It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 38h offset

QuadSPIx_BUF2IND field descriptions

Field	Description
31–3 TPINDEX2	Top index of buffer 2.
Reserved	This field is reserved.

10.2.14.12 Serial Flash Address Register (QuadSPIx_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24bit mode, only bits 23-0 are sent to the flash, in 32bit mode, bits 27-0 are used with bits 31-28 driven to 0. Refer to [Table 10-7](#) for the mapping between the access mode and the QSPI_SFAR content and to [Normal Mode](#) for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in [Table 10-7](#).

Write:

- $QSPI_SR[IP_ACC] = 0$

Address: Base address + 100h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter, indicates how many entries of 4 bytes have been removed from the RX Buffer. For example a value of 0x2 would indicate 8bytes have been removed It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDF]. The QSPI_RSER[RBDE] defines which pop has to be done. For further details please refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) and "Data Transfer from the QuadSPI Module Internal Buffers section in Flash Read section.
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level, indicates how many entries of 4 bytes are still available in the RX Buffer. For example a value of 0x2 would indicate 8bytes are available.
Reserved	This field is reserved.

10.2.14.15 RX Buffer Control Register (QuadSPIx_RBCT)

This register contains control data related to the receive data buffer.

Write:

- $QSPI_SR[IP_ACC] = 0$

Address: Base address + 110h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W	Reserved								RXBRD	Reserved			WMRK			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout: This bit specifies the access scheme for the RX Buffer readout. 0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to Exclusive Access to Serial Flash for AHB Commands . 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR31.
7–5 Reserved	This field is reserved.
WMRK	RX Buffer Watermark: This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted. The value should be entered as the number of 4byte entries minus 1. For example a value of 0x0 would set the watermark to 4bytes, 1 to 8bytes, 2 to 12bytes etc. For details, refer to DMA Usage .

10.2.14.16 TX Buffer Status Register (QuadSPIx_TBSR)

This register contains information related to the transmit data buffer.

Address: Base address + 150h offset

QuadSPIx_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written into the QSPI_MCR[CLR_TXF] bit. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TX Buffer Data Register (QuadSPI_TBDR) for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

10.2.14.17 TX Buffer Data Register (QuadSPIx_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 128 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to [Table 10-16](#) for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- $QSPI_SR[TXFULL] = 0$

32-bit write access required

NOTE

There is no limitation on Flash programming size. But the data size written to TX Buffer should be 64 Byte aligned. If flash programming size is not 64 bytes aligned, please write redundant data to TX Buffers. The redundant data will be ignored by QuadSPI controller.

Address: Base address + 154h offset

**QuadSPIx_TBDR field descriptions**

Field	Description
TXDATA	<p>TX Data</p> <p>On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly.</p> <p>On a read access, the last data written to the register is returned.</p>

10.2.14.18 Status Register (QuadSP1x_SR)

The QSPI_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer and TX Buffer and the AHB Buffer.

Address: Base address + 15Ch offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 TXEDA	<p>Tx Buffer Enough Data Available</p> <p>Asserted when TX Buffer contains enough data for any pop operation to take place. There must be at least 128bit data available in TX FIFO for any pop operation otherwise QSPI_FR[TBUF] will be set.</p>

Table continues on the next page...

QuadSPIx_SR field descriptions (continued)

Field	Description
23 RXDMA	RX Buffer DMA: Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full: Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded: Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full: Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full: Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full: Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full: Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty: Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty: Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty: Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty: Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending: Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration .
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access: Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access: Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy: Asserted when module is currently busy handling a transaction to an external flash device.

10.2.14.19 Flag Register (QuadSPIx_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write: Enabled Mode

Address: Base address + 160h offset

AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

QuadSPiX_FR field descriptions

Field	Description
31 DLFFF	NOTE: Data learning is not implemented on this chip. Data Learning Pattern Failure Flag: Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30 Reserved	This field is reserved.
29–28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag: Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag: Set when the module tried to pull data although TX Buffer was empty or the buffer contains less than 128bits of data. The application must ensure that the buffer never goes empty during a transaction expect for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid tx underrun. The application must clear the TX Buffer in response to this event by writing a 1 into the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag: Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to Table 10-14 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag: Set when not all the data read from the serial flash device could be pushed into the RX Buffer. The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
	The content of the RX Buffer is not changed.
16 RBDF	<p>RX Buffer Drain Flag: Will be set if the QuadSPI_SR[RXWE] status bit is asserted.</p> <p>Writing 1 into this bit triggers one of the following actions:</p> <ul style="list-style-type: none"> • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. <p>The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.</p>
15 ABSEF	<p>AHB Sequence Error Flag: Set when the execution of an AHB Command is started with an WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p> <p>The AHB bus request which triggered this command is answered with an ERROR response.</p>
14 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
13 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
12 ABOF	<p>AHB Buffer Overflow Flag: Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly.</p> <p>The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device.</p> <p>The content of the AHB Buffer is not changed.</p>
11 IUEF	<p>IP Command Usage Error Flag: Set when in parallel flash mode the execution of an IP Command is started and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to Table 10-14 table for the related commands.</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p>
10–8 Reserved	This field is reserved.
7 IPAIEF	<p>IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs:</p> <ul style="list-style-type: none"> • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAIEF flag is ignored.
6 IPIEF	<p>IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs:</p> <ul style="list-style-type: none"> • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored • Write access to the QSPI_SFAR register. • Write access to the QSPI_RBCT register.
5 Reserved	This field is reserved.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
4 IPGEF	IP Command Trigger during AHB Grant Error Flag: Set when the following condition occurs: <ul style="list-style-type: none"> A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag: Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

1. QSPI_BUFxCR implies anyone of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR

10.2.14.20 Interrupt and DMA Request Select and Enable Register (QuadSPIx_RSER)

The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

Write:Anytime

Address: Base address + 164h offset

QuadSPIx_RSER field descriptions

10.2.14.21 Sequence Suspend Status Register (QuadSP1x_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: Base address + 168h offset

AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

QuadSPIx_SPNDST field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

10.2.14.22 Sequence Pointer Clear Register (QuadSPIx_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

Address: Base address + 16Ch offset

10.2.14.27 RX Buffer Data Register (QuadSPIx_RBDRn)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to [Table 10-16](#) for the byte ordering scheme.

AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: Base address + 200h offset + (4d × i), where i=0d to 31d

QuadSPIx_RBDRn field descriptions

Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in Byte Ordering of Serial Flash Read Data .

10.2.14.28 LUT Key Register (QuadSPIx_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to [Look-up Table](#) for details.

Write: Anytime

Address: Base address + 300h offset

QuadSPIx_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

10.2.14.29 LUT Lock Configuration Register (QuadSPiX_LCKCR)

The LUT lock configuration register is used along with QSPI_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI_LUTKEY register for the lock or unlock operation to be successful. Refer to [Look-up Table](#) for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Write: Just after writing the LUT Key Register

(QSPI_LUTKEY)

Address: Base address + 304h offset

1 UNLOCK	Unlocks the LUT when the following two conditions are met: <ol style="list-style-type: none"> 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key
0 LOCK	Locks the LUT when the following condition is met: <ol style="list-style-type: none"> 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key

10.2.14.30 Look-up Table register (QuadSPiX_LUT0)

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI_LUT[0], QSPI_LUT[4], QSPI_LUT[8] QSPI_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. A maximum of 16 sequences can be defined at one time. [Look-up Table](#) describes the LUT registers in detail.

Write: Once the LUT is unlocked

10.3 Ultra Secured Digital Host Controller (uSDHC)

10.3.1 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in [Figure 10-35](#).

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:

The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.

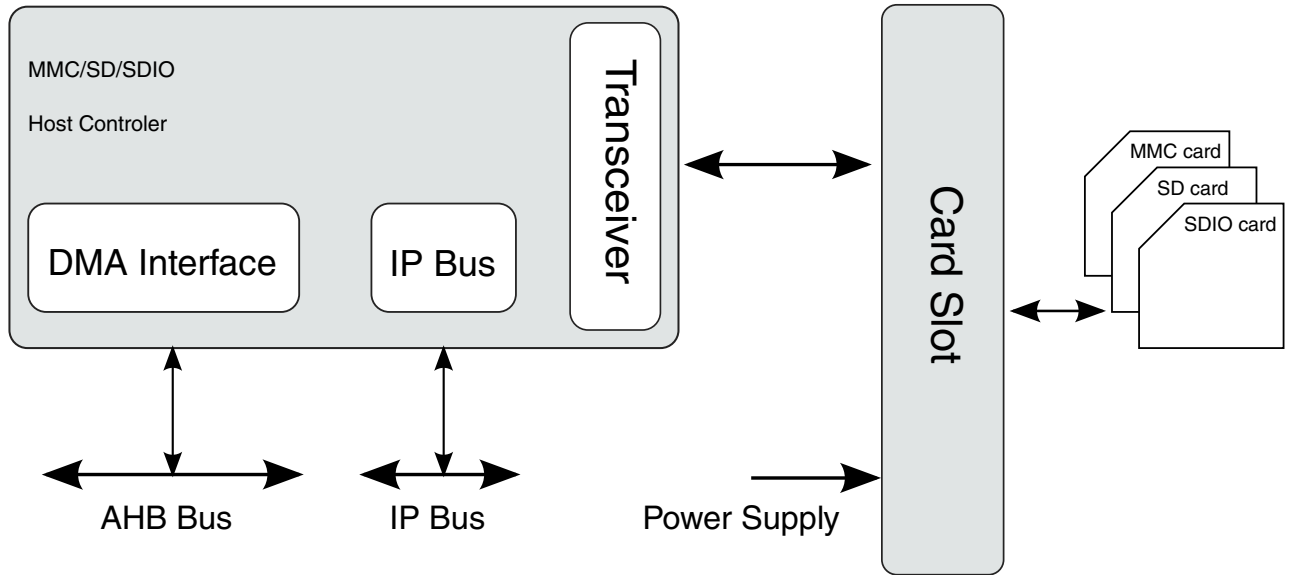

Figure 10-35. System Connection of the uSDHC

Figure 10-36. ultra Secure Digital Host Controller Block Diagram

10.3.1.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/5.0
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
 - Up to 832 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
 - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
 - Up to 832 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
 - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
 - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
 - Up to 3200 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access

10.3.1.2 Modes and Operations

10.3.1.2.1 Data Transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode (up to 208 MHz in SDR mode, up to 50 MHz in DDR mode)

10.3.2 External Signals

The following table describes the external signals of USDHC:

Table 10-40. USDHC External Signals

Signal	Description	Pad	Mode	Direction
SD1_CD_B	Card detection pin If not used(for the embedded memory),tie low to indicate there is a card attached.	SD1_CD_B	ALT0	I
SD1_CLK	Clock for MMC/SD/SDIO card	SD1_CLK	ALT0	O
SD1_CMD	CMD line connect to card	SD1_CMD	ALT0	IO
SD1_DATA0	DATA0 line in all modes Also used to detect busy state	SD1_DATA0	ALT0	IO
SD1_DATA1	DATA1 line in 4/8-bit mode Also used to detect interrupt in 1/4- bit mode	SD1_DATA1	ALT0	IO
SD1_DATA2	DATA2 line or Read Wait in 4-bit mode. Read Wait in 1-bit mode	SD1_DATA2	ALT0	IO
SD1_DATA3	DATA3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	SD1_DATA3	ALT0	IO

Table continues on the next page...

