. they can all be contending for access to the GPMI data bus. It is impossible to predict which NAND device will enter the BCH engine with a transfer first, because each chain includes a wait4ready command structure. As a result, firmware should look at the BCH_STATUS0_COMPLETED_CE bit field to determine which block is being reported in the status register. There is also a 16-bit HANDLE field in the GPMI_ECCCTRL register that is passed down the pipeline with each transaction. This handle field can be used to speed firmware's detection of which transaction is being reported.

These examples of reading and writing have focused on full page transfers of 4K page NAND devices. Other device configurations can be specified by changing the ECCOUNT field in the GPMI registers and reprogramming the BCH's FLASHnLAYOUTm registers.

The BCH and GPMI blocks are designed to be very efficient at reading single 512 (or 1024)-byte pages in one transaction. With no errors, the transaction takes less than 20 HCLKs longer than the time to read the raw data from the NAND.

To summarize, the APBH DMA command chain for a BCH decode operation is shown in [Figure 9-37](#). Seven DMA command structures must be present for each NAND read transaction decoded by the BCH. The seven DMA command structures for multiple NAND read transaction blocks can be chained together to make larger units of work for the BCH, and each will produce an appropriate error report in the BCH PIO space. Multiple NAND devices can have such multiple chains scheduled. The results can come back out of order with respect to the multiple chains.

9.5.4.3 Interrupts

There are two interrupt sources used in processing BCH protected NAND read and write transfers.

Since all BCH operations are initiated by GPMI DMA command structures, the DMA completion interrupt for the GPMI is an important ISR. Both of the flow charts of [Figure 9-33](#) and [Figure 9-36](#) show the GPMI DMA complete ISR skeleton. In both reads and writes, the GPMI DMA completion interrupt is used to schedule work *INTO* the error correction pipeline. As the front end processing completes, the DMA interrupt is

generated and additional work, such as DMA chains, are passed to the GPMI DMA to keep it *fed*. For write operations, this is the only interrupt that is generated for processing the NAND write transfer.

For reads, however, two interrupts are needed. Every read is started by a GPMI DMA command chain and the front end queue is fed as described above. The back end of the read pipeline is drained by monitoring the BCH completion interrupt found in `HW_BCH_CTRL_COMPLETE_IRQ`.

An BCH transaction consists of reading or writing all of the blocks requested in the `HW_GPMI_ECCCTRL_BUFFER_MASK` bit field. As every read transaction completes, it posts the status of all of the blocks to the `HW_BCH_STATUS0` and `HW_BCH_STATUS1` registers and sets the completion interrupt. The five stages of the BCH read pipeline completes, one in the GPMI and four in the BCH, are independently stalled as they complete and try to deliver to the next stage in the data flow. Several of these stages can be skipped if no-errors are found or once an uncorrectable error is found in a block.

In any case, the final stage will stall if the status register is busy waiting for the CPU to take status register results. The hardware monitors the state of the `HW_BCH_CTRL_COMPLETE_IRQ` bit. If it is still set when the last pipeline stage is ready to post data, then the stage will stall. It follows that the next previous stage will stall when it is ready to hand off work to the final stage, and so on up the pipeline.

CAUTION

It is important that firmware read the STATUS0/1 results and save them before clearing the interrupt request bit. Otherwise, a transaction and its results could be completely lost.

9.5.4.4 Randomizer

BCH ECC has a Randomizer module that is interfaced through the GPMI APBHDMA chain. The Randomizer can generate random data based on BCH ECC encoded/decoded data. It can be employed to reduce the disturbances caused by a neighboring cell in the NAND chip, thus reducing bit errors.

To enable the Randomizer module, set `GPMI_ECCCTRL[RANDOMIZER_ENABLE]` to 1, then set `GPMI_ECCCOUNT[RANDOMIZER_PAGE]` to select randomizer page number needed to be randomized. All these registers can be programmed by the DMA chain. The randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled,

GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

9.5.5 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically. The example code is shown below.

```
// A soft reset can take multiple clocks to complete, so do NOT gate the
// clock when setting soft reset. The reset process will gate the clock
// automatically. Poll until this has happened before subsequently
// preparing soft-reset and clock gate
BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
// asserting soft-reset
BCH_CTRL_SET(BM_BCH_CTRL_SFTRST);
// waiting for confirmation of soft-reset
while (!BCH_CTRL.B.CLKGATE)
{
// busy wait
}
// Done.
BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
```

9.5.6 BCH Memory Map/Register Definition

BCH Hardware Register Format Summary

BCH memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
3300_4000	Hardware BCH ECC Accelerator Control Register (BCH_CTRL)	32	R/W	C000_0000h	9.5.6.1/2480
3300_4004	Hardware BCH ECC Accelerator Control Register (BCH_CTRL_SET)	32	R/W	C000_0000h	9.5.6.1/2480

9.5.6.1 Hardware BCH ECC Accelerator Control Register (BCH_CTRLn)

The BCH CTRL provides overall control of the hardware ECC accelerator

Address: 3300_4000h base + 0h offset + (4d × i), where i=0d to 3d

BCH_CTRLn field descriptions

Field	Description
31 SFTRST	Set this bit to 0 to enable normal BCH operation. Set this bit to 1 (default) to disable clocking with the BCH and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the BCH block to its default state. This bit resets all state machines except for the AHB master state machine 0x0 RUN — Allow BCH to operate normally. 0x1 RESET — Hold BCH in reset.
30 CLKGATE	This bit must be set to 0 for normal operation. When set to 1 it gates off the clocks to the block. 0x0 RUN — Allow BCH to operate normally. 0x1 NO_CLKS — Do not clock BCH gates in order to minimize power consumption.
29–23 RSVD5	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUGSYNDROME	(For debug purposes only). Enable write of computed syndromes to memory on BCH decode operations. Computed syndromes will be written to the auxiliary buffer after the status block. Syndromes will be written as padded 16-bit values.
21–20 RSVD4	This field is reserved. This read-only field is reserved and always has the value 0
19–18 M2M_LAYOUT	Selects the flash page format for memory-to-memory operations.
17 M2M_ENCODE	Selects encode (parity generation) or decode (correction) mode for memory-to-memory operations.
16 M2M_ENABLE	NOTE! WRITING THIS BIT INITIATES A MEMORY-TO-MEMORY OPERATION. The BCH module must be inactive (not processing data from the GPMI) when this bit is set. The M2M_ENCODE and M2M_LAYOUT bits as well as the ENCODEPTR, DATAPTR, and METAPTR registers are used for memory-to-memory operations and must be correctly programmed before writing this bit.
15–11 RSVD3	This field is reserved. This read-only field is reserved and always has the value 0
10 DEBUG_STALL_IRQ_EN	1 = interrupt on debug stall mode is enabled. The IRQ is raised on every block
9 RSVD2	This field is reserved. This read-only field is reserved and always has the value 0.
8 COMPLETE_IRQ_EN	1 = interrupt on completion of correction is enabled.
7–4 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
3 BM_ERROR_IRQ	AHB Bus interface Error Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
2 DEBUG_STALL_IRQ	DEBUG STALL Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
1 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

BCH_CTRLn field descriptions (continued)

Field	Description
0 COMPLETE_IRQ	This bit indicates the state of the external interrupt line. Write a 1 to the SCT clear address to clear the interrupt status bit. NOTE: subsequent ECC completions will be held off as long as this bit is set. Be sure to read the data from BCH_STATUS0, 1 before clearing this interrupt bit.

9.5.6.2 Hardware ECC Accelerator Status Register 0 (BCH_STATUS0n)

The BCH STAT register provides visibility into the run-time status of the BCH and status information when processing is complete. It provides overall status of the hardware ECC accelerator.

Address: 3300_4000h base + 10h offset + (4d × i), where i=0d to 3d

BCH_STATUS0n field descriptions

Field	Description
31–20 HANDLE	Software supplies a 12 bit handle for this transfer as part of the GPMI DMA PIO operation that started the transaction. That handle passes down the pipeline and ends up here at the time the BCH interrupt is signaled.
19–16 COMPLETED_CE	This is the chip enable number corresponding to the NAND device from which this data came.
15–8 STATUS_BLK0	Count of symbols in error during processing of first block of flash (metadata block). The number of errors reported will be in the range of 0 to the ECC correction level for block 0. 0x00 ZERO — No errors found on block. 0x01 ERROR1 — One error found on block. 0x02 ERROR2 — One errors found on block. 0x03 ERROR3 — One errors found on block. 0x04 ERROR4 — One errors found on block. 0xFE UNCORRECTABLE — Block exhibited uncorrectable errors. 0xFF ERASED — Page is erased.
7–5 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
4 ALLONES	1 = All data bits of this transaction are ONE.
3 CORRECTED	1 = At least one correctable error encountered during last processing cycle.
2 UNCORRECTABLE	1 = Uncorrectable error encountered during last processing cycle.
RSVD0	This field is reserved.

Table continues on the next page...

BCH_STATUS0n field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.

9.5.6.3 Hardware ECC Accelerator Mode Register (BCH_MODEn)

The BCH MODE register provides additional mode controls.

Contains additional global mode controls for the BCH engine.

Address: 3300_4000h base + 20h offset + (4d × i), where i=0d to 3d

BCH_MODEn field descriptions

Field	Description
31–8 RSVD	This field is reserved. This read-only field is reserved and always has the value 0.
ERASE_ THRESHOLD	This value indicates the maximum number of zero bits on a flash subpage for it to be considered erased. For SLC NAND devices, this value should be programmed to 0 (meaning that the entire page should consist of bytes of 0xFF. For MLC NAND devices, bit errors may occur on reads (even on blank pages), so this threshold can be used to tune the erased page checking algorithm.

9.5.6.4 Hardware BCH ECC Loopback Encode Buffer Register (BCH_ENCODEPTRn)

When performing memory to memory operations, indicates the address of the encode buffer. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register.

For memory to memory operations, this register is used as the pointer to the encoded data, which is an output when encoding and an input while decoding.

Address: 3300_4000h base + 30h offset + (4d × i), where i=0d to 3d

BCH_ENCODEPTR n field descriptions

Field	Description
ADDR	Address pointer to encode buffer. This is the source for decode operations and the destination for encode operations. This value must be aligned on a 4 bytes boundary.

9.5.6.5 Hardware BCH ECC Loopback Data Buffer Register (BCH_DATAPTR n)

When performing memory to memory operations, indicates the address of the data buffer.

For memory to memory operations, this register is used as the pointer to the data to encode or the destination buffer for decode operations.

Address: 3300_4000h base + 40h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_DATAPTR n field descriptions

Field	Description
ADDR	Address pointer to data buffer. This is the source for encode operations and the destination for decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 byte boundary.

9.5.6.6 Hardware BCH ECC Loopback Metadata Buffer Register (BCH_METAPTR n)

When performing memory to memory operations, indicates the address of the metadata buffer.

For memory to memory operations, this register is used as the pointer to the metadata to encode or the extracted metadata for decode operations.

Address: 3300_4000h base + 50h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_METAPTR_n field descriptions

Field	Description
ADDR	Address pointer to metadata buffer. This is the source for encode metadata read operations and the destination for metadata decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 bytes boundary.

9.5.6.7 Hardware ECC Accelerator Layout Select Register (BCH_LAYOUTSELECT_n)

The BCH LAYOUTSELECT register provides a mapping of chip selects to layout registers.

When the BCH engine receives a request to process a data block from the GPMI interface, it will use this register to map the incoming chip select to one of the four possible flash layout registers

Address: 3300_4000h base + 70h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BCH_LAYOUTSELECT_n field descriptions

Field	Description
31–30 CS15_SELECT	Selects which layout is used for chip select 15.
29–28 CS14_SELECT	Selects which layout is used for chip select 14.
27–26 CS13_SELECT	Selects which layout is used for chip select 13.
25–24 CS12_SELECT	Selects which layout is used for chip select 12.
23–22 CS11_SELECT	Selects which layout is used for chip select 11.
21–20 CS10_SELECT	Selects which layout is used for chip select 10.
19–18 CS9_SELECT	Selects which layout is used for chip select 9.

Table continues on the next page...

BCH_LAYOUTSELECT n field descriptions (continued)

Field	Description
17–16 CS8_SELECT	Selects which layout is used for chip select 8.
15–14 CS7_SELECT	Selects which layout is used for chip select 7.
13–12 CS6_SELECT	Selects which layout is used for chip select 6.
11–10 CS5_SELECT	Selects which layout is used for chip select 5.
9–8 CS4_SELECT	Selects which layout is used for chip select 4.
7–6 CS3_SELECT	Selects which layout is used for chip select 3.
5–4 CS2_SELECT	Selects which layout is used for chip select 2.
3–2 CS1_SELECT	Selects which layout is used for chip select 1.
CS0_SELECT	Selects which layout is used for chip select 0.

9.5.6.8 Hardware BCH ECC Flash 0 Layout 0 Register (BCH_FLASH0LAYOUT0 n)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT1 register to control the format for the devices selecting layout 0 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections [Flash Page Layout](#) and [Determining the ECC layout for a device](#) for more detail information on setting up the flash layout registers.

62BIT Correcting ECC Accelerator (BCH)

Address: 3300_4000h base + 80h offset + (4d × i), where i=0d to 3d

BCH_FLASH0LAYOUT0n field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23–16 META_SIZE	Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design support from 0 to 255 bytes for metadata—if set to 0, no metadata will be stored. Metadata is stored before the associated data in block 0. If the DATA0_SIZE field is programmed to a 0, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and covered by a single parity block.
15–11 ECC0	Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 0x0 NONE — No ECC to be performed 0x1 ECC2 — ECC 2 to be performed 0x2 ECC4 — ECC 4 to be performed : — 0x1E ECC60 — ECC 60 to be performed 0x1F ECC62 — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATA0_SIZE	Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block only contains metadata.

9.5.6.9 Hardware BCH ECC Flash 0 Layout 1 Register (BCH_FLASH0LAYOUT1n)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT0 register to control the format for the device selecting layout 0 in the LAYOUTSELECT register.

Address: 3300_4000h base + 90h offset + (4d × i), where i=0d to 3d

BCH_FLASH0LAYOUT1n field descriptions

Field	Description
31–16 PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accommodate different flash configurations that may be available in the future.
15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 NONE — No ECC to be performed 0x1 ECC2 — ECC 2 to be performed 0x2 ECC4 — ECC 4 to be performed : — 0x1E ECC60 — ECC 60 to be performed 0x1F ECC62 — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

9.5.6.10 Hardware BCH ECC Flash 1 Layout 0 Register (BCH_FLASH1LAYOUT0n)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH1LAYOUT1 register to control the format for the devices selecting layout 1 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections [Flash Page Layout](#) and [Determining the ECC layout for a device](#) for more detail information on setting up the flash layout registers.

Address: 3300_4000h base + A0h offset + (4d × i), where i=0d to 3d

BCH_FLASH1LAYOUT0n field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.

DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

9.5.6.12 Hardware BCH ECC Flash 2 Layout 0 Register (BCH_FLASH2LAYOUT0n)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH2LAYOUT1 register to control the format for the devices selecting layout 2 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections [Flash Page Layout](#) and [Determining the ECC layout for a device](#) for more detail information on setting up the flash layout registers.

Address: 3300_4000h base + C0h offset + (4d × i), where i=0d to 3d

BCH_FLASH2LAYOUT0n field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that eight subsequent blocks are present for a total of nine blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23–16 META_SIZE	Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design support from 0 to 255 bytes for metadata—if set to 0, no metadata will be stored. Metadata is stored before the associated data in block 0. If the DATA0_SIZE field is programmed to a 0, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and will be covered by a single parity block.
15–11 ECC0	Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 0x0 NONE — No ECC to be performed 0x1 ECC2 — ECC 2 to be performed 0x2 ECC4 — ECC 4 to be performed : — 0x1E ECC60 — ECC 60 to be performed 0x1F ECC62 — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATA0_SIZE	Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block will only contain metadata.

9.5.6.13 Hardware BCH ECC Flash 2 Layout 1 Register (BCH_FLASH2LAYOUT1n)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH2LAYOUT0 register to control the format for the device selecting layout 2 in the LAYOUTSELECT register.

Address: 3300_4000h base + D0h offset + (4d × i), where i=0d to 3d

BCH_FLASH2LAYOUT1n field descriptions

Field	Description
31–16 PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accommodate different flash configurations that may be available in the future.
15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 NONE — No ECC to be performed 0x1 ECC2 — ECC 2 to be performed 0x2 ECC4 — ECC 4 to be performed : — 0x1E ECC60 — ECC 60 to be performed 0x1F ECC62 — ECC 62 to be performed

9.5.6.16 Hardware BCH ECC Debug Register0 (BCH_DEBUG0n)

The hardware BCH accelerator internal state machines and signals can be seen in the ECC debug register.

The BCH_DEBUG0 register provides access to various internal state information which might prove useful during hardware debug and validation.

Address: 3300_4000h base + 100h offset + (4d × i), where i=0d to 3d

62BIT Correcting ECC Accelerator (BCH)

BCH_DEBUG0n field descriptions

Field	Description
31–25 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
24–16 KES_DEBUG_ SYNDROME_ SYMBOL	The 9 bit value in this bit field shifts into the syndrome register array at the input of the KES engine whenever BCH_DEBUG0_KES_DEBUG_SHIFT_SYND is toggled. 0x0 NORMAL — Bus master address generator for SYND_GEN writes operates normally. 0x1 TEST_MODE — Bus master address generator always addresses last four bytes in Auxiliary block.
15 KES_DEBUG_ SHIFT_SYND	Toggling this bit causes the value in BCH_DEBUG0_KES_SYNDROME_SYMBOL to be shift into the syndrome register array at the input to the KES engine. After shifting in 16 symbols, one can kick off both KES and CF cycles by toggling BCH_DEBUG0_KES_DEBUG_KICK. Make sure that set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
14 KES_DEBUG_ PAYLOAD_FLAG	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input payload flag. 0x1 DATA — Payload is set for 512 bytes data block. 0x1 AUX — Payload is set for 65 or 19 bytes auxiliary block.
13 KES_DEBUG_ MODE4K	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input mode (4K or 2K pages). 0x1 4k — Mode is set for 4K NAND pages. 0x1 2k — Mode is set for 2K NAND pages.
12 KES_DEBUG_ KICK	Toggling causes KES engine FSM to start as if kick by the Bus Master. This allows stand alone testing of the KES and Chien Search engines. Be sure to set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
11 KES_ STANDALONE	Set to one, cause the KES engine to suppress toggling the KES_BM_DONE signal to the bus master and suppress toggling the CF_BM_DONE signal by the CF engine. 0x0 NORMAL — Bus master address generator for SYND_GEN writes operates normally. 0x1 TEST_MODE — Bus master address generator always addresses last four bytes in Auxiliary block.

Table continues on the next page...

BCH_DEBUG0n field descriptions (continued)

Field	Description
10 KES_DEBUG_STEP	Toggleing this bit causes the KES FSM to skip passed the stall state if it is in DEBUG_STALL mode and completed processing a block.
9 KES_DEBUG_STALL	Set to one to cause KES FSM to stall after notifying Chien search engine to start processing its block but before notifying the bus master that the KES computation is complete. This allows a diagnostic to stall the FSM after each blocks key equations are solved. This also has the effect of stalling the CSFE search engine so it's state can be examined after it finishes processing the KES stalled block. 0x0 NORMAL — KES FSM proceeds to next block supplied by bus master. 0x1 WAIT — KES FSM waits after current equations are solved and the search engine is started.
8 BM_KES_TEST_BYPASS	1 = Point all SYND_GEN writes to dummy area at the end of the AUXILLIARY block so that diagnostics can preload all payload, parity bytes and computed syndrome bytes for test the KES engine. 0x0 NORMAL — Bus master address generator for SYND_GEN writes operates normally. 0x1 TEST_MODE — Bus master address generator always addresses last four bytes in Auxilliary block.
7–6 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.
DEBUG_REG_SELECT	The value loaded in this bit field is used to select the internal register state view of KES engine or the Chien search engine.

9.5.6.17 KES Debug Read Register (BCH_DBGKESREADn)

The hardware BCH ECC accelerator key equation solver internal state machines and signals can be seen in the ECC debug registers.

Address: 3300_4000h base + 110h offset + (4d × i), where i=0d to 3d

9.6 General Purpose Media Interface (GPMI)

9.6.1 Overview

The GPMI controller is a flexible interface to supporting up to four NAND flash chip selects.

- ONFI3.2, DDR Mode, Samsung / Toshiba Toggle NAND protocol compatible.
- Fully configurable address and command behavior, providing support for future devices not yet specified.

The GPMI resides on the APBH. The GPMI also provides an interface to the BCH module to allow direct parity processing.

Registers are clocked on the HCLK domain. The I/O and pin timing are clocked on a dedicated GPMICK domain. GPMICK can be set to maximize I/O performance.

The following figure shows a block diagram of the GPMI controller.

General Purpose Media Interface (GPMI)

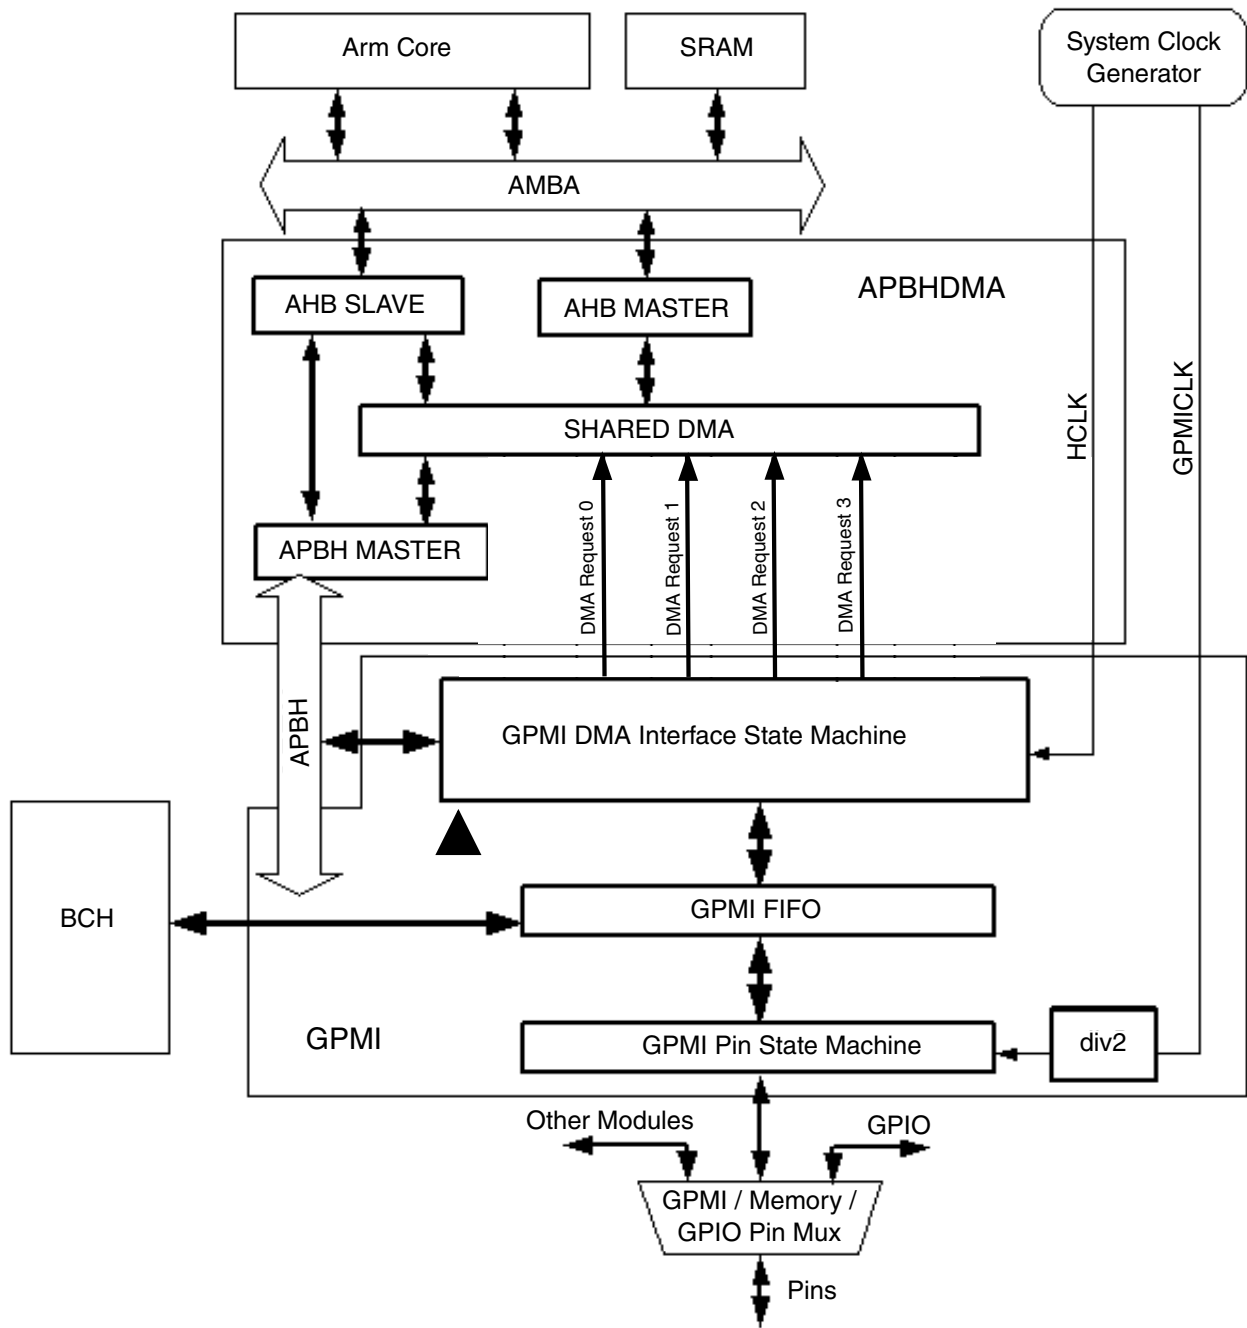

Figure 9-38. General-Purpose Media Interface Controller Block Diagram

9.6.2 External Signals

The table found here describes the external signals of GPMI.

Table 9-21. GPMI External Signals

Signal	Description	Pad	Mode	Direction
NAND_ALE	Address latch enable signal	SD3_CMD	ALT1	O
NAND_CE0_B	Chip enable signal	SAI1_TXC	ALT1	O
NAND_CE1_B	Chip enable signal	SAI1_RXD	ALT1	O
NAND_CE2_B	Chip enable signal	SAI1_RXFS	ALT1	O

9.6.3 Clocks

The table found here describes the clock sources for GPMI.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 9-22. GPMI Clocks

Clock name	Clock Root	Description
bch_input_apb_clk	nand_usdhc_bus_clk_root	BCH to APBH input clock
gpmi_bch_input_bch_clk	nand_usdhc_bus_clk_root	BCH input clock

Table continues on the next page...

Table 9-22. GPMI Clocks (continued)

Clock name	Clock Root	Description
gpmi_bch_input_gpmi_io_clk	nand_clk_root	GPMI IO input clock
gpmi_input_apb_clk	nand_usdhc_bus_clk_root	GPMI to APBH clock

9.6.4 GPMI NAND Mode

The general-purpose media interface has several features to efficiently support NAND:

- Individual chip select pins and ganged ready/busy pin for up to four NANDs.
- Individual state machine and DMA channel for each chip select.
- Special command modes work with DMA controller to perform all normal NAND functions without CPU intervention.
- Configurable timing based on a dedicated clock allows optimal balance of high NAND performance and low system power.

GPMI and DMA have been designed to handle complex multi-page operations without CPU intervention. The DMA uses a linked descriptor function with branching capability to automatically handle all of the operations needed to read/write multiple pages:

- **Data/Register Read/Write**-The GPMI can be programmed to read or write multiple cycles to the NAND address, command or data registers.
- **Wait for NAND Ready**-The GPMI's Wait-for-Ready mode can monitor the ready/busy signal of a single NAND flash and signal the DMA when the device has become ready. It also has a time-out counter and can indicate to the DMA that a time-out error has occurred. The DMAs can conditionally branch to a different descriptor in the case of an error.
- **Check Status**-The Read-and-Compare mode allows the GPMI to check NAND status against a reference. If an error is found, the GPMI can instruct the DMA to branch to an alternate descriptor, which attempts to fix the problem or asserts a CPU IRQ.

9.6.4.1 Multiple NAND Support

The GPMI supports up to four NAND chip selects, with ganged ready/busy pins. Since they share a data bus and control lines, the GPMI can only actively communicate with a single NAND at a time. However, all NANDs can concurrently perform internal read, write, or erase operations. With fast NAND flash and software support for concurrent

NAND operations, this architecture allows the total throughput to approach the data bus speed, which can be as high as 50 MB/s (8-bit bus running at 50 MHz single clock edge) in asynchronous mode and 200MB/s (8-bit bus running at 100MHz both clock edges) in Source Synchronous mode.

There are two options for controlling the four NAND chip selects via the DMA interface. The first option is the one to one mapping, where the each DMA channel is tied to its own NAND chip select. For example DMA channel 'n' accesses only NAND attached to chip select 'n'. The second option is the decoupled mode where a DMA channel can access any or all NAND chip selects connected to the GPMI. A DMA channel will signify the NAND chip select it wants to access by writing its chip select value in the GPMI_CTRL0[CS] field and setting the GPMI_CTRL1[DECOUPLE_CS] to 1. This option is useful if software chooses to use only one DMA channel to access all the attached NAND devices.

9.6.4.2 GPMI NAND Timing and Clocking

The dedicated clock, GPMICK, is used as a timing reference for NAND flash I/O. Since various NANDs have different timing requirements, GPMICK may need to be adjusted for each application.

While the actual pin timings are limited by the NAND chips used and the I/O pad configuration, the GPMI can support data bus speeds of up to 200 MHz x 8 bits. The actual read/write strobe timing parameters are adjusted as indicated in the register descriptions in Memory Map.

9.6.4.3 Basic NAND Timing

9.6.4.3.1 NAND Asynchronous Timing

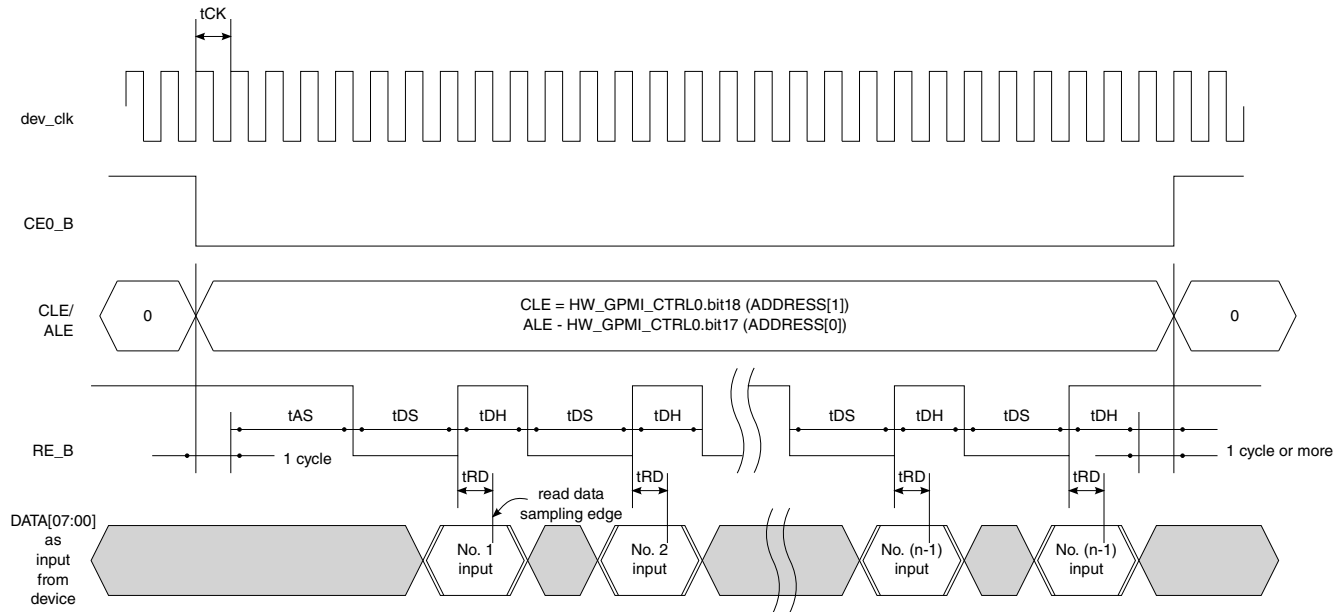

[Figure 9-40](#) and illustrates the operation of the output (from host to device) timing parameters in NAND ONFI asynchronous mode.

General Purpose Media Interface (GPMI)

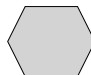

- tAS is configurable by programming HW_GPML_TIMING0 Address_Setup; in this example, Address_Setup = 4, tAS is equal to 4 dev_clk cycles.
- tDS is configurable by programming HW_GPML_TIMING0 Data_Setup; in this example, Data_Setup = 3, tDS is equal to 3 dev_clk cycles
- tDH is configurable by programming HW_GPML_TIMING0 Data_Hold; in this example, Data_Hold = 2, tDH is equal to 2 dev_clk cycles
- tAS/tDS/tDH will extend, if the output data is not ready in device fifo.

Figure 9-39. Asynchronous Mode Basic Write Timing Diagram (command write, address write, or data write)

- *tAS* is configurable by programming HW_GPML_TIMING0 Address_Setup; in this example, Address_Setup = 4, *tAS* is equal to 4 *dev_clk* cycles.
- *tDS* is configurable by programming HW_GPML_TIMING0 Data_Setup; in this example, Data_Setup = 3, *tDS* is equal to 3 *dev_clk* cycles
- *tDH* is configurable by programming HW_GPML_TIMING0 Data_Hold; in this example, Data_Hold = 2, *tDH* is equal to 2 *dev_clk* cycles
- *tRD* is the delay from *RE_B* rising edge to the read data sampling edge. If SDR DLL is not enabled, *tRD* is 0. If SDR DLL enabled, the delay depends on SDR DLL delay.
- *tAS/tDS/tDH* will extend, if the output data is not ready in device fifo.

 Host controller drives the DATA[07:00] bus
And also don't care if device will drive that or not and what will be driven

ONFI asynchronous mode basic read timing diagram
(data read)

Figure 9-40. ONFI Asynchronous Mode Basic Read Timing Diagram (data read)

9.6.4.3.2 NAND Asynchronous EDO Mode Timing

In high-speed NANDS, the read data may not be valid until after the read strobe (*NAND_RE_B*) deasserts. This is the case when the minimum *tDS* is programmed to achieve higher bandwidth.

The GPML implements a feedback read strobe to sample the read data. The feedback read strobe can be delayed to support fast nand EDO (Extended Data Out) timing where the read strobe may deassert before the read data is valid, and read data is valid for some time after read strobe. Nand EDO timings is applied typically for read cycle frequency above 33 MHz. See [Figure 9-41](#).

The GPML provides control over the amount of delay applied to the feedback read strobe. This delay depends on the maximum read access time (*tREA*) of the nand and the read pulse width (*tRP*) used to access the nand. *tRP* is specified by *GPML_TIMING0[DATA_SETUP]* register. When (*tREA* + 4ns) is less than *tRP*, no

delay is required to sample to nand read data. (The 4ns provides adequate data setup time for the GPMI.) In this case set $GPMI_CTRL1[HALF_PERIOD] = 0$;
 $GPMI_CTRL1[RDN_DELAY] = 0$; $GPMI_CTRL1[DLL_ENABLE] = 0$.

When $(t_{REA} + 4ns)$ is greater than or equal to t_{RP} , a delay of the feedback read strobe is required to sample to nand read data. This delay is equal to the difference between these two timings:

$$DELAY = t_{REA} + 4ns - t_{RP}$$

Since the GPMI delay chain is limited to 6ns maximum, if $DELAY > 6ns$ then increase t_{RP} by increasing the value of $GPMI_TIMING0[DATA_SETUP]$ until $DELAY$ is less than or equal to 6ns.

The GPMI programming for this $DELAY$ depends on the $GPMICLK$ period. The GPMI DLL will not function properly if the $GPMICLK$ period is greater than 12ns: disable the DLL if this is the case. If the $GPMICLK$ period is greater than 6ns (and not greater than 12ns), set the $GPMI_CTRL1[HALF_PERIOD]=1$; This will cause the DLL reference period (RP) to be one-half of the $GPMICLK$ period. If the $GPMICLK$ period is 6ns or less then set the $GPMI_CTRL1[HALF_PERIOD]=0$; This will cause the DLL reference period (RP) to be equal to the $GPMICLK$ period. $DELAY$ is a multiple (0 to 1.875) of RP.

The $GPMI_CTRL1[RDN_DELAY]$ is encoded as a 1-bit integer and 3-bit fraction delay factor. $DELAY$ is a multiple of the delay factor and the reference period. See table below for details.

Table 9-23. RDN DELAY

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
0	0.000
1	0.125
2	0.250
3	0.375
4	0.500
5	0.625
6	0.750
7	0.875
8	1.000
9	1.125
10	1.250
11	1.375
12	1.500
13	1.625

Table continues on the next page...

Table 9-23. RDN DELAY (continued)

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
14	1.750
15	1.875

$DELAY = DelayFactor \times RP$ or $DELAY = GPMI_CTRL1[RDN_DELAY] \times 0.125 \times RP$.

Use this equation to calculate the value for GPMI_CTRL1[RDN_DELAY]. Then set GPMI_CTRL1[DLL_ENABLE]=1.

Figure 9-41. NAND Read Path Timing

For example, a NAND with $tRE_{max} = 20$ ns, $tRP_{min} = 12$ ns, and $tRC_{min} = 25$ ns (read cycle time) may be programmed as follows:

- GPMICK clock frequency: Consider $480/6 = 80$ MHz which is 12.5 ns clock period. This is too close to the minimum NAND spec if we program the data setup and hold to 1 GPMICK cycle. Consider $480/7 = 68.57$ MHz which is 14.58 ns clock period. With data setup and hold set to 1, we have a tRP of 14.58 ns and a tRC of 29.16 ns (good margins).
- Since $(tREA + 4ns)$ is greater than tRP , required $DELAY = tREA + 4ns - tRP = 20 + 4 - 14.58ns = 9.42$ ns.

- $\text{GPMI_CTRL1[HALF_PERIOD]} =$, since GPMICLK period is ns. So $\text{RP} = \text{GPMICLK period} = \text{ns}$.
- $\text{DELAY} = \text{GPMI_CTRL1[RDN_DELAY]} \times 0.125 \times \text{RP}$. $9.42 \text{ ns} = \text{GPMI_CTRL1[RDN_DELAY]} \times 0.125 \times \text{ns}$. $\text{GPMI_CTRL1[RDN_DELAY]} =$

NOTE

It is recommended that the drive strength of NAND_RE_B and NAND_WE_B output pins be set to 8 mA. This will reduce the transition time under heavy loads. Low transition times will be important when NAND interface read and write cycle times are below 30 ns. The other GPMI pins may remain at 4 mA, since their frequency is only up to half that of NAND_RE_B and NAND_WE_B.

9.6.4.3.3 NAND ONFI Source Synchronous Mode Timing

NOTE

In the following figures, CLK shares the same pin as WE_B in Async Mode. And W/R# shares the same pin as RE_B in Async Mode.

$$tCR = (HW_GPMI_TIMING2.TCR + 1) * tCK$$

$$tRPSTH = HW_GPMI_TIMING2.TRPSTH * tCK$$

Figure 9-51. Toggle Mode Data Read Timing Diagram

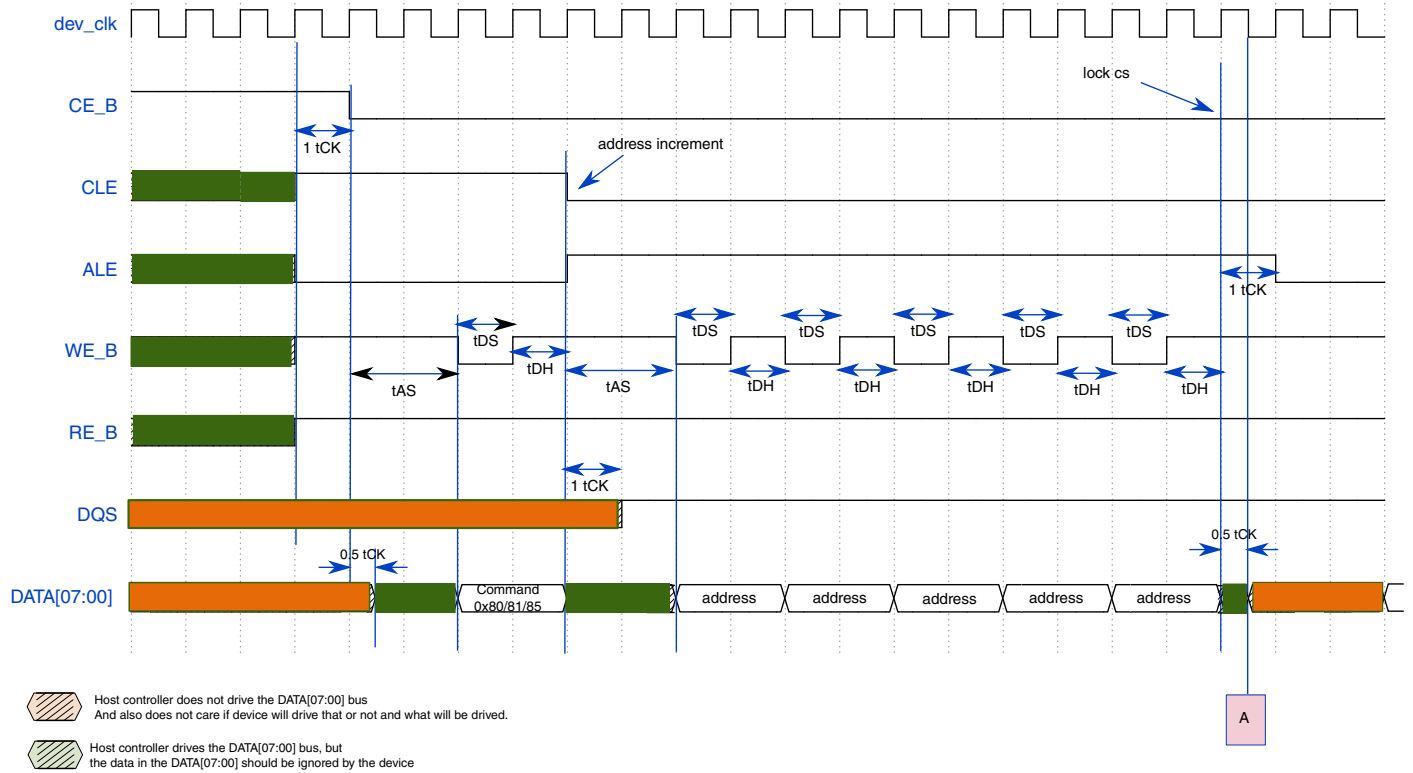

Figure 9-52. Toggle Mode Program Timing Diagram (A)

General Purpose Media Interface (GPMI)

Figure 9-53. Toggle Mode Program Timing Diagram (B)

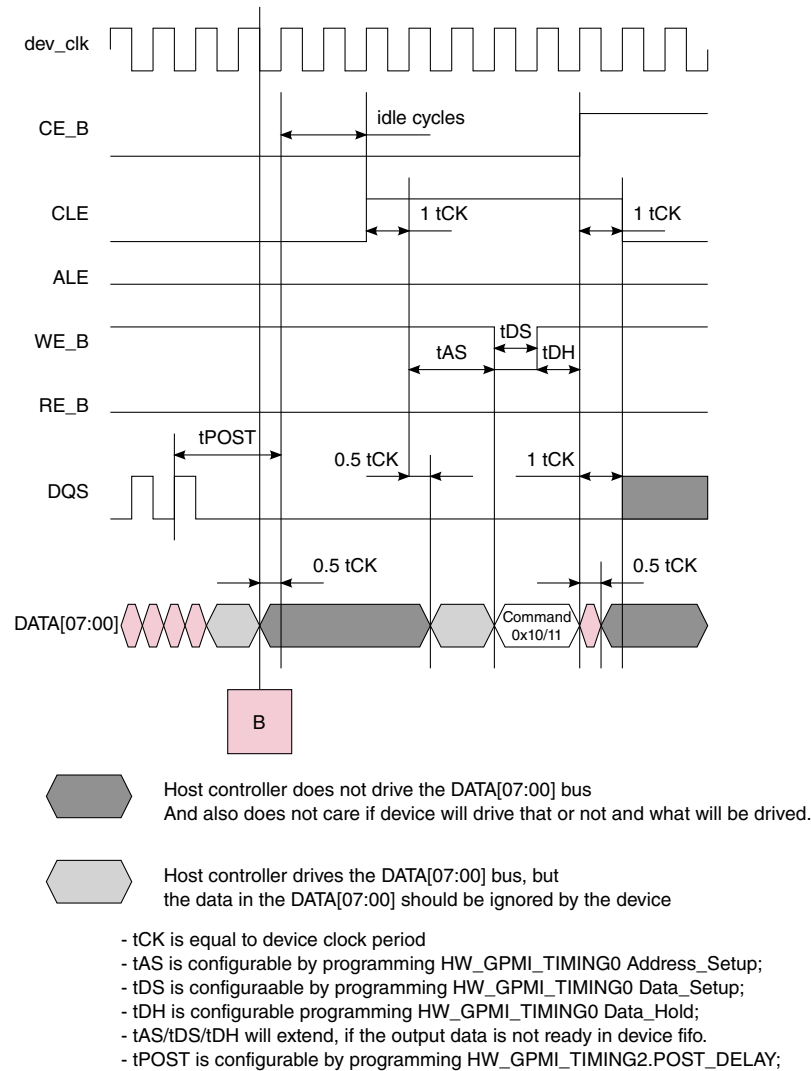

Figure 9-54. Toggle Mode Program Timing Diagram (C)

9.6.4.4 Hardware BCH Interface

The GPMI provides an interface to the BCH module. This reduces the SOC bus traffic and the software involvement.

The GPMI also provides an interface to the Randomizer module. The Randomizer can generate random data based on BCH ECC encoded / decoded data. It can be employed to reduce the disturbances caused by neighboring cells in the NAND chip, thus reducing bit errors. To enable the Randomizer module, set GPMI_ECCCTRL[RANDOMIZER_ENABLE] to 1, then set GPMI_ECCCOUNT[RANDOMIZER_PAGE] to select randomizer page number needed

to be randomized. All these registers can be programmed by the DMA chain. The randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled, GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

When BCH ECC is enable, parity information is inserted on-the-fly during writes to 8-bit NAND devices. The BCH will supply payload and parity to the GPMI to write to the NAND. During NAND reads, parity is checked and ECC processing is performed after each read block. In this case the GPMI reads the NAND device and redirects the data and parity to the BCH module for ECC processing.

To program the BCH for NAND writes, remove the soft reset and clock gates from BCH_CTRL[SFTRST] and BCH_CTRL[CLKGATE]. The bulk of BCH programming is actually applied to the GPMI via PIO operations embedded in its DMA command structures. This has a subtle implication when writing to the GPMI ECC registers: access to the these registers must be written in progressive register order. Thus, to write to the GPMI_ECCECOUNT register, write first (in order) to registers GPMI_CTRL0, GPMI_COMPARE, and GPMI_ECCCTRL before writing to GPMI_ECCECOUNT. These additional register writes need to be accounted for in the CMDWORDS field of the respective DMA channel command register.

NOTE

Note that the GPMI_PAYLOAD and GPMI_AUXILIARY pointers need to be word-aligned for proper ECC operation. If those pointers are non-word-aligned, then the BCH engine will not operate properly and could possibly corrupt system memory in the adjoining memory regions.

9.6.5 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST. The reset process gates the clocks automatically.

9.6.6 GPMI Memory Map/Register Definition

The following registers provide control for programmable elements of the GPMI module.

NOTE

All ATA or UDMA features are not supported for the chip.

NOTE

GPMI does not support the Set feature command in Toggle mode. The NANDF_DQS output is only enabled in program operation for Toggle mode, but the Set feature command also needs to use the NANDF_DQS signal to write data to Toggle NAND flash. So the Set feature command in Toggle mode is not supported.

9.6.6.1 GPMI Control Register 0 Description (GPMI_CTRL0n)

The GPMI control register 0 specifies the GPMI transaction to perform for the current command chain item.

Address: 3300_2000h base + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_CTRL0n field descriptions

Field	Description
31 SFTRST	Set to zero for normal operation. When this bit is set to one (default), then the entire block is held in its reset state. This will not work if the CLKGATE bit is already set to '1'. CLKGATE must be cleared to '0' before issuing a soft reset. Also the GPMICLK must be running for this to work properly. RUN = 0x0 Allow GPMI to operate normally. RESET = 0x1 Hold GPMI in reset.
30 CLKGATE	Set this bit zero for normal operation. Setting this bit to one (default), gates all of the block level clocks off for minimizing AC energy consumption. RUN = 0x0 Allow GPMI to operate normally. NO_CLKS = 0x1 Do not clock GPMI gates in order to minimize power consumption.
29 RUN	The GPMI is busy running a command whenever this bit is set to '1'. The GPMI is idle whenever this bit set to zero. This can be set to one by a CPU write. In addition, the DMA sets this bit each time a DMA command has finished its PIO transfer phase. IDLE = 0x0 The GPMI is idle. BUSY = 0x1 The GPMI is busy running a command.

Table continues on the next page...

GPMI_CTRL0n field descriptions (continued)

Field	Description
28 DEV_IRQ_EN	When set to '1' and ATA_IRQ pin is asserted, the GPMI_IRQ output will assert.
27 LOCK_CS	For ATA/NAND mode: 0= Deassert chip select (CS) after RUN is complete. 1= Continue to assert chip select (CS) after RUN is complete. For Camera Mode: 0= Dont wait for VSYNC rising edge before capturing data. 1= Wait for VSYNC rising edge before capturing data (Camera mode only). DISABLED = 0x0 Deassert chip select (CS) after RUN is complete. ENABLED = 0x1 Continue to assert chip select (CS) after RUN is complete.
26 UDMA	DISABLED = 0x0 Use ATA-PIO mode on the external bus. ENABLED = 0x1 Use ATA-Ultra DMA mode on the external bus. 0 Use ATA-PIO mode on the external bus. 1 Use ATA-Ultra DMA mode on the external bus.
25–24 COMMAND_ MODE	WRITE = 0x0 Write mode. READ = 0x1 Read mode. READ_AND_COMPARE = 0x2 Read and Compare mode (setting sense flop). WAIT_FOR_READY = 0x3 Wait for Ready mode. For ATA WAIT_FOR_READY command set CS=01. 00 Write mode. 01 Read Mode. 10 Read and Compare Mode (setting sense flop). 11 Wait for Ready.
23 WORD_LENGTH	This bit should only be changed when RUN==0. Reserve = 0x0 Reserved. 8_BIT = 0x1 8-bit Data Bus mode. 0 Reserved. 1 8-bit Data Bus mode.
22–20 CS	Selects which chip select is active for this command. For ATA WAIT_FOR_READY command, this must be set to b01.
19–17 ADDRESS	Specifies the three address lines for ATA mode. In NAND mode, use A0 for CLE and A1 for ALE. NAND_DATA = 0x0 In NAND mode, this address is used to read and write data bytes. NAND_CLE = 0x1 In NAND mode, this address is used to write command bytes. NAND_ALE = 0x2 In NAND mode, this address is used to write address bytes.
16 ADDRESS_ INCREMENT	In ATA mode, the address will increment with each cycle. In NAND mode, the address will increment once, after the first cycle (going from CLE to ALE). DISABLED = 0x0 Address does not increment. ENABLED = 0x1 Increment address. 0 Address does not increment. 1 Increment address.
XFER_COUNT	Number of bytes to transfer for this command. A value of zero will transfer 64K bytes.

9.6.6.2 GPMI Compare Register Description (GPMI_COMPARE)

The GPMI compare register specifies the expect data and the xor mask for comparing to the status values read from the device. This register is used by the Read and Compare command.

GPMI_COMPARE 0x010

Address: 3300_2000h base + 10h offset = 3300_2010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MASK																REFERENCE															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_COMPARE field descriptions

Field	Description
31–16 MASK	16-bit mask which is applied after the read data is XORed with the REFERENCE bit field.
REFERENCE	16-bit value which is XORed with data read from the NAND device.

9.6.6.3 GPMI Integrated ECC Control Register Description (GPMI_ECCCTRL_n)

The GPMI ECC control register handles configuration of the integrated ECC / Randomizer accelerator.

Address: 3300_2000h base + 20h offset + (4d × i), where i=0d to 3d

GPMI_ECCCTRL_n field descriptions

Field	Description
31–16 HANDLE	This is a register available to software to attach an identifier to a transaction in progress. This handle will be available from the ECC register space when the completion interrupt occurs.
15 RSVD2	Always write zeroes to this bit field.
14–13 ECC_CMD	ECC Command information. DECODE = 0x0 Decode. ENCODE = 0x1 Encode. RESERVE2 = 0x2 Reserved. RESERVE3 = 0x3 Reserved.
12 ENABLE_ECC	Enable ECC processing of GPMI transfers. ENABLE = 0x1 Use integrated ECC for read and write transfers. DISABLE = 0x0 Integrated ECC remains in idle.
11 RANDOMIZER_ENABLE	Enable randomizer function. If this bit is set to enable, ENABLE_ECC should be also enable.

Table continues on the next page...

GPMI_ECCCTRLn field descriptions (continued)

Field	Description
	0x0 disable 0x1 enable
10–9 RANDOMIZER_ TYPE	Set randomizer type 0x00 Type 0 0x01 Type 1 0x10 Type 2
BUFFER_MASK	ECC buffer information. The BCH error correction only allows two configurations of the buffer mask - software may either read just the first block on the flash page or the entire flash page. Write operations must be for the entire flash page. Invalid buffer mask values will cause the DMA descriptor command to be terminated. BCH_AUXONLY = 0x100 Set to request transfer from only the auxiliary buffer (block 0 on flash). BCH_PAGE = 0x1FF Set to request transfer to/from the entire page.

9.6.6.4 GPMI Integrated ECC Transfer Count Register Description (GPMI_ECCCOUNT)

The GPMI ECC Transfer Count Register contains the count of bytes that flow through the ECC / Randomizer subsystem.

GPMI_ECCCOUNT 0x030

Address: 3300_2000h base + 30h offset = 3300_2030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
R	0																																															
W	0																RANDOMIZER_PAGE																COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0																

GPMI_ECCCOUNT field descriptions

Field	Description
31–24 -	Always write zeroes to this bit field.
23–16 RANDOMIZER_ PAGE	Set NAND page number needed to be randomized. The value is between 0-255
COUNT	Number of bytes to pass through ECC. This is the GPMI transfer count plus the syndrome count that will be inserted into the stream by the ECC. In DMA2ECC_MODE this count must match the GPMI_CTRL0_XFER_COUNT. A value of zero will transfer 64K words.

9.6.6.5 GPMI Payload Address Register Description (GPMI_PAYLOAD)

The GPMI payload address register specifies the location of the data buffers in system memory. This value must be word aligned.

GPMI_PAYLOAD 0x040

Address: 3300_2000h base + 40h offset = 3300_2040h

GPMI_PAYLOAD field descriptions

Field	Description
31–2 ADDRESS	Pointer to an array of one or more 512 byte payload buffers.
RSVD0	Always write zeroes to this bit field.

9.6.6.6 GPMI Auxiliary Address Register Description (GPMI_AUXILIARY)

The GPMI auxiliary address register specifies the location of the auxiliary buffers in system memory. This value must be word aligned.

GPMI_AUXILIARY 0x050

Address: 3300_2000h base + 50h offset = 3300_2050h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADDRESS															RSVD0
W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_AUXILIARY field descriptions

Field	Description
31–2 ADDRESS	Pointer to ECC control structure and meta-data storage.
RSVD0	Always write zeroes to this bit field.

9.6.6.7 GPMI Control Register 1 Description (GPMI_CTRL1n)

The GPMI control register 1 specifies additional control fields that are not used on a per-transaction basis.

Address: 3300_2000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

GPMI_CTRL1n field descriptions

Field	Description
31 DEV_CLK_STOP	set this bit to 1 will stop gpmi io working clk.
30 SSYNC_CLK_STOP	set this bit to 1 will stop the source synchronous mode clk.

Table continues on the next page...

GPMI_CTRL1n field descriptions (continued)

Field	Description
29 WRITE_CLK_STOP	In onfi source synchronous mode, host may save power during the data write cycles by holding the CLK signal high (i.e. stopping the CLK). The host may only stop the CLK during data write, by setting this bit to 1, if the device supports this feature as indicated in the parameter page.
28 TOGGLE_MODE	enable samsung toggle mode.
27 GPMI_CLK_DIV2_EN	This bit should be reset to 0 in asynchronous mode. The frequency ratio of (device clock : ccm gpmi clock) will be (1 : 1). This bit should be set to 1, in source synchronous mode or toggle mode. The frequency ratio of (device clock : ccm gpmi clock) will be (1 : 2). enable the gpmi clk divider. 0x0 internal factor-2 clock divider is disabled 0x1 internal factor-2 clock divider is enabled.
26 UPDATE_CS	force the CS value is be updated to external chip select pin, even GPMI is idle.
25 SSYNCMODE	source synchronous mode 1 or asynchronous mode 0. ASYNC = 0x0 Asynchronous mode. SSYNC = 0x1 Source Synchronous mode.
24 DECOUPLE_CS	Decouple Chip Select from DMA Channel. Setting this bit to 1 will allow a DMA channel to specify any value in the CTRL0_CS register field. Software can use one DMA channel to access all 8 Nand devices.
23–22 WRN_DLY_SEL	Since the GPMI write strobe (WRN) is a fast clock pin, the delay on this signal can be programmed to match the load on this pin. 0 = ~2ns; 1 = ~4ns; 2 = ~6ns; 3 = no delay.
21 TEST_TRIGGER	Test Trigger Enable 0 Disable 1 Enable
20 TIMEOUT_IRQ_EN	Setting this bit to '1' will enable timeout IRQ for transfers in ATA mode only, and for WAIT_FOR_READY commands in both ATA and Nand mode. The Device_Busy_Timeout value is used for this timeout.
19 GANGED_RDYBUSY	Set this bit to 1 will force all Nand RDY_BUSY inputs to be sourced from (tied to) RDY_BUSY0. This will free up all, except one, RDY_BUSY input pins.
18 BCH_MODE	This bit selects which error correction unit will access GPMI. This bit must always be set to '1', since only the BCH unit is available in this design.
17 DLL_ENABLE	Set this bit to 1 to enable the GPMI DLL. This is required for fast NAND reads (above 30 MHz read strobe). After setting this bit, wait 64 GPMI clock cycles for the DLL to lock before performing a NAND read.
16 HALF_PERIOD	Set this bit to 1 if the GPMI clock period is greater than 16ns for proper DLL operation. DLL_ENABLE must be zero while changing this field.
15–12 RDN_DELAY	This variable is a factor in the calculated delay to apply to the internal read strobe for correct read data sampling. The applied delay (AD) is between 0 and 1.875 times the reference period (RP). RP is one half of the GPMI clock period if HALF_PERIOD=1 otherwise it is the full GPMI clock period. The equation is: AD = RDN_DELAY x 0.125 x RP. This value must not exceed 16ns.

Table continues on the next page...

GPMI_CTRL1n field descriptions (continued)

Field	Description
	This variable is used to achieve faster NAND access. For example if the Read Strobe is asserted from time 0 to 13ns but the read access time is 20ns, then choose AD=12ns will cause the data to be sampled at time 25ns (13+12) giving a 5ns data setup time. If RP=13ns then $RDN_DELAY = 12 / (0.125 \times 13ns)$ = 7.38 (0111b). DLL_ENABLE must be zero while changing this field.
11 DMA2ECC_ MODE	This is mainly for testing HWECC without involving the Nand device. Setting this bit will cause DMA write data to redirected to HWECC module (instead of Nand Device) for encoding or decoding.
10 DEV_IRQ	This bit is set when an Interrupt is received from the ATA device. Write 0 to clear.
9 TIMEOUT_IRQ	This bit is set when a timeout occurs using the Device_Busy_Timeout value. Write 0 to clear.
8 BURST_EN	When set to 1 each DMA request will generate a 4-transfer burst on the APB bus.
7 ABORT_WAIT_ REQUEST	Request to abort "wait for ready" command on channel indicated by ABORT_WAIT_FOR_READY_CHANNEL. Hardware will clear this bit when abort is done.
6-4 ABORT_WAIT_ FOR_READY_ CHANNEL	Abort a wait for ready command on selected channel. Set the ABORT_WAIT_REQUEST to kick of operation.
3 DEV_RESET	ENABLED = 0x0 NANDF_WP_B(WPN) pin is held low (asserted). DISABLED = 0x1 NANDF_WP_B(WPN) pin is held high (de-asserted). 0 NANDF_WP_B pin is held low (asserted). 1 NANDF_WP_B pin is held high (de-asserted).
2 ATA_IRQRDY_ POLARITY	For ATA MODE: Note NAND_RDY_BUSY[3:2] are not affected by this bit. ACTIVELOW = 0x0 ATA IORDY and IRQ are active low, or NAND_RDY_BUSY[1:0] are active low ready. ACTIVEHIGH = 0x1 ATA IORDY and IRQ are active high, or NAND_RDY_BUSY[1:0] are active high ready. 0 External ATA IORDY and IRQ are active low. 1 External ATA IORDY and IRQ are active high. For NAND MODE: 0 External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when low and busy when high. 1 External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when high and busy when low.
1 CAMERA_MODE	When set to 1 and ATA UDMA is enabled the UDMA interface becomes a camera interface.
0 GPMI_MODE	ATA mode is only supported on channel zero. If ATA mode is selected, then only channel three is available for NAND use. NAND = 0x0 NAND mode. ATA = 0x1 ATA mode.

Table continues on the next page...

GPMI_CTRL1n field descriptions (continued)

Field	Description
0	NAND mode.
1	ATA mode.

9.6.6.8 GPMI Timing Register 0 Description (GPMI_TIMING0)

The GPMI timing register 0 specifies the timing parameters that are used by the cycle state machine to guarantee the various setup, hold and cycle times for the external media type.

GPMI_TIMING0 0x070

Address: 3300_2000h base + 70h offset = 3300_2070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPMI_TIMING0 field descriptions

Field	Description
31–24 RSVD1	Always write zeroes to this bit field.
23–16 ADDRESS_SETUP	Number of GPMICKL cycles that the CE/ADDR signals are active before a strobe is asserted. A value of zero is interpreted as 0. For ATA PIO modes this is known in the ATA7 specification as "Address valid to DIOR-/DIOW- setup"
15–8 DATA_HOLD	Data bus hold time in GPMICKL cycles. Also the time that the data strobe is de-asserted in a cycle. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as "DIOR-/DIOW- recovery time"
DATA_SETUP	Data bus setup time in GPMICKL cycles. Also the time that the data strobe is asserted in a cycle. This value must be greater than 2 for ATA devices that use IORDY to extend transfer cycles. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as ""DIOR-/DIOW-"

9.6.6.9 GPMI Timing Register 1 Description (GPMI_TIMING1)

The GPMI timing register 1 specifies the timeouts used when monitoring the NAND READY pin or the ATA IRQ and IOWAIT signals.

GPMI_TIMING1 0x080

Address: 3300_2000h base + 80h offset = 3300_2080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPMI_TIMING1 field descriptions

Field	Description
31–16 DEVICE_BUSY_ TIMEOUT	Timeout waiting for NAND Ready/Busy or ATA IRQ. Used in WAIT_FOR_READY mode. This value is the number of GPMI_CLK cycles multiplied by 4096.
RSVD1	Always write zeroes to this bit field.

9.6.6.10 GPMI Timing Register 2 Description (GPMI_TIMING2)

The GPMI timing register 2 specifies the double data rate timing parameters that are used by the cycle state machine to guarantee the various cs delay, pre-amble delay, post-amble delay, command/address delay, data delay, TCR, TRPSTH, and read latency cycle times for the external media type.

GPMI_TIMING2 0x090

Address: 3300_2000h base + 90h offset = 3300_2090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPMI_TIMING2 field descriptions

Field	Description
31–29 TRPSTH	Only for Toggle NAND timing control delay TRPSTH GPMICLK cycles for CEn_B high to RE_B high, A value of zero is interpreted as 8
28–27 TCR	Only for Toggle NAND timing control delay (TCR+1) GPMICLK cycles for CEn_B low to RE_B low, 0 is less than or equal to TCR, which is less than the PREAMBLE_DELAY
26–24 READ_ LATENCY	This field is for double data rate read latency configuration. others READ LATENCY is 3 000 READ LATENCY is 0 001 READ LATENCY is 1 010 READ LATENCY is 2 011 READ LATENCY is 3 100 READ LATENCY is 4 101 READ LATENCY is 5

Table continues on the next page...

GPMI_TIMING2 field descriptions (continued)

Field	Description
23–21 RSVD0	Always write zeroes to this bit field.
20–16 CE_DELAY	GPMI dealy from CEn assert to W/Rn changing edge. value of zero is interpreted as 32.
15–12 PREAMBLE_ DELAY	GPMI pre-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
11–8 POSTAMBLE_ DELAY	GPMI post-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
7–4 CMDADD_ PAUSE	GPMI delay time from command or adres pause to command or address resume in GPMICLK cycles. A value of zero is interpreted as 16.
DATA_PAUSE	GPMI delay time from data pause to data resume in GPMICLK cycles. A value of zero is interpreted as 16.

9.6.6.11 GPMI DMA Data Transfer Register Description (GPMI_DATA)

The GPMI DMA data transfer register is used by the DMA to read or write data to or from the ATA/NAND control state machine.

GPMI_DATA 0x0A0

Address: 3300_2000h base + A0h offset = 3300_20A0h

GPMI_DATA field descriptions

Field	Description
DATA	In 8-bit mode, one, two, three or four bytes can can be accessed to send the same number of bus cycles.

9.6.6.12 GPMI Status Register Description (GPMI_STAT)

The GPMI control and status register provides a read back path for various operational states of the GPMI controller.

GPMI_STAT 0x0B0

Address: 3300_2000h base + B0h offset = 3300_20B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	READY_BUSY								RDY_TIMEOUT

GPMI_STAT field descriptions

Field	Description
31–24 READY_BUSY	Read-only view of NAND Ready_Busy Input pins.
23–16 RDY_TIMEOUT	<p>State of the RDY/BUSY Timeout Flags. When any bit is set to '1' in this field, it indicates that a time out has occurred while waiting for the ready state of the requested NAND device. Multiple bits may be set simultaneously.</p> <p>When GPMI_CTRL1_DECOUPLE_CS = 0, RDY_TIMEOUT[n] is associated with the NAND device on chip_select[n].</p> <p>When GPMI_CTRL1_DECOUPLE_CS = 1, these flags become associated to a DMA channel instead of a NAND device.</p> <p>For example if DMA channel 6 sends a WAIT_FOR_READY command for NAND Device 2, and a timeout occurred on READY_BUSY2, then READY_TIMEOUT[6] will be set instead of READY_TIMEOUT[2].</p>
15 DEV7_ERROR	<p>DMA channel 7 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 7. 1 An Error has occurred on ATA/NAND Device accessed by</p>
14 DEV6_ERROR	<p>DMA channel 6 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 6. 1 An Error has occurred on ATA/NAND Device accessed by</p>
13 DEV5_ERROR	<p>DMA channel 5 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 5. 1 An Error has occurred on ATA/NAND Device accessed by</p>
12 DEV4_ERROR	<p>DMA channel 4 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 4. 1 An Error has occurred on ATA/NAND Device accessed by</p>
11 DEV3_ERROR	<p>DMA channel 3 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 3. 1 An Error has occurred on ATA/NAND Device accessed by</p>
10 DEV2_ERROR	<p>DMA channel 2 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 2. 1 An Error has occurred on ATA/NAND Device accessed by</p>
9 DEV1_ERROR	<p>DMA channel 1 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 1. 1 An Error has occurred on ATA/NAND Device accessed by</p>
8 DEV0_ERROR	<p>DMA channel 0 (Timeout or compare failure, depending on COMMAND_MODE).</p> <p>0 No error condition present on ATA/NAND Device accessed by DMA channel 0. 1 An Error has occurred on ATA/NAND Device accessed by</p>
7–5 RSVD1	Always write zeroes to this bit field.

Table continues on the next page...

GPMI_STAT field descriptions (continued)

Field	Description
4 ATA_IRQ	Status of the ATA_IRQ input pin.
3 INVALID_BUFFER_MASK	Buffer Mask Validity bit. 0 ECC Buffer Mask is not invalid. 1 ECC Buffer Mask is invalid.
2 FIFO_EMPTY	NOT_EMPTY = 0x0 FIFO is not empty. EMPTY = 0x1 FIFO is empty. 0 FIFO is not empty. 1 FIFO is empty.
1 FIFO_FULL	NOT_FULL = 0x0 FIFO is not full. FULL = 0x1 FIFO is full. 0 FIFO is not full. 1 FIFO is full.
0 PRESENT	UNAVAILABLE = 0x0 GPMI is not present in this product. AVAILABLE = 0x1 GPMI is present in this product. 0 GPMI is not present in this product. 1 GPMI is present is in this product.

9.6.6.13 GPMI Debug Information Register Description (GPMI_DEBUG)

The GPMI debug information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

GPMI_DEBUG 0x0C0

Address: 3300_2000h base + C0h offset = 3300_20C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	WAIT_FOR_READY_END								DMA_SENSE								DMAREQ				CMD_END												
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_DEBUG field descriptions

Field	Description
31–24 WAIT_FOR_READY_END	Read Only view of the Wait_For_Ready End toggle signals to DMA. One per channel

Table continues on the next page...