Table 10-40. USDHC External Signals (continued)

Signal	Description	Pad	Mode	Direction
	low to indicate it's not write protected.	SD3_DATA6	ALT2	

10.3.2.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.
- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD# means that a card is inserted, and a high on WP means that the write protect switch is active.
- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

10.3.3 Clocks

The table found here describes the clock sources for uSDHC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 10-41. uSDHC Clocks

Clock name	Clock Root	Description
hclk	ahb_clk_root	AHB bus clock
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_perclk	usdhc_clk_root	Base clock
ipg_clk_s	ipg_clk_root	Peripheral access clock for register accesses

10.3.4 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

10.3.4.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words. The burst lengths for read and write are also configurable and can be from 1 to 31 words.

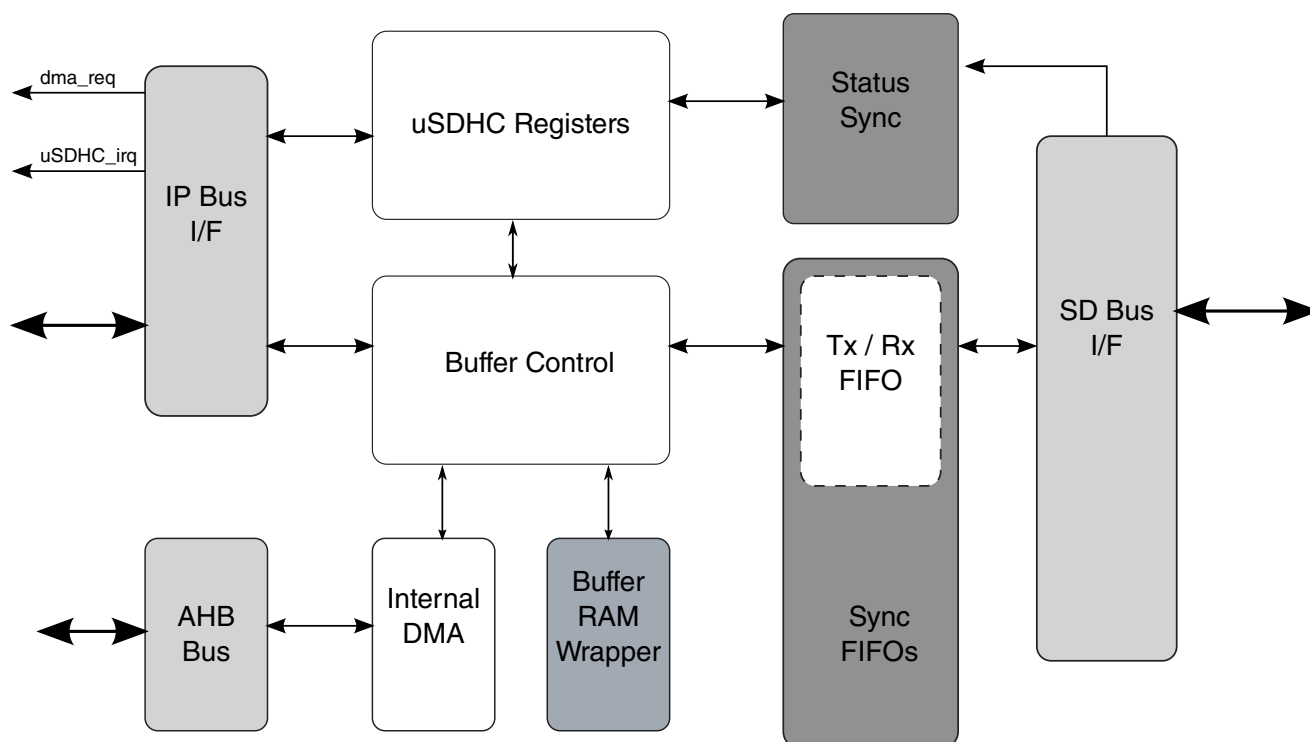

Figure 10-37. uSDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- CPU polling mode:
 - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.
- External DMA mode:
 - For a read operation, when there are more words received in the buffer than the amount set in the RD_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, the DMA request is asserted again. For instance, if there are twice as many words in the buffer as there are in the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar. Note the accesses CPU polling mode and external DMA mode both use the IP bus, and if the external DMA is enabled, in both modes an external DMA request is sent when the buffer is ready.
- Internal DMA mode (includes simple and advanced DMA accesses):
 - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark Level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

Figure 10-38. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode

Figure 10-39. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode

10.3.4.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even

though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

10.3.4.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

10.3.4.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

10.3.4.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).

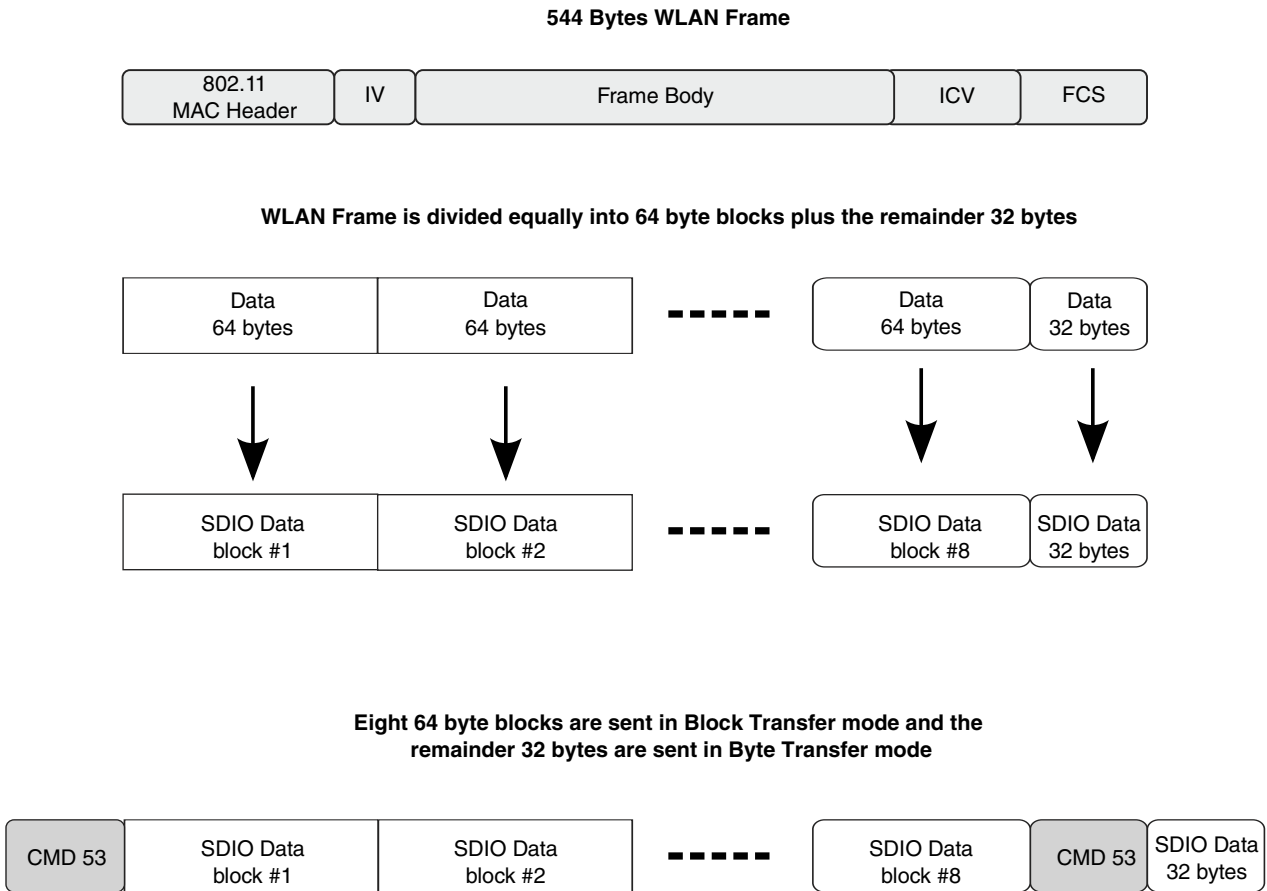

Figure 10-40. Example for Dividing Large Data Transfers

10.3.4.1.5 External DMA Request

When the internal DMA is not in use and external DMA is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal uSDHC_dreq_b is asserted to 0, informing the Host System of a DMA write.

The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's free space can't meet the watermark condition (free space > write watermark level).

On read operation, when the number of RD_WML words are already in the buffer, the signal uSDHC_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's data can't meet the watermark condition (the number of data in buffer > read watermark level).

If the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access there is no such issue, as the last access in the block transfer can be controlled by software. The watermark level can be any value, even larger than the block size (but no greater than 128 words) because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The uSDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of words. For this case, the BLKSIZE bits of the Block Attribute register will be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the uSDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. See [DMA Burst Length](#) for more details about the dynamic watermark level of the data buffer.

For the above example, even though 8 words are transferred via the Data Port register, the uSDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously or invalid data will be transferred to and from the card.