GPMI_DEBUG field descriptions (continued)

Field	Description
23–16 DMA_SENSE	Read-only view of sense state of the 8 DMA channels. A value of "1" in any bit position indicates that a read and compare command failed or a timeout occurred for the corresponding channel.
15–8 DMAREQ	Read-only view of DMA request line for 8 DMA channels. A toggle on any bit position indicates a DMA request for the corresponding channel.
CMD_END	Read Only view of the Command End toggle signals to DMA. One per channel

9.6.6.14 GPMI Version Register Description (GPMI_VERSION)

This register reflects the version number for the GPMI.

GPMI_VERSION 0x0D0

Address: 3300_2000h base + D0h offset = 3300_20D0h

GPMI_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

9.6.6.15 GPMI Debug2 Information Register Description (GPMI_DEBUG2)

The GPMI Debug2 information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

GPMI_DEBUG2 0x0E0

Address: 3300_2000h base + E0h offset = 3300_20E0h

GPMI_DEBUG2 field descriptions

Field	Description
31–28 RSVD1	Always write zeroes to this bit field.
27–24 UDMA_STATE	USM_IDLE = 4'h0, idle USM_DMARQ = 4'h1, DMA req USM_ACK = 4'h2, DMA ACK USM_FIFO_E = 4'h3, Fifo empty USM_WPAUSE = 4'h4, WR DMA Paused by device USM_TSTRB = 4'h5, Toggle HSTROBE USM_CAPTUR = 4'h6, Capture Stage, (data sampled with DSTROBE is valid) USM_DATOUT = 4'h7, Change Burst DATAOUT USM_CRC = 4'h8, Source CRC to Device USM_WAIT_R = 4'h9, Waiting for DDMARDY- USM_END = 4'ha; Negate DMAACK (end of DMA) USM_WAIT_S = 4'hb, Waiting for DSTROBE USM_RPAUSE = 4'hc, Rd DMA Paused by Host USM_RSTOP = 4'hd, Rd DMA Stopped by Host USM_WTERM = 4'he, Wr DMA Termination State USM_RTERM = 4'hf, Rd DMA Termination state
23 BUSY	When asserted the GPMI is busy. Undefined results may occur if any registers are written when BUSY is asserted. DISABLED = 0x0 The GPMI is not busy. ENABLED = 0x1 The GPMI is busy.
22–20 PIN_STATE	parameter PSM_IDLE = 3'h0, PSM_BYTCNT = 3'h1, PSM_ADDR = 3'h2, PSM_STALL = 3'h3, PSM_STROBE = 3'h4, PSM_ATARDY = 3'h5, PSM_DHOLD = 3'h6, PSM_DONE = 3'h7. PSM_IDLE = 0x0 PSM_BYTCNT = 0x1 PSM_ADDR = 0x2 PSM_STALL = 0x3 PSM_STROBE = 0x4 PSM_ATARDY = 0x5 PSM_DHOLD = 0x6 PSM_DONE = 0x7
19–16 MAIN_STATE	parameter MSM_IDLE = 4'h0, MSM_BYTCNT = 4'h1, MSM_WAITFE = 4'h2, MSM_WAITFR = 4'h3, MSM_DMAREQ = 4'h4, MSM_DMAACK = 4'h5, MSM_WAITFF = 4'h6, MSM_LDFIFO = 4'h7, MSM_LDDMAR = 4'h8, MSM_RDCMP = 4'h9, MSM_DONE = 4'ha. MSM_IDLE = 0x0 MSM_BYTCNT = 0x1 MSM_WAITFE = 0x2 MSM_WAITFR = 0x3

Table continues on the next page...

GPMI_DEBUG2 field descriptions (continued)

Field	Description
	MSM_DMAREQ = 0x4 MSM_DMAACK = 0x5 MSM_WAITFF = 0x6 MSM_LDFIFO = 0x7 MSM_LDDMAR = 0x8 MSM_RDCMP = 0x9 MSM_DONE = 0xA
15–12 SYND2GPMI_BE	Data byte enable Input from BCH.
11 GPMI2SYND_VALID	Data handshake output to BCH.
10 GPMI2SYND_READY	Data handshake output to BCH.
9 SYND2GPMI_VALID	Data handshake Input from BCH.
8 SYND2GPMI_READY	Data handshake Input from BCH.
7 VIEW_DELAYED_RDN	Set to a 1 to select the delayed feedback RE_B to drive the GPMI_ADDR[0] (Nand CLE) pin. For debug purposes, this will allow you see if DLL is functioning properly.
6 UPDATE_WINDOW	A 1 indicates that the DLL is busy generating the required delay.
RDN_TAP	This is the DLL tap calculated by the DLL controller. The selects the amount of delay form the DLL chain.

9.6.6.16 GPMI Debug3 Information Register Description (GPMI_DEBUG3)

The GPMI Debug3 information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

GPMI_DEBUG3 0x0F0

Address: 3300_2000h base + F0h offset = 3300_20F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_DEBUG3 field descriptions

Field	Description
31–16 APB_WORD_CNTR	Reflects the number of bytes remains to be transferred on the APB bus.
DEV_WORD_CNTR	Reflects the number of bytes remains to be transferred on the ATA/Nand bus.

9.6.6.17 GPMI Double Rate Read DLL Control Register Description (GPMI_READ_DDR_DLL_CTRL)

GPMI DDR Read Delay Loop Lock Control Register. This register provides programmability in DDR mode for data input timing and data formats.

GPMI_READ_DDR_DLL_CTRL 0x100

Address: 3300_2000h base + 100h offset = 3300_2100h

GPMI_READ_DDR_DLL_CTRL field descriptions

Field	Description
31–28 REF_UPDATE_INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two GPMICLK cycles. Programming this field results in a DLL control loop update interval of $(2 + \text{REF_UPDATE_INT}) * \text{GPMICLK}$. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 SLV_UPDATE_INT	Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 GPMICLK cycles. A value of 0 results in an update interval of 256 GPMICLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–18 RSVD1	Reserved
17–10 SLV_OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
9 SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
8 REFCLK_ON	set this bit to 1 will turn on the reference clock
7 GATE_UPDATE	Setting this bit to 1, forces the slave delay line not update
6–3 SLV_DLY_TARGET	The delay target for the read clock is can be programmed in 1/16th increments of an GPMICLK half-period. So the input read-clock can be delayed relative input data from $(\text{GPMICLK}/2)/16$ to $\text{GPMICLK}/2$.
2 SLV_FORCE_UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
1 RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an GPMICLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

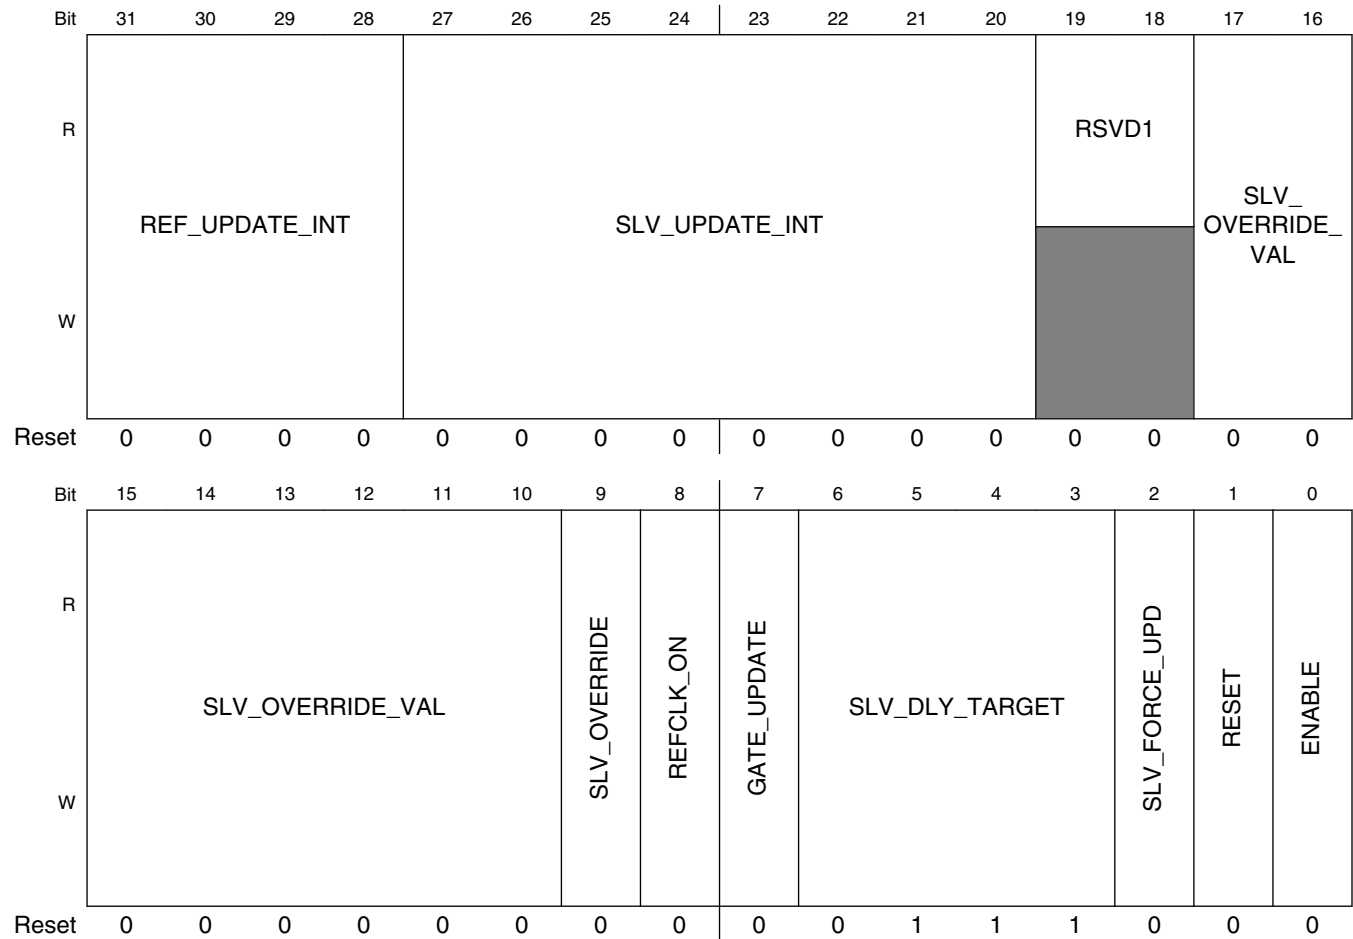

9.6.6.18 GPMI Double Rate Write DLL Control Register Description (GPMI_WRITE_DDR_DLL_CTRL)

GPMI DDR Write Delay Loop Lock Control Register. This register provides programmability in DDR mode for data output timing and data formats.

GPMI_WRITE_DDR_DLL_CTRL 0x110

General Purpose Media Interface (GPMI)

Address: 3300_2000h base + 110h offset = 3300_2110h

GPMI_WRITE_DDR_DLL_CTRL field descriptions

Field	Description
31–28 REF_UPDATE_INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two GPMICLK cycles. Programming this field results in a DLL control loop update interval of $(2 + \text{REF_UPDATE_INT}) * \text{GPMICLK}$. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)

0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE_VAL, the DLL does not need to be enabled.

9.6.6.19 GPMI Double Rate Read DLL Status Register Description (GPMI_READ_DDR_DLL_STS)

GPMI Double Rate Read DLL Status Register, Read Only. GPMI DLL status fields are provided in this register.

GPMI_READ_DDR_DLL_STS 0x120

Address: 3300_2000h base + 120h offset = 3300_2120h

General Purpose Media Interface (GPMI)

GPMI_READ_DDR_DLL_STS field descriptions

Field	Description
31–25 RSVD1	Reserved
24–17 REF_SEL	Reference delay line select status.
16 REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase GPMICKLK shift, allowing the slave delay-line to perform programmed clock delays.
15–9 RSVD0	Reserved
8–1 SLV_SEL	Slave delay line select status
0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

9.6.6.20 GPMI Double Rate Write DLL Status Register Description (GPMI_WRITE_DDR_DLL_STS)

GPMI Double Rate Write DLL Status Register, Read Only. GPMI DLL status fields are provided in this register.

GPMI_WRITE_DDR_DLL_STS 0x130

Address: 3300_2000h base + 130h offset = 3300_2130h

GPMI_WRITE_DDR_DLL_STS field descriptions

Field	Description
31–25 RSVD1	Reserved
24–17 REF_SEL	Reference delay line select status.
16 REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase GPMICKLK shift, allowing the slave delay-line to perform programmed clock delays.
15–9 RSVD0	Reserved
8–1 SLV_SEL	Slave delay line select status

Table continues on the next page...

GPMI_WRITE_DDR_DLL_STS field descriptions (continued)

Field	Description
0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

9.7 External Interface Module (EIM)

9.7.1 Overview

The EIM handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with NOR-Flash-like or PSRAM-like interface.

Figure 9-55. EIM Diagram

9.7.1.1 Features

- Six chip selects for external devices
 - Flexible address decoding. Each chip select memory space determined separately, according to VIA port configuration (see [Chip Select Memory Map](#)). Configurable Chip Select 0 base address (by VIA)
 - Individual select signal for each one of the memory space defined. Up to 6 memory spaces may be defined and programmed individually.
- Selectable Write Protection for each Chip Select
- Support for multiplexed address / data bus operation x16 port size
- Programmable Data Port Size for each Chip Select (x8, x16)
- Programmable Wait-State generator for each Chip Select, for write and read accesses separately
- Asynchronous accesses with programmable setup and hold times for control signals
- Support for Asynchronous page mode accesses (x16 port size)
- Independent synchronous Memory Burst Read Mode support for NOR-Flash and PSRAM memories (x16 port size)
- Independent synchronous Memory Burst Write Mode support for PSRAM and NOR-Flash like memories (CellularRAM™ from Micron, Infineon, and Cypress, OneNAND™ and utRAM™ from Samsung, and COSMORAM™ from Toshiba)
- Support of NAND-Flash devices with NOR-Flash like interface - MDOC™ (M-Systems), OneNAND™ (Samsung)
- Independent programmable variable/fix Latency support for read and write synchronous (burst) mode
- Support for Big Endian and Little Endian operation modes per access
- Arm AXI slave interface. One ID at a time support.

9.7.1.2 Modes of Operation

The EIM has the following modes of operation:

- Asynchronous Mode
- Asynchronous Page Mode
- Multiplexed Address/Data mode
- Burst Clock Mode
- Low Power Modes
- Boot Mode

See details in the [EIM Operational Modes](#).

9.7.1.2.1 Asynchronous Mode

This is a non-burst mode that is used for SRAM access. In this mode, a single data is read/written with each access (asserted address).

All controls' timings are controlled by preset values in Chip Select Configuration Registers.

9.7.1.2.2 Asynchronous Page Read Mode

Setting the APR bit causes the EIM to perform memory burst accesses by emulating page mode operation.

The external address asserts for each piece of data. The initial access timing is according to RWSC field, and the next address assertions timing is according to PAT field. When APR bit is set, RCSN OEN, RADVN and RBEN fields are ignored for burst access to the external device.

The page size can be set via the BL field to 2, 4, 8, or 16 words (the word size is determined by the DSZ field).

9.7.1.2.3 Multiplexed Address/Data Mode

In this mode, multiplexing addresses and data bits on the same pins is supported for synchronous/asynchronous accesses to x8/x16 data width memory devices.

For more information about the pins that drive data/address in 8/16 non-muxed mode and 16 muxed mode, see the following table.

9.7.1.2.4 Burst Clock Mode

The controller has the ability to support burst synchronous operations in various frequencies, depending on the frequency of the input clock supplied by the system (EIM clock).

The EIM clock can be divided by one, two, three or four, and its frequency can be changed according to the requirements. Variable and fix latency are supported for this mode, according to the external device requirements.

- Synchronous read mode. This is a burst mode, which is used for reading from Flash/PSRAM memory devices. In this mode, after address assertion a burst of sequential data can be read. Data exchange is carried out according to BCLK being generated

by EIM. An access is delayed according to external WAIT_B signal assertion (signal from the memory device).

- Synchronous write mode. A burst mode used for accessing external devices, which support synchronous write type of access (PSRAM protocol). In this mode, after address assertion a burst of sequential data can be written to the external device. Access may be delayed according to WAIT_B signal assertion (signal from the memory device) before first piece of data arrived to the external device.

NOTE

Maximum frequency of the EIM main clock is 133 MHz. It may be reduced by the system for special cases of external devices, which demand a different frequency then integer division of the 133 MHz clock.

9.7.1.2.5 Low Power Modes

The input clock is gated by ACT_CS bits. When all the ACT_CS are negated (all CS disable) the internal clock is turned off; awready/wready & arready signal are de-asserted and the master can't access the EIM.

9.7.1.2.6 Boot Mode

It is possible to perform a boot operation from external device located on CS0. The configuration of the relevant bits are done with boot mode signals according to the external device parameters (for example, port size and protocol assertion).

See for more details.

9.7.2 External Signals

The following table describes the external signals of EIM:

Table 9-24. EIM External Signals

Signal	Description	Pad	Mode	Direction
EIM_ACLK_FREERUN	AXI clock signal	LCD1_DATA17	ALT4	I
EIM_AD00	LSB multiplexed Address/Data Bus signal	EPDC1_DATA00	ALT4	IO

EIM_DATA11	MSB Data Bus signal	LCD1_DATA11	ALT4	IO
EIM_DATA12	MSB Data Bus signal	LCD1_DATA12	ALT4	IO
EIM_DATA13	MSB Data Bus signal	LCD1_DATA13	ALT4	IO

Table continues on the next page...

Table 9-24. EIM External Signals (continued)

Signal	Description	Pad	Mode	Direction
EIM_DATA14	MSB Data Bus signal	LCD1_DATA14	ALT4	IO
EIM_DATA15	MSB Data Bus signal	LCD1_DATA15	ALT4	IO
EIM_DTACK_B	Data Acknowledge, asynchronous access. This input is used as a data acknowledge signal for single asynchronous accesses.	LCD1_RESET	ALT4	I
EIM_EB0	Byte Enable. These active-low output signals indicate valid data bytes for the current access. They may be configured to assert for write cycles only. EIM_EB[0] corresponds to DATA_OUT[7:0] For asynchronous write accesses, behavior is affected by the WBEA and WBEN fields of the EIM_CS1WCR1-EIM_CS5WCR1 Registers. On synchronous or asynchronous read accesses, these signals are always asserted at the start of the access and negated at end of the access.	EPDC1_DATA14	ALT4	O
EIM_EB1	Byte Enable. These active-low output signals indicate valid data bytes for the current access. They may be configured to assert for write cycles only. EIM_EB[1] corresponds to DATA_OUT[15:8] For asynchronous write accesses, behavior is affected by the WBEA and WBEN fields of the EIM_CS1WCR1-EIM_CS5WCR1 Registers. On synchronous or asynchronous read accesses, these signals are always asserted at the start of the access and negated at end of the access.	EPDC1_PWRSTAT	ALT4	O
EIM_LBA_B	Address Valid. This active-low output signal is asserted during burst mode accesses to cause the external burst capable device to load a new starting burst address. Assertion of LBA indicates that a valid address is present on the address bus. Its behavior is affected by the SWR, SRD, BCD, and BCS fields of the EIM_CSxGCR1 registers, the RADVA and RADVN fields of the EIM_CSxRCR1 registers, and the WADVA and WADVN fields of the EIM_CSxWCR1 registers. In asynchronous mode, LBA length is affected by the RADVA, WADVA,	EPDC1_DATA12	ALT4	O

Table continues on the next page...

Table 9-24. EIM External Signals (continued)

Signal	Description	Pad	Mode	Direction
	RADVn, and WADVn fields. Minimum length of LBA signal in all modes is one EIM clock cycle.			
EIM_OE	Output Enable. This active-low output signal indicates the bus access is a read and enables external devices to drive the data bus with read data. Its behavior is affected by the OEA and OEN bit fields in the Chip Select Configuration Registers.	EPDC1_DATA08	ALT4	O
EIM_RW	Memory Write Enable. This activelow output signal indicates the bus access is a write and enables external devices to sample the data bus. Its behavior is affected by the WEA and WEN bit fields in the Chip Select Configuration Registers.	EPDC1_DATA09	ALT4	O
EIM_WAIT	Ready/Busy/Wait signal. This activelow input signal is asserted by external burst capable devices which support fixed or variable latency of data. It is serviced in synchronous mode only (EIM_CSxGCR1[SWR, SRD] =1). WAIT will have a pull up resistor in pad. The signal indicates whether the External device is ready for data transaction or not. Busy cycles (or wait cycles) of the external device can occur at the start of a Burst access or at page boundary crossover. NOTE: For burst devices, WAIT output should be configured to change one cycle before data is ready (before delay). NOTE: Some External devices may not use this input signal for ready state indication (fix latency without WAIT signal monitoring). For these devices EIM should be configured accordingly (see RFL, WFL, and PSZ field descriptions). NOTE: This is same as what is shown in IP_IND_WAIT_B	EPDC1_DATA13	ALT4	I

9.7.2.1 Other Important Block I/O Signals Internal to the SoC

The following table provides a description of other signals internal to the chip that are important in understanding the function of EIM.

Table 9-25. EIM Important Internal Signals

Name	I/O	Description
EIM_FB_BCLK	Input	Burst Clock Feedback. This block input is used to sample read data during high transfer speeds. The signal provides feedback from the I/O pad of the BCLK output pin and tends to align more closely with data from the external memory device.
EIM_BOOT	Input	EIM Boot Configuration. These block inputs determine the reset state of DSZ[1:0] and MUM.
ACLK	Input	AXI clock, maximum frequency 133 Mhz
IPG_CLK_S	Input	EIM module IPG clock
RST_B	Input	Active low HW reset
EIM_WARM_RESET	Input	Warm Reset. If this signal is asserted the rst_b will reset only the internal FF and state machine while S/W registers will keep their current state. This signal is active high signal.

9.7.3 Clocks

The following table describes the clock sources for EIM. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 9-26. EIM Clocks

Clock name	Clock Root	Description
aclk	aclk_eim_slow_clk_root	EIM clock (main)
aclk_slow	aclk_eim_slow_clk_root	EIM clock (slow)
ipg_clk_s	ipg_clk_root	Peripheral access clock
aclk_exsc	aclk_eim_slow_clk_root	EIM clock (external device)

- **ACLK**: EIM clock (main clock, AXI clock) with a Max frequency of 133 MHz. Can be gated externally when there is no active AXI access.
- **ACLK_SLOW**: EIM all time running ACLK. Used for flip-flops that must be active even when EIM is in low power down mode to provide clock for lpack/lpmd registers, IP registers and IP to AXI sync registers.
- **IPG_CLK_S**: IPG clock for IP accesses. IP registers are activated by ACLK_SLOW clock.
- **ACLK_EXSC**: Clock created from EIM clock for External device usage. Integer division by 1, 2, 3 and 4 of the clock can be use with BCD bit field configuration, according to external devices demands. EIM clock frequency may be reduced for lower frequency support which cannot be achieved via BCD bit field.

9.7.4 Chip Select Memory Map

The following four configurations are supported:

- CS0 (128 MB), CS1 (0 MB), CS2 (0 MB), CS3 (0 MB) [default configuration]
- CS0 (64 MB), CS1 (64 MB), CS2 (0 MB), CS3 (0 MB)
- CS0 (64 MB), CS1 (32 MB), CS2 (32 MB), CS3 (0 MB)
- CS0 (32 MB), CS1 (32 MB), CS2 (32 MB), CS3 (32 MB)

9.7.5 Functional Description

This section provides the functional description for the EIM.

9.7.5.1 Bus Sizing Configuration

The EIM supports byte, half word and word operands allowing access to x8, x16 ports. It can be address/data multiplexed in x16 ports. The port size is programmable via the DSZ bit field in the corresponding Chip Select Configuration Register. An 8-bit port can reside in each one of the bytes of the data bus.

In the case of a multi-cycle transfer, the lower two address bits (ADDR[1:0]) are incremented appropriately. The EIM address bus is configured according to DSZ bit field and AUS bits.

The EIM has a data multiplexer which takes the four bytes of the AXI data bus and routes them to their required positions to properly interface to memory.

NOTE

A word access to or from a x16 port requires two external bus cycles to complete the transfer.

A word access to or from a x8 port requires four external bus cycles to complete the transfer.

9.7.5.1.1 8 BIT PORT SUPPORT

EIM has limited support for mot68000 & intel 386 protocols.

9.7.5.1.1.1 MOTOROLA 68000

EIM has limited support for mot68000 protocol. Only basic read or write asynchronous operations are supported.

The following operations are not supported:

- Read modify write
- Sync access
- All special accesses (Arm platform space, bus arbitration, bus control, bus error & reset operations)
- FC outputs

9.7.5.1.1.2 INTEL 386

EIM has limited support for intel 386 protocol. Only basic read or write async non-pipelined operations are supported.

The following operations are not supported:

- Other bus cycles (interrupt, halt & refresh)
- Bus lock
- M/IO, DC, LBA, NA, REFRESH & BS8 signals

9.7.5.2 EIM Operational Modes

Listed here are the main operational modes for EIM selected by control bit fields settings.

For details, see the bit field descriptions of SWR / SRD / MUM. All modes are supported in with 8-, 16- or 32-bit port configuration, according to DSZ bit field.

Table 9-27. EIM Operation Modes Field Settings

Control bit fields			Brief mode description
MUM	SRD	SWR	
0	0	0	Asynchronous write / Asynchronous read for APR=0 / Asynchronous page read for APR=1, none multiplexed
		1	Synchronous write/ Asynchronous read or APR=0 / Asynchronous page read for APR=1,none multiplexed
	1	0	Asynchronous write/Synchronous read none multiplexed
		1	Synchronous write/read none multiplexed
1	0	0	Asynchronous write/read multiplexed
		1	Synchronous write/ Asynchronous read multiplexed

Table continues on the next page...

Table 9-27. EIM Operation Modes Field Settings (continued)

Control bit fields			Brief mode description
MUM	SRD	SWR	
	1	0	Asynchronous write/Synchronous read multiplexed
		1	Synchronous write/read multiplexed

9.7.5.3 Burst Mode (Synchronous) Memory Operation

This mode is enabled for read or write access. Bit SWR sets the burst mode for write operations at the corresponding chip select and bit SRD sets it for read operation.

When this mode is set, the controller attempts to translate the Master burst accesses to memory burst accesses, being limited by the memory burst length, predefined by BL value, or memory and Master WRAP/INCR boundary crossing non-matching. Only the first address accessed is put by the controller on the external address bus in a memory burst sequence.

EIM may translate from some Master sequential accesses to one or several memory bursts, but not from two Master individual accesses to one memory burst.

For the first access in a memory burst sequence, the EIM asserts \overline{ADV} , causing the external burst device to latch the starting burst address; then toggle the burst clock (BCLK) for a predefined number of cycles in order to latch the first unit of data. Subsequent accessed data units can then be burst in fewer clock cycles, realizing an overall increase in bus bandwidth.

NOTE

The BCLK signal toggles only when burst access is executed toward the external device (BCM=1'b0 for normal mode use). It runs with a 50% duty cycle until the end of access is reached. When access is terminated, BCLK stops toggling.

Memory burst accesses are terminated by the EIM whenever it detects the following:

- The specific burst length has executed completely (end of access)
- Write access - missing data in write buffer (Master is delaying the data transfer toward the EIM)
- Next sequential access crosses boundary with unequal condition (wrap/increment, burst length) on the Master and memory
- Current memory burst length reached

9.7.5.4 Burst Clock Divisor (BCD)

In some cases, it may be necessary to slow the external bus in relation to the internal bus to allow accesses to burst devices that have a maximum operating frequency less than the operating frequency of the internal bus.

The internal bus frequency can be divided by one, two, three or four for presentation on the external bus in burst mode operation.

BCLK can only be set to integer divisions of the incoming clock frequency. To get a specific frequency on BCLK, configure the divider to change the incoming EIM clock accordingly.

By programming the BCD bit field to various values, two signals on the external bus are affected; \overline{ADV} and BCLK. The \overline{ADV} signal is asserted according to RADVA or WADVA bit fields programming, and is negated according to the formula mentioned in RADVN and WADVN bit fields description. The BCLK signal runs with a 50% duty cycle until the end of access is reached.

If $BCM = 1$, the BCLK runs at frequency according to GBCD bit field settings on every async memory access, regardless of the SWR and SRD bits configuration. Caution should be exercised when using BCM bit; GBCD bit field should be updated once and should not change when BCLK is toggling. The BCM bit is used mainly for system debug mode. It has no functional use of the EIM in normal mode.

9.7.5.5 Burst Clock Start (BCS)

In an effort to allow greater flexibility in achieving the minimum number of wait states on burst accesses, you can determine when you want the BCLK to start toggling after the start of access. This allows the BCLK to be skewed from point of data capture on the EIM clock by any number of EIM clock cycles.

Care must be exercised when setting BCS bit field in conjunction with the BCD and RWSC/WWSC bit fields. See the external timing diagrams in [Burst \(Synchronous Mode\) Read Memory Accesses Timing Diagram - BCD=1](#) and [Burst \(Synchronous Mode\) Read Memory Accesses Timing Diagram - BCD=0](#) for examples of how to use the BCS, BCD and RWSC/WWSC bit fields together.

9.7.5.6 Multiplexed Address/Data Mode Support

The control bit MUM allows support memory with multiplexed address/data bus both in asynchronous and in synchronous modes.

Caution should be exercised for using OEA/WEA & ADH bit fields. They should be configured according to the external device requirements, as it determines the time point of end of address phase and start of data phase.

9.7.5.7 Mixed Master/Memory Burst Modes Support

To provide mixed sequential/wrap accesses with different length, EIM interprets burst signal and generate additional \overline{ADV} signals whenever there appear unequal address or burst boundary crossing condition.

BL bit field is used to notify EIM about current memory burst and wrap condition for properly external address generation. In case of non-matching boundaries in both the memory and Master access, EIM starts a new memory burst access by updating address from Master on address bus and generating \overline{ADV} signal.

9.7.5.8 AXI (Master) Bus Cycles Support

The EIM uses an Arm AXI slave interface. It has a 32-bit bus and supports one access (one ID) at a time. No out of order or parallel accesses are supported.

The following AXI protocol signals are not supported:

- AWLOCK
- AWCACHE
- ARLOCK
- ARCACHE

ARID bus is sampled when:

- new read access is valid on the read address channel and is reflected on the RID bus output toward the master.

AWID bus is sampled when:

- new write access is valid on the write address channel and is reflected on the WID/BID bus output toward the master.

ARPROT and AWPROT signal are partially used. ARPROT[0] and AWPROT[0] bits are used for normal/privileged access detection. ARPROT[2:1] and AWPROT[2:1] are not used.

When sampling a valid access on both of the address channels, the read access will be performed first while write access is pending. After last data transfer completed, the pending write will be executed.

A new access may be executed one cycle after sampling a valid access on the read or write address channels, assuming there is no current access (back to back) which can cause a recovery or end of access penalty cycles, for write access, also assuming data is in write buffer for fast execution.

NOTE

- Only 32-bit word size accesses are supported for burst mode accesses.
- Only 8-bit (1 byte), 16-bit (2 byte) and 32-bit (4 byte) word size supported for single access.
- Maximum number of burst length is 16.
- According to AXI protocol, burst access should not cross 4 KB blocks. In case EIM gets an access that crosses the 4 KB, memory address calculation is invalid.

AXI transfers shown in the table below are also supported. These AXI cycles will be translated into the necessary cycles on the memory side. For example, for optimal operation in case Arm cache is configured to 8 beat burst with wrap, a synchronous flash and cellular RAM memory should be configured in 16 word wrap burst mode when using a 16-bit data port, and in 8 word wrap burst mode when using a 32-bit data port. EIM uses BL bit field to support different memory configurations. The controller splits the transaction when needed in some cases. See [Table 9-29](#).

Table 9-28. AXI Burst Cycles Supported

Burst Length - Number of data transfers	Burst size - Bytes in transfer	Burst type	Description
1	1	INCR	Single transfer
1	2	INCR	Single transfer
1	4	INCR	Single transfer
2	4	WRAP	2-beat wrapping burst
4	4	WRAP	4-beat wrapping burst
8	4	WRAP	8-beat wrapping burst
16	4	WRAP	16-beat wrapping burst
2	4	INCR	2-beat incrementing burst
3	4	INCR	3-beat incrementing burst
4	4	INCR	4-beat incrementing burst
5	4	INCR	5-beat incrementing burst
6	4	INCR	6-beat incrementing burst
7	4	INCR	7-beat incrementing burst
8	4	INCR	8-beat incrementing burst
9	4	INCR	9-beat incrementing burst
10	4	INCR	10-beat incrementing burst

Table continues on the next page...

Table 9-28. AXI Burst Cycles Supported (continued)

Burst Length - Number of data transfers	Burst size - Bytes in transfer	Burst type	Description
11	4	INCR	11-beat incrementing burst
12	4	INCR	12-beat incrementing burst
13	4	INCR	13-beat incrementing burst
14	4	INCR	14-beat incrementing burst
15	4	INCR	15-beat incrementing burst
16	4	INCR	16-beat incrementing burst

Table 9-29. AXI to Memory Burst Splits Number

AXI Burst Type	Memory Burst Type Config.	# of accesses to X8 Memory Port size	# of accesses to X16 Memory Port size	# of accesses to X32 Memory Port size

WRAP8 Unaligned Addr.	WRAP16	2 or 3	1	2
	Cont.	2	2	2

9.7.5.9 WAIT_B Signal, RWSC and WWSC bit fields Usage

Most of the external devices supporting burst mode for write or read accesses provide a signal which indicates data is valid on the memory bus (a.k.a. handshake mode). For this mode, RFL and WFL bits should be cleared and RWSC/ WWSC bit fields indicate when the controller should start sampling this signal from the external device or, in other words, how many BCLK cycles should be masked.

For devices which do not use this signal or have a fixed latency ability, the RFL and WFL bits may be set for internal calculation regarding BCLK cycles penalty until data is valid (memory initial access time). For this mode, RWSC/ WWSC indicates when the data is ready for sampling by the controller (read access) or the external device (write access). There is separation between read and write accesses wait-state control. For read access, RWSC bit field is valid and WWSC bit field is ignored; for write access, WWSC is valid and RWSC is ignored.

9.7.5.10 IPS Register Interface

Access to the registers of the EIM, read or write, is made with IPS protocol signals. The system should avoid changing the registers while master/memory transaction is valid, as this can cause an unknown behavior of the controller.

Register access size is 32-bit as the register size definition, other size of access (byte or half word) is not supported.

9.7.5.11 MRS Set for PSRAM

Memory registers of PSRAM devices can be configured according to external signal, which indicates whether the access is to a memory array or memory register domain.

When the CRE bit is set, the following transactions to the external device will assert the CRE signal. The polarity of this signal is determined by the CREP bit for active low or active high assertion of the signal.

9.7.5.12 EIM Access Termination

EIM is monitoring the corresponding CSx control signal every time variable latency access or dtack access is performed toward the external device.

In variable latency accesses, the Watchdog Timer (WDOG-1) counts BCLK cycles. If it reaches the wdog_limit (according to the WDOG_LIMIT bit field in the WCR) before the device signals can drive/sample new data, the controller will terminate the access and generate an error response transfer toward the Master.

In dtack access, WDOG-1 counts ACLK cycles instead of BCLK and it reaches the wdog_limit before the device asserts the dtack signal, the controller will terminate the access and generate an error response transfer toward the Master.

WDOG-1 can be disabled by WDOG_EN bit in the WCR.

9.7.5.13 Error Conditions

The following conditions cause an error (AXI error or IPS error) response signal:

- AXI errors
 - Access to a disabled chip select - access to a mapped chip select address space where the CSEN bit in the corresponding chip select Configuration Register is clear
 - Access to a non mapped address - access to an address that is not mapped to any CS.
 - User access to a supervisor-protected chip select address space (the SP bit in the corresponding chip select Configuration Register is set)
 - User access in fixed mode access
 - User performs write access to write protected chip select
 - First write data ID and write address ID do not match. (No data is written to the memory.)
 - First Write Data ID and write address ID match but one or more of the other Write data IDs does not match the First Write data ID (data is written to memory according)
 - Access duration to external device from CSx signal assertion is 128/256/512/1024 cycles (access is terminated by the controller) - This error can be disabled by software.
- IPS errors
 - User read or write access to a reserved/non-valid address in the EIM Configuration Register

9.7.5.14 DTACK Mode

In DTACK mode, the EIM uses DTACK signal as an indication of when to end the access.

DTACK is an asynchronous edge/level sensitive signal. DTACK polarity is configurable by the DAP bit in CsxGCR2 (default value is 0).

In this case, EIM begins the access and after a few cycles (according DAPS field) and waits until DTACK (after synchronization) becomes asserted, then samples the data in read access and completes the current data access (see [Figure 9-69](#), [Figure 9-70](#) & [Figure 9-71](#)).

If more than one data is needed, CS will be negated between access (CSREC field is not zero) and the AXI burst access will be split into single accesses (see [Figure 9-73](#)).

9.7.5.15 EIM_GRANT / EIM_BUSY Handshake Description

Prior to executing command to one of the external device (chip select), EIM asserts EIM_BUSY signal (1'b1) and checks the EIM_GRANT signal status.

If EIM_GRANT signal is high, it indicates external data bus is not used by other slaves (NAND Flash Controller) and EIM may start to execute the access. If EIM_GRANT is low, EIM waits until it is set (1'b1) before executing the access.

EIM keeps EIM_BUSY signal set until it completes the access toward the external device.

Once EIM_GRANT signal is set, it can not be reset until EIM_BUSY signal is cleared by EIM.

NOTE

In 16-bit Muxed EIM doesn't use the data bus, therefore there is no sharing of the data bus with NFC. EIM doesn't wait for EIM_GRANT signal from NFC and doesn't assert the EIM_BUSY signal.

9.7.5.16 LPMD / LPACK Handshake Description

These signals are used for frequency and/or voltage change, and for entering low power mode during normal operation of the EIM. Before any change can take place, the controller and all the relevant external devices should be in idle state, which means no access or data transfer is in process.

LPMD input signal is asserted once EIM detects the assertion of LPMD, all ready signals of the AXI channels are negated, and EIM is not sampling new accesses. It finishes all the ongoing accesses and already pending ones. When EIM is in idle state, the LPACK output signal is asserted. EIM will stay in idle state and the LPACK signal will stay asserted until the LPMD signal is negated.

9.7.5.17 Endianness

Big and Little endianness are supported by the controller according to the following table.

Table 9-30. EIM Out/in Data in Case AXI Out/in Data is 0xB3B2B1B0

Endian mode	AXI access	AXI address [1:0]	Port size and used bits									
			Word port				Half word port			Byte port		
			[31:24]	[23:16]	[15:8]	[7:0]	External address [0]	[31:24] ([15:8])	[23:16] ([7:0])	External address [1:0]	[31:24] ([23:16]) ([15:8]) ([7:0])	
Big	Word	0	0xB3	0xB2	0xB1	0xB0	0	0xB3	0xB2	0	0xB3	
							1			1	0xB2	
							2			2	0xB1	
							3			3	0xB0	
	Half Word	0			0xB1	0xB0	0	0xB3	0xB2	0	0xB3	
							1			1	0xB2	
							2	0xB3	0xB2		2	0xB1
							3			3	0xB0	
	Byte	0			0xB1	0xB0	0		0xB3	0	0xB3	
							1		0xB2	1	0xB2	
							2	0xB2		2	0xB1	
							3	0xB3		3	0xB0	
Little	Word	0	0xB3	0xB2	0xB1	0xB0	0	0xB1	0xB0	0	0xB0	
							1			1	0xB1	
							2			2	0xB2	
							3			3	0xB3	
	Half Word	0			0xB1	0xB0	0	0xB1	0xB0	0	0xB0	
							1			1	0xB1	
							2	0xB3	0xB2		2	0xB2
							3			3	0xB3	
	Byte	0			0xB1	0xB0	0		0xB0	0	0xB0	
							1		0xB1	1	0xB1	
							2	0xB2		2	0xB2	
							3	0xB3		3	0xB3	

9.7.5.18 Strobe Signal Use

The strobe signal is toggling according to address/data valid condition on the external bus for read and write accesses, and for both synchronous and asynchronous modes.

At any time point when address/data is valid on the external bus, the strobe signal will generate a positive edge, which can be used to sample the external data and control signal.

NOTE

Strobe signal for read data is active (RL + 1) cycles after data on external bus is valid.

9.7.6 Initialization Information**9.7.6.1 Booting from EIM**

EIM is ready to work with CS0 after the hardware reset, but it has been configured for very slow access (for boot purposes), with additional setup and hold time.

Other CSs are disabled by hardware reset. Therefore, all CSs must be properly initialized before use in writing values to the corresponding chip select configuration registers.

DSZ[1:0] and MUM fields are set according to EIM_BOOT [2:0] block inputs.

9.7.7 Typical Application

Application note uses following functions to illustrate EIM and memory accesses:

- WR16(address, data) is a 16 bit write access
- WR32(address, data) is a 32 bit write access
- RD16(address, data) is a 16 bit read access
- RD32(address, data) is a 32 bit read access
- WR_I(address, data, delta, counter) is a write data sequence, there $data(i+1) = data(i) + delta$
- COMMAND_SEQUENCE
- CHECK_STATUS

NOTE

COMMAND_SEQUENCE and CHECK_STATUS are described in [AMD Flash Utility](#), [Intel Sibley Flash Utility](#), [MDOC Device Utility](#), [Samsung OneNAND Utility](#), and [Spansion Flash Utility](#).

All addresses are byte addresses. "CS0" is a Chip Select 0 base address. "EIM_" is a prefix of EIM's registers. 'h is a prefix of hexadecimal constant. "///" is a comment beginning. csba[cs] is a dimension of CS base addresses. "addr" means an address offset in current CS address space. Examples use CS0 address space, but it may apply to any CS except for boot mode functionality.

Configuration examples were verified with the memory models listed below and may require some adjustments for other family members.

9.7.7.1 Access to Intel Sibley Flash

The following configurations are intended to Sibley family muxed and non-muxed devices.

9.7.7.1.1 Intel Sibley Flash Asynchronous Mode Configuration

- WR32('EIM_CS0GCR1,'h00210081);
- WR32('EIM_CS0RCR1,'h0e020000);
- WR32('EIM_CS0RCR2,'h00000000);
- WR32('EIM_CS0WCR1,'h0704a040);

9.7.7.1.2 Intel Sibley Flash Synchronous Mode Configuration

Configuration used for 133 MHz synchronous access to flash:

```
// Set memory to synchronous read mode
WR16('CS0+('h5903<<1), 'h0060);
WR16('CS0+('h5903<<1), 'h0003);
WR16('CS0+('h0000<<1), 'h00ff);
// Set EIM configuration to synchronous timing
WR32('EIM_CS0GCR1, 'h50214225);           // 133 MHz
WR32('EIM_CS0RCR1, 'h0c000000);         // 12 cycles on memory
```

Configuration used for 66 MHz synchronous access to muxed flash:

```
// Set memory to synchronous read mode
WR16('CS0+('h3103<<1), 'h0060);
WR16('CS0+('h3103<<1), 'h0003);
WR16('CS0+('h0000<<1), 'h00ff);
//-----
// Set EIM configuration to synchronous timing
WR32('EIM_CS0GCR1, 'h5021122d);           // 66 MHz
WR32('EIM_CS0RCR1, 'h07000000);         // 7cycles on memory
```

9.7.7.1.3 Intel Sibley Flash Utility

```
// Single data word programming to addr
WR16('CS0+addr, 'h0060);           // Unlock
WR16('CS0+addr, 'h00d0);
WR16('CS0+addr, 'h0041);
WR16('CS0+addr, data);
WR16('CS0+caddr, 'h0070);           // Read Status command
while('CS0+data[7] == 0)           // Wait / Polling
    RD16('CS0+addr, data);         // Read status
RD16('CS0+addr, data);             // Read status
WR16('CS0+'h0000, 'h00ff);
// Write buffer programming
WR16('CS0+addr, 'h0060);           // Unlock
WR16('CS0+addr, 'h00d0);
data = 0;
```

```

WR16('CS0+addr, 'h0070);           // Read Status command
while(data[7] == 0)                 // Wait
    RD16('CS0+addr, data);         // Read status
WR16('CS0+'h0000, 'h00ff);
WR16('CS0+addr, 'h00e9);           // Write Buffer command
WR16('CS0+addr, 255);              // Word counter (<256)
for(i=0; i<'h200; i = i + 'h40)
    WR_I('CS0+addr+i, data+((i>2)*'h0010_0001), 'h0010_0001, 16); // Data
WR16('CS0+addr, 'h00d0);           // Write Confirm command
data = 0;
while(data[7] == 0)                 // Wait
    RD16('CS0+addr, data);         // Read status
RD16('CS0+addr, data);             // Read status
WR16('CS0+'h0000, 'h00ff);

```

9.7.7.2 Access to MDOC Device

The following configurations are intended to MDOC H3 device.

9.7.7.2.1 MDOC Device Boot

To boot from the MDOC device the ERRST bit should be configured to 1, so that EIM will hold the first read access to CS0 until the MDOC asserts the RDY signal.

9.7.7.2.2 MDOC Device Asynchronous Mode Configuration

```

// Non-muxed mode
WR32('EIM_CS0GCR1, 'h00410081);
WR32('EIM_CS0RCR1, 'h0e121010);
WR32('EIM_CS0RCR2, 'h00000000);
WR32('EIM_CS0WCR1, 'h12092492);
// Muxed mode
WR32('EIM_CS0GCR1, 'h00410081);
WR32('EIM_CS0RCR1, 'h0e121010);
WR32('EIM_CS0RCR2, 'h00000000);
WR32('EIM_CS0WCR1, 'h12092492);

```

9.7.7.2.3 MDOC Device Utility

```

// Read Manufacturer ID and Device ID
RE16('CS0+'h9400, 'h4833);
RE16('CS0+'h9422, 'hb7cc);

```

9.7.7.3 Access to Micron PSRAM

The following configurations are intended to mt45w4mw16bfb_706.

9.7.7.3.1 Micron PSRAM Asynchronous Mode Configuration

```

// 16 bit memory
WR32('EIM_CS0GCR1, 'h403104b1);
WR32('EIM_CS0RCR1, 'h0b010000);

```

```

WR32('EIM_CS0RCR2,'h00000008);
WR32('EIM_CS0WCR1,'h0b040040);
// 32 bit memory
WR32('EIM_CS0GCR1,'h403304b1);
WR32('EIM_CS0RCR1,'h0f010000);
WR32('EIM_CS0RCR2,'h00000008);
WR32('EIM_CS0WCR1,'h0f040040);

```

9.7.7.3.2 Micron PSRAM Synchronous Mode Configuration

```

// 16 bit memory
WR32('EIM_CS0GCR1,'h403104b1);
WR32('EIM_CS0WCR1,'h0b040000);
WR16('CS0+('h85947<<1),'h0040); // memory configuration
WR32('EIM_CS0GCR1,'h4021_5487); // fixed latency memory wrap 4
WR32('EIM_CS0RCR1,'h04000000);
WR32('EIM_CS0RCR2,'h00000008);
WR32('EIM_CS0WCR1,'h04000000);
// 32 bit memory
WR32('EIM_CS0GCR1,'h6003_04f1);
WR32('EIM_CS0WCR1,'h0b04_0000);
WR32('CS0+('h85947<<2),'h0040); // memory configuration
WR32('EIM_CS0GCR1,'h4003_1487); // var latency memory inc. page size 128
WR32('EIM_CS0RCR1,'h04000000);
WR32('EIM_CS0RCR2,'h00000008);
WR32('EIM_CS0WCR1,'h04000000);

```

9.7.7.4 Access to Samsung OneNAND

Mentioned below are the configurations intended for Samsung OneNAND muxed and non-muxed devices.

9.7.7.4.1 Samsung OneNAND Boot

There are two ways to boot from Samsung OneNAND. In the first way, the ERRST bit is set to 0 and the user has to poll the interrupt status in the OneNAND interrupt register (or set interrupt handler there). In the second way, the ERRST bit is set to 1 and the user should enable the device interrupt output before the first read from CS0 access is issued.

Load sectors 2,3 to DataRAM, page 0 done in the next example:

- WR16('CS0+('hF241<<1),'h0); // Clear interrupt status
- WR16('CS0+('hF100<<1),'h0); // block[8:0] address
- WR16('CS0+('hF107<<1),'h2); // sector[1:0] and page[7:2] addresses
- WR16('CS0+('hF200<<1),'h802); // buffer[11:8] address and counter[1:0]
- WR16('CS0+('hF101<<1),'h0); // DDP choose
- WR16('CS0+('hF220<<1),'h0); // Set command

9.7.7.4.2 Samsung OneNAND Asynchronous Mode Configuration

```

// Non-muxed memory
WR32('EIM_CS0GCR1,'h00410081);

```

```

WR32 ('EIM_CS0RCR1, 'h0b010000);
WR32 ('EIM_CS0RCR2, 'h00000000);
WR32 ('EIM_CS0WCR1, 'h0c092480);
// Muxed memory
WR32 ('EIM_CS0GCR1, 'h00410089);
WR32 ('EIM_CS0RCR1, 'h0b010000);
WR32 ('EIM_CS0RCR2, 'h00000000);
WR32 ('EIM_CS0WCR1, 'h0c092480);

```

9.7.7.4.3 Samsung OneNAND Synchronous Mode Configuration

Set memory and EIM to synchronous read mode is shown in the next example:

```

WR16 ('CS0+('hF221<<1), 'hc0e0); // Synchronous read, 4 clk latency
WR32 ('EIM_CS0GCR1, 'h50412405); // 44 MHz (non-muxed)
WR32 ('EIM_CS0RCR1, 'h05010000);

```

The muxed Samsung OneNAND supports synchronous write, too:

```

// Set memory & EIM to synchronous read and write mode
WR16 ('CS0+('hF221<<1), 'hc0f2); // Sync. read and write, 4 clk latency
WR32 ('EIM_CS0GCR1, 'h5041240f); // 44 MHz
WR32 ('EIM_CS0RCR1, 'h05010000);
WR32 ('EIM_CS0WCR1, 'h05040000);

```

9.7.7.4.4 Samsung OneNAND Utility

The following utility algorithms are used on the Samsung OneNAND:

```

// Unlock Block command
WR16 ('CS0+('hF100<<1), 'h0); // DFS
WR16 ('CS0+('hF100<<1), 'h0); // DBS
WR16 ('CS0+('hF24c<<1), 'h2); // SBA - block number (2)
WR16 ('CS0+('hF241<<1), 'h0); // Clear interrupt status
WR16 ('CS0+('hF220<<1), 'h23); // Unlock command
data = 'h0;
while (!(data & 'h0004)) // Polling
    RD32 ('WIAR, data); // Read status
// Erase block command
WR16 ('CS0+('hF100<<1), 'h2); // DFS and block ([8:0]) address
WR16 ('CS0+('hF101<<1), 'h0); // DBS
WR16 ('CS0+('hF241<<1), 'h0); // Clear interrupt status
WR16 ('CS0+('hF220<<1), 'h94); // Erase command
data = 'h0;
while (!(data & 'h0004)) // Wait
    RD32 ('WIAR, data); // Read status
// Program page command
WR16 ('CS0+('hF100<<1), 'h2); // DFS and block[8:0] address
WR16 ('CS0+('hF107<<1), 'h0); // sector[1:0] and page[7:2] addresses
WR16 ('CS0+('hF200<<1), 'h800); // buffer[11:8] address and counter[1:0]
WR16 ('CS0+('hF241<<1), 'h0); // Clear interrupt status
WR16 ('CS0+('hF220<<1), 'h80); // Program command
data = 'h0;
while (!(data & 'h0004)) // Wait
    RD32 ('WIAR, data); // Read status

```

9.7.7.5 Access to Samsung UtRAM

Below mentioned configurations are intended for Samsung UtRAM.

9.7.7.5.1 Samsung UtRAM Asynchronous Mode Configuration

```
WR32 ('EIM_CS0GCR1, 'h400104b1);
WR32 ('EIM_CS0RCR1, 'h0a010000);
WR32 ('EIM_CS0RCR2, 'h00000008);
WR32 ('EIM_CS0WCR1, 'h0b040040);
```

9.7.7.5.2 Samsung UtRAM Synchronous Mode Configuration

```
RD16 ('CS0+('hff_ffff<<1), data); // command sequence
RD16 ('CS0+('hff_ffff<<1), data);
RD16 ('CS0+('hff_ffff<<1), data);
RD16 ('CS0+('hff_feff<<1), data);
RD16 ('CS0+('h00_82a0<<1), data); // memory sync. configuration
WR32 ('EIM_CS0GCR1, 'h4021_53b7); // fixed latency memory wrap 32
WR32 ('EIM_CS0RCR1, 'h0500_0000);
WR32 ('EIM_CS0WCR1, 'h0300_0000);
```

9.7.7.6 Access to Spansion Flash

Below mentioned configurations are intended for Spansion Flash.

9.7.7.6.1 Spansion Flash Asynchronous Mode Configuration

```
WR32 ('EIM_CS0GCR1, 'h00410081);
WR32 ('EIM_CS0RCR1, 'h0a018000);
WR32 ('EIM_CS0RCR2, 'h00000000);
WR32 ('EIM_CS0WCR1, 'h0704a240);
WR16 ('CS0+('hF220<<1), 'h94); // Erase command
data = 'h0;
while (!(data & 'h0004)) // Wait
    RD32 ('WIAR, data); // Read status
// Program page command
WR16 ('CS0+('hF100<<1), 'h2); // DFS and block[8:0] address
WR16 ('CS0+('hF107<<1), 'h0); // sector[1:0] and page[7:2] addresses
WR16 ('CS0+('hF200<<1), 'h800); // buffer[11:8] address and counter[1:0]
WR16 ('CS0+('hF241<<1), 'h0); // Clear interrupt status
WR16 ('CS0+('hF220<<1), 'h80); // Program command
data = 'h0;
while (!(data & 'h0004)) // Wait
    RD32 ('WIAR, data); // Read status
```

9.7.7.6.2 Spansion Flash Synchronous Mode Configuration

```
WR16 ('CS0+('h0555<<1), 'h00aa); // command sequence
WR16 ('CS0+('h02aa<<1), 'h0055);
WR16 ('CS0+('h0555<<1), 'hd0);
WR16 ('CS0+('h0000<<1), 'hle4); // memory sync. configuration
WR32 ('EIM_CS0GCR1, 'h50411325); // 66 MHz
WR32 ('EIM_CS0RCR1, 'h05000000); // 5 cycles on memory
```

9.7.7.6.3 Spansion Flash Utility

```
// Single word programming
COMMAND_SEQUENCE(cs, 16, 'ha0); // single word programming
```

```

    WR16('CS0+addr, data);
    CHECK_STATUS('CS0+addr,data,16,1,errst);
// Write buffer programming
COMMAND_SEQUENCE(0,16,'h25);           // write buffer programming
WR16('CS0+addr,'h001f);                // counter-1
WR_I('CS0+addr, data, 'h0010_0001, 16); // data
WR16('CS0+addr,'h0029);                // write buffer to flash
CHECK_STATUS('CS0+addr+'h3e,data[31:16]+'h00f0,16,1,errst);

```

There `COMMAND_SEQUENCE` and `CHECK_STATUS` are next functions:

```

task COMMAND_SEQUENCE;
    input [2:0]    cs;
    input [7:0]    port_size;
    input [31:0]   code;
begin
    if(port_size == 16)
        begin
            WR16(csba[cs]+('h0555<<1), 'h00aa);
            WR16(csba[cs]+('h02aa<<1), 'h0055);
            WR16(csba[cs]+('h0555<<1), code);
        end
    else
        begin
            WR32(csba[cs]+('h0555<<2), 'h00aa);
            WR32(csba[cs]+('h02aa<<2), 'h0055);
            WR32(csba[cs]+('h0555<<2), code);
        end
end
endtask
task    CHECK_STATUS;
    input [31:0] addr;
    input [31:0] edata;
    input [7:0]  port_size;
    input [7:0]  opcode;
    output [7:0] errst;
    reg [31:0]   data;
    reg [31:0]   data3;
begin
    errst = 0;
    data  = 0;
    data3 = 0;
while(!(data == edata) && !errst) // Wait operation
    begin: BR_EN
        RD16(addr, data);           // Read status
        if(data[7] != edata[7])
            begin
                if(data[5] == 1)
                    begin
                        RD16(addr, data3);
                        RD16(addr, data);
                        if(data[6] != data3[6])
                            begin
                                $display("CHECK_STATUS: Error timeout on single data program");
                                errst = 1;
                                disable BR_EN;
                            end
                        end
                    end
                else
                    begin
                        if(opcode == 2)
                            if(data[1] == 1)
                                begin
                                    RD16(addr, data3);
                                    if(port_size == 32)
                                        RD32(addr, data);
                                    else
                                        RD16(addr, data);
                                    if(data[1] == 1 && data != edata)

```

External Interface Module (EIM)

```
begin
    $display("CHECK_STATUS: Error on write buffer");
    errst =3;
    disable BR_EN;
end
end
end
else
begin
RD16(addr, data3);
if(port_size == 32)
    RD32(addr, data);
else
begin
RD16(addr, data);
edata[31:16] = 16'h0;
end
if(data != edata)
begin
$display("CHECK_STATUS: Error in data write on single data program");
errst =2;
disable BR_EN;
end
end
end
end
endtask
```

9.7.7.7 8 bit support

This section details the pin connections for Intel mode and Motorola mode.

Intel Mode - For intel mode use the following connection:

Table 9-31. Intel Mode pin connections

Arm platform Pin	EIM Pin	Notes
ADS#	IPP_DO_ADV_B	WAL = 1,RAL = 1
W/R	IPP_DO_BE_B	WBED = 1
WR#	WE#	
RD#	OE#	

Mot. Mode - For intel mode use the following connection:

Table 9-32. Motorola Mode pin connections

Arm platform Pin	EIM Pin	Notes
AS#	IPP_DO_CS_B	
R/W#	WE#	
LDS#	BE#	

9.7.8 External Bus Timing Diagrams

The following timing diagrams show the timing of accesses to memory or a peripheral with different timing parameters. All examples done for CS0, but are valid for any others chip select. BE means one from current used BE[3:0].

9.7.9 EIM Memory Map/Register Definition

The EIM includes 33 user-accessible 32-bit registers. The the EIM Configuration Register (EIM_WCR) contains control bits that configure the EIM for certain operation modes.

The 160 bits used to control Individual Chip Select are divided into five registers:

- Chip Select n General Configuration Register 1 (EIM_CSnGCR1)
- Chip Select n General Configuration Register 2 (EIM_CSnGCR2)
- Chip Select n Read Configuration Register 1 (EIM_CSnRCR1)
- Chip Select n Read Configuration Register 2 (EIM_CSnRCR2)
- Chip Select n Write Configuration Register (EIM_CSnWCR)

In addition there are 3 general registers: EIM_WCR, EIM_WIAR, and EIM_EAR.

NOTE

- All EIM registers are sampled by IPG_CLK_S, therefore IPG_CLK_S must be active when accessing through IP bus.
- Read access from all registers (except EIM_WIAR and EIM_EAR) will generate one IPG_XFR_WAIT cycle.
- Read access from EIM_WIAR and EIM_EAR will generate six IPG_XFR_WAIT cycles.
- Write access to all registers (except EIM_EAR) will generate three IPG_XFR_WAIT cycles.
- Write access to EIM_EAR will generate six IPG_XFR_WAIT cycles.

EIM_CS n GCR1 field descriptions

Field	Description
31–28 PSZ	<p>Page Size. This bit field indicates memory page size in words (word is defined by the DSZ field). PSZ is used when fix latency mode is applied, WFL=1 for sync. write accesses, RFL=1 for sync. Read accesses. When working in fix latency mode WAIT signal from the external device is not being monitored, PSZ is used to determine if page boundary is reached and renewal of access is preformed. This bit field is ignored when sync. Mode is disabled or fix latency mode is not being used for write or read access separately.</p> <p>It can be valid for both access type, read or write, or only for one type, according to configuration. PSZ is cleared by a hardware reset.</p> <p>0000 8 words page size 0001 16 words page size 0010 32 words page size 0011 64 words page size 0100 128 words page size 0101 256 words page size 0110 512 words page size 0111 1024 (1k) words page size 1000 2048 (2k) words page size 1001 - 1111 Reserved</p>
27 WP	<p>Write Protect. This bit prevents writes to the address range defined by the corresponding chip select. WP is cleared by a hardware reset.</p> <p>0 Writes are allowed in the memory range defined by chip. 1 Writes are prohibited. All attempts to write to an address mapped by this chip select result in a error response and no assertion of the chip select output.</p>
26–24 GBC	<p>Gap Between Chip Selects. This bit field, according to the settings shown below, determines the minimum time between end of access to the current chip select and start of access to different chip select. GBC is cleared by a hardware reset.</p> <p>Example settings:</p> <p>000 minimum of 0 EIM clock cycles before next access from different chip select (async. mode only) 001 minimum of 1 EIM clock cycles before next access from different chip select 010 minimum of 2 EIM clock cycles before next access from different chip select 111 minimum of 7 EIM clock cycles before next access from different chip select</p>
23 AUS	<p>Address UnShifted. This bit indicates an unshifted mode for address assertion for the relevant chip select accesses. AUS bit is cleared by hardware reset.</p> <p>0 Address shifted according to port size (DSZ config) (128 Mbyte maximum supported memory density). 1 Address unshifted (32 Mbyte maximum supported memory density).</p>
22–20 CSREC	<p>CS Recovery. This bit field, according to the settings shown below, determines the minimum pulse width of CS, OE, and WE control signals before executing a new back to back access to the same chip select. CSREC is cleared by a hardware reset.</p> <p>NOTE: The reset value for EIM_CS0GCR1, CSREC[2:0] is 0b110. For EIM_CS1GCR1 - EIM_CS5GCR, the reset value is 0b000.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles minimum width of CS, OE and WE signals (read async. mode only) 001 1 EIM clock cycles minimum width of CS, OE and WE signals</p>

Table continues on the next page...

EIM_CS n GCR1 field descriptions (continued)

Field	Description
	010 2 EIM clock cycles minimum width of CS, OE and WE signals 111 7 EIM clock cycles minimum width of CS, OE and WE signals
19 SP	Supervisor Protect. This bit prevents accesses to the address range defined by the corresponding chip select when the access is attempted in the User mode. SP is cleared by a hardware reset. 0 User mode accesses are allowed in the memory range defined by chip select. 1 User mode accesses are prohibited. All attempts to access an address mapped by this chip select in User mode results in an error response and no assertion of the chip select output.
18–16 DSZ	Data Port Size. This bit field defines the width of an external device's data port as shown below. NOTE: Only async. access supported for 8 bit port. NOTE: The reset value for EIM_CS0GCR1, DSZ[2] = 0, DSZ[1:0] = EIM_BOOT[1:0]. For EIM_CS1GCR1 - EIM_CS5GCR1, the reset value is 0b001. 000 Reserved. 001 16 bit port resides on DATA[15:0] 010 16 bit port resides on DATA[31:16] 011 32 bit port resides on DATA[31:0] 100 8 bit port resides on DATA[7:0] 101 8 bit port resides on DATA[15:8] 110 8 bit port resides on DATA[23:16] 111 8 bit port resides on DATA[31:24]
15–14 BCS	Burst Clock Start. When SRD=1 or SWR=1, this bit field determines the number of EIM clock cycles delay from start of access before the first rising edge of BCLK is generated. When BCD=0 value of BCS=0 results in a half clock delay after the start of access. For other values of BCD a one clock delay after the start of access is applied, not an immediate assertion. BCS is cleared by a hardware reset. 00 0 EIM clock cycle additional delay 01 1 EIM clock cycle additional delay 10 2 EIM clock cycle additional delay 11 3 EIM clock cycle additional delay
13–12 BCD	Burst Clock Divisor. This bit field contains the value used to program the burst clock divisor for BCLK generation. It is used to divide the internal EIMbus frequency. BCD is cleared by a hardware reset. NOTE: For other than the mentioned below frequency such as 104 MHz, EIM clock (input clock) should be adjust accordingly. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
11 WC	Write Continuous. The WI bit indicates that write access to the memory are always continuous accesses regardless of the BL field value. WI is cleared by hardware reset. 0 Write access burst length occurs according to BL value. 1 Write access burst length is continuous.
10–8 BL	Burst Length. The BL bit field indicates memory burst length in words (word is defined by the DSZ field) and should be properly initialized for mixed wrap/increment accesses support. Continuous BL value corresponds to continuous burst length setting of the external memory device. For fix memory burst size,

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	<p>type is always wrap. In case not matching wrap boundaries in both the memory (BL field) and Master access on the current address, EIM update address on the external device address bus and regenerates the access.</p> <p>BL is cleared by a hardware reset.</p> <p>When APR=1, Page Read Mode is applied, BL determine the number of words within the read page burst. BL is cleared by a hardware reset for EIM_CS0GCR1 - EIM_CS5GCR1.</p> <p>000 4 words Memory wrap burst length (read page burst size when APR = 1) 001 8 words Memory wrap burst length (read page burst size when APR = 1) 010 16 words Memory wrap burst length (read page burst size when APR = 1) 011 32 words Memory wrap burst length (read page burst size when APR = 1) 100 Continuous burst length (2 words read page burst size when APR = 1) 101 Reserved 110 Reserved 111 Reserved</p>
7 CREP	<p>Configuration Register Enable Polarity. This bit indicates CRE memory pin assertion state, active-low or active-high, while executing a memory register set command to the external device (PSRAM memory type). CREP is set by a hardware reset.</p> <p>NOTE: Whenever PSRAM is connected the CREP value must be correct also for accesses where CRE is disabled.</p> <p>For Non-PSRAM memory CREP value should be 1.</p> <p>0 CRE signal is active low 1 CRE signal is active high</p>
6 CRE	<p>Configuration Register Enable. This bit indicates CRE memory pin state while executing a memory register set command to PSRAM external device. CRE is cleared by a hardware reset.</p> <p>0 CRE signal use is disable 1 CRE signal use is enable</p>
5 RFL	<p>Read Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start sampling data according to RWSC field, it only valid in synchronous mode. RFL is cleared by a hardware reset.</p> <p>When RFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device.</p> <p>0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)</p>
4 WFL	<p>Write Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start data transfer according to WWSC field, it only valid in synchronous mode. WFL is cleared by a hardware reset.</p> <p>When WFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device</p> <p>0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)</p>
3 MUM	<p>Multiplexed Mode. This bit determines the address/data multiplexed mode for asynchronous and synchronous accesses for 8 bit, 16 bit or 32 bit devices (DSZ config. dependent).</p>

Table continues on the next page...

EIM_CS n GCR1 field descriptions (continued)

Field	Description
	<p>NOTE: The reset value for EIM_CS0GCR1[MUM] = EIM_BOOT[2]. For EIM_CS1GCR1 - EIM_CS5GCR1 the reset value is 0.</p> <p>0 Multiplexed Mode disable 1 Multiplexed Mode enable</p>
2 SRD	<p>Synchronous Read Data. This bit field determine the read accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SRD is cleared by a hardware reset.</p> <p>NOTE: Sync. accesses supported only for 16/32 bit port.</p> <p>0 read accesses are in Asynchronous mode 1 read accesses are in Synchronous mode</p>
1 SWR	<p>Synchronous Write Data. This bit field determine the write accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SWR is cleared by a hardware reset.</p> <p>NOTE: Sync. accesses supported only for 16/32 bit port.</p> <p>0 write accesses are in Asynchronous mode 1 write accesses are in Synchronous mode</p>
0 CSEN	<p>CS Enable. This bit controls the operation of the chip select pin. CSEN is set by a hardware reset for CSGCR0 to allow external boot operation. CSEN is cleared by a hardware reset to CSGCR1-CSGCR5.</p> <p>NOTE: Reset value for EIM_CS0GCR1 for CSEN is 1. For EIM_CS1GCR1-CS1GCR5 reset value is 0.</p> <p>0 Chip select function is disabled; attempts to access an address mapped by this chip select results in an error respond and no assertion of the chip select output 1 Chip select is enabled, and is asserted when presented with a valid access.</p>

9.7.9.2 Chip Select n General Configuration Register 2 (EIM_CS n GCR2)

Address: 30BC_0000h base + 4h offset + (24d × i), where i=0d to 5d

EIM_CS n GCR2 field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 MUX16_BYP_ GRANT	Muxed 16 bypass grant. This bit when asserted causes EIM to bypass the grant/ack. arbitration with NFC (only for 16 bit muxed mode accesses). 0 EIM waits for grant before driving a 16 bit muxed mode access to the memory. 1 EIM ignores the grant signal and immediately drives a 16 bit muxed mode access to the memory.
11–10 Reserved	This read-only field is reserved and always has the value 0.
9 DAP	Data Acknowledge Polarity. This bit indicates DTACK memory pin assertion state, active-low or active-high, while executing an async access using DTACK signal from the external device. DAP is cleared by a hardware reset. 0 DTACK signal is active high 1 DTACK signal is active low
8 DAE	Data Acknowledge Enable. This bit indicates external device is using DTACK pin as strobe/terminator of an async. access. DTACK signal may be used only in asynchronous single read (APR=0) or write accesses. DTACK poling start point is set by DAPS bit field. polarity of DTACK is set by DAP bit field. DAE is cleared by a hardware reset. 0 DTACK signal use is disable 1 DTACK signal use is enable
7–4 DAPS	Data Acknowledge Poling Start. This bit field determine the starting point of DTACK input signal polling. DAPS is used only in asynchronous single read or write accesses.