10.3.4.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the `uSDHC_dreq_b` will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

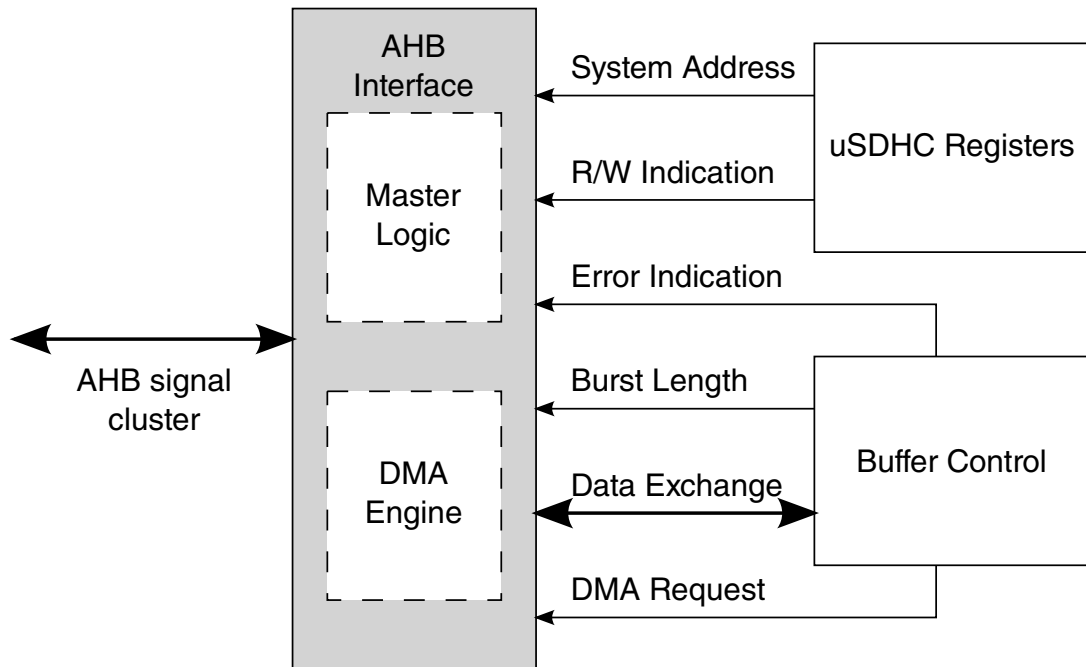

Figure 10-41. DMA AHB Interface Block

10.3.4.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (`uSDHC_dreq_b`) is disabled.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is $(31 - 6 * 4) / 4 = 2$. The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

10.3.4.2.2 DMA Burst Length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in [Internal DMA Request](#). After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

10.3.4.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

10.3.4.2.4 ADMA Engine

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.

The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

10.3.4.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

See [Figure 10-42](#) for the format of the descriptor table for ADMA1.

[Figure 10-45](#) explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned(lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-42. Format of the ADMA1 Descriptor Table

System Address Register points to the head node of Descriptor Table

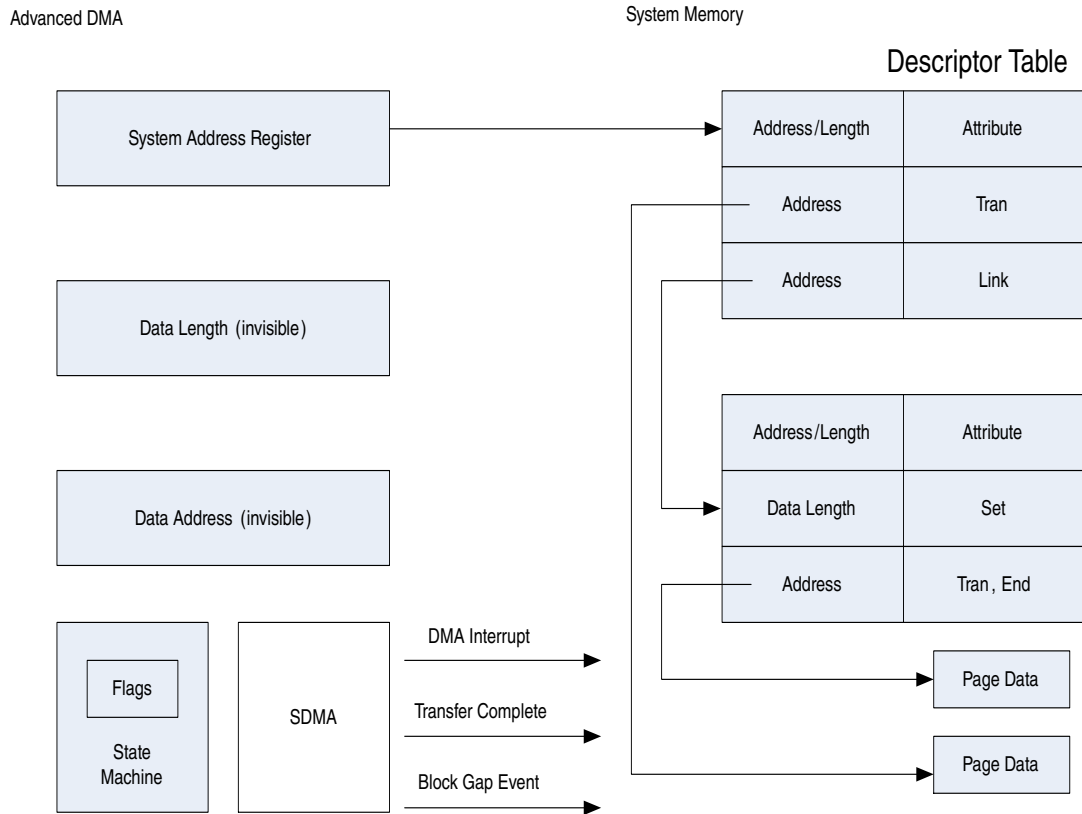

Figure 10-43. Concept and Access Method of ADMA1 Descriptor Table

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-44. Format of the ADMA2 Descriptor Table

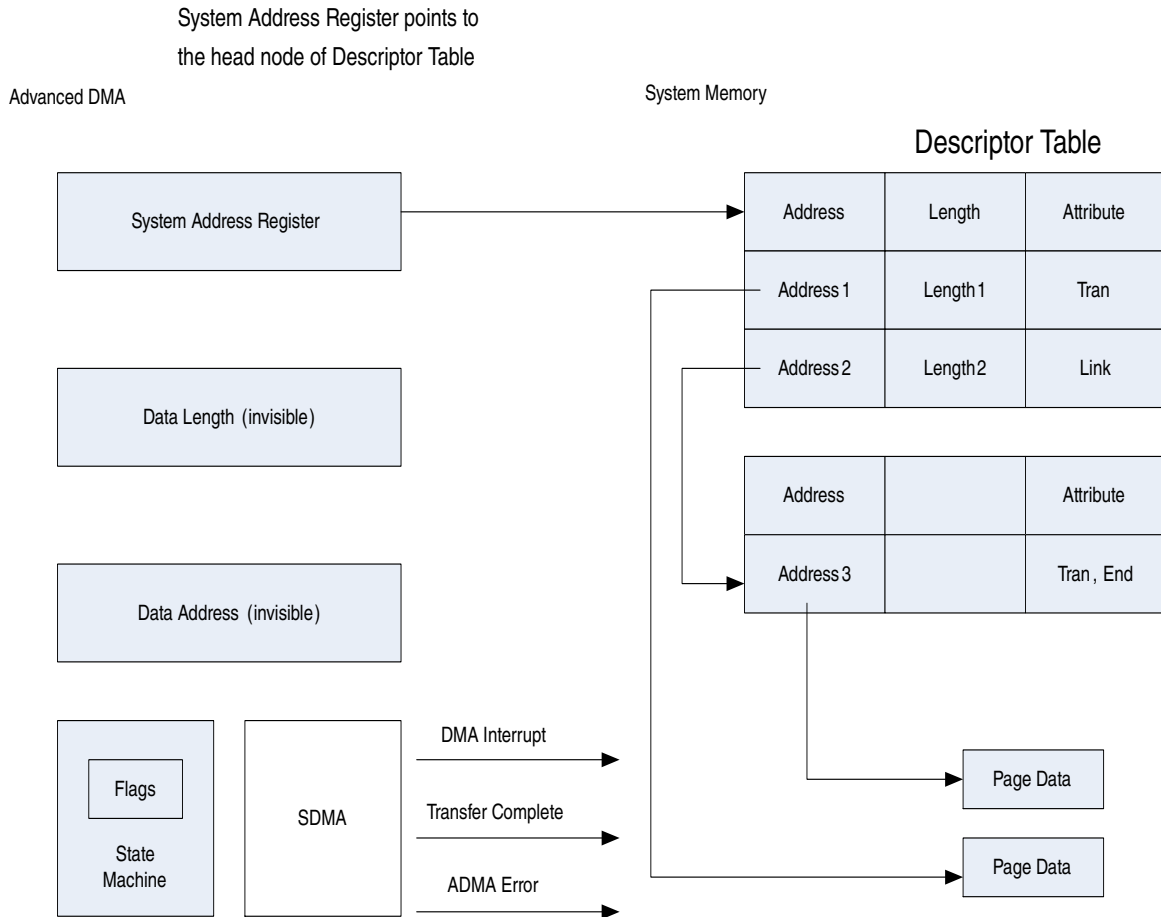

Figure 10-45. Concept and Access Method of ADMA2 Descriptor Table

10.3.4.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

10.3.4.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

10.3.4.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See [Figure 10-46](#) below for the block diagram.

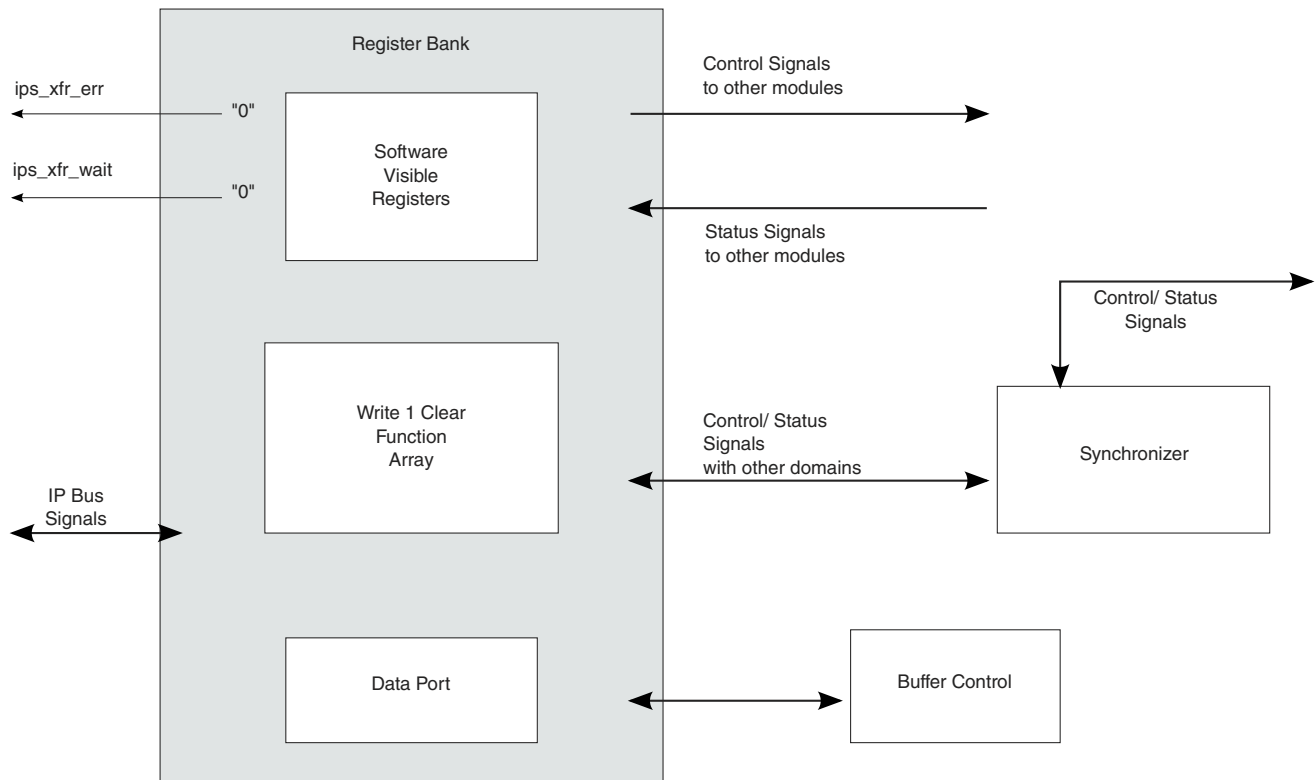

Figure 10-46. Register Bank Diagram

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

10.3.4.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.
2. Command control.

3. Data control.
4. Clock control

10.3.4.3.2 SD control misc

In the SD control misc unit, the card detect(include the CD_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

10.3.4.3.3 SD Clock control

If the internal data buffer is near full(for read) or near empty(for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space(for read) or has data(for write), the clock gate of this module will open and the SD clock will be active again.

10.3.4.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.

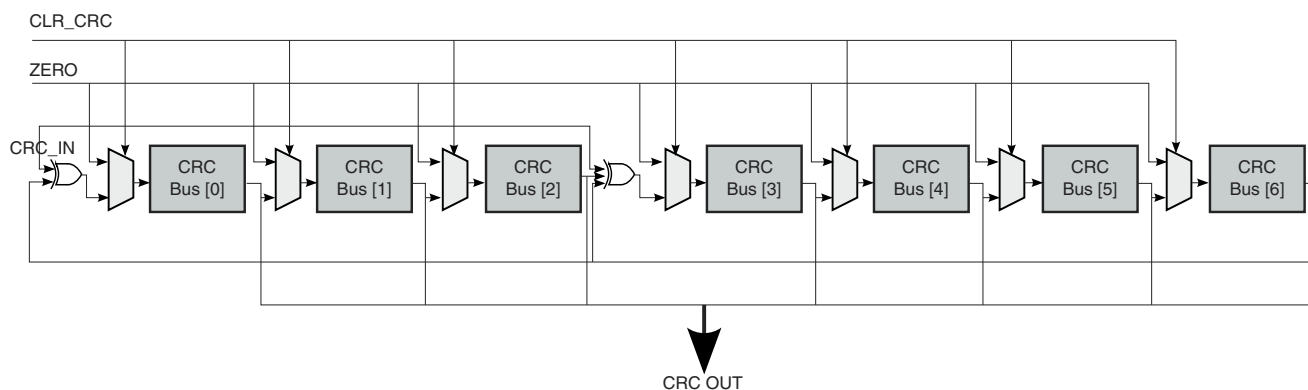

Figure 10-47. Command CRC Shift Register

The CRC polynomials for the CMD are as follows:

Ultra Secured Digital Host Controller (uSDHC)

Generator polynomial: $G(x) = x^7 + x^3 + 1$
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$
 $\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$

10.3.4.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$
 $M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \dots + (\text{last bit}) * x^0$
 $\text{CRC}[15:0] = \text{Remainder} [(M(x) * x^{16}) / G(x)]$

10.3.4.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

10.3.4.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages.

Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

Figure 10-48. Two Stages of the Clock Divider

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual internal working clock (`card_clk`). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see [Figure 10-37](#)) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV , $DIV/2$, $DIV/4$,..., or $DIV/256$. Thus the highest frequency of the `card_clk` is Base, and the next highest is $Base/2$, while the lowest frequency is $Base/4096$. If the duty cycle of Base clock is 50%, the duty cycle of `card_clk` is also 50%, even when the compound divisor is an odd value.

Please note, in SDR mode and DDR mode, the CLK are different.

- In SDR mode, CLK is equal to the internal working clock(`card_clk`).
- In DDR mode, CLK is equal to the `card_clk/2`.

10.3.4.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

10.3.4.6.1 Interrupts in 1-bit Mode

In this case the DATA1 pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

10.3.4.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two

clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

10.3.4.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

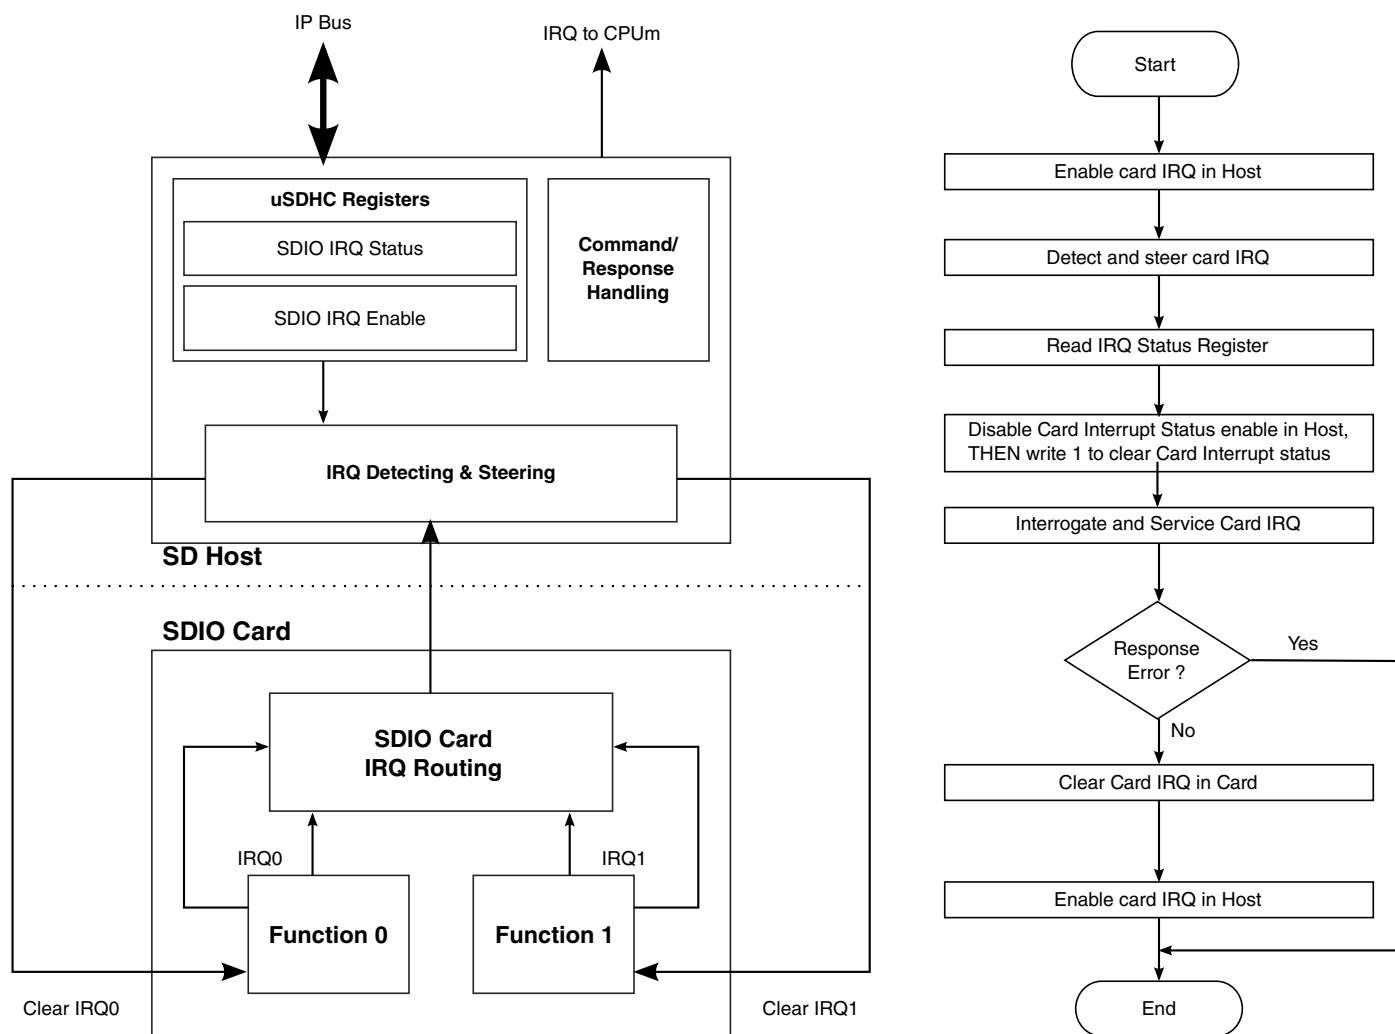

Figure 10-49. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure

10.3.4.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

10.3.4.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the `ipg_clk` and `ipg_perclk` in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to [Protocol Control \(uSDHC_PROT_CTRL\)](#) for more information on the uSDHC Protocol Control register.