Table continues on the next page...

EIM_CS*n*GCR2 field descriptions (continued)

Field	Description
	<p>NOTE: Since DTACK is an async. signal the start point of DTACK signal polling is at least 3 cycles after the start of access.</p> <p>DAPS is cleared by a hardware reset.</p> <p>Example settings:</p> <p>0000 3 EIM clk cycle between start of access and first \overline{DTACK} check</p> <p>0001 4 EIM clk cycles between start of access and first \overline{DTACK} check</p> <p>0010 5 EIM clk cycles between start of access and first \overline{DTACK} check</p> <p>0111 10 EIM clk cycles between start of access and first \overline{DTACK} check</p> <p>1011 14 EIM clk cycles between start of access and first DTACK check</p> <p>1111 18 EIM clk cycles between start of access and first DTACK check</p>
3–2 Reserved	This read-only field is reserved and always has the value 0.
ADH	<p>Address hold time - This bit field determine the address hold time after ADV negation when mum = 1 (muxed mode).</p> <p>When mum = 0 this bit has no effect. For read accesses the field determines when the pads direction will be switched.</p> <p>NOTE: Reset value for EIM_CS0GCR2 for ADH is 10. For EIM_CS1GCR2-EIM_CS5GCR2 reset value is 00.</p> <p>00 0 cycle after ADV negation</p> <p>01 1 cycle after ADV negation</p> <p>10 2 cycle after ADV negation</p> <p>11 Reserved</p>

9.7.9.3 Chip Select *n* Read Configuration Register 1 (EIM_CS*n*RCR1)

Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
29–24 RWSC	<p>Read Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous read access to the external device connected to the chip select.</p> <p>When SRD=1 and RFL=0, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the controller can start sample data. Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode.</p> <p>When SRD=1 and RFL=1, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode.</p> <p>When SRD=0, RFL bit is ignored, RWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer.</p> <p>RWSC is cleared by a hardware reset.</p> <p>NOTE: The reset value for EIM_CS0RCR1, RWSC[5:0] = 0b011100. For CG1RCR1 - CS1RCR5 the reset value is 0b000000.</p> <p>Example settings:</p> <p>000000 Reserved 000001 RWSC value is 1 000010 RWSC value is 2 111101 RWSC value is 61 111110 RWSC value is 62 111111 RWSC value is 63</p>
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 RADVA	<p>ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous read modes according to the settings shown below. RADVA is cleared by a hardware reset.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion</p>
19 RAL	Read ADV Low. This bit field determine ADV signal negation time. When RAL=1, RADVN bit field is ignored and ADV signal will stay asserted until end of access. When RAL=0 negation of ADV signal is according to RADVN bit field configuration.
18–16 RADVN	<p>ADV Negation. This bit field determines when ADV signal to memory is negated during read accesses.</p> <p>When SRD=1 (synchronous read mode), ADV negation occurs according to the following formula: (RADVN + RADVA + BCD + BCS + 1) EIM clock cycles from start of access.</p> <p>When asynchronous read mode is applied (SRD=0) and RAL=0 ADV negation occurs according to the following formula: (RADVN + RADVA + 1) EIM clock cycles from start of access. RADVN is cleared by a hardware reset.</p> <p>NOTE: the reset value for EIM_CS0RCR1[RADVN] = 2. For EIM_CS1RCR1 - EIM_CS5RCR1, the reset value is 0b000.</p> <p>NOTE: This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time with the end of access user should RAL bit.</p>

Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 OEA	<p>OE Assertion. This bit field determines when OE signal are asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. OEA is cleared by a hardware reset.</p> <p>In muxed mode OE assertion occurs (OEA + RADVN + RADVA + ADH + 1) EIM clock cycles from start of access.</p> <p>NOTE: The reset value for EIM_CS0RCR1[OEA] is 0b000 if EIM_BOOT[2] = 0. If EIM_BOOT[2] is 1, the reset value for EIM_CS0RCR1 is 0b010. The reset value of this field for EIM_CS1RCR1 - EIM_CS5RCR1 is 0b000.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of access and OE assertion 001 1 EIM clock cycles between beginning of access and OE assertion 010 2 EIM clock cycles between beginning of access and OE assertion 111 7 EIM clock cycles between beginning of access and OE assertion</p>
11 Reserved	This read-only field is reserved and always has the value 0.
10–8 OEN	<p>OE Negation. This bit field determines when OE signal is negated during read cycles in asynchronous single mode only (SRD=0 and APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. OEN is cleared by a hardware reset.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between end of access and OE negation 001 1 EIM clock cycles between end of access and OE negation 010 2 EIM clock cycles between end of access and OE negation 111 7 EIM clock cycles between end of access and OE negation</p>
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 RCSA	<p>Read CS Assertion. This bit field determines when CS signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RCSA is cleared by a hardware reset.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of read access and CS assertion 001 1 EIM clock cycles between beginning of read access and CS assertion 010 2 EIM clock cycles between beginning of read access and CS assertion 111 7 EIM clock cycles between beginning of read access and CS assertion</p>
3 Reserved	This read-only field is reserved and always has the value 0.
RCSN	<p>Read CS Negation. This bit field determines when CS signal is negated during read cycles in asynchronous single mode only (SRD=0 and APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. RCSN is cleared by a hardware reset.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between end of read access and CS negation 001 1 EIM clock cycles between end of read access and CS negation 010 2 EIM clock cycles between end of read access and CS negation 111 7 EIM clock cycles between end of read access and CS negation</p>

9.7.9.4 Chip Select n Read Configuration Register 2 (EIM_CS_nRCR2)

Address: 30BC_0000h base + Ch offset + (24d × i), where i=0d to 5d

EIM_CS_nRCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 APR	Asynchronous Page Read. This bit field determine the asynchronous read mode to the external device. When APR=0, the async. read access is done as single word (where word is defined by the DSZ field). when APR=1, the async. read access executed as page read. page size is according to BL field config., RCSN,RBEN,OEN and RADVN are being ignored. APR is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. NOTE: SRD=0 and MUM=0 must apply when APR=1
14–12 PAT	Page Access Time. This bit field is used in Asynchronous Page Read mode only (APR=1). the initial access is set by RWSC as in regular asynchronous mode. the consecutive address assertions width determine by PAT field according to the settings shown below. when APR=0 this field is ignored. PAT is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. 000 Address width is 2 EIM clock cycles 001 Address width is 3 EIM clock cycles 010 Address width is 4 EIM clock cycles 011 Address width is 5 EIM clock cycles 100 Address width is 6 EIM clock cycles 101 Address width is 7 EIM clock cycles 110 Address width is 8 EIM clock cycles 111 Address width is 9 EIM clock cycles
11–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 RL	Read Latency. This bit field indicates cycle latency when executing a synchronous read operation. The fields holds the feedback clock loop delay in aclk cycle units. This field is cleared by a hardware reset. 00 Feedback clock loop delay is up to 1 cycle for BCD = 0 or 1.5 cycles for BCD != 0 01 Feedback clock loop delay is up to 2 cycles for BCD = 0 or 2.5 cycles for BCD != 0 10 Feedback clock loop delay is up to 3 cycles for BCD = 0 or 3.5 cycles for BCD != 0 11 Feedback clock loop delay is up to 4 cycles for BCD = 0 or 4.5 cycles for BCD != 0

Table continues on the next page...

EIM_CS n R C R2 field descriptions (continued)

Field	Description
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 RBEA	Read BE Assertion. This bit field determines when BE signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RBEA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of read access and BE assertion 001 1 EIM clock cycles between beginning of read access and BE assertion 010 2 EIM clock cycles between beginning of read access and BE assertion 111 7 EIM clock cycles between beginning of read access and BE assertion
3 RBE	Read BE enable. This bit field determines if BE will be asserted during read access. 0 - BE are disabled during read access. 1- BE are enable during read access according to value of RBEA and RBEN bit fields.
RBEN	Read BE Negation. This bit field determines when BE signal is negated during read cycles in asynchronous single mode only (SRD=0 and APR=0), according to the settings shown below. This bit field is ignored when SRD=1. RBEN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and BE negation 001 1 EIM clock cycles between end of read access and BE negation 010 2 EIM clock cycles between end of read access and BE negation 111 7 EIM clock cycles between end of read access and BE negation

9.7.9.5 Chip Select n Write Configuration Register 1 (EIM_CS n W C R1)

Address: 30BC_0000h base + 10h offset + (24d × i), where i=0d to 5d

EIM_CS_nWCR1 field descriptions

Field	Description
31 WAL	Write ADV Low. This bit field determine ADV signal negation time in write accesses. When WAL=1, WADV _N bit field is ignored and ADV signal will stay asserted until end of access. When WAL=0 negation of ADV signal is according to WADV _N bit field configuration.
30 WBED	Write Byte Enable Disable. When asserted this bit prevent from IPP_DO_BE_B[x] to be asserted during write accesses. This bit is cleared by hardware reset.
29–24 WWSC	<p>Write Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous write access to the external device connected to the chip select.</p> <p>When SWR=1 and WFL=0, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the memory can sample the first data. Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode.</p> <p>When SWR=1 and WFL=1, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode.</p> <p>When SWR=0, WFL bit is ignored, WWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer.</p> <p>WWSC is cleared by a hardware reset.</p> <p>NOTE: The reset value for EIM_CS0WCR1, WWSC[5:0] = 0b011100. For EIM_CS1WCR1 - EIM_CS5WCR1, the reset value of this field is 0b000000.</p> <p>Example settings:</p> <p>000000 Reserved 000001 WWSC value is 1 000010 WWSC value is 2 000011 WWSC value is 3 111111 WWSC value is 63</p>
23–21 WADVA	<p>ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous write modes according to the settings shown below. WADVA is cleared by a hardware reset.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion</p>
20–18 WADV _N	<p>ADV Negation. This bit field determines when ADV signal to memory is negated during write accesses.</p> <p>When SWR=1 (synchronous write mode), ADV negation occurs according to the following formula: (WADV_N + WADVA + BCD + BCS + 1) EIM clock cycles.</p> <p>When asynchronous read mode is applied (SWR=0) ADV negation occurs according to the following formula: (WADV_N + WADVA + 1) EIM clock cycles.</p> <p>NOTE: Reset value for EIM_CS0WCR for WADV_N is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000.</p> <p>NOTE: This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time as the end of access, S/W should set the WAL bit.</p>
17–15 WBEA	BE Assertion. This bit field determines when BE signal is asserted during write cycles in async. mode only (SWR=0), according to the settings shown below. BEA is cleared by a hardware reset.

Table continues on the next page...

EIM_CS n WCR1 field descriptions (continued)

Field	Description
	<p>NOTE: Reset value for EIM_CS0WCR for WBEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of access and BE assertion 001 1 EIM clock cycles between beginning of access and BE assertion 010 2 EIM clock cycles between beginning of access and BE assertion 111 7 EIM clock cycles between beginning of access and BE assertion</p>
14–12 WBEN	<p>BE[3:0] Negation. This bit field determines when BE[3:0] bus signal is negated during write cycles in async. mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. BEN is cleared by a hardware reset.</p> <p>NOTE: Reset value for EIM_CS0WCR for WBEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between end of access and WE negation 001 1 EIM clock cycles between end of access and WE negation 010 2 EIM clock cycles between end of access and WE negation 111 7 EIM clock cycles between end of access and WE negation</p>
11–9 WEA	<p>WE Assertion. This bit field determines when WE signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below. This bit field is ignored when executing a read access to the external device. WEA is cleared by a hardware reset.</p> <p>NOTE: Reset value for EIM_CS0WCR for WEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIM clock cycles between beginning of access and WE assertion</p>
8–6 WEN	<p>WE Negation. This bit field determines when WE signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WEN is cleared by a hardware reset.</p> <p>NOTE: Reset value for EIM_CS0WCR for WEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIM clock cycles between beginning of access and WE assertion</p>
5–3 WCSA	<p>Write CS Assertion. This bit field determines when CS signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below. this bit field is ignored when executing a read access to the external device. WCSA is cleared by a hardware reset.</p> <p>Example settings:</p> <p>000 0 EIM clock cycles between beginning of write access and CS assertion</p>

Table continues on the next page...

Hardware Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

EIM_WCR field descriptions

Field	Description
31–12 Reserved	Reserved This read-only field is reserved and always has the value 0.
11 FRUN_ACLK_EN	Free run ACLK enable
10–9 WDOG_LIMIT	Memory Watchdog (WDOG) cycle limit. This bit field determines the number of BCLK cycles (ACLK cycles in dtack mode) before the WDOG counter terminates the access and send an error response to the master. 00 128 BCLK cycles 01 256 BCLK cycles 10 512 BCLK cycles 11 1024 BCLK cycles
8 WDOG_EN	Memory WDOG enable. This bit controls the operation of the wdog counter that terminates the EIM access. 0 Memory WDOG is Disabled 1 Memory WDOG is Enabled

Table continues on the next page...

EIM_WCR field descriptions (continued)

Field	Description
7–6 Reserved	This read-only field is reserved and always has the value 0.
5 INTPOL	Interrupt Polarity. This bit field determines the polarity of the external device interrupt. 0 External interrupt polarity is active low 1 External interrupt polarity is active high
4 INTEN	Interrupt Enable. When this bit is set the External signal RDY_INT as active interrupt. When interrupt occurs, INT bit at the WCR will be set and t EIM_EXT_INT signal will be asserted correspondingly. This bit is cleared by a hardware reset. 0 External interrupt Disable 1 External interrupt Enable
3 CONT_BCLK_ SEL	Continuous BCLK select When this bit is set BCLK pin output continuous clock. Otherwise, BCLK will output clock only when nesserary. 0 BCLK When nesserary 1 BCLK Continuous
2–1 GBCD	General Burst Clock Divisor. When BCM bit is set, this bit field contains the value used to program the burst clock divisor for Continuous BCLK generation. The other BCD bit fields for each chip select are ignored. It is used to divide the internal AXI bus frequency. When BCM=0 GBCD bit field has no influence. GBCD is cleared by a hardware reset. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
0 BCM	Burst Clock Mode. This bit selects the burst clock mode of operation. It is used for system debug mode. BCM is cleared by a hardware reset. NOTE: The BCLK frequency in this mode is according to GBCD bit field. NOTE: The BCLK phase is opposite to the EIM clock in this mode if GBCD is 0. NOTE: This bit should be used only in async. accesses. No sync access can be executed if this bit is set. NOTE: When this bit is set bcd field shouldn't be configured to 0. 0 The burst clock runs only when accessing a chip select range with the SWR/SRD bits set. When the burst clock is not running it remains in a logic 0 state. When the burst clock is running it is configured by the BCD and BCS bit fields in the chip select Configuration Register. 1 The burst clock runs whenever ACLK is active (independent of chip select configuration)

9.7.9.8 DLL Control Register (EIM_DCR)

Address: 30BC_0000h base + 94h offset = 30BC_0094h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DLL_CTRL_REF_UPDATE_INT				DLL_CTRL_SLV_UPDATE_INT				DLL_CTRL_REF_INITIAL_VAL							
W	DLL_CTRL_REF_UPDATE_INT				DLL_CTRL_SLV_UPDATE_INT				DLL_CTRL_REF_INITIAL_VAL							
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DLL_CTRL_SLV_OVERRIDE_VAL								DLL_CTRL_SLV_OVERRIDE	DLL_CTRL_GATE_UPDATE	DLL_CTRL_SLV_OFFSET		DLL_CTRL_SLV_OFFSET_DEC	DLL_CTRL_SLV_FORCE_UPD	DLL_CTRL_RESET	DLL_CTRL_ENABLE
W	DLL_CTRL_SLV_OVERRIDE_VAL								DLL_CTRL_SLV_OVERRIDE	DLL_CTRL_GATE_UPDATE	DLL_CTRL_SLV_OFFSET		DLL_CTRL_SLV_OFFSET_DEC	DLL_CTRL_SLV_FORCE_UPD	DLL_CTRL_RESET	DLL_CTRL_ENABLE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_DCR field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT	Reference DLL Update Interval DLL control loop update interval. The interval cycle is $(2 + \text{REF_UPDATE_INT}) * \text{ref_clock}$. By default, the DLL control loop shall update every two ref_clock cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–23 DLL_CTRL_SLV_UPDATE_INT	Slave DLL Update Interval If default 0 is used, it means 256 cycles of ref_clock. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
22–16 DLL_CTRL_REF_INITIAL_VAL	This field is used to select the initial value of reference chain before DLL enabled. It's recommended to set the initial value close to the locked value to accelerate the locking.
15–9 DLL_CTRL_SLV_OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0

Table continues on the next page...

EIM_DCR field descriptions (continued)

Field	Description
7 DLL_CTRL_ GATE_UPDATE	Set this bit to 1 to force DLL not update from now on. Since when clock exists, glitches might appear during update. This bit is used by software if we met such kind of condition. Set it to 0 to let DLL update automatically
6-4 DLL_CTRL_ SLV_OFFSET	OFFSET value for DLL_CTRL_SLV_SEL
3 DLL_CTRL_ SLV_OFFSET_ DEC	Slave Chain Offset Decrease Decrease(or increase) the value defined by DLL_CTRL_SLV_OFFSET when calculating DLL_STS_SLV_SEL 0 DLL_STS_SLV_SEL = DLL_STS_REF_SEL + DLL_CTRL_SLV_OFFSET 1 DLL_STS_SLV_SEL = DLL_STS_REF_SEL - DLL_CTRL_SLV_OFFSET
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when EIM is idle.
1 DLL_CTRL_ RESET	DLL Reset Bit Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-lock. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled

9.7.9.9 DLL Status Register (EIM_DSR)

Address: 30BC_0000h base + 98h offset = 30BC_0098h

EIM_DSR field descriptions

Field	Description
31–16 Reserved	Reserved This read-only field is reserved and always has the value 0.
15–9 DLL_STS_REF_SEL	Reference delay line select taps. Be noted this is encoded by 7 bits for 127taps.
8–2 DLL_STS_SLV_SEL	Slave delay line select status. This is the instant value generated from reference chain. Since only when ref_lock is detected can the reference chain get updated, this value should be the right value next be update to the slave line when reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to feedback BCLK, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid delay has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

9.7.9.10 EIM IP Access Register (EIM_WIAR)

Address: 30BC_0000h base + 9Ch offset = 30BC_009Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	[Shaded]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_WIAR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 ACLK_EN	ACLK enable. This bit gates the ACLK for the EIM except from FFs that get ipg_aclk_s. After reset ACLK is enabled. 0 ACLK is disabled 1 ACLK is enabled

Table continues on the next page...

EIM_WIAR field descriptions (continued)

Field	Description
3 ERRST	<p>READY After Reset. This bit controls the initial ready/busy status for external devices on CS0 immediately after hardware reset. This is a sticky bit which is cleared once the RDY_INT signal is asserted by the external device.</p> <p>When ERRST = 1 the first fetch access from EIM to the external device located on CS0 will be pending until RDY_INT signal indicates that the external device is ready, then EIM will execute the access.</p> <p>NOTE: Reset value for ERRST is EIM_BOOT[4].</p> <p>0 RDY_INT After Reset Disable 1 RDY_INT After Reset Enable</p>
2 INT	<p>Interrupt. This bit indicates interrupt assertion by an external device according to RDY_INT signal. When polling this bit, INT=0 indicates interrupt not occurred and INT=1 indicates assertion of the external device interrupt. This bit is cleared by a hardware reset.</p>
1 IPS_ACK	<p>IPS ACK. The EIM is ready for ips access. There is no active AXI access and no new AXI access is accepted till this bit is cleared. This bit is cleared by the master after it completes the ips accesses.</p> <p>0 Master cannot access ips. 1 Master can access ips.</p>
0 IPS_REQ	<p>IPS request. The Master requests to access one of the IPS registers. During such access the EIM should not perform any AXI/memory accesses. The EIM finishes the AXI accesses that already starts and asserts the IPS_ACK bit.</p> <p>0 No Master requests ips access 1 Master requests ips access</p>

9.7.9.11 Error Address Register (EIM_EAR)

Address: 30BC_0000h base + A0h offset = 30BC_00A0h

EIM_EAR field descriptions

Field	Description
Error_ADDR	<p>Error Address. This bit field holds the AXI address of the last access that caused error. This register is read only register.</p>

Chapter 10

Mass Storage

10.1 Enhanced Configurable SPI (ECSPI)

10.1.1 Overview

The Enhanced Configurable Serial Peripheral Interface (ECSPI) is a full-duplex, synchronous, four-wire serial communication block.

The ECSPI contains a 64 x 32 receive buffer (RXFIFO) and a 64 x 32 transmit buffer (TXFIFO). With data FIFOs, the ECSPI allows rapid data communication with fewer software interrupts. The figure below shows a block diagram of the ECSPI.

Figure 10-1. ECSPI Block Diagram

10.1.1.1 Features

Key features of the ECSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- Four Chip Select (SS) signals to support multiple peripherals
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 64-entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Max operation frequency up to the reference clock frequency.

10.1.1.2 Modes and Operations

The ECSPi supports the modes described in the indicated sections:

- [Master Mode](#)
- [Slave Mode](#)
- [Low Power Modes](#)

As described in [Operations](#), the ECSPi supports the operations described in the indicated sections:

- [Typical Master Mode](#)
 - [Master Mode with SPI_RDY](#)
 - [Master Mode with Wait States](#)
 - [Master Mode with SS_CTL\[3:0\] Control](#)
 - [Master Mode with Phase Control](#)
- [Typical Slave Mode](#)

10.1.2 External Signals

Table 10-1. eCSPI External Signals

Signal	Description	Pad	Mode	Direction

Figure 10-2 shows the ECSPI in master mode connected to four external devices in a one-way communication link.

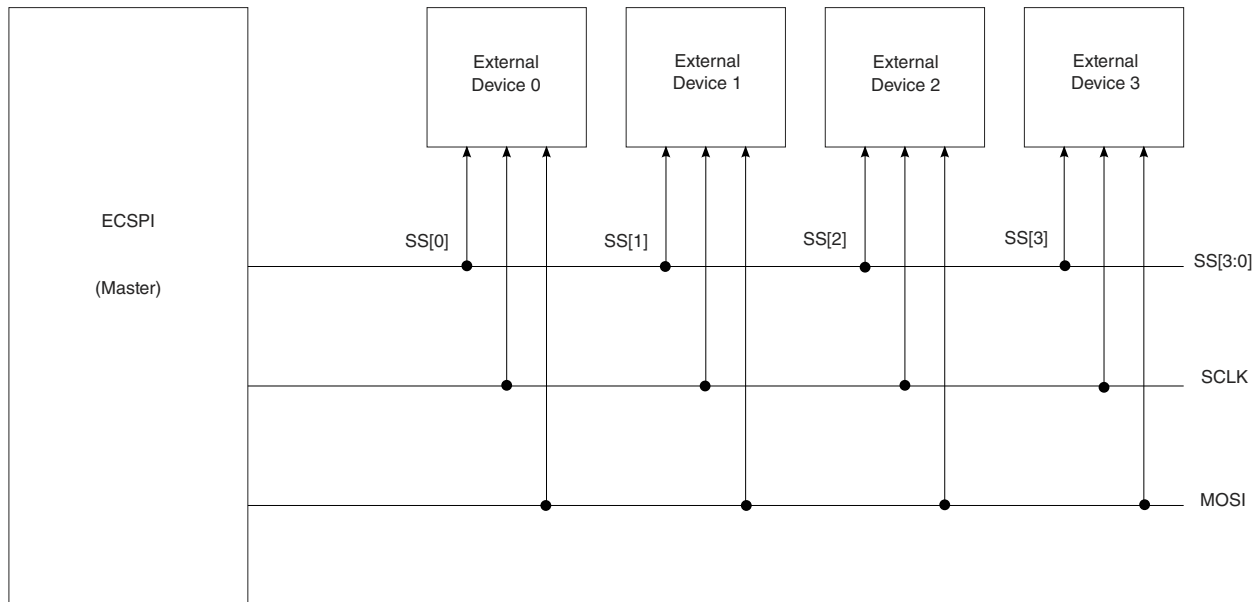

Figure 10-2. Example Connection Diagram

10.1.3 Clocks

The following table describes the clock sources for eCSPI. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 10-2. eCSPI Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_32k	ckil_sync_clk_root	Low-frequency reference clock (32kHz)
ipg_clk_per	ecspi_clk_root	eCSPI module clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

10.1.4 Functional Description

This section provides a complete functional description of the ECSPI. The figure found here shows the relationship of SCLK and data lines while ECSPI has been configured with different POL and PHA settings.

Figure 10-3. ECSPI SCLK, MISO, and MOSI Relationship

10.1.4.1 Master Mode

When the ECSPI is configured as a master, it uses a serial link to transfer data between the ECSPI and an external slave device.

One of the Chip Select (SS) signals and the clock signal (SCLK) are used to transfer data between two devices. If the external device is a transmit-only device, the ECSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, Chip Select (SS) and SPI_RDY, are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

10.1.4.2 Slave Mode

When the ECSPI is configured as a slave, software can configure the ECSPI Control register to match the external SPI master's timing.

In this configuration, Chip Select (\overline{SS}) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

Slave mode only supports the case when `ECSPiX_CONFIGREG[SS_CTL]` is cleared. The accurate burst length should always be specified using the `BURST_LENGTH` parameter. `ECSPiX_CONFIGREG[SS_CTL]` set to 1 is not supported in slave mode.

10.1.4.3 Low Power Modes

The ECSPI does not operate under low power mode.

It holds its operation when its clock is gated off in master mode. In slave mode, the ECSPI does not respond when its clock is gated off.

10.1.4.4 Operations

The information found here describes the ECSPI's operations.

10.1.4.4.1 Typical Master Mode

The ECSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register.

The `SPI_RDY` enables fast data communication with fewer software interrupts. By programming the `ECSPiX_PERIODREG` register accordingly, the ECSPI can be used for a fixed data transfer rate.

When the ECSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input.

Figure 10-4. Typical SPI Burst (8-bit Transfer)

In the above figure, the Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The figure above shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

10.1.4.4.1.1 Master Mode with SPI_RDY

By default, the ECSPI does not use the SPI_RDY signal in master mode (MODE =1).

A SPI burst begins when the following events happen:

- The ECSPI is enabled, TXFIFO has data in it, and ECSPI_CONREG[XCH] bit or the ECSPI_CONREG[SMC] bit is set.
- When the SPI Data Ready Control (ECSPI_CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If ECSPI_CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal has been detected.

The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

Figure 10-5. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (ECSPI_CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low.

The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The ECSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

Figure 10-6. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

10.1.4.4.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device.

The following figure shows wait states inserted between SPI bursts.

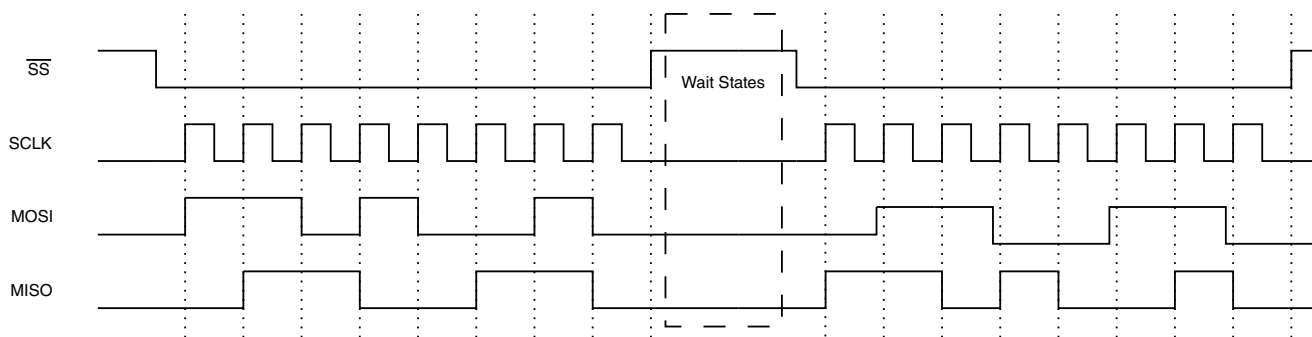

Figure 10-7. SPI Bursts with Wait States

In this case, the number of wait states is controlled by ECSPI_PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by ECSPI_PERIODREG[CSRC].

10.1.4.4.1.3 Master Mode with SS_CTL[3:0] Control

The SPI SS Control (SS_CTL[3:0]) controls whether the current operation is single burst or multiple bursts.

When the SPI SS Wave Form Select (SS_CTL[3:0]) is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SS_CTL[3:0]) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the ECSPI_CONREG register.

Figure 10-8. SPI Burst While SS_CTL[3:0] is Clear

In [Figure 10-8](#), two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined by the BURST LENGTH and limited by the FIFO size. ([Figure 10-8](#) corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the ECSPI is transmitting.

Figure 10-9. SPI Bursts While SS_CTL[3:0] is Set

In [Figure 10-9](#), two FIFO entries are transmitted, one entry with each SPI burst. The ECSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

10.1.4.4.1.4 Master Mode with Phase Control

The Phase Control (ECSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (ECSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When ECSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master. [Figure 10-10](#) shows how SPI burst works with different POL and PHA configuration.

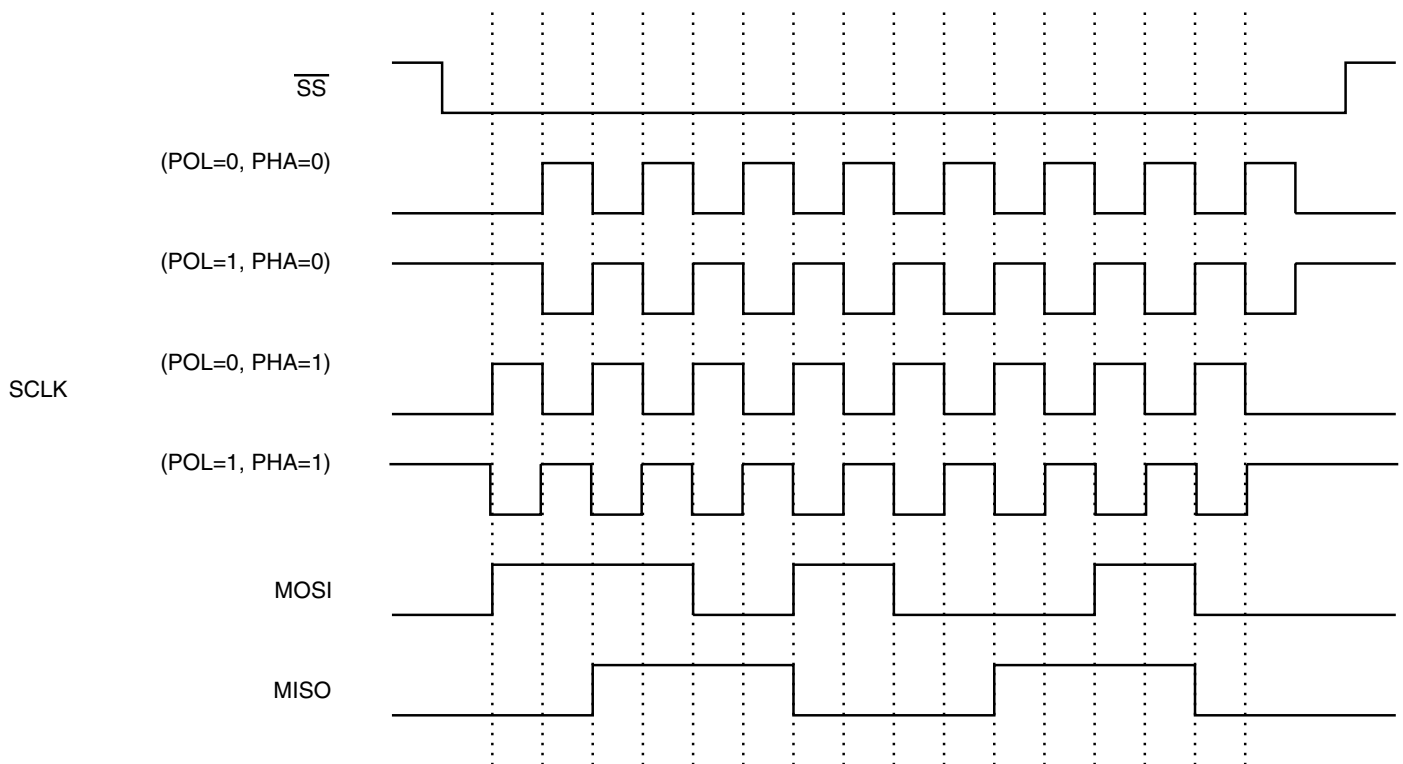

Figure 10-10. SPI Burst with Different POL and PHA Configurations

10.1.4.4.2 Typical Slave Mode

When the ECSPI is configured as a slave (Mode = 0), software can configure the ECSPI Control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SS_POL=0 is set while the ECSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SS_POL = 1), the data FIFO will advance on the falling edge of the SS signal.

The figure below shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

Figure 10-11. Advancing the Data FIFO on the Rising Edge of \overline{SS}

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

10.1.4.5 Reset

Whenever a device reset occurs, a reset is performed on the ECSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see [ECSPI](#).

10.1.4.6 Interrupts

Interrupt control provides a way to manage the ECSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO data request, and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO data request, and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 64 words and will not accept any other words.

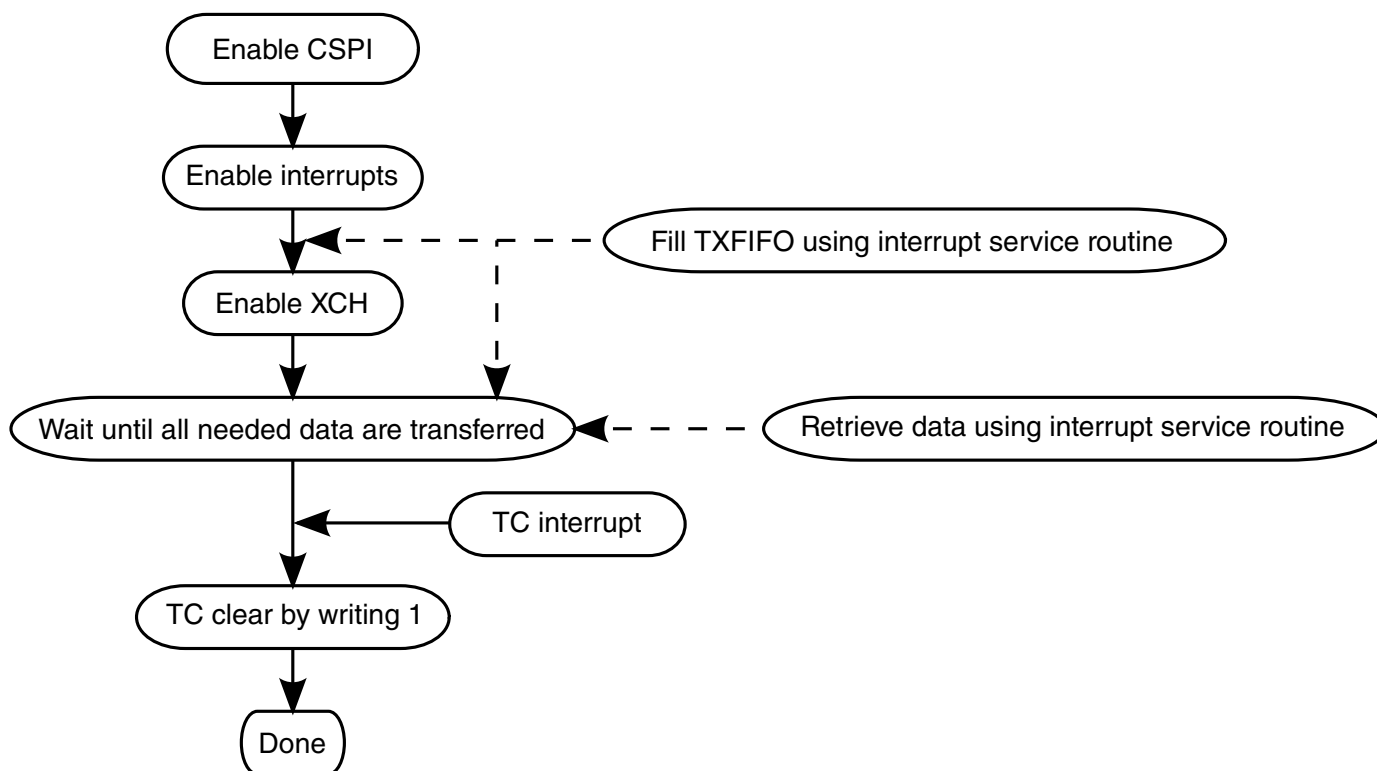

Figure 10-12. Program Sequence of SPI Burst Using Interrupt Control

10.1.4.7 DMA

DMA control provides another method to utilize the FIFOs in the ECSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request.

The DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO data request
- RXFIFO data request
- RXFIFO full

The figure below shows a program sequence of SPI bursts using DMA control.

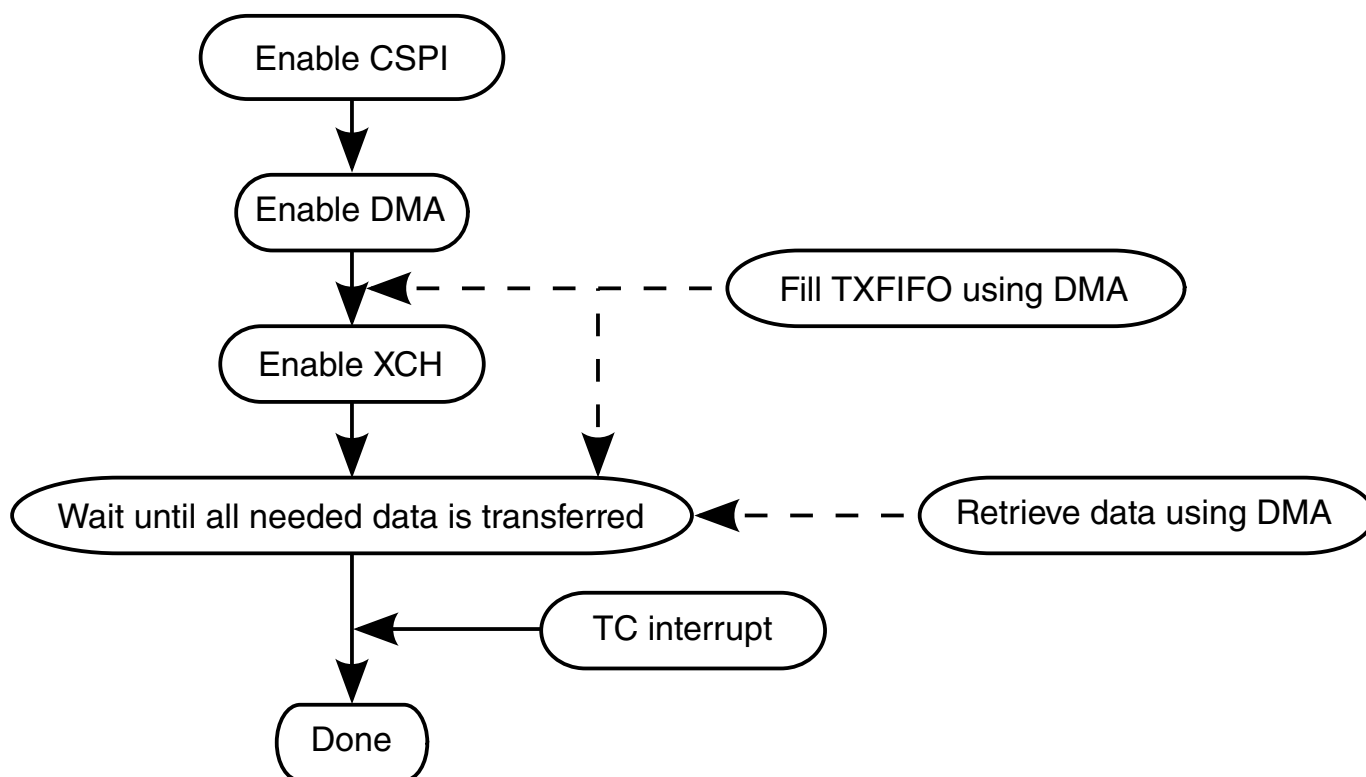

Figure 10-13. Program Sequence of SPI Burst Using DMA

10.1.4.8 Byte Order

The ECSPI does not support byte re-ordering in hardware.

10.1.5 Initialization

This section provides initialization information for ECSPI.

To initialize the block:

1. Clear the EN bit in ECSPI_CONREG to reset the block.
2. Enable the clocks for ECSPI within the CCM.
3. Configure the Control Register and then set the EN bit in the ECSPI_CONREG to put ECSPI out of reset.
4. Configure corresponding IOMUX for ECSPI external signals.
5. Configure registers of ECSPI properly according to the specifications of the external SPI device.

10.1.6 Applications

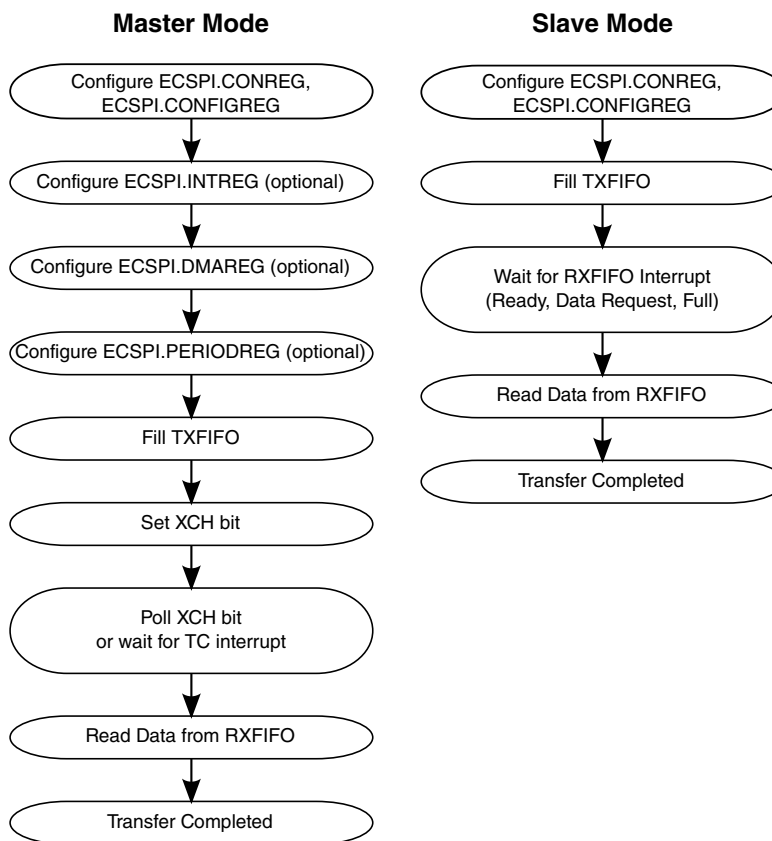

Figure 10-14. Flowchart of the ECSPI Operation

10.1.7 ECSPI Memory Map/Register Definition

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

ECSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

10.1.7.1 Receive Data Register (ECSPIx_RXDATA)

The Receive Data register (ECSPI_RXDATA) is a read-only register that forms the top word of the 64 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Address: Base address + 0h offset

ECSPIx_RXDATA field descriptions

Field	Description
ECSPI_RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when ECSPI is disabled.

10.1.7.2 Transmit Data Register (ECSPIx_TXDATA)

The Transmit Data (ECSPI_TXDATA) register is a write-only data register that forms the bottom word of the 64 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in ECSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the ECSPI is disabled (ECSPI_CONREG[EN] bit is cleared).

Address: Base address + 4h offset

ECSPi_x_TXDATA field descriptions

Field	Description
ECSPI_TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BURST_LENGTH field of the corresponding SPI Control register. If this field contains more bits than the number specified by BURST_LENGTH, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the ECSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when ECSPI is disabled.

10.1.7.3 Control Register (ECSPi_x_CONREG)

The Control Register (ECSPI_CONREG) allows software to enable the ECSPI, configure its operating modes, specify the divider value, and SPI_RDY control signal, and define the transfer length.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ECSPi_x_CONREG field descriptions

Field	Description
31-20 BURST_LENGTH	<p>Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2¹² bits can be transferred in a single SPI burst.</p> <p>In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored.</p> <p>Number of Valid Bits in a SPI burst.</p> <p>0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. ... 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word. ...</p>

Table continues on the next page...

ECSPiX_CONREG field descriptions (continued)

Field	Description
	0xFFE A SPI burst contains the 31 LSB in first word and $2^7 - 1$ words. 0xFFF A SPI burst contains 2^7 words.
19–18 CHANNEL_SELECT	SPI CHANNEL SELECT bits. Select one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the Chip Select (SSn) outputs. Only the selected Chip Select (SSn) signal can be active at a given time; the remaining three signals will be negated. 00 Channel 0 is selected. Chip Select 0 (SS0) will be asserted. 01 Channel 1 is selected. Chip Select 1 (SS1) will be asserted. 10 Channel 2 is selected. Chip Select 2 (SS2) will be asserted. 11 Channel 3 is selected. Chip Select 3 (SS3) will be asserted.
17–16 DRCTL	SPI Data Ready Control. This field selects the utilization of the $\overline{\text{SPI_RDY}}$ signal in master mode. ECSPiX checks this field before it starts an SPI burst. 00 The $\overline{\text{SPI_RDY}}$ signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
15–12 PRE_DIVIDER	SPI Pre Divider. ECSPiX uses a two-stage divider to generate the SPI clock. This field defines the pre-divider of the reference clock. 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 3. ... 1101 Divide by 14. 1110 Divide by 15. 1111 Divide by 16.
11–8 POST_DIVIDER	SPI Post Divider. ECSPiX uses a two-stage divider to generate the SPI clock. This field defines the post-divider of the reference clock using the equation: 2^n . 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 4. ... 1110 Divide by 2^{14} . 1111 Divide by 2^{15} .
7–4 CHANNEL_MODE	SPI CHANNEL MODE selects the mode for each SPI channel. CHANNEL MODE[3] is for SPI channel 3. CHANNEL MODE[2] is for SPI channel 2. CHANNEL MODE[1] is for SPI channel 1. CHANNEL MODE[0] is for SPI channel 0. 0 Slave mode. 1 Master mode.
3 SMC	Start Mode Control. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1).

Table continues on the next page...

ECSPi_x_CONREG field descriptions (continued)

Field	Description
	<p>It controls how the ECSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to.</p> <p>0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SS_CTL). Refer to XCH and SS_CTL descriptions.</p> <p>1 Immediately starts a SPI burst when data is written in TXFIFO.</p>
2 XCH	<p>SPI Exchange Bit. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SS_CTL). The XCH bit remains set while either the data exchange is in progress, or when the ECSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out.</p> <p>0 Idle.</p> <p>1 Initiates exchange (write) or busy (read).</p>
1 HT	<p>Hardware Trigger Enable. This bit is used in master mode only. It enables hardware trigger (HT) mode. Note, HT mode is not supported by this product.</p> <p>0 Disable HT mode.</p> <p>1 Enable HT mode.</p>
0 EN	<p>SPI Block Enable Control. This bit enables the ECSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the ECSPi_x_CONREG. The block's internal clocks are gated off whenever the block is disabled.</p> <p>0 Disable the block.</p> <p>1 Enable the block.</p>

10.1.7.4 Config Register (ECSPi_x_CONFIGREG)

The Config Register (ECSPi_x_CONFIGREG) allows software to configure each SPI channel, configure its operating modes, specify the phase and polarity of the clock, configure the Chip Select (SS), and define the HT transfer length. Note, HT mode is not supported by this product.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPiX_CONFIGREG field descriptions

Field	Description
31–29 -	This field is reserved. Reserved
28–24 HT_LENGTH	HT LENGTH. This field defines the message length in HT Mode. Note, HT mode is not supported by this product. The length in bits of one message is (HT LENGTH + 1).
23–20 SCLK_CTL	SCLK CTL. This field controls the inactive state of SCLK for each SPI channel. SCLK CTL[3] is for SPI channel 3. SCLK CTL[2] is for SPI channel 2. SCLK CTL[1] is for SPI channel 1. SCLK CTL[0] is for SPI channel 0. 0 Stay low. 1 Stay high.
19–16 DATA_CTL	DATA CTL. This field controls inactive state of the data line for each SPI channel. DATA CTL[3] is for SPI channel 3. DATA CTL[2] is for SPI channel 2. DATA CTL[1] is for SPI channel 1. DATA CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
15–12 SS_POL	SPI SS Polarity Select. In both Master and Slave modes, this field selects the polarity of the Chip Select (SS) signal. SS POL[3] is for SPI channel 3. SS POL[2] is for SPI channel 2. SS POL[1] is for SPI channel 1. SS POL[0] is for SPI channel 0. 0 Active low. 1 Active high.
11–8 SS_CTL	SPI SS Wave Form Select. In master mode, this field controls the output wave form of the Chip Select (SS) signal when the SMC (Start Mode Control) bit is cleared. The SS_CTL are ignored if the SMC bit is set. SS CTL[3] is for SPI channel 3. SS CTL[2] is for SPI channel 2. SS CTL[1] is for SPI channel 1. SS CTL[0] is for SPI channel 0. In slave mode, this bit controls when the SPI burst is completed. An SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data. 0 In master mode - only one SPI burst will be transmitted.

Table continues on the next page...

ECSPi_x_CONFIGREG field descriptions (continued)

Field	Description
	<p>1 In master mode - Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty.</p> <p>0 In slave mode - an SPI burst is completed when the number of bits received in the shift register is equal to (BURST LENGTH + 1). Only the n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid.</p> <p>1 Reserved</p>
7-4 SCLK_POL	<p>SPI Clock Polarity Control. This field controls the polarity of the SCLK signal. See Figure 10-10 for more information.</p> <p>SCLK_POL[3] is for SPI channel 3. SCLK_POL[2] is for SPI channel 2. SCLK_POL[1] is for SPI channel 1. SCLK_POL[0] is for SPI channel 0.</p> <p>0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).</p>
SCLK_PHA	<p>SPI Clock/Data Phase Control. This field controls the clock/data phase relationship. See Figure 10-10 for more information.</p> <p>SCLK PHA[3] is for SPI channel 3. SCLK PHA[2] is for SPI channel 2. SCLK PHA[1] is for SPI channel 1. SCLK PHA[0] is for SPI channel 0.</p> <p>0 Phase 0 operation. 1 Phase 1 operation.</p>

10.1.7.5 Interrupt Control Register (ECSPIx_INTREG)

The Interrupt Control Register (ECSPI_INTREG) enables the generation of interrupts to the host processor. If the ECSPI is disabled, this register reads zero.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ECSPIx_INTREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RDREN	RXFIFO Data Request Interrupt enable. This bit enables the RXFIFO Data Request Interrupt when the number of data entries in the RXFIFO is greater than RX_THRESHOLD. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable

Table continues on the next page...

ECSPIx_INTREG field descriptions (continued)

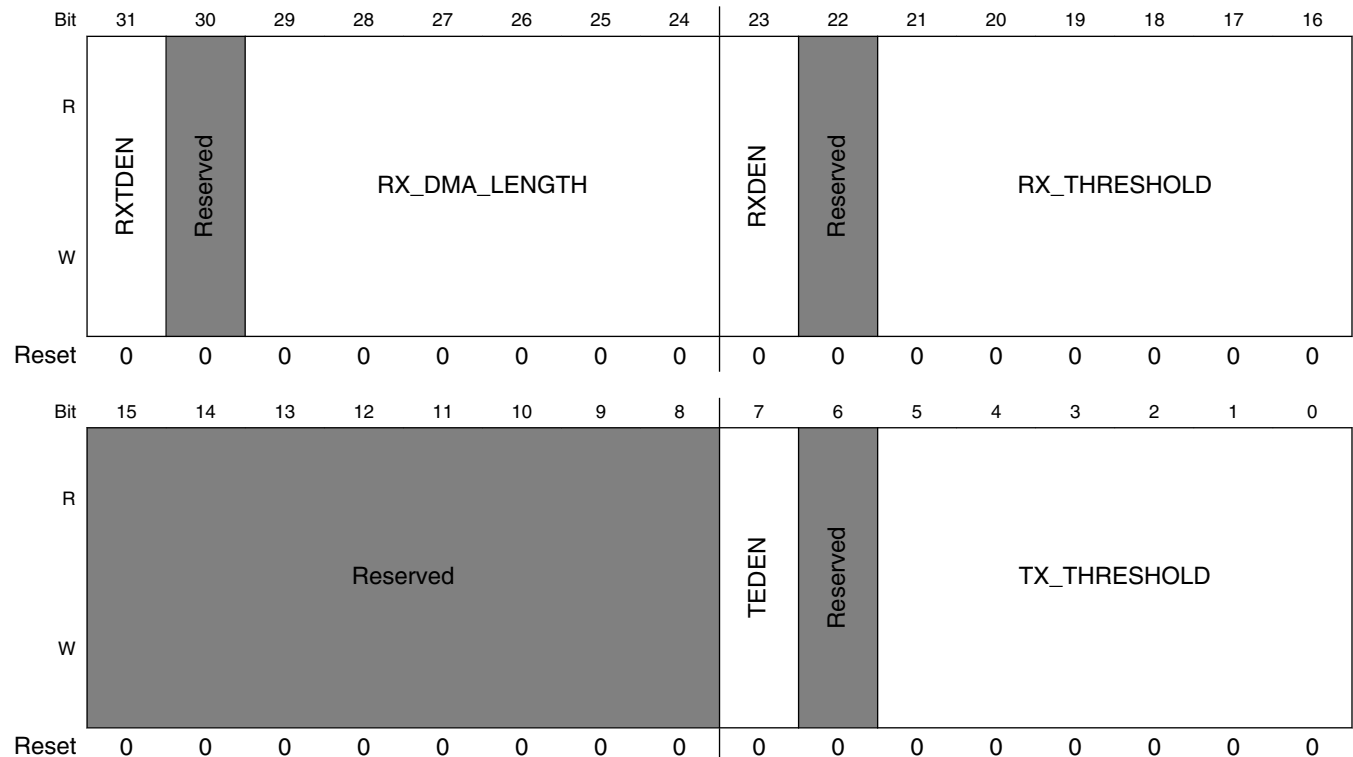

Field	Description
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 TDREN	TXFIFO Data Request Interrupt enable. This bit enables the TXFIFO Data Request Interrupt when the number of data entries in the TXFIFO is less than or equal to TX_THRESHOLD. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

10.1.7.6 DMA Control Register (ECSPIx_DMAREG)

The Direct Memory Access Control Register (ECSPI_DMAREG) provides software a way to use an on-chip DMA controller for ECSPI data. Internal DMA request signals enable direct data transfers between the ECSPI FIFOs and system memory. The ECSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the ECSPI is disabled, this register is read as 0.

Address: Base address + 14h offset

ECSPiX_DMAREG field descriptions

Field	Description
31 RXTDEN	RXFIFO TAIL DMA Request/Interrupt Enable. This bit enables an internal counter that is increased at each read of the RXFIFO. This counter is cleared automatically when it reaches RX DMA LENGTH. If the number of words remaining in the RXFIFO is greater than or equal to RX DMA LENGTH, a DMA request/interrupt is generated even if it is less than or equal to RX_THRESHOLD. 0 Disable 1 Enable
30 -	This field is reserved. Reserved
29–24 RX_DMA_LENGTH	RX DMA LENGTH. This field defines the burst length of a DMA operation. Applies only when RXTDEN is set.
23 RXDEN	RXFIFO DMA Request Enable. This bit enables/disables the RXFIFO DMA Request. 0 Disable 1 Enable
22 -	This field is reserved. Reserved
21–16 RX_THRESHOLD	RX THRESHOLD. This field defines the FIFO threshold that triggers a RX DMA/INT request. A RX DMA/INT request is issued when the number of data entries in the RXFIFO is greater than RX_THRESHOLD.
15–8 -	This field is reserved. Reserved
7 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request. 0 Disable 1 Enable
6 -	This field is reserved. Reserved
TX_THRESHOLD	TX THRESHOLD. This field defines the FIFO threshold that triggers a TX DMA/INT request. A TX DMA/INT request is issued when the number of data entries in the TXFIFO is not greater than TX_THRESHOLD.

10.1.7.7 Status Register (ECSPIx_STATREG)

The ECSPI Status Register (ECSPI_STATREG) reflects the status of the ECSPI's operating condition. If the ECSPI is disabled, this register reads 0x0000_0003.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TC	RO	RF	RDR	RR	TF	TDR	TE
W	Reserved								w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

ECSPIx_STATREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. Writing 1 to this bit clears it. 0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.
4 RDR	RXFIFO Data Request. 0 When RXTDE is set - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is set - Number of data entries in the RXFIFO is greater than RX_THRESHOLD or a DMA TAIL DMA condition exists. 0 When RXTDE is clear - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is clear - Number of data entries in the RXFIFO is greater than RX_THRESHOLD.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full.

Table continues on the next page...

ECSPiX_STATREG field descriptions (continued)

Field	Description
	0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TDR	TXFIFO Data Request. 0 Number of valid data slots in TXFIFO is greater than TX_THRESHOLD. 1 Number of valid data slots in TXFIFO is not greater than TX_THRESHOLD.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

10.1.7.8 Sample Period Control Register (ECSPiX_PERIODREG)

The Sample Period Control Register (ECSPiX_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the current channel is operating in Master mode (ECSPiX_CONREG[CHANNEL MODE] = 1). ECSPiX_PERIODREG also contains the CSD CTRL field used to insert a delay between the Chip Select's active edge and the first SPI Clock edge.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
31–22 -	This field is reserved. Reserved

Table continues on the next page...

ECSPi_x_PERIODREG field descriptions (continued)

Field	Description
21–16 CSD_CTL	Chip Select Delay Control bits. This field defines how many SPI clocks will be inserted between the chip select's active edge and the first SPI clock edge. The range is from 0 to 63.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
SAMPLE_PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SS_CTL control field in the ECSPi_CONREG register. 0x0000 0 wait states inserted 0x0001 1 wait state inserted 0x7FFE 32766 wait states inserted 0x7FFF 32767 wait states inserted

10.1.7.9 Test Control Register (ECSPi_x_TESTREG)

The Test Control Register (ECSPi_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the ECSPI, and monitor the contents of the receive and transmit FIFOs.

Address: Base address + 20h offset

ECSPiX_TESTREG field descriptions

Field	Description
31 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the ECSPi connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
30–28 -	This field is reserved. Reserved, all bits should be ignored.
27–15 -	This field is reserved. Reserved
14–8 RXCNT	RXFIFO Counter. This field indicates the number of words in the RXFIFO.
7 -	This field is reserved. Reserved
TXCNT	TXFIFO Counter. This field indicates the number of words in the TXFIFO.

10.1.7.10 Message Data Register (ECSPiX_MSGDATA)

The Message Data Register (ECSPiX_MSGDATA) forms the top word of the 16 x 32 MSG Data FIFO. Only word-size accesses are allowed for this register. Reads to this register return zero, and writes to this register store data in the MSG Data FIFO.

Address: Base address + 40h offset

ECSPiX_MSGDATA field descriptions

Field	Description
ECSPiX_MSGDATA	ECSPiX_MSGDATA holds the top word of MSG Data FIFO. The MSG Data FIFO is advanced for each write of this register. The data read is zero. The data written to this register is stored in the MSG Data FIFO.

10.2 Quad Serial Peripheral Interface (QuadSPI)

10.2.1 Overview

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one or two external serial flash devices, each with up to four bidirectional data lines. The following figure is a block diagram of the QuadSPI module.

Figure 10-15. QuadSPI Block Diagram

The following figure describes the serial flash clock diagram in QuadSPI:

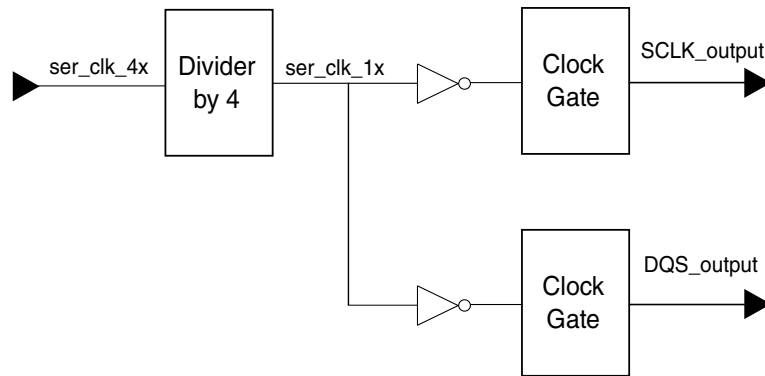

Figure 10-16. Flash Clock Diagram

ser_clk_4x is the serial clock root from CCM

ser_clk_1x' is generated clock from 'ser_clk_4x' divided by 4

SCLK_output is serial output clock generated from 'ser_clk_1x' with inverter and clock gate, it's used as Clock by external serial flash device.

DQS_output is serial flash data strobe signal generated from 'ser_clk_1x' with inverter and clock gate. This signal could be loopback from pad and used as sampling clock for serial flash data.

10.2.1.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices.
- Single, dual, quad mode of operation.
- DDR/DTR mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and SDR mode.
- Two identical serial flash devices can be connected and accessed in parallel for data read operations, forming one (virtual) flash memory with doubled readout bandwidth.
- DMA support to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access).
 - Inner loop size of DMA access can be configured.
- Multi master accesses with priority

- Flexible and configurable buffer for each master
- Thirteen interrupt conditions (see [Table 10-12](#))
- Memory mapped read access to connected flash devices.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations.
 - Supports 3-byte and 4-byte addressing.
 - TXFIFO size is 512Byte
 - RXFIFO size is 512Byte
 - AHB BUF size is 1KByte

10.2.1.2 QuadSPI Modes of Operation

This section provides information about the modes in which the QuadSPI module can be used.

10.2.1.2.1 Normal Mode

In this mode, one or two external serial flash memory devices can be accessed. Further details about this mode of operation can be found in [Modes of Operation \(Normal Mode\)](#).

10.2.1.2.2 Module Disable Mode

This mode is used for power management of the device containing the QuadSPI module. It is controlled by signals external to the QuadSPI. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode.

10.2.1.3 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 10-3. Acronyms and Abbreviations

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select
DMA	Direct Memory Access

Table continues on the next page...

Table 10-3. Acronyms and Abbreviations (continued)

Terms	Description
MB	Megabyte. Each MB is 1024 * 1024 bytes
IFM	Individual Flash Mode
PFM	Parallel Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a 1 to this field resets the flag

10.2.1.4 Glossary for QuadSPI module

Table 10-4. Glossary

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in Table 10-9 . Refer to AHB Commands for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
QSPI_AMBA_BASE	First address of QuadSPI address space on system memory map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.

Table continues on the next page...

Table 10-4. Glossary (continued)

Term	Definition
RX Buffer PUSH Event	Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added. The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to Serial Flash Access Schemes for details.
Parallel Flash Mode	Read access to two serial flash devices attached to the QuadSPI module in parallel. Refer to Serial Flash Access Schemes for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to Table 10-22 for details on errors.
Single/Dual/Quad Instructions	Depending on the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines. <ul style="list-style-type: none"> • Single: Single line I/O with one data out and one data in line to/from the serial flash device. • Dual: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module • Quad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode-and/or dummy bytes, transmit and/or receive data.
LUT	Look-up table.

10.2.2 External Signals

The following table describes the external signals of QSPI:

Table 10-5. QSPI External Signals

Signal	Description	Pad	Mode	Direction
QSPI_A_DATA0	I/O data signal 1 port 0 for serial flash device A	EPDC1_DATA00	ALT2	IO
QSPI_A_DATA1	I/O data signal 1 port 1 for serial flash device A	EPDC1_DATA01	ALT2	IO
QSPI_A_DATA2	I/O data signal 1 port 2 for serial flash device A	EPDC1_DATA02	ALT2	IO
QSPI_A_DATA3	I/O data signal 1 port 3 for serial flash device A	EPDC1_DATA03	ALT2	IO
QSPI_A_DQS	Data strobe signal 1 to serial flash device A	EPDC1_DATA04	ALT2	I

Table continues on the next page...

**Table 10-5. QSPI External Signals
(continued)**

Signal	Description	Pad	Mode	Direction
QSPI_A_SCLK	Serial clock output 1 to serial flash device A	EPDC1_DATA05	ALT2	O
QSPI_A_SS0_B	Chip select 1 port 0 for serial flash device A	EPDC1_DATA06	ALT2	O
QSPI_A_SS1_B	Chip select 1 port 1 for serial flash device A	EPDC1_DATA07	ALT2	O
QSPI_B_DATA0	I/O data signal 1 port 0 for serial flash device B	EPDC1_DATA08	ALT2	IO
QSPI_B_DATA1	I/O data signal 1 port 1 for serial flash device B	EPDC1_DATA09	ALT2	IO
QSPI_B_DATA2	I/O data signal 1 port 2 for serial flash device B	EPDC1_DATA10	ALT2	IO
QSPI_B_DATA3	I/O data signal 1 port 3 for serial flash device B	EPDC1_DATA11	ALT2	IO
QSPI_B_DQS	Data strobe signal 1 to serial flash device B	EPDC1_DATA12	ALT2	I
QSPI_B_SCLK	Serial clock output 1 to serial flash device B	EPDC1_DATA13	ALT2	O
QSPI_B_SS0_B	Chip select 1 port 0 for serial flash device B	EPDC1_DATA14	ALT2	O
QSPI_B_SS1_B	Chip select 1 port 1 for serial flash device B	EPDC1_DATA15	ALT2	O

10.2.2.1 Driving External Signals

The different phases of serial flash access scheme are shown in the following figure.

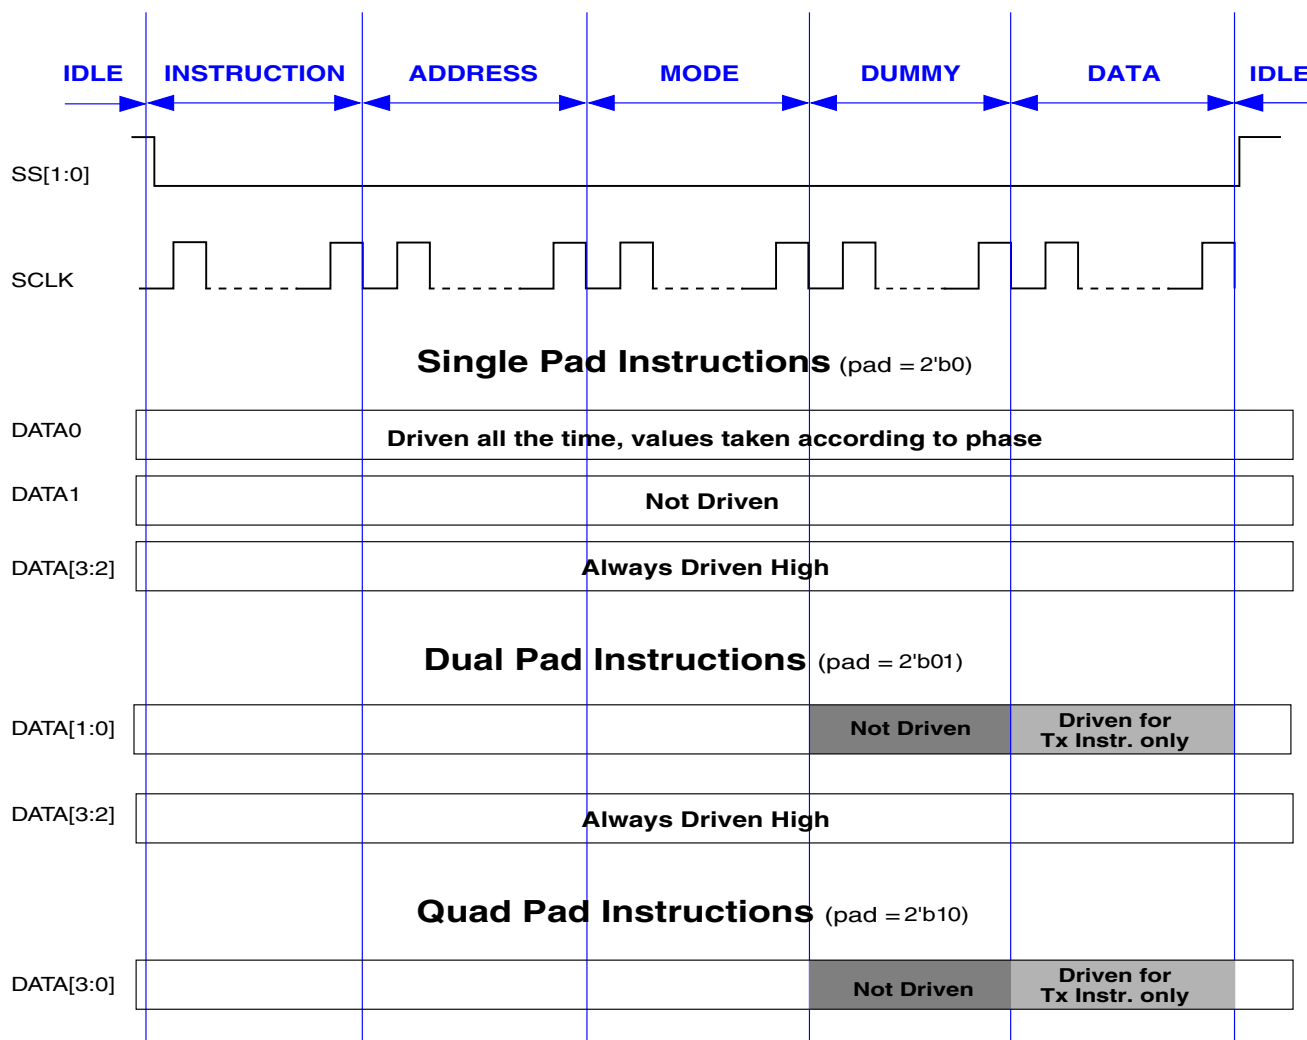

Figure 10-17. Serial Flash Access Scheme

The different phases and the I/O driving characteristics of the QuadSPI module are characterized in the following way:

- **IDLE:** Serial flash device not selected. No interaction with the serial flash device. All DATA signals driven.
- **INSTRUCTION:** Serial flash device selected. The instruction is sent to the serial flash device. All DATA signals are driven.
- **ADDRESS:** Serial Flash Address is sent to the device. All DATA signals are driven. Note that this phase is not applicable for all SFM Commands.
- **MODE:** Mode bytes are sent to the serial flash device. All DATA signals are driven. Note that this phase is not applicable for all SFM Commands.