10.3.4.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

10.3.4.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

10.3.4.9.1 Boot operation

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

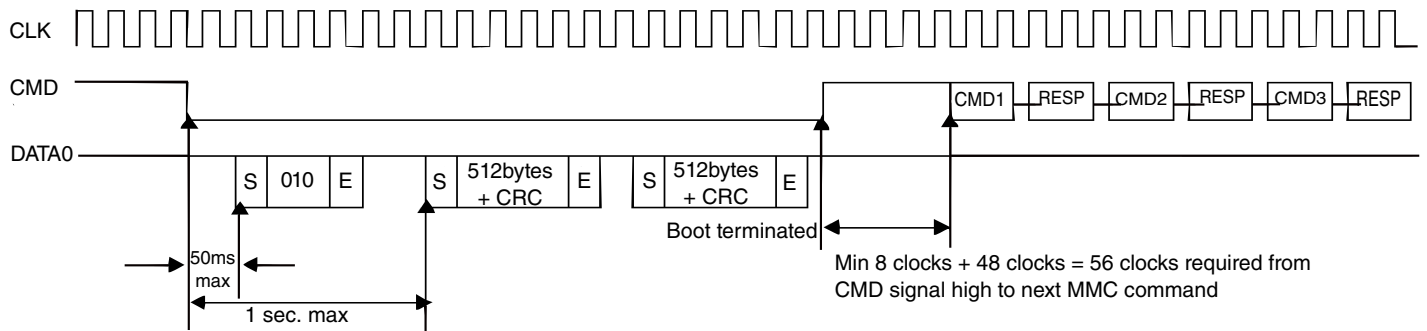

Figure 10-50. MultiMediaCard state diagram (normal boot mode)

10.3.4.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

NOTE 1. CMD0 with argument 0xFFFFFFFF

Figure 10-51. MultiMediaCard state diagram (alternative boot mode)

10.3.5 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, ALL_SEND_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to [Commands for MMC/SD/SDIO](#) for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to [Commands for MMC/SD/SDIO](#) for the commands of ac and adtc categories.

10.3.5.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

Ultra Secured Digital Host Controller (uSDHC)

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, C1CEN, CCCEN, RSTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
    set MSBSEL bit;
    if (finite block number) {
        set BCEN bit;
        if (auto12 command is to use) set AC12EN bit;
    }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function `wait_for_response` is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

10.3.5.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

10.3.5.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.

Figure 10-52. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

10.3.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)

- Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

Figure 10-53. Flow Chart for Reset of the uSDHC and SD I/O Card

```

software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set_DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
  
```

10.3.5.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for V_{dd} are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```

voltage_validation(voltage_range_argument)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
    if (0 < number of IO functions) {
        label the card as SDIO;
        IORDY = 0;
        while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
            send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
            wait_for_response(IO_SEND_OP_COND);
        } // end of while ...
    } // end of if (0 < ...
    if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
    send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
    wait_for_response(SD_APP_OP_COND); // voltage range is set
    if (Card type is UNKNOWN) label the card as SD;
    return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
    deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card if (card is already labelled as SDCombo)
{ //
change label

```

```

        re-label the card as SDIO;
        ignore the error or report it;
        return; // card is identified as SDIO card
    } // of if (card is ...
    send_command(SEND_OP_COND, <voltage range>, <...>);
    if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
        label the card as UNKNOWN;
        return;
    } // of if (RESP_TIMEOUT ...
} // of else
}

```

10.3.5.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while

bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```

card_registry()
{
do { // decide RCA for each card until response time-out
    if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
        send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
        retrieve RCA from response;
    } // end if (card is labelled as SDCombo ...
    else if (card is labelled as SD) { // for SD card
        send_command(ALL_SEND_CID, <...>);
        if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
        send_command(SET_RELATIVE_ADDR, <...>);
        retrieve RCA from response;
    } // else if (card is labelled as SD ...
    else if (card is labelled as MMC) {
        send_command(ALL_SEND_CID, <...>);
        rca = 0x1; // arbitrarily set RCA, 1 here for example
        send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
        } // end of else if (card is labelled as MMC ...
    } while (response is not time-out);
}

```

10.3.5.3 Card Access

Information about Block Write, Block Read, Suspend Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

10.3.5.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

10.3.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
 4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
 5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
 6. Wait for the Transfer Complete interrupt.
 7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

10.3.5.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

10.3.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in [Normal Write](#), the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
 - For SD/MMC, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to

send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

10.3.5.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

10.3.5.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
 - For SD/MMC, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

10.3.5.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

10.3.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in [Normal Read](#), the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:

- For SD/MMC, use SET_BLOCKLEN (CMD16)
 - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
 6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
 7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
 8. Set the SABGREQ bit.
 9. Wait for the Transfer Complete interrupt.
 10. Clear the SABGREQ bit.
 11. Check the status bit to see if read CRC error occurred.
 12. Set the CREQ bit to continue the read operation.
 13. Wait for the Transfer Complete interrupt.
 14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

10.3.5.3.2.4 DLL (Delay Line) in Read Path

The DLL(Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns, setting target vaule of 16 means $5\text{ns} = (16/32) * 10\text{ns}$. Software can disable automatic update by setting dll_gate_update bit. Please refer to [Figure 10-54](#).

Since the user may change the frequency of the card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: clear DLL_CTRL_RESET bit

Step 5: Wait until both DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: set DLL_CTRL_SLV_FORCE_UPD

Step 7: clear DLL_CTRL_SLV_FORCE_UPD

NOTE:Software should make sure the DLL_CTRL_SLV_FORCE_UPD is lasted for at least one card_clk. So software may need to add some delay between step6 and step7.

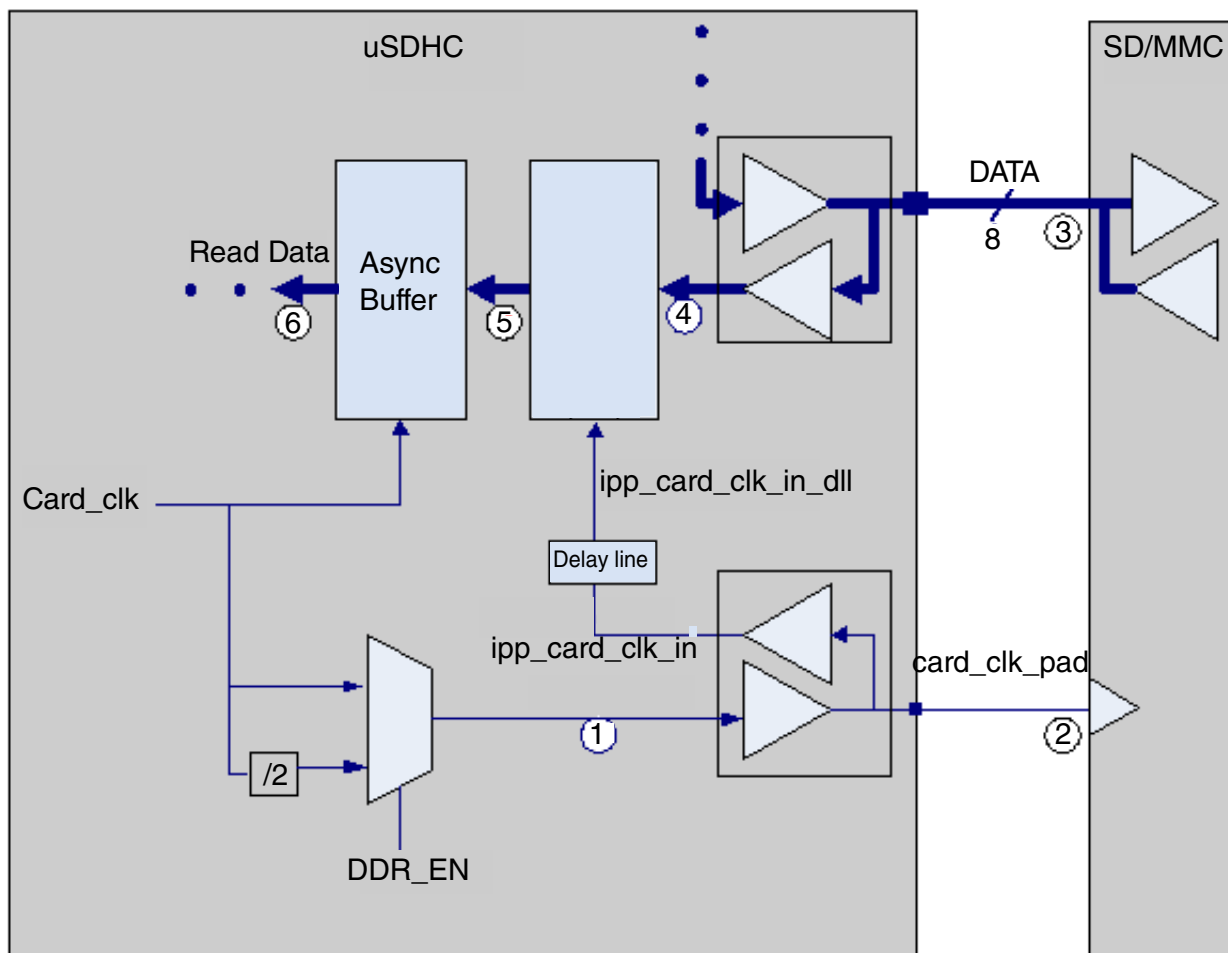

Figure 10-54. DLL(Delay Line) in Read Path

10.3.5.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

10.3.5.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

10.3.5.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

10.3.5.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.

6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

10.3.5.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are detailed in the sections below.

10.3.5.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

10.3.5.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.

2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

10.3.5.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

10.3.5.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

10.3.5.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to [Card Interrupt Handling](#) for the card interrupt handling flow.

10.3.5.4 Switch Function

A switch command must be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

10.3.5.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

10.3.5.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/SDR104/DDR50

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
```

```
(data transactions like normal peers)
}
```

10.3.5.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into USDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into USDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

10.3.5.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

10.3.5.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.

10.3.5.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
```

Ultra Secured Digital Host Controller (uSDHC)

```
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

10.3.5.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

10.3.5.6 Fast Boot Operation

10.3.5.6.1 Normal fast boot flow

1. Software must configure `init_active` bit (system control register bit 27) to make sure 74 card clocks are finished.

2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept at the default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.
7. DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.

10.3.5.6.2 Alternative fast boot flow

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.

3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, C ICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process..
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

10.3.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the

first time, so that that the host will stop at the block gap when the uSDHC controller gets VALUE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.

3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM) and data length (ie, 512 byte * VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2 word (record as VALUE2). Note: the second couple desc also transfer useful data even at least 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.
7. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFF in alternative fast boot, and don't need set in normal fast boot.
8. Software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Block Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.
10. When TC, BGE bit is 1, SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code (VALUE3 the remain boot code block). Remember set the last descriptor with END.
11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit 31-bit 16 to set the $(BLK_CNT - (VALUE1 + 1 + VALUE3))$, that host will stop at block gap when *the uSDHC controller gets (VALUE1 + 1 + VALUE3) blocks from device totally include the blocks received in step 9*. And need to configure bit 3-bit 0 to select the ack

timeout value according to the sd clk frequency. Please note, Software doesn't need to configure the *BLK_CNT* again, because it's counted down automatically by the uSDHC controller.

12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

10.3.6 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).

Response: a response is a token which is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 10-42. Commands for MMC/SD/SDIO Cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3 ¹	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_AD DR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6 ²	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6 ³	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISSION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6 ⁴	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13 ⁴	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22 ⁴	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23 ⁴	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD41 ⁴	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42 ⁴	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51 ⁴	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in [Table 2](#).
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT_CSD Access Modes are shown below.

Table 10-43. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

10.3.7 Software Restrictions

10.3.7.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

10.3.7.2 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

10.3.7.3 Suspend Operation

In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.

10.3.7.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

10.3.7.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

10.3.7.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or external DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

10.3.7.7 Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

10.3.7.8 Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

10.3.8 uSDHC Memory Map/Register Definition

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

uSDHC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
30B4_0000	DMA System Address (uSDHC1_DS_ADDR)	32	R/W	0000_0000h	10.3.8.1/2838

10.3.8.1 DMA System Address (uSDHCx_DS_ADDR)

This register contains the physical system memory address used for DMA transfers.

Address: Base address + 0h offset

uSDHCx_DS_ADDR field descriptions

Field	Description
31–2 DS_ADDR	<p>DMA System Address:</p> <p>This register contains the 32-bit system memory address for a DMA transfer. Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.</p> <p>This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register.</p> <p>The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions .</p>
Reserved	This read-only field is reserved and always has the value 0.

10.3.8.2 Block Attributes (uSDHCx_BLK_ATT)

This register is used to configure the number of data blocks and the number of bytes in each block.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BLKCNT																0		BLKSIZE[12:0]													
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_BLK_ATT field descriptions

Field	Description
31–16 BLKCNT	<p>Blocks Count For Current Transfer:</p> <p>This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</p> <p>This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.</p>

Table continues on the next page...

uSDHCx_BLK_ATT field descriptions (continued)

Field	Description
	<p>When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when Suspend command is sent out, uSDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count.</p> <p>When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count.</p> <p>NOTE: Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL bit is indicating a single block transfer, the read value of BLKCNT is always 1.</p> <p>FFFF 65535 blocks 0002 2 blocks 0001 1 block 0000 Stop Count</p>
15–13 Reserved	This read-only field is reserved and always has the value 0.
BLKSIZE[12:0]	<p>Transfer Block Size:</p> <p>This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored.</p> <p>1000 4096 Bytes 800 2048 Bytes 200 512 Bytes 1FF 511 Bytes 004 4 Bytes 003 3 Bytes 002 2 Bytes 001 1 Byte 000 No data transfer</p>

10.3.8.3 Command Argument (uSDHCx_CMD_ARG)

This register contains the SD / MMC Command Argument.

Address: Base address + 8h offset

uSDHCx_CMD_ARG field descriptions

Field	Description
CMDARG[31:0]	<p>Command Argument</p> <p>The SD / MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification. This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.</p>

10.3.8.4 Command Transfer Type (uSDHCx_CMD_XFR_TYP)

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 10-44. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits as well as the name of the response type.

Table 10-45. Relationship Between Parameters and the Name of the Response Type

Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Address: Base address + Ch offset

uSDHCx_CMD_XFR_TYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0.
29–24 CMDINX[5:0]	Command Index These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. <ul style="list-style-type: none"> • Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register. • Resume Command: The Host Driver re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The uSDHC will check for a pending busy state before starting write transfers. • Abort Command: If this command is set when executing a read transfer, the uSDHC will stop reads to the buffer. If this command is set when executing a write transfer, the uSDHC will stop driving the DATA line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction). 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR 10 Resume CMD52 for writing Function Select in CCCR 01 Suspend CMD52 for writing Bus Suspend in CCCR 00 Normal Other commands
21 DPSEL	Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DATA line. It is set to 0 for the following: <ul style="list-style-type: none"> • Commands using only the CMD line (e.g. CMD52). • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b e.g. CMD38)

Table continues on the next page...

uSDHCx_CMD_XFR_TYP field descriptions (continued)

Field	Description
	<p>NOTE: In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (i.e. the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.</p> <p>1 Data Present 0 No Data Present</p>
20 CICEN	<p>Command Index Check Enable</p> <p>If this bit is set to 1, the uSDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.</p> <p>1 Enable 0 Disable</p>
19 CCEN	<p>Command CRC Check Enable</p> <p>If this bit is set to 1, the uSDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Command Transfer Type (uSDHC_CMD_XFR_TYP) .)</p> <p>1 Enable 0 Disable</p>

uSDHCx_CMD_RSP1 field descriptions

Field	Description
CMDRSP1[31:0]	Command Response 1 Refer to Command Response3 (uSDHC_CMD_RSP3) for the mapping of command responses from the SD Bus to this register for each response type.

10.3.8.7 Command Response2 (uSDHCx_CMD_RSP2)

This register is used to store part 2 of the response bits from the card.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CMDRSP2[31:0]																															
W	[Shaded]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_CMD_RSP2 field descriptions

Field	Description
CMDRSP2[31:0]	Command Response 2 Refer to Command Response3 (uSDHC_CMD_RSP3) for the mapping of command responses from the SD Bus to this register for each response type.

10.3.8.8 Command Response3 (uSDHCx_CMD_RSP3)

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus.

Table 10-46. Response Bit Definition for Each Response Type

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows

the uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Address: Base address + 1Ch offset

uSDHCx_CMD_RSP3 field descriptions

Field	Description
CMDRSP3[31:0]	Command Response 3 Refer to Command Response3 (uSDHC_CMD_RSP3) for the mapping of command responses from the SD Bus to this register for each response type.

10.3.8.9 Data Buffer Access Port (uSDHCx_DATA_BUFF_ACC_PORT)

This is a 32-bit data port register used to access the internal buffer.

Address: Base address + 20h offset

uSDHCx_DATA_BUFF_ACC_PORT field descriptions

Field	Description
DATCONT[31:0]	Data Content The Buffer Data Port register is for 32-bit data access by the Arm platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

10.3.8.10 Present State (uSDHCx_PRES_STATE)

The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be

Ultra Secured Digital Host Controller (uSDHC)

issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

- Note: the reset value of Present State Register depend on testbench connectivity.

Address: Base address + 24h offset

Field	Description
31–24 DLSL[7:0]	<p>DATA[7:0] Line Signal Level</p> <p>This status is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up.</p> <p>DATA7 Data 7 line signal level DATA6 Data 6 line signal level DATA5 Data 5 line signal level DATA4 Data 4 line signal level DATA3 Data 3 line signal level</p>

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
	DATA2 Data 2 line signal level DATA1 Data 1 line signal level DATA0 Data 0 line signal level
23 CLSL	CMD Line Signal Level This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.
22–20 Reserved	This read-only field is reserved and always has the value 0.
19 WPSPL	Write Protect Switch Pin Level The Write Protect Switch is supported for memory and combo cards. This bit reflects the inverted value of the WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 1 Write enabled (WP = 0) 0 Write protected (WP = 1)
18 CDPL	Card Detect Pin Level This bit reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the CD_B pin (i.e. when a card is inserted in the socket, it is 0 on the CD_B input, and consequently the CDPL reads 1.) 1 Card present (CD_B = 0) 0 No card present (CD_B = 1)