- **DUMMY:** Dummy clocks are provided to the serial flash device. Refer to the [Figure 10-17](#) for the DATA signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.
- **DATA:** Serial flash data are sent to or received from the serial flash device. Refer to the preceding figure for the DATA signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.

The SS[1:0] and SCLK signals are driven permanently throughout all the phases.

In Individual Flash Mode this applies to the selected flash device. In Parallel Flash Mode this applies to both serial flash devices simultaneously.

10.2.3 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

10.2.3.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 10-6. Register Write Access Restrictions

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if <code>QSPI_MCR[MDIS] = 1</code> .
Normal Mode	Write access only if the module is in <i>Normal Mode</i> .

• Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

10.2.3.2 Serial Flash Address Assignment

The serial flash address assignment may be modified by writing into [Serial Flash A1 Top Address \(QuadSPI_SFA1AD\)](#) and [Serial Flash A2 Top Address \(QuadSPI_SFA2AD\)](#) for device A and into [Serial Flash B1 Top Address \(QuadSPI_SFB1AD\)](#) and [Serial Flash B2 Top Address \(QuadSPI_SFB2AD\)](#) for device B. The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

Table 10-7. Serial Flash Address Assignment

Parameter	Function	Access Mode
QSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to Serial Flash A1
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to Serial Flash A2
TOP_ADDR_MEMB1(TPADB1)	Top address for the external flash B1 (first device of the dual die flash B, or the first of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 will be routed to Serial Flash B1
TOP_ADDR_MEMB2(TPADB2)	Top address for the external flash B2 (second device of the dual die flash B or the second of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 will be routed to Serial Flash A2

10.2.3.3 AMBA Bus Register Memory Map

QSPI_AMBA_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map..

Table 10-8. QuadSPI AMBA Bus Memory Map

Address	Register Name
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A	
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A for details and to Table 10-16 and Table 10-20 for information about the byte ordering.
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B	
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B for details and to Table 10-16 and Table 10-20 for information about the byte ordering.
Parallel Flash Mode	
QSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 0x01)	Parallel Flash Mode Refer to Parallel Flash Mode for details and to Table 10-19 and Table 10-20 for information about the byte ordering.
AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)	
QSPI_ARDB_BASE to... (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) Refer to Table 10-16 and Table 10-18 for information about the byte ordering.

Note

Any read access to non-implemented addresses will provide undefined results.

In case single die flash devices, TOP_ADDR_MEMA2 and TOP_ADDR_MEMB2 should be initialized/programmed to TOP_ADDR_MEMA1 and TOP_ADDR_MEMB1 respectively- in effect, setting the size of these devices to 0. This would ensure that the complete memory map is assigned to only one flash device.

Parallel Flash Mode is valid only for commands related to data read from the serial flash. The first device of flash A has to be paired with the first device of flash B and the second device of flash A has to be paired with the second device of flash B in parallel mode. Parallel mode is selected via the QSPI_BFGENCR[PAR_EN] bit for all masters in AHB driven mode and via the QSPI_IPCR[PAR_EN] in IP driven mode. In parallel mode, the incoming address (SFAR address in case of IP initiated transactions and the incoming AHB address in case of AHB initiated transactions) is divided by 2 and sent to the two flashes connected in parallel.

Any IP Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[IUEF] flag and any AHB Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by SFADR [23:0] or SFADR [31:0] as given in the table above.

In Parallel Flash Mode, both flashes are read with the same starting address of 3/4 (as programmed in the instruction/operand in the sequence) bytes in size. This address is derived from SFADR [24:1] or SFADR [31:1] as given in the table above. The LSB of the SFADR field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

10.2.3.4 AHB Bus Register Memory Map Descriptions

This chapter contains definitions of registers in the AMBA address space.

10.2.3.4.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the QSPI_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.
- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

10.2.3.4.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address QSPI_AMBA_BASE the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address QSPI_AMBA_BASE with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 10-16](#) and for 64 bit read access the byte ordering is given in [Table 10-20](#).

Table 10-9. Memory Mapped Individual Flash Mode - Flash A Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
QSPI_AMBA_BASE + 0x00	QSPI_AMBA_BASE + 0x00	0x00_0000 to 0x00_0003	A1
QSPI_AMBA_BASE + 0x04		0x00_0004 to 0x00_0007	
...	
TOP_ADDR_MEMA1 - 0x08	TOP_ADDR_MEMA1 - 0x08	(TOP_ADDR_MEMA1 - 0x08) to (TOP_ADDR_MEMA1 - 0x04 - 0x01)	
TOP_ADDR_MEMA1 - 0x04		(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)	
TOP_ADDR_MEMA1 + 0x00	TOP_ADDR_MEMA1 + 0x00_0000	0x00_0000 to 0x00_0003	A2
TOP_ADDR_MEMA1 + 0x04		0x00_0004 to 0x00_0007	
.....	
TOP_ADDR_MEMA2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMA2 - 0x04		(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

10.2.3.4.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address TOP_ADDR_MEMA2 the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address TOP_ADDR_MEMA2 with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual

die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 10-16](#) and for 64 bit read access the byte ordering is given in [Table 10-20](#).

Table 10-10. Memory Mapped Individual Flash Mode - Flash B Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA2 + 0x00	TOP_ADDR_MEMA2 + 0x00	0x00_0000 to 0x00_0003	B1
TOP_ADDR_MEMA2 + 0x04		0x00_0004 to 0x00_0007	
...	
TOP_ADDR_MEMB1 - 0x08	TOP_ADDR_MEMB1 - 0x08	(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMB1 - 0x04		(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x01)	
TOP_ADDR_MEMB1 + 0x00	TOP_ADDR_MEMB1 + 0x00_0000	0x00_0000 to 0x00_0003	B2
TOP_ADDR_MEMB1 + 0x04		0x00_0004 to 0x00_0007	
.....	
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)	
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

10.2.3.4.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI_BFGENCR[PAR_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 10-18](#) and for 64 bit read access the byte ordering is given in [Table 10-20](#).

Table 10-11. Memory Mapped Parallel Flash Mode Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to Parallel mode and Dual Die Flashes .	0x00_0000	0x00_0000
QSPI_AMBA_BASE + 0x0000_0004		-	-
		0x00_0001	0x00_0001
		0x00_002	0x00_0002
		-	-
		0x00_0003	0x00_0003
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0004	0x00_0004
		-	-
		0x00_0005	0x00_0005
QSPI_AMBA_BASE + 0x0000_000C		0x00_0006	0x00_0006
		-	-
		0x00_0007	0x00_0007
...
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2$	$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2$
TOP_ADDR_MEMB2 - 0x04		$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01$	$(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01$

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

10.2.4 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 10-12. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rfdf	RBDF	RX Buffer Drain
ipi_int_overrun		Buffer Overflow/Underrun Error Logical OR from:

Table continues on the next page...

Table 10-12. Assignment of Interrupt Request Lines (continued)

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
	IUEF	Peripheral Command Usage Error
ipi_int_ored	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, IUEF	Logical OR from all the QSPI_FR flags mentioned

10.2.5 Functional Description

This section provides the functional information of the QuadSPI module.

10.2.5.1 Serial Flash Access Schemes

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to 4 bidirectional data lines. Depending from the serial flash devices attached to the QuadSPI module the following access schemes are possible:

Table 10-13. Access Schemes for Serial Flash Data Access

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	Yes	N/a	Yes
Individual Flash Mode: Access to Flash B	N/a	Yes	Yes
Parallel Flash Mode: Read from Flash A and Flash B	N/a	N/a	Yes

Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

10.2.5.2 Modes of Operation

Refer to [QuadSPI Modes of Operation](#) for an overview over the possible operational modes of the QuadSPI block.

- Normal Mode can be used for write or read accesses to an external serial flash device.
 - Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to [Flash Programming](#) for further details.
 - Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see [Flash Read](#).

- **Stop Mode:** The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- **Module Disable Mode:** The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

10.2.5.3 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

10.2.5.3.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 10-14. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2}	8 bit command value	Provide the serial flash with operand on the number of pads specified
ADDR	6'd2	2'd1 - Two pads 2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions .
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)

Table continues on the next page...

Table 10-14. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads ¹ specified
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads ² specified
READ	6'd7	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions.
WRITE	6'd8		Write data size in bytes	Write data on number of pads specified. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
JMP_ON_CS	6'd9	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions .
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash ³
MODE4_DDR	6'd13	N=2'd{0,1}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash ⁴ .
READ_DDR	6'd14	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register

Table continues on the next page...

Table 10-14. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
DATA_LEARN ⁵	6'd16		8 bit Data learning pattern	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the <code>QSPI_SMPR[DDRSMP]</code> values are ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern. ⁶
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.
5. Data learning is not implemented on this chip.
6. t is not recommended to have 0x00 or 0xFF as the data learning pattern.

A sequence of such instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed in the LUT is referred to by its index.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

10.2.5.3.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated. The size of buffer 0 is defined as being from 0 to `QSPI_BUF0IND`. The Size of buffer 1 is from `QSPI_BUF0IND` to `QSPI_BUF1IND`, buffer2 is from `QSPI_BUF1IND` to `QSPI_BUF2IND` and buffer 3 is from `QSPI_BUF2IND` to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the `QSPI_BUF3CR[ALLMST]` bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash. As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. Figure 10-18 shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to [Look-up Table](#) for details.

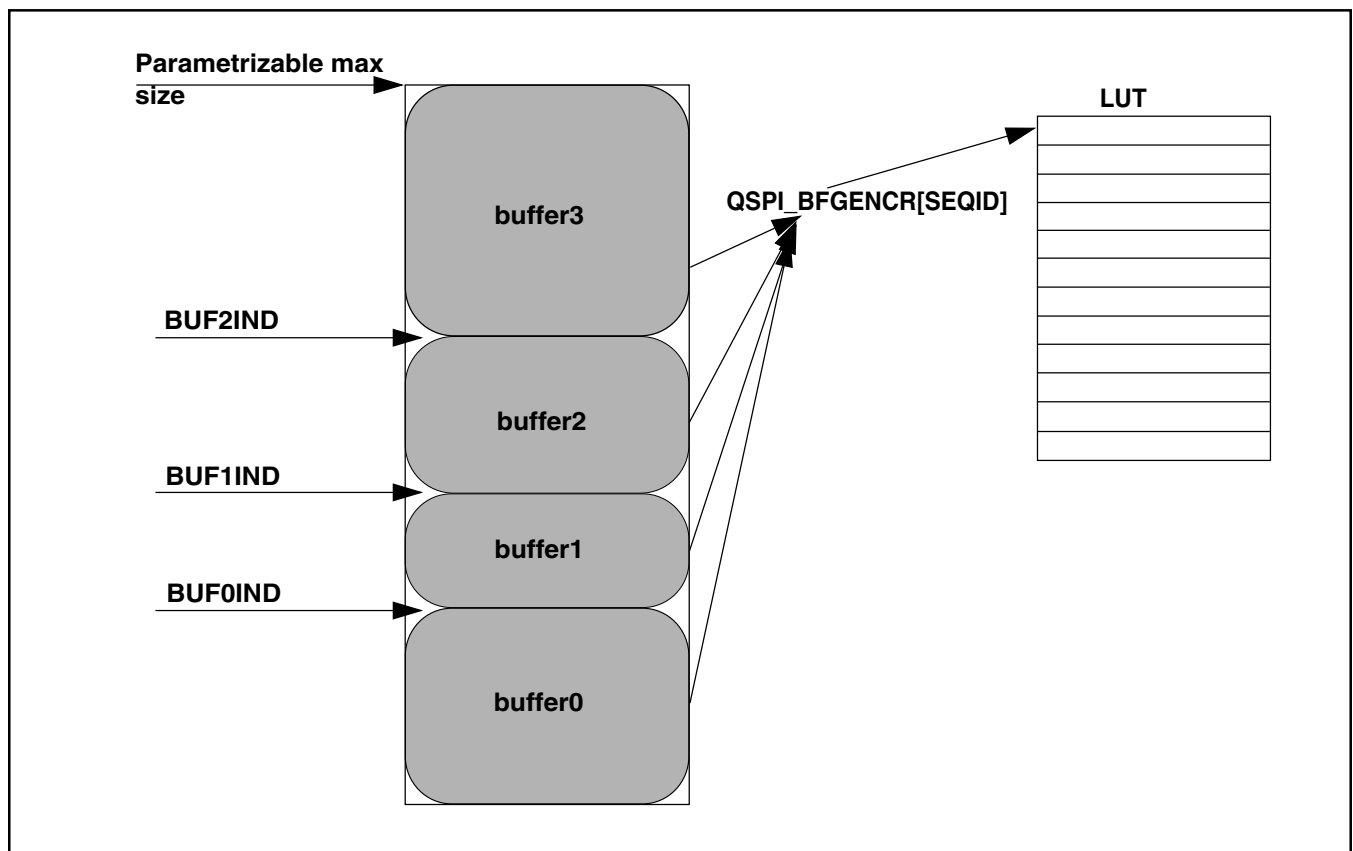

Figure 10-18. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes,

the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from [Sequence Suspend Status Register \(QuadSPI_SPNDST\)](#).

10.2.5.3.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

10.2.5.3.4 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

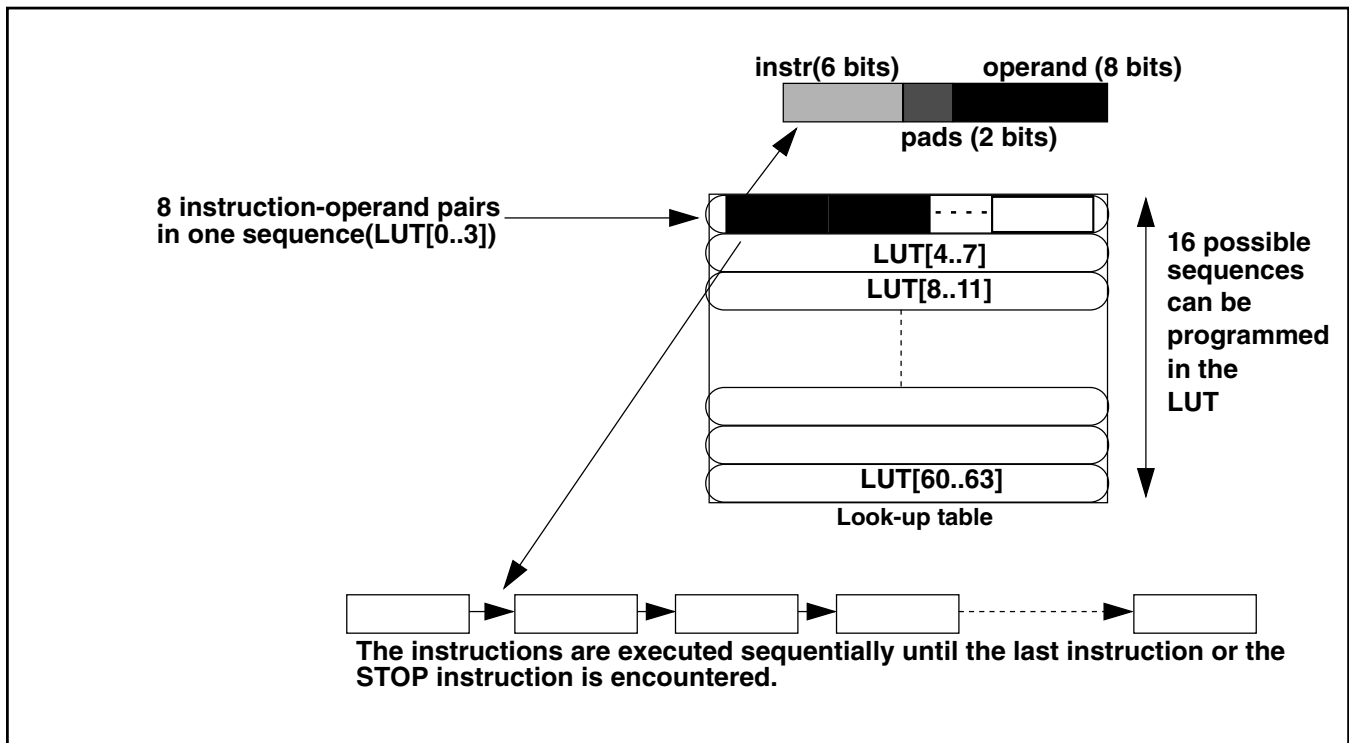

Figure 10-19. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in [Table 10-15](#). After reset the complete LUT may be reprogrammed according to the device connected on board. In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key (**0x5AF05AF0**) in to the [LUT Key Register \(QuadSPI_LUTKEY\)](#).
2. Write 0b01 to the [LUT Lock Configuration Register \(QuadSPI_LCKCR\)](#). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key (**0x5AF05AF0**) into the [LUT Key Register \(QuadSPI_LUTKEY\)](#)
2. Write 0b10 to the [LUT Lock Configuration Register \(QuadSPI_LCKCR\)](#). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from QSPI_LCKCR[UNLOCK] and QSPI_LCKCR[LOCK] bit.

Some example sequences are defined in [Example Sequences](#). The reset sequence at LUT index 0 is given in the following table.

Table 10-15. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

10.2.5.3.5 Issuing SFM Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.
4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI_SR[BUSY] is reset. In case of an IP Command the QSPI_FR[TFF] flag is asserted.

Further details are given in below in [Flash Programming](#) and [Flash Read](#).

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

For IP Commands the required components need to be written into the following registers:

- Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to [Serial Flash Address Register \(QSPI_SFAR\)](#). For IP Commands not related to specific addresses, the base address of the related flash need to be

programmed. For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.

- Write the sequence ID and data size details in the [IP Configuration Register \(QSPI_IPCR\)](#).
- Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to [IP Configuration Register \(QSPI_IPCR\)](#) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in [Command Arbitration](#).

- **Using AHB commands**

Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in [Flexible AHB buffers](#).

An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#) and [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#).

Again the possible error conditions are described in [Command Arbitration](#).

10.2.5.3.6 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check that the TX Buffer is empty. If the QSPI_SR[TXEDA] bit is set then the TX Buffer must be cleared by writing 1 into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register.
3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR). At least four word of data must be written into the TX Buffer up to a maximum of 32.

4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed. The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register. The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **32** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented by four after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

10.2.5.3.7 Flash Read

Host access to the data stored in the external serial flash device is done in two steps. First, the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. Reading Serial Flash Data into the QuadSPI Module Internal Buffers

A read access to the external serial flash device can be triggered in two different ways:

- **IP Command Read:** For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QuadSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should program the Serial Flash Address Register (QSPI_SFAR) and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QuadSPI_MCR[CLR_RXF] field.

From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command, the IP_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBCT[RXBRD].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

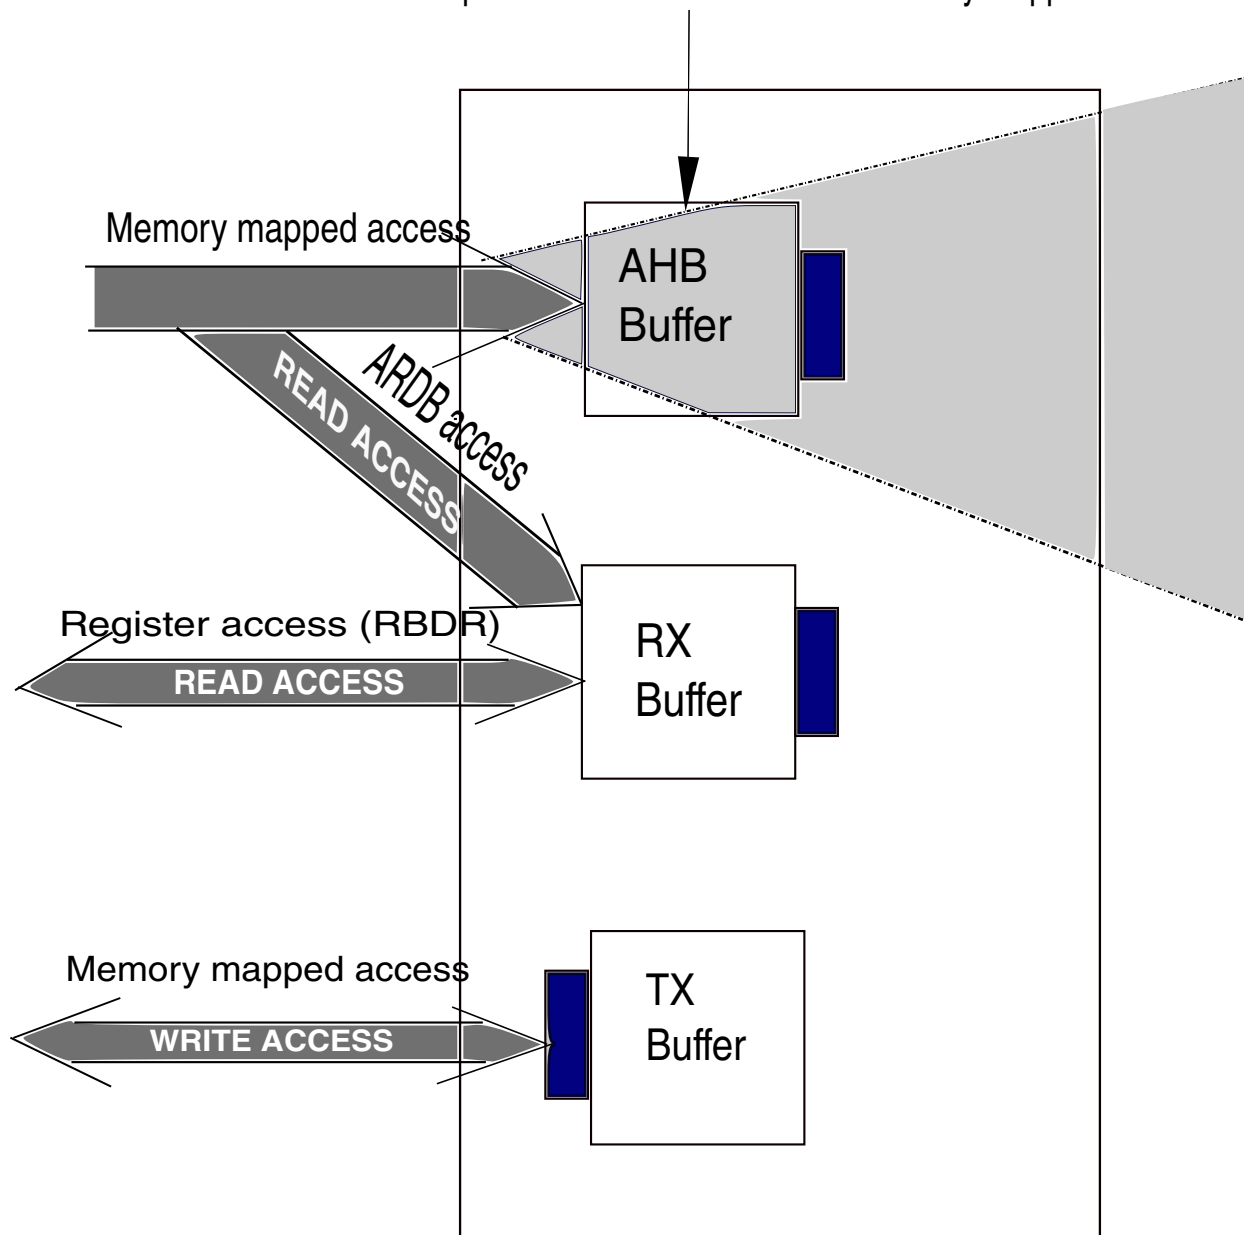

- **AHB Command Read:** For **reading flash data into the AHB Buffer** the user must set up a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should also program the buffer registers corresponding to the AHB master initiating the request, this is depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module (refer to [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#), [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#) and [Parallel Flash Mode](#).)

On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the QSPI_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI_SR[AHB_ACC] status bit is set driving in turn the QSPI_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. Data Transfer from the QuadSPI Module Internal Buffers

The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to [Block Diagram](#) for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

This Buffer is transparent to the user and is non-memory mapped

Note:  Byte Swapper for endianness

Figure 10-20. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR31

In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB31. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in [RX Buffer Data Register \(QuadSPI_RBDR \$n\$ \)](#) and in [AHB RX Data Buffer \(QSPI_ARDB0 to QSPI_ARDB31\)](#).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDR n) or the AHB address space (QSPI_ARDB n). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module. The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in [DMA Usage](#).

DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDR n or QSPI_ARDB n related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in [Table 10-8](#) table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress*. If this is not the case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is possible to run sequential reads from the AHB buffer at arbitrary speed without

the need to monitor any information about the availability of the data. Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

10.2.5.3.8 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI_SFAR[SFADR] field - corresponds to bit position QSPI_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

- Flash A or Flash B in Individual Flash Mode
- All AHB data read commands with access size of 32 bit

Table 10-16. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

• **Byte Ordering in Parallel Flash Mode**

In Parallel Flash Mode each byte is combined out of 2 half bytes which are read in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI_RBDR0 register.

Table 10-17. Serial Flash Device Half Byte Ordering

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fb10
1	fah1	fal1	fbh1	fb11
2	fah2	fal2	fbh2	fb12
3	fah3	fal3	fbh3	fb13
4	fah4	fal4	fbh4	fb14
5	fah5	fal5	fbh5	fb15
6	fah6	fal6	fbh6	fb16
7	fah7	fal7	fbh7	fb17
8	fah8	fal8	fbh8	fb18

The table entry naming reflects the half byte positioning in the serial flash devices:

- **<fa>h0** means **Flash A**, **<fb>h0** means **Flash B**.
- **fa<h>0** means half byte in **high position**, **fa<l>0** means half byte in **low position**.
- **fah<0>** means **physical byte address 0** in the serial flash device, **fal<1>** means **physical byte address 1** in the serial flash device.

Table 10-18. Byte Ordering in Parallel Flash Mode - RX Buffer

QSPI_SFAR[SFADR] set to 0x000_0000

Table continues on the next page...

**Table 10-18. Byte Ordering in Parallel Flash Mode - RX Buffer
(continued)**

QSPI_RBDR0 QSPI_ARDB0	fal1	fbl1	fah1	fbh1	fa0	fb0	fah0	fbh0
QSPI_RBDR1 QSPI_ARDB1	fal3	fbl3	fah3	fbh3	fa2	fb2	fah2	fbh2
QSPI_SFAR[SFADR] set to 0x000_0001								
QSPI_RBDR0 QSPI_ARDB0	fal2	fbl2	fah2	fbh2	fa1	fb1	fah1	fbh1
QSPI_RBDR1 QSPI_ARDB1	fal4	fbl4	fah4	fbh4	fa3	fb3	fah3	fbh3

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

* Applicable only for single io mode.

Table 10-19. Byte Ordering in Parallel Flash Mode - AHB Buffer

AHB Address (32 Bit Access)	fal1	fbl1	fah1	fbh1	fa0	fb0	fah0	fbh0
AHB Address 0x800_0004 (32 Bit Access)	fal3	fbl3	fah3	fbh3	fa2	fb2	fah2	fbh2

Note

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Buffer Entry Ordering for 64 Bit Read Access**

For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 10-20. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

10.2.5.3.9 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the [Flag Register \(QSPI_FR\)](#).

Table 10-21. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_FR)	DMA
Data Learn pattern Failure	DLPPF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
IP Command Usage Error	IUEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the [Flag Register \(QSPI_FR\)](#) and a Request Enable bit in the [DMA Request Select and Enable Register \(QSPI_RSER\)](#). The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- Transmit Buffer Fill Interrupt Request:

The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSIP_RSER[TBFIE]) is set. Refer to [TX Buffer Operation](#), for details about the assertion of the QSPI_FR[TBFF] flag.

- Receive Buffer Drain Interrupt or DMA Request:

The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer Overflow/Underrun Interrupt Request:

The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

- TBUF - TX Buffer Underrun, enabled by TBUIE
- RBOF - RX Buffer Overflow, enabled by RBOIE
- ABOF - AHB Buffer Overflow, enabled by ABOIE

The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TFUFIE] bit is set.

The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

If the IPAEF, IPIEF, IPGEF or IUEF flags in the QSPI_FR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

The IP Command Transaction Finished IRQ indicates the completion of the current IP Command. It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

10.2.5.3.10 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least four entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag. The TX buffer underrun flag is also asserted when TX buffer contains less than 128 bits of data and QuadSPI module tries to pull out data from it. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is all F's i.e. once the underrun flag is set under this condition, it will return F's until the required number of bytes are not sent. This has been done to ensure that the software need not to erase whole sector after underrun, just reprogramming from failure point will serve the purpose. When this Sequence Command is finished, the QSPI_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI_TBSR[TRBFL] field.

Refer to [TX Buffer Status Register \(QuadSPI_TBSR\)](#) and [Flag Register \(QuadSPI_FR\)](#) for details about the TX Buffer related registers.

10.2.5.3.11 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode.

- **Extended Address Mode**

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR command should be programmed with 8'd32 as the operand value. By default, the QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

10.2.6 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

10.2.6.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

10.2.6.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

10.2.6.2.1 IP Commands

Refer to [IP Configuration Register \(QuadSPI_IPCR\)](#) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

Refer to [Table 10-22](#) below.

10.2.6.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in [Flash Read](#) for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

Refer to [Table 10-22](#) below.

10.2.6.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 10-22. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flag	ABSEF	Flash transaction is aborted	AHB sequence contains <ul style="list-style-type: none"> • WRITE instruction • WRITE_DDR instruction
AHB Error Flag	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
Miscellaneous Error Flag	DLFFF ¹	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.
Miscellaneous Error Flag	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
Command Arbitration Error	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and <ul style="list-style-type: none"> • write attempt to QSPI_IPCR register. • write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
Command Arbitration Error	IPAEF		<ul style="list-style-type: none"> • AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
Command Arbitration Error	IPGEF		<ul style="list-style-type: none"> • Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
IP Command Error	IUEF	—	<ul style="list-style-type: none"> • IP Command Usage Error
Buffer Related Error	RBOF	TFF is asserted on completion	<ul style="list-style-type: none"> • RX Buffer Overrun

Table continues on the next page...

Table 10-22. Overview of QSPI_FR Error Flags (continued)

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
Buffer Related Error	TBUF		<ul style="list-style-type: none"> TX Buffer Underrun

1. Data learning is not implemented on this chip.

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

10.2.6.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[PIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for a description of the flags and [Command Arbitration](#), for details about possible command collisions.

10.2.6.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDR n register) and the other masters by triggering AHB Commands (via ARDB n Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer. Refer to [Figure 10-20](#) To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

10.2.6.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1.

10.2.6.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR31.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0), allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

10.2.6.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in [Exclusive Access to Serial Flash for AHB Commands](#) is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[IPIEF] flag is asserted when the host tries to write into the QSPI_IPCR

register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for details), this command is stalled until the currently running IP Command is finished.

- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to [Flag Register \(QuadSPI_FR\)](#) for the description of these flags.

When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

10.2.6.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to [Serial Flash Address Register \(QuadSPI_SFAR\)](#) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to [AMBA Bus Register Memory Map](#) for details.

10.2.6.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

10.2.6.6.1 DMA Usage in Normal Mode

10.2.6.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading data from the RX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result.

AHB Bus Side (data read):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles
- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 8 bytes (64 bit read size): Assume 2 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the `QSPI_RBCT[WMRK]` field, therefore the overhead given above distributes among $(\text{QSPI_RBCT[WMRK]}+1)/2$ read accesses of 64 bit each.

The following table gives some examples for typical use cases:

Table 10-23. Access Duration Examples - Bus Clock Side

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop ¹	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
0	4	$12+2 = 14$	~117ns
1	8	$12+2 = 14$	~117ns
3	16	$12+4 = 16$	~133ns
7	32	$12+8 = 20$	~167ns
11	48	$12+12 = 24$	~200ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data read):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): 2 cycles for Quad DDR mode instructions in Parallel Flash Mode, 4 cycles for Quad (SDR) mode instruction in parallel flash mode or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 10-24. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop ¹	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM ² Quad	IFM Quad DDR	PFM ³ Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	9	5	3	~150ns	~83ns	~50ns
1	8	17	9	5	~282ns	~150ns	~83ns
3	16	33	17	9	~548ns	~282ns	~150ns
7	32	65	33	17	~1079ns	~548ns	~282ns
11	48	97	49	25	~1610ns	~813ns	~415ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.