17 Reserved	This read-only field is reserved and always has the value 0.
16 CINST	Card Inserted This bit indicates whether a card has been inserted. The uSDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit. The Software Reset For All in the System Control register does not effect this bit. A software reset does not effect this bit. 1 Card Inserted 0 Power on Reset or No Card
15 TSCD	Tape Select Change Done This bit indicates the dealy setting is effective after write CLK_TUNE_CTRL_STATUS register. 1 Delay cell select change is finished. 0 Delay cell select change is not finished.
14–13 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
12 RTR	<p>Re-Tuning Request (only for SD3.0 SDR104 mode)</p> <p>Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.</p> <p>This bit is cleared when a command is issued with setting Execute Tuning bit in MIXER_CTRL register.</p> <p>Changing of this bit from 0 to 1 generates Re-Tuning Event. Refer to Interrupt status registers for more detail.</p> <p>This bit isn't set to 1 if Sampling Clock Select in the MIXER_CTRL register is set to 0 (using fixed sampling clock).</p> <p>1 Sampling clock needs re-tuning 0 Fixed or well tuned sampling clock</p>
11 BREN	<p>Buffer Read Enable</p> <p>This status bit is used for non-DMA read transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when some reads from the buffer(read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this bit from 0 to 1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled.</p> <p>1 Read enable 0 Read disable</p>
10 BWEN	<p>Buffer Write Enable</p> <p>This status bit is used for non-DMA write transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when some writes to the buffer(write DATPORT(Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled.</p> <p>1 Write enable 0 Write disable</p>
9 RTA	<p>Read Transfer Active</p> <p>This status bit is used for detecting completion of a read transfer.</p> <p>This bit is set for either of the following conditions:</p> <ul style="list-style-type: none"> • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. <p>A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions:</p> <ul style="list-style-type: none"> • When the last data block as specified by block length is transferred to the System, i.e. all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. <p>1 Transferring data 0 No valid data</p>

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
8 WTA	<p>Write Transfer Active</p> <p>This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the uSDHC.</p> <p>This bit is set in either of the following cases:</p> <ul style="list-style-type: none"> • After the end bit of the write command. • When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer. <p>This bit is cleared in either of the following cases:</p> <ul style="list-style-type: none"> • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple). • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. <p>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state.</p> <p>1 Transferring data 0 No valid data</p>
7 SDOFF	<p>SD Clock Gated Off Internally</p> <p>This status bit indicates that the SD Clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON bit is 0 to stop the SD clock in idle status. Set IPG_PERCLK_SOFT_EN and CARD_CLK_SOFT_EN to 0 also gate off SD clock. This bit is for the Host Driver to debug data transaction on the SD bus.</p> <p>1 SD Clock is gated off. 0 SD Clock is active.</p>
6 PEROFF	<p>IPG_PERCLK Gated Off Internally</p> <p>This status bit indicates that the IPG_PERCLK is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK will be gated off, otherwise IPG_PERCLK will be always active.</p> <p>1 IPG_PERCLK is gated off. 0 IPG_PERCLK is active.</p>
5 HCKOFF	<p>HCLK Gated Off Internally</p> <p>This status bit indicates that the HCLK is internally gated off. This bit is for the Host Driver to debug during a data transfer.</p> <p>1 HCLK is gated off. 0 HCLK is active.</p>
4 IPGOFF	<p>IPG_CLK Gated Off Internally</p> <p>This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug.</p> <p>1 IPG_CLK is gated off. 0 IPG_CLK is active.</p>
3 SDSTB	<p>SD Clock Stable</p>

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
	<p>This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON bit in System Control register to remove glitches on the card clock when the frequency is changing.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>1 Clock is stable. 0 Clock is changing frequency and not stable.</p>
2 DLA	<p>Data Line Active</p> <p>This status bit indicates whether one of the DATA lines on the SD Bus is in use.</p> <p>In the case of read transactions:</p> <p>This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. <p>This bit will be cleared in either of the following cases:</p> <p>(1) When the end bit of the last data block is sent from the SD Bus to the uSDHC. (2) When the Read Wait state is stopped by a Suspend command and the DATA2 line is released.</p> <p>The uSDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait.</p> <p>In the case of write transactions:</p> <p>This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register.</p> <p>This bit will be set in either of the following cases:</p> <ul style="list-style-type: none"> • After the end bit of the write command. • When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer. <p>This bit will be cleared in either of the following cases:</p> <ul style="list-style-type: none"> • When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request. <p>In the case of command with busy pending:</p> <p>This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released.</p> <p>1 DATA Line Active 0 DATA Line Inactive</p>

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
1 CDIHB	<p>Command Inhibit (DATA)</p> <p>This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.</p> <p>NOTE: The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.</p> <p>1 Cannot issue command which uses the DATA line 0 Can issue command which uses the DATA line</p>
0 CIHB	<p>Command Inhibit (CMD)</p> <p>If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line.</p> <p>This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit.</p> <p>1 Cannot issue command 0 Can issue command using only CMD line</p>

10.3.8.11 Protocol Control (uSDHCx_PROT_CTRL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

Ultra Secured Digital Host Controller (uSDHC)

uSDHCx_PROT_CTRL field descriptions

Field	Description
31 -	Reserved. Always write as 0
30 NON_EXACT_ BLK_RD	Current block read is non-exact block read. It is only used for SDIO. 1 The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read. 0 The block read is exact block read. Host driver doesn't need to issue abort command to terminate this multi-block read.
29-27 BURST_LEN_EN	BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLES on the AXI side. xx1 Burst length is enabled for INCR x1x Burst length is enabled for INCR4 / INCR8 / INCR16 1xx Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP
26 WECRM	Wakeup Event Enable On SD Card Removal This bit enables a wakeup event, via a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Removal Status and the uSDHC interrupt. 1 Enable 0 Disable
25 WECINS	Wakeup Event Enable On SD Card Insertion This bit enables a wakeup event, via a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the uSDHC

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	<p>interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Insertion Status and the uSDHC interrupt.</p> <p>1 Enable 0 Disable</p>
24 WECINT	<p>Wakeup Event Enable On Card Interrupt</p> <p>This bit enables a wakeup event, via a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Interrupt Status and the uSDHC interrupt.</p> <p>1 Enable 0 Disable</p>
23–21 -	Reserved. Always write as 3'b100
20 RD_DONE_NO_8CLK	<p><i>Read done no 8 clock:</i></p> <p><i>According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end bit of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks will be active after the end bit of the last read data transaction.</i></p> <p><i>However, this 8 clocks should not be active if user wants to use stop at block gap(include the auto stop at block gap in boot mode) feature for read and the RWCTL bit(bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid this 8 clocks. Otherwise, the device may send extra data to uSDHC while uSDHC ignores these data.</i></p> <p><i>In a summary, this bit should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.</i></p>
19 IABG	<p>Interrupt At Block Gap</p> <p>This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</p> <p>1 Enabled 0 Disabled</p>
18 RWCTL	<p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation.</p> <p>1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set</p>
17 CREQ	Continue Request

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	<p>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer.</p> <p>The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored.</p> <p>1 Restart 0 No effect</p>
16 SABGREQ	<p>Stop At Block Gap Request</p> <p>This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined.</p> <p>This bit effects Read Transfer Active, Write Transfer Active, DATA Line Active and Command Inhibit (DATA) in the Present State register.</p> <p>1 Stop 0 Transfer</p>
15–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 DMASEL	<p>DMA Select</p> <p>This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation.</p> <p>00 No DMA or Simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 reserved</p>
7 CDSS	<p>Card Detect Signal Selection</p> <p>This bit selects the source for the card detection.</p> <p>1 Card Detection Test Level is selected (for test purpose). 0 Card Detection Level is selected (for normal purpose).</p>
6 CDTL	<p>Card Detect Test Level</p> <p>This bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion.</p> <p>1 Card Detect Test Level is 1, card inserted 0 Card Detect Test Level is 0, no card inserted</p>
5–4 EMODE	Endian Mode

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	<p>The uSDHC supports all three endian modes in data transfer. Refer to Data Buffer for more details.</p> <p>00 Big Endian Mode 01 Half Word Big Endian Mode 10 Little Endian Mode 11 Reserved</p>
3 D3CD	<p>DATA3 as Card Detection Pin</p> <p>If this bit is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the uSDHC does not support.</p> <p>1 DATA3 as Card Detection Pin 0 DATA3 does not monitor Card Insertion</p>
2–1 DTW[1:0]	<p>Data Transfer Width</p> <p>This bit selects the data width of the SD bus for a data transfer. The Host Driver shall set it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits.</p> <p>10 8-bit mode 01 4-bit mode 00 1-bit mode 11 Reserved</p>
0 LCTL	<p>LED Control</p> <p>This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands.</p> <p>1 LED on 0 LED off</p>

10.3.8.12 System Control (uSDHCx_SYS_CTRL)

Address: Base address + 2Ch offset

uSDHCx_SYS_CTRL field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 RSTT	Reset Tuning When set this bit to 1, it will reset tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning bit in AUTOCMD12_ERR_STATUS will also set this bit to 1 to reset tuning circuit
27 INITA	Initialization Active When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (i.e. when command line or data lines are active, write to this bit is not allowed). On the otherhand, when this bit is set, i.e., during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared.
26 RSTD	Software Reset For DATA Line

Table continues on the next page...

uSDHCx_SYS_CTRL field descriptions (continued)

Field	Description
	<p>Only part of the data circuit is reset. DMA circuit is also reset. After this bit is set, SW waits for self-clear.</p> <p>The following registers and bits are cleared by this bit:</p> <ul style="list-style-type: none"> • Data Port register • Buffer is cleared and initialized. • Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DATA Line Active • Command Inhibit (DATA) Protocol Control register • Continue Request • Stop At Block Gap Request Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete <p>NOTE: When reset, SW must make sure there is no incomplete data transferring. If there is data transfer going on, SW need wait TC or DC uSDHC_INT_STATUS register is set.</p> <p>1 Reset 0 No Reset</p>
25 RSTC	<p>Software Reset For CMD Line</p> <p>Only part of the command circuit is reset. After this bit is set, SW waits for self-clear.</p> <p>The following registers and bits are cleared by this bit:</p> <ul style="list-style-type: none"> • Present State register Command Inhibit (CMD) • Interrupt Status register Command Complete <p>1 Reset 0 No Reset</p>