2. Individual flash mode.

3. Parallel flash mode.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

10.2.6.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Both write and read operations are supported in parallel mode. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

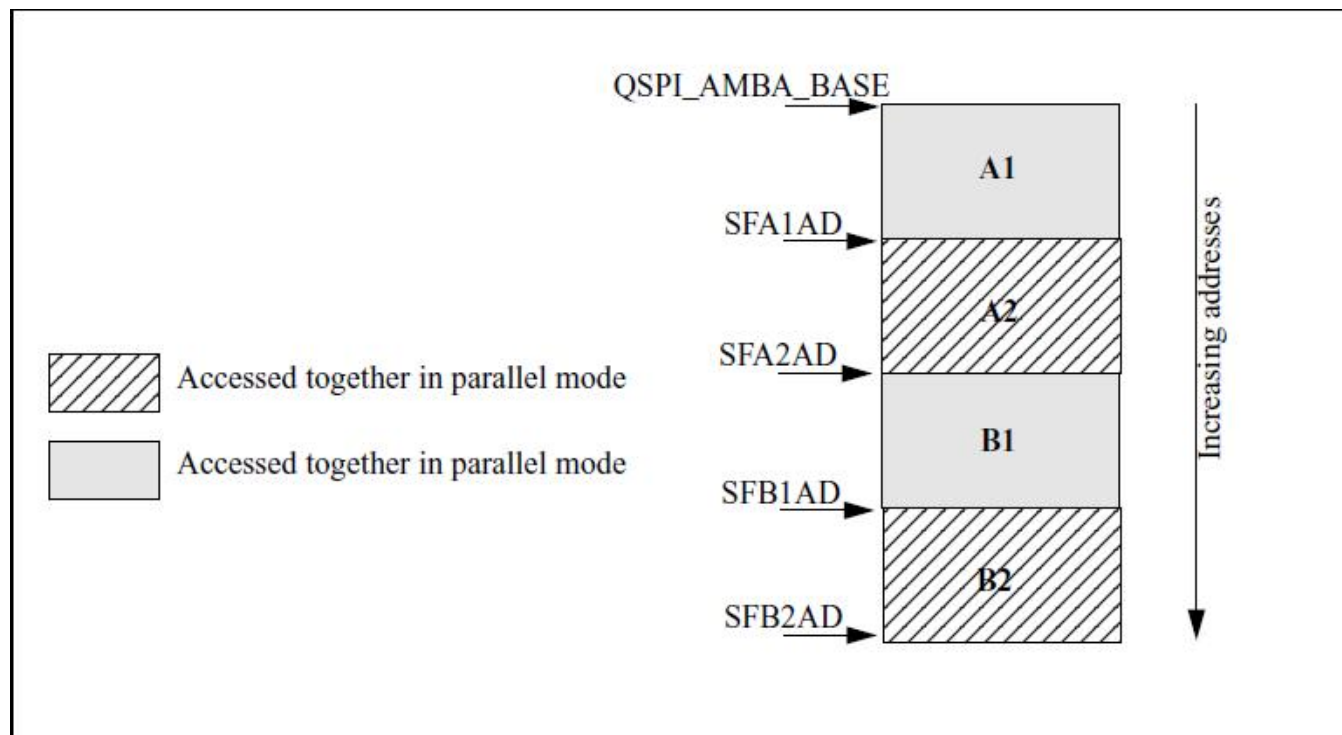

Figure 10-21. Flash addressing

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI_AMBA_BASE - 0x10000000
- QSPI_SFA1AD[TPADA1] - 0x20000000
- QSPI_SFA2AD[TPADA2] - 0x30000000
- QSPI_SFB1AD[TPADB1] - 0x40000000
- QSPI_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

Flash Address = (Memory mapped address - QSPI_AMBA_BASE)/2

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

$$\text{Flash Address} = (\text{Memory mapped address} - \text{SFA2AD})/2$$

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

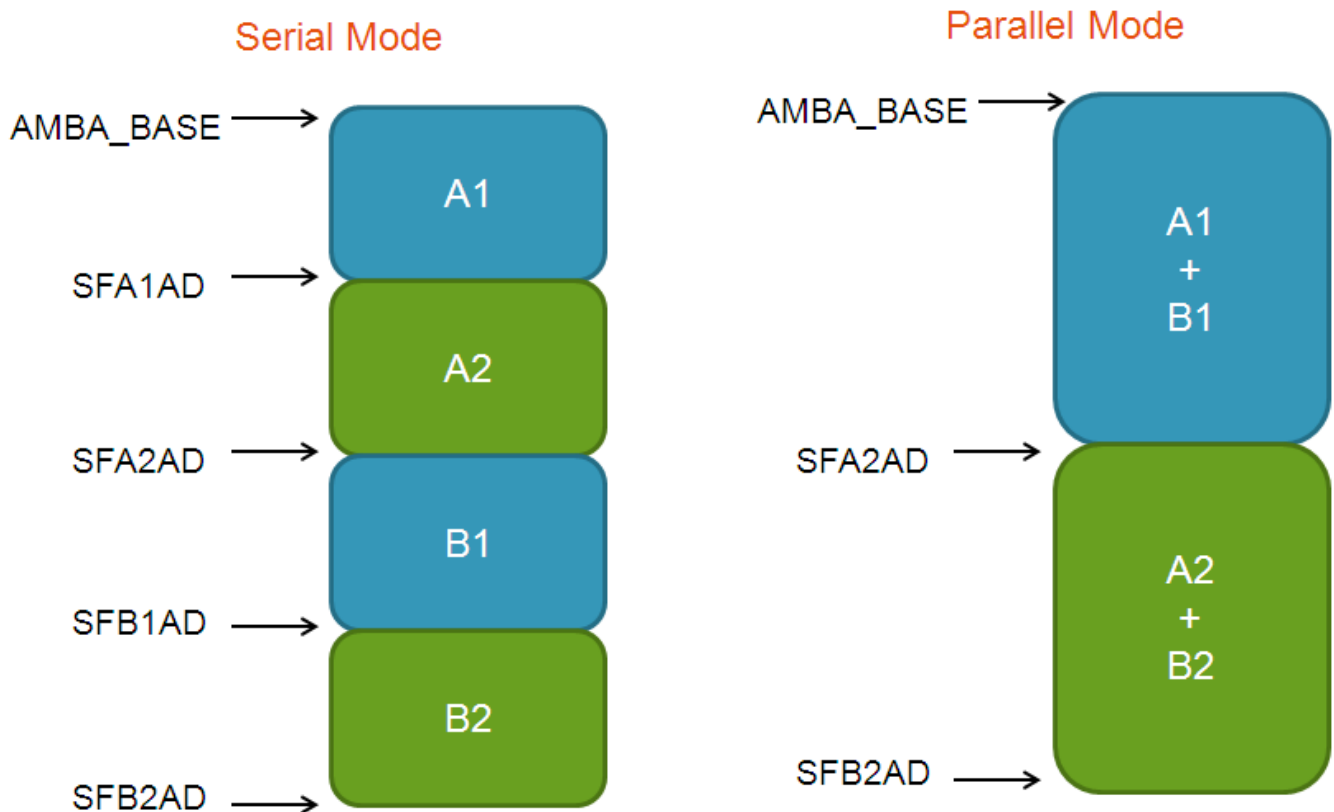

Figure 10-22. Memory map - Serial and Parallel

10.2.7 Byte Ordering - Endianness

QuadSPI provides support for swapping the flash read/write data based on the configuration of the QSPI_MCR[END_CFG]. By default the data is always returned in 64 bit LE format on the AHB bus and 32 bit LE format on the IPS interface when read via the RX buffer and written in 32 bit LE format when written via the TX buffer.

The table(QSPI_MCR[END_CFG]) below shows the complete bit ordering. BE signifies Big Endian which means the high order bits of the associated data vectors are associated with low order address positions. LE signifies Little Endian which means the lower order bits of the associated data vectors are associated with low order address positions. Refer to figure [Figure 10-20](#)

Table 10-25. QSPI_MCR[END_CFG]

00	64 bit BE
01	32 bit LE
10	32 bit BE
11	64 bit LE

The tables below (Byte ordering configuration in AHB) and (Byte ordering configuration in IPS) show how this configuration is implemented in QSPI AHB and IPS interfaces respectively. B in the table signifies Byte and the index 1-8 refers to the byte position i.e. 1 refer to bits[7:0], 8 refer to bits[63:56] and so on.

Table 10-26. Byte ordering configuration in AHB

64 bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64 bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32 bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32 bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 10-27. Byte ordering configuration in IPS

32BE	B1	B2	B3	B4
32LE	B4	B3	B2	B1

The examples below show the byte ordering in 64 bit BE configuration for AHB Buffer and 32 bit BE for TX/RX Buffer:

10.2.7.1 Programming Flash Data

CPU write instructions to the QSPI_TBDR register like

- Write QSPI_TBDR -> 0x01_02_03_04
- Write QSPI_TBDR -> 0x05_06_07_08

result in the following content of the TX Buffer:

Table 10-28. Example of QuadSPI TX Buffer

TX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

Programming the TX Buffer into the external serial flash device results in the following byte order to be sent to the serial flash:

- 01...02...03...04...05...06...07...08

10.2.7.2 Reading Flash Data into the RX Buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

This results in the RX Buffer filled with:

Table 10-29. Resulting RX Buffer Content

RX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

10.2.7.2.1 Readout of the RX Buffer via QSPI_RBDRn

The RX Buffer content appears at CPU read access via the Peripheral bus interface in the following order:

- Read QSPI_RBDR0 <- 0x01_02_03_04
- Read QSPI_RBDR1 <- 0x05_06_07_08

10.2.7.2.2 Readout of the RX Buffer via ARDBn

The RX Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04
- (2a): 32 Bit Access: Read QSPI_ARDB1 <- 0x05_06_07_08
- (1b/2b): 64 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04_05_06_07_08

10.2.7.3 Reading Flash Data into the AHB Buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

This results in the AHB Buffer filled with:

Table 10-30. Resulting AHB Buffer Content

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

10.2.7.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01_02_03_04
- (2a): 32 Bit Read Access: <- 0x05_06_07_08
- (1/2): 64 Bit Read Access: <- 0x01_02_03_04_05_06_07_08

10.2.8 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

10.2.8.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 10-31. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

10.2.8.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flashes.

Table 10-32. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.8.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 10-33. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.8.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 10-34. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.8.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 10-35. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

10.2.8.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 10-36. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

10.2.8.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 10-37. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

10.2.8.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

Table 10-38. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

10.2.8.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

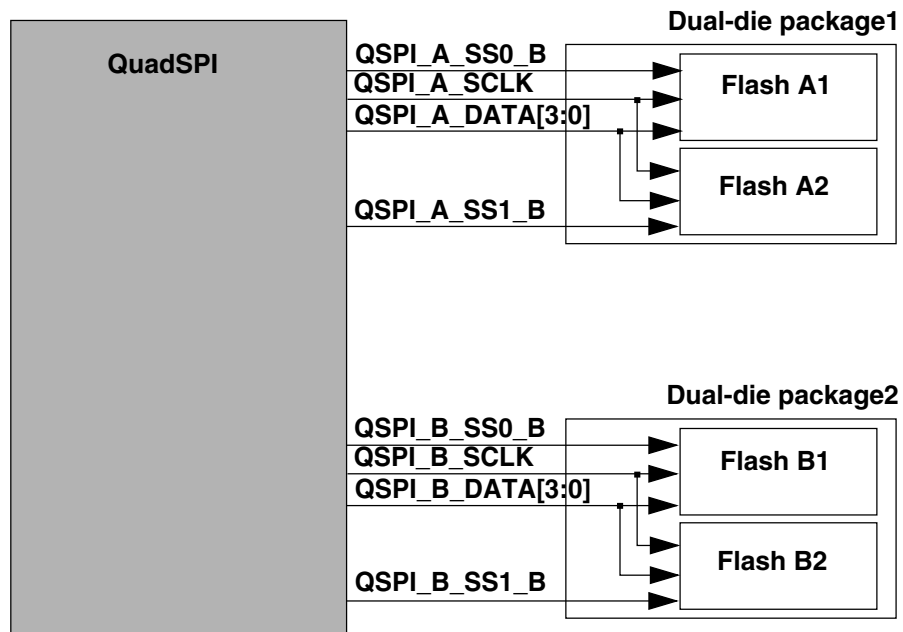

Figure 10-23. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

10.2.8.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)
- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.

- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
 - The total sizes of all the flashes connected on board
 - Whether DDR mode supported
 - Frequency of DDR operation
 - Continuous mode entry sequence
 - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
 - Quad Mode enabled
 - Dummy reads to enter into XIP
- QuadSPI is configured
 - Parallel enable set
 - LUT configured for highest performance reads
 - DDR mode enabled (if applicable)
 - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

10.2.9 Sampling of Serial Flash Input Data

10.2.9.1 Internal Sampling of Serial Flash Input Data

Depending from the actual implementation there is a delay between the internal clocking in the QuadSPI module and the external serial flash device. Refer to the following figure for an overview of this scheme.

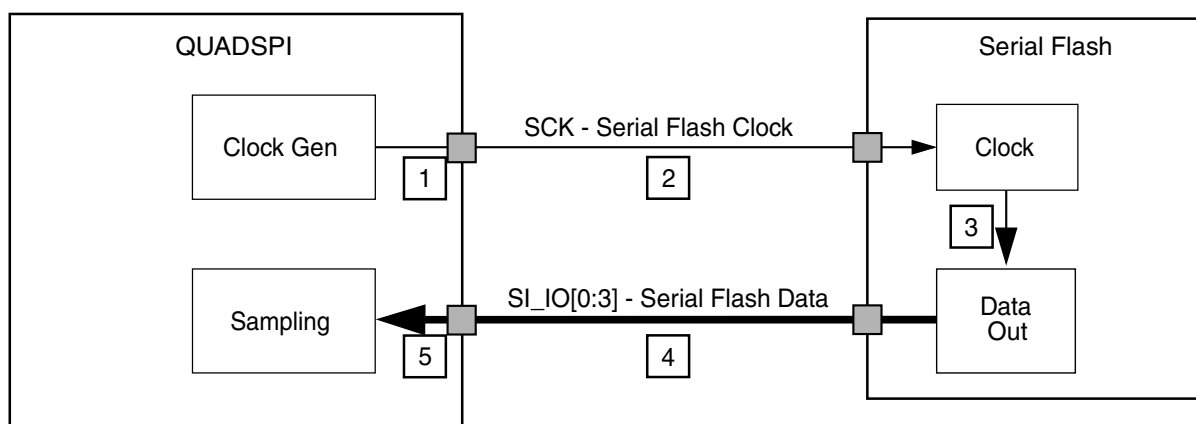

Figure 10-24. Serial Flash Sampling Clock Overview

Note

The arrival of the serial flash data in the sampling stage of the QuadSPI module are given in the following figure. Note that the amount of the total delay $t_{Del,total}$ is very specific to the characteristics of the actual implementation.

Note also that the serial flash device clock SCK is inverted with respect to the QuadSPI internal reference clock.

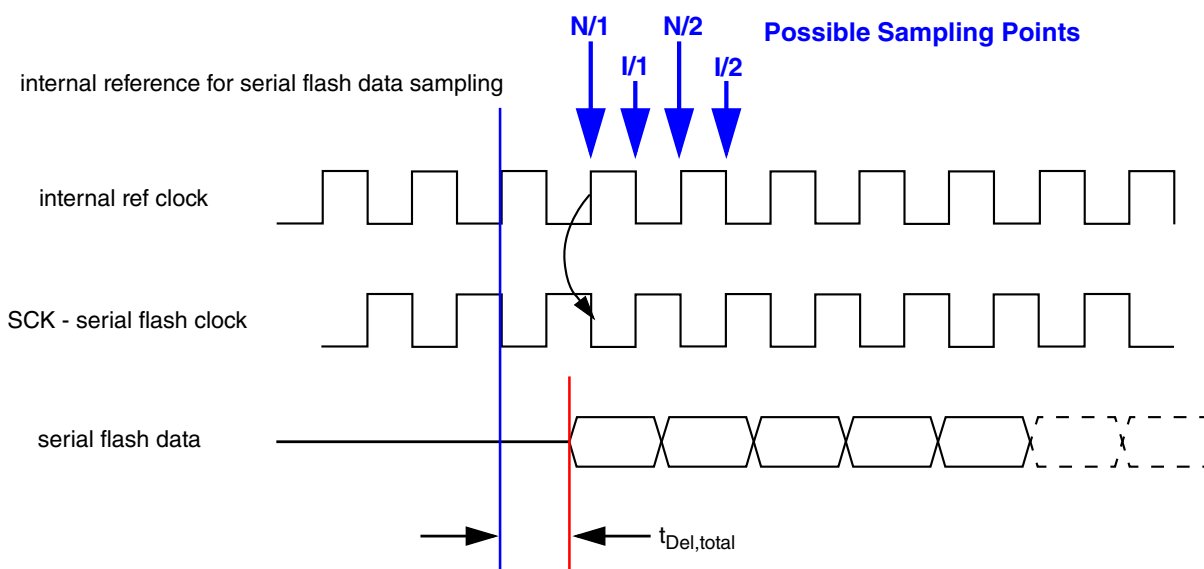

Figure 10-25. Serial Flash Sampling Clock Timing

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrive at the internal sampling stage of the QuadSPI module.

According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Input delay belonging to the data in input

The possible points in time for the sampling of the incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register, refer to [Sampling Register \(QuadSPI_SMPR\)](#) for details. Note that the falling edges of the reference clock are not actually used, instead the inverted clock is used for sampling at these positions. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 10-39. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting ¹
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending from the actual delay and the serial flash clock frequency the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be 2 settings possible to capture the correct data since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending from the timing uncertainties it may turn out in actual applications that only one possible sample positions remains. This is subject to careful consideration depending from the actual implementation.

- The delay $t_{Del,total}$ is an absolute size to shift the point in time when the serial flash data get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SMPR register.

10.2.9.2 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

10.2.10 Serial Flash Data Input Timing

There are sampling modes for input flash data:

- Internal sampling - Input serial flash data is captured by internal serial clock. In SDR mode, serial data is sampled by serial clock 1x (ser_clk_1x) rise edge. In DDR mode, serial data is sampled by serial clock 4x (ser_clk_4x) rise edge.
- Loopback DQS sampling - Soc will output serial data strobe with internal serial clock. This serial data strobe would be loopback from pad and used to sample input serial data. In SDR mode, serial data is sampled by loopback DQS rise edge. In DDR mode, serial data is sampled by loopback DQS both edge

NOTE

DQS pad need to be set to force input for loopback.

- Flash DQS sampling - Some serial Flash device provide the data strobe output together with serial data. This strobe signal is used to sample input serial data directly. In SDR mode, serial data is sampled by Flash DQS rise edge. In DDR mode, serial data is sampled by Flash DQS both edge

Following table shows selection for sampling mode:

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Internal sampling	0	doesn't matter

Table continues on the next page...

Quad Serial Peripheral Interface (QuadSPI)

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Loopback DQS sampling	1	1
Flash DQS sampling	1	0

Serial flash data and clock path for input timing is shown in the following figure.

Figure 10-26. Serial flash data and clock path

NOTE

The red line is for data input path, the blue line is for DQS loopback path, and the purple line is for DQS input path from Serial Flash.

Total delay ($T_{total_delay_data}$) for serial flash data input is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to Output Valid time of external Serial Flash Device
4. Wire delay of serial flash data (SIO) from external serial Flash Device to SOC
5. Input delay of serial flash data from SIO pad to internal sample register

Total delay ($T_{total_delay_loopback_dqs}$) for loopback DQS clock is the sum of following delay:

1. Output delay of DQS clock from internal serial clock to DQS pad inside SOC
2. Input delay of DQS clock from DQS pad to internal sample register

Total delay ($T_{total_delay_flash_dqs}$) for Flash DQS clock is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device

3. Clock to DQS Output time of external Serial Flash Device
4. Wire delay of serial flash data strobe (DQS) from external serial Flash Device to SOC
5. Input delay of DQS clock from DQS pad to internal sample register

10.2.10.1 Input timing in SDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the figure below.

Figure 10-27. Internal sample SDR

There are four sample points for this sampling mode, which is determined by register field `QSPI_SMPR.SDRSMP`.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

- For sample point N, Setup requirement is: $T_{\text{cycle}} * (N+2) / 2 > T_{\text{total_delay_data,max}}$
- For sample point N, Hold requirement is: $T_{\text{total_delay_data,min}} > T_{\text{cycle}} * N / 2$

NOTE

T_{cycle} is the cycle of `ser_clk_1x`. $T_{\text{total_delay_data,max}}$ is maximum delay of serial data input path. $T_{\text{total_delay_data,min}}$ is the minimum delay of serial data input path. $N=0,1,2,3$

10.2.10.2 Input timing in DDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

There are 8 sample points for this sampling mode, which is determined by register field DDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

- For sample point N, Setup requirement is: $T_{cycle} * (N+2)/8 > T_{total_delay_data,max}$
- For sample point N, Hold requirement is: $T_{total_delay_data,min} > T_{cycle} * N/8$

10.2.10.3 Input timing in SDR mode with loopback DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

Figure 10-28. Input timing in SDR mode with loopback DQS sampling

In SDR mode and loopback sampling mode, DQS_PHASE_EN should be set 1.

For this sample point, the Setup requirement is: $T_{\text{cycle}} > \max(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}})$. The Hold requirement is: $\min(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}}) > 0$.

10.2.10.4 Input timing in DDR mode with loopback DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

Figure 10-29. Input timing in DDR mode with loopback DQS sampling

In DDR mode and loopback sampling mode, DQS_PHASE_EN should be set 0.

For this sample point, the Setup requirement is: $T_{\text{cycle}} > \max(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}})$. The Hold requirement is: $\min(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}}) > 0$.

10.2.10.5 Input timing in SDR mode with flash DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

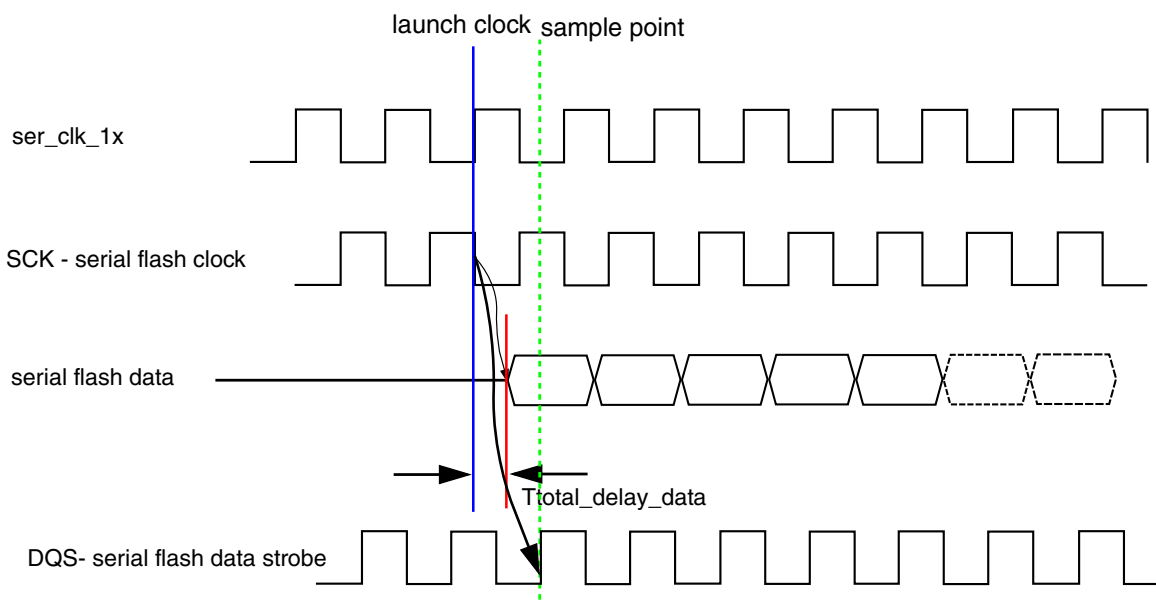

Figure 10-30. Input timing in SDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

10.2.10.6 Input timing in DDR mode with flash DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

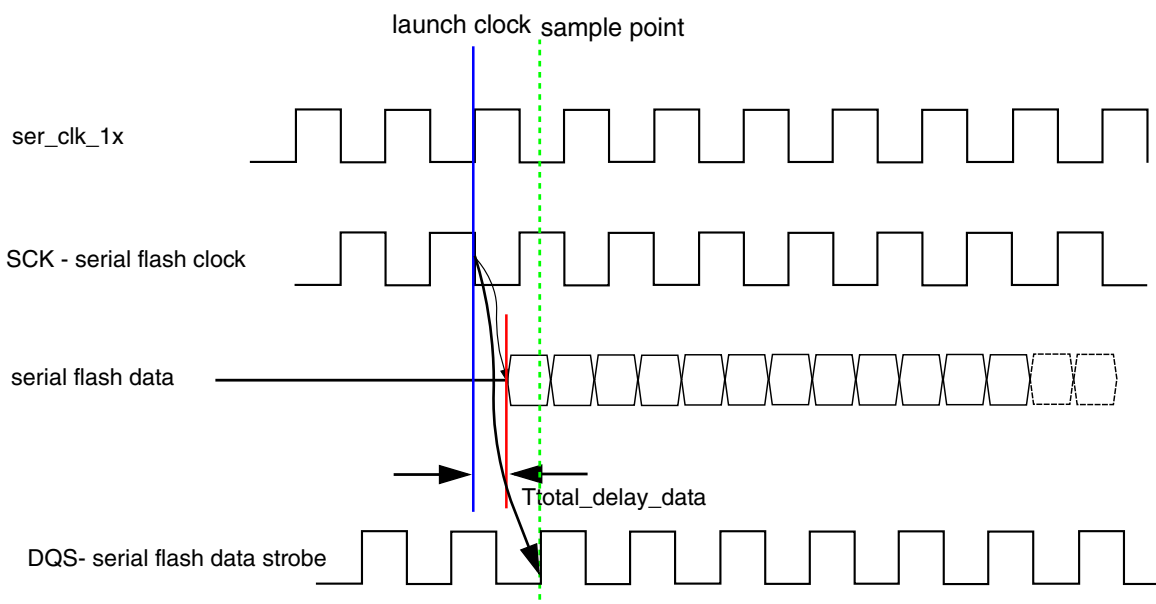

Figure 10-31. Input timing in DDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

10.2.10.7 Data Strobe Signal functionality

Some external serial flashes provide the data strobe (DQS/RDS) output which is fed directly to the QuadSPI module. The strobe (DQS/RDS) signal needs to be delayed to have the edges aligned to the data valid period. QuadSPI internally samples the incoming data at posedge of the strobe signal for SDR and on both the edges of the strobe signal for DDR. Refer to the figure for more detail.

Figure 10-32. Data strobe signal functionality

10.2.11 Output timing in SDR mode

Output timing diagram in SDR mode is show in the following figure.

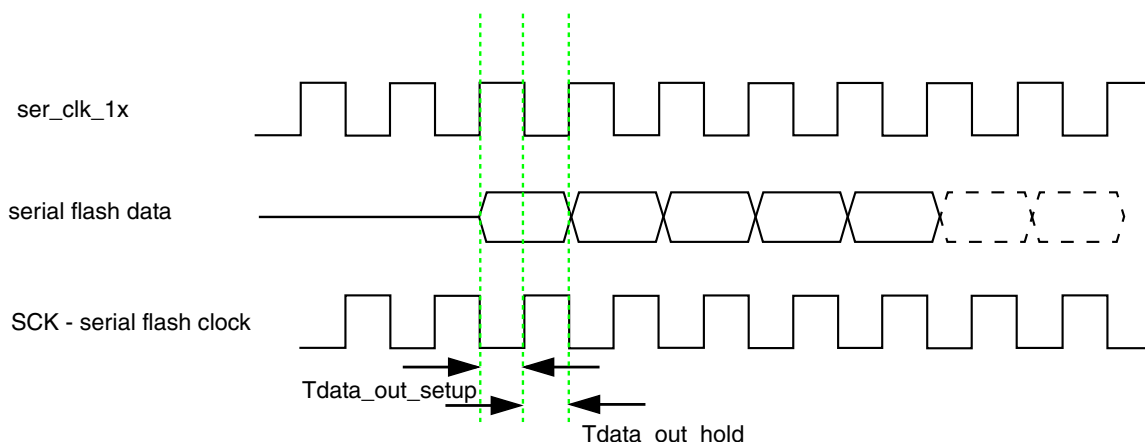

Figure 10-33. Output timing in SDR mode

In SDR mode, quadspi output serial data with internal serial clock rise edge 1x (`ser_clk_1x`). Flash Device has requirement on Data and Clock setup and hold timing.

10.2.12 Output timing in DDR mode

Output Timing diagram in DDR mode is show in the following figure.

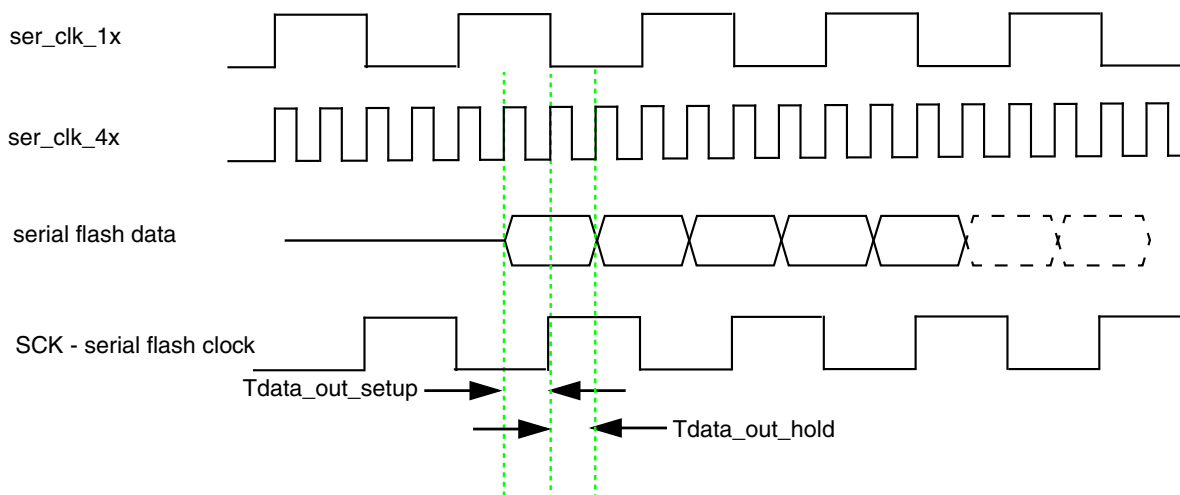

Figure 10-34. Output timing in DDR mode

In DDR mode, quadspi output serial data with internal serial clock both edge 1x (`ser_clk_1x`) and then delay one `ser_clk_4x` cycle for hold timing.

NOTE

TX_DDR_DELAY_EN should be set to 1 for DDR mode.

10.2.13 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

10.2.13.1 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

NOTE

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

10.2.13.1.1 AHB RX Data Buffer register (ARDBn)

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in [Flash Read](#) section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to [Byte Ordering of Serial Flash Read Data](#) for the byte ordering scheme.

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

ARDBn field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

10.2.14 Peripheral Bus Register Descriptions

This section provides the peripheral bus register information of the QuadSPI module.

This section provides the memory map and register definitions of the QuadSPI module.

10.2.14.1 Module Configuration Register (QuadSPIx_MCR)

The QuadSPI_MCR holds configuration data associated with QuadSPI operation.

Write:

- All other fields: Anytime

Address: Base address + 0h offset

QuadSPIx_MCR field descriptions

Field	Description
31-27 Reserved	This field is reserved.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
26 DQS_PHASE_EN	This bit controls internal DQS output phase. If DQS_EN and DQS_LOOPBACK_EN are both set to 1, this bit should be set in SDR mode, and cleared in DDR mode. If either DQS_EN or DQS_LOOPBACK_EN is set to 0, this bit is ignored.
25 DQS_LOOPBACK_EN	Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. This bit is a don't care when DQS_EN is set to 0. 1'b1 DQS loopback sampling enabled 1'b0 DQS loopback sampling disabled
24 DQS_LOOPBACK_FROM_PAD	This bit should always be set to '1' when DQS_LOOPBACK_EN is set to '1'. When DQS_LOOPBACK_EN is set to '1', this bit is ignored.
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. Please refer to , for more information. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidate the TX Buffer content. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidate the RX Buffer. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable: 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable: This field is valid for both SDR and DDR mode. For more details Refer Data Strobe Signal Functionality

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
	0 DQS disabled. 1 DQS enabled- When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5-4 Reserved	This field is reserved.
3-2 END_CFG	Defines the endianness of the QSPI module. For more details refer to Byte Ordering Endianness
1 SWRSTHD	Software reset for AHB domain NOTE: Please keep other fields value when write to SWRSTHD and SWRSTSD NOTE: These software reset don't reset register setting but only reset internal flip-flops in quadspi controller NOTE: To remove the reset, need to write 0 to SWRSTHD and SWRSTSD 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.
0 SWRSTSD	Software reset for Serial Flash domain NOTE: Please keep other fields value when write to SWRSTHD and SWRSTSD NOTE: These software reset don't reset register setting but only reset internal flip-flops in quadspi controller NOTE: To remove the reset, need to write 0 to SWRSTHD and SWRSTSD 0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

10.2.14.2 IP Configuration Register (QuadSPIx_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to [Normal Mode](#) , for details about the command triggering and command execution.

Write:

- $QSPI_SR[IP_ACC]=0$

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				SEQID				Reserved							PAR_EN
W	Reserved				SEQID				Reserved							PAR_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IDATSZ															
W	IDATSZ															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this bit -field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
IDATSZ	IP data transfer size: Defines the data transfer size in bytes of the IP command.

10.2.14.3 Flash Configuration Register (QuadSPIx_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- $QSPI_SR[AHB_ACC] = 0$
- $QSPI_SR[IP_ACC] = 0$

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																TDH	Reserved			TCSH		Reserved			TCSS						
W	Reserved																TDH	Reserved			TCSH		Reserved			TCSS						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1

QuadSPIx_FLSHCR field descriptions

Field	Description
31–18 Reserved	This field is reserved.
17–16 TDH	Serial flash Data In hold time: This helps in meeting the Data In Hold time requirement of a Flash. This is valid only in DDR mode. Refer to Data input hold requirement of Flash for details. NOTE: This field should be set to 01 in DDR mode (DDR_EN=1) and set to 00 in SDR mode (DDR_EN=0). Other value are reserved. 00 Data aligned with the posedge of Internal reference clock of QuadSPI 01 Data aligned with 2x serial flash half clock 10 Reserved 11 Reserved
15–12 Reserved	This field is reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles. NOTE: The actual delay between chip select assertion and clock fall edge is defined as: <ul style="list-style-type: none"> • 1 SCK cycle if TCSH is set 0 or 1 • N SCK cycle if TCSH is set N (N>1)
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles. NOTE: <ol style="list-style-type: none"> 1. The actual delay between chip select assertion and clock fall edge is defined as: <ul style="list-style-type: none"> • 0.5 SCK cycle if TCSS is set 0 or 1 • N+0.5 SCK cycle if TCSS is set N (N>1) 2. Any update to TCSS register bits is visible on the flash interface only from the second transaction following the update.

10.2.14.4 Buffer0 Configuration Register (QuadSPIx_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of the BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 10h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADATSZ								Reserved				MSTRID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable: When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer.

10.2.14.5 Buffer1 Configuration Register (QuadSPIx_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of the BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																ADATSZ				Reserved		MSTRID									
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.

Table continues on the next page...

QuadSPIx_BUF1CR field descriptions (continued)

Field	Description
7-4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer.

10.2.14.6 Buffer2 Configuration Register (QuadSPIx_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of the BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF2CR field descriptions

Field	Description
31-16 Reserved	This field is reserved. Reserved.
15-8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7-4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer.

10.2.14.7 Buffer3 Configuration Register (QuadSPIx_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of the BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the ALLMST field is set, any transaction where the master port number does not match any of the buffer MSTRID fields will be routed to this buffer. In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ALLMST

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable: When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer.

10.2.14.8 Buffer Generic Configuration Register (QuadSPIx_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 20h offset

QuadSPIx_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table . NOTE: If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

10.2.14.9 Buffer0 Top Index Register (QuadSP1x_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned, as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 give 16bytes etc.

The size of buffer0 is the difference between the BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TPINDX0																Reserved															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSP1x_BUF0IND field descriptions

Field	Description
31–3 TPINDX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

10.2.14.10 Buffer1 Top Index Register (QuadSP1x_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less. The size of buffer1 is the difference between the BUF1IND and BUF0IND.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 34h offset

QuadSPIx_BUF1IND field descriptions

Field	Description
31–3 TPINDEX1	Top index of buffer 1.
Reserved	This field is reserved.

10.2.14.11 Buffer2 Top Index Register (QuadSPIx_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. The size of buffer2 is the difference between the BUF2IND and BUF1IND.