24 RSTA	<p>Software Reset For ALL</p> <p>This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver shall set this bit to 1 to reset the uSDHC. The uSDHC shall reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it. After this bit is set, SW should wait for self-clear.</p> <p>In tuning process, after every CMD19 is finished, this bit will be set to retest the uSDHC.</p> <p>NOTE: When reset, SW must make sure there is no incomplete data transferring. If there is data transfer going on, SW need wait TC or DC uSDHC_INT_STATUS register is set.</p> <p>1 Reset 0 No Reset</p>
23 IPP_RST_N	<p>This register's value will be output to CARD from pad directly for hardware reset of the card if the card supports this feature.</p>
22 -	Reserved

Table continues on the next page...

uSDHCx_SYS_CTRL field descriptions (continued)

Field	Description
21–20 Reserved	This read-only field is reserved and always has the value 0.
19–16 DTCV	<p>Data Timeout Counter Value</p> <p>This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value.</p> <p>The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events.</p> <p>1111b SDCLK x 2²⁹ 1110b SDCLK x 2²⁸ ... 0001b SDCLK x 2¹⁵ 0000b SDCLK x 2¹⁴</p>
15–8 SDCLKFS	<p>SDCLK Frequency Select</p> <p>This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register.</p> <p><i>In Single Data Rate mode(DDR_EN bit of MIXERCTRL is '0')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1</p> <p><i>While in Dual Data Rate mode(DDR_EN bit of MIXERCTRL is '1')</i></p> <p>Only the following settings are allowed:</p> <p>80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2</p>

Table continues on the next page...

uSDHCx_SYS_CTRL field descriptions (continued)

Field	Description										
	<p><i>When S/W changes the DDR_EN bit, SDCLKFS may need to be changed also!</i></p> <p>In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD Clock.</p> <p>Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.</p> <p>The frequency of SDCLK is set by the following formula:</p> $\text{Clock Frequency} = (\text{Base Clock}) / (\text{prescaler} \times \text{divisor})$ <p>For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.</p> <p>The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz.</p> <p>According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p><i>If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.</i></p>										
7-4 DVS[3:0]	<p>Divisor</p> <p>This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle.</p> <p><i>Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.</i></p> <p>The setting are as following:</p> <table> <tr> <td>0000</td> <td>Divide-by-1</td> </tr> <tr> <td>0001</td> <td>Divide-by-2</td> </tr> <tr> <td>.....</td> <td></td> </tr> <tr> <td>1110</td> <td>Divide-by-15</td> </tr> <tr> <td>1111</td> <td>Divide-by-16</td> </tr> </table>	0000	Divide-by-1	0001	Divide-by-2		1110	Divide-by-15	1111	Divide-by-16
0000	Divide-by-1										
0001	Divide-by-2										
.....											
1110	Divide-by-15										
1111	Divide-by-16										
-	Reserved. Always write as 1.										

10.3.8.13 Interrupt Status (uSDHCx_INT_STATUS)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

Table 10-47. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 10-48. uSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

Table 10-49. uSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

uSDHCx_INT_STATUS field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 DMAE	<p>DMA Error</p> <p>Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the Host Driver shall re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size.</p> <p>1 Error 0 No Error</p>
27 Reserved	This read-only field is reserved and always has the value 0.
26 TNE	<p>Tuning Error: (only for SD3.0 SDR104 mode)</p> <p>This bit is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning.</p>
25 Reserved	This read-only field is reserved and always has the value 0.
24 AC12E	<p>Auto CMD12 Error</p> <p>Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error.</p> <p>1 Error 0 No Error</p>
23 Reserved	This read-only field is reserved and always has the value 0.
22 DEBE	<p>Data End Bit Error</p> <p>Occurs either when detecting 0 at the end bit position of read data, which uses the DATA line, or at the end bit position of the CRC.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
21 DCE	<p>Data CRC Error</p> <p>Occurs when detecting a CRC error when transferring read data, which uses the DATA line, or when detecting the Write CRC status having a value other than 010.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>
20 DIOE	<p>Data Timeout Error</p> <p>Occurs when detecting one of following time-out conditions.</p> <ul style="list-style-type: none"> • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. <p>This bit will be not asserted in tuning process.</p> <p>1 Time out 0 No Error</p>
19 CIE	<p>Command Index Error</p> <p>Occurs if a Command Index error occurs in the command response.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Error 0 No Error</p>
18 CEBE	<p>Command End Bit Error</p> <p>Occurs when detecting that the end bit of a command response is 0.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 End Bit Error Generated 0 No Error</p>
17 CCE	<p>Command CRC Error</p> <p>Command CRC Error is generated in two cases.</p> <ul style="list-style-type: none"> • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The uSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the uSDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict. <p>This bit will be not asserted in tuning process.</p> <p>1 CRC Error Generated. 0 No Error</p>
16 CTOE	<p>Command Timeout Error</p> <p>Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the uSDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set (as shown in Interrupt Status (uSDHC_INT_STATUS)), this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the uSDHC.</p>

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	This bit will be not asserted in tuning process. 1 Time out 0 No Error
15 Reserved	This read-only field is reserved and always has the value 0.
14 TP	Tuning Pass:(only for SD3.0 SDR104 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 Reserved	This read-only field is reserved and always has the value 0.
12 RTE	Re-Tuning Event: (only for SD3.0 SDR104 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 1 Re-Tuning should be performed 0 Re-Tuning is not required
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 CINT	Card Interrupt This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted
6 CINS	Card Insertion This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	<p>register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.</p> <p>1 Card inserted 0 Card state unstable or removed</p>
5 BRR	<p>Buffer Read Ready</p> <p>This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information.</p> <p>This bit indicates that cmd19 is finished in tuning process.</p> <p>1 Ready to read buffer 0 Not ready to read buffer</p>
4 BWR	<p>Buffer Write Ready</p> <p>This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information.</p> <p>1 Ready to write buffer: 0 Not ready to write buffer</p>
3 DINT	<p>DMA Interrupt</p> <p>Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set.</p> <p>1 DMA Interrupt is generated 0 No DMA Interrupt</p>
2 BGE	<p>Block Gap Event</p> <p>If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function.</p> <p>In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing).</p> <p>1 Transaction stopped at block gap 0 No block gap event</p>
1 TC	<p>Transfer Complete</p> <p>This bit is set when a read or write transfer is completed.</p> <p>In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System).</p>

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	<p>In the case of a Write Transaction: This bit is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released).</p> <p>In the case of a command with busy, this bit is set when busy is deasserted.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Transfer complete 0 Transfer not complete</p>
0 CC	<p>Command Complete</p> <p>This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register.</p> <p>This bit will be not asserted in tuning process.</p> <p>1 Command complete 0 Command not complete</p>

10.3.8.14 Interrupt Status Enable (uSDHCx_INT_STATUS_EN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

10.3.8.15 Interrupt Signal Enable (uSDHCx_INT_SIGNAL_EN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

10.3.8.16 Auto CMD12 Error Status (uSDHCx_AUTOCMD12_ERR_STATUS)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 10-50. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
 - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
 - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
 - Check errors correspond to bits 1-4.
 - Set bits 1-4 corresponding to detected errors.
 - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
 - Set bit 7 to 1 if there is a command that can't be issued
 - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Ultra Secured Digital Host Controller (uSDHC)

uSDHCx_AUTOCMD12_ERR_STATUS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 SMP_CLK_SEL	<p>Sample Clock Select</p> <p>When std_tuning_en bit is set, this bit is used to select sampling clock to receive CMD and DATA. Otherwise, this bit is reserved. This bit is set by ty tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this bit is not allowed while the Host controller us receiving response or a read data block.</p>

Table continues on the next page...

uSDHCx_AUTOCMD12_ERR_STATUS field descriptions (continued)

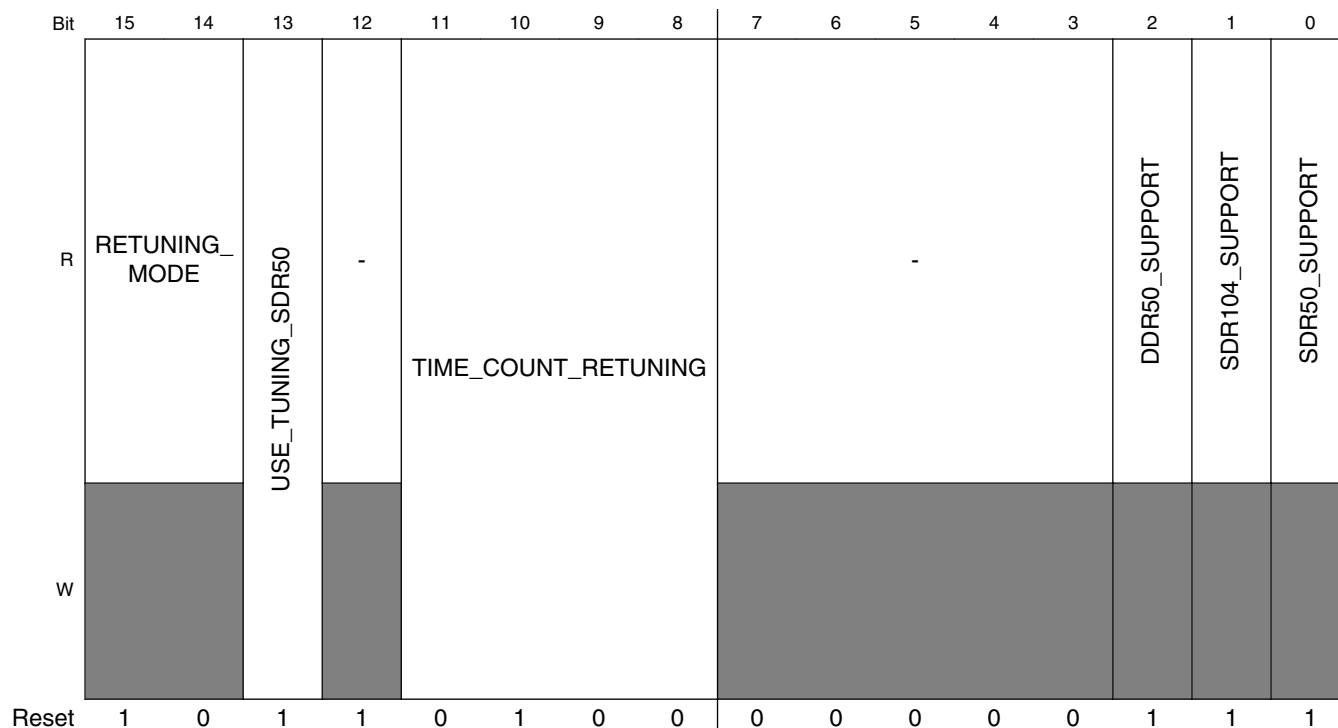

Field	Description
	1 Tuned clock is used to sample data 0 Fixed clock is used to sample data
22 EXECUTE_TUNING	Execute Tuning When std_tuning_en bit is set, this bit is used to start tuning procedure. Otherwise, this bit is reserved. This bit is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to sam_clk_sel bit. Tuning procedure is aborted by writing 0.
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. 1 Not Issued 0 No error
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 AC12IE	Auto CMD12 / 23 Index Error Occurs if the Command Index error occurs in response to a command. 1 Error, the CMD index in response is not CMD12/23 0 No error
3 AC12CE	Auto CMD12 / 23 CRC Error Occurs when detecting a CRC error in the command response. 1 CRC Error Met in Auto CMD12/23 Response 0 No CRC error
2 AC12EBE	Auto CMD12 / 23 End Bit Error Occurs when detecting that the end bit of command response is 0 which should be 1. 1 End Bit Error Generated 0 No error
1 AC12TOE	Auto CMD12 / 23 Timeout Error Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to 1, the other error status bits (2-4) have no meaning. 1 Time out 0 No error
0 AC12NE	Auto CMD12 Not Executed If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means the uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning. 1 Not executed 0 Executed

10.3.8.17 Host Controller Capabilities (uSDHCx_HOST_CTRL_CAP)

This register provides the Host Driver with information specific to the uSDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset.

2 DDR50_ SUPPORT	DDR50 support This bit indicates support of DDR50 mode.
1 SDR104_ SUPPORT	SDR104 support This bit indicates support of SDR104 mode.
0 SDR50_ SUPPORT	SDR50 support This bit indicates support of SDR50 mode.

10.3.8.18 Watermark Level (uSDHCx_WTMK_LVL)

Both write and read watermark levels (FIFO threshold) are configurable. Their value can range from 1 to 128 words. Both write and read burst lengths are also configurable. Their value can range from 1 to 31 words.

Address: Base address + 44h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

uSDHCx_WTMK_LVL field descriptions

Field	Description
31-29 Reserved	This read-only field is reserved and always has the value 0.
28-24 WR_BRST_ LEN[4:0]	Write Burst Length ¹ The number of words the uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
23-16 WR_WML[7:0]	Write Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15-13 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_WTMK_LVL field descriptions (continued)

Field	Description
12-8 RD_BRST_LEN[4:0]	Read Burst Length ² The number of words the uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
RD_WML[7:0]	Read Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

1. Due to system restriction, the actual burst length may not exceed 16.
2. Due to system restriction, the actual burst length may not exceed 16.

10.3.8.19 Mixer Control (uSDHCx_MIX_CTRL)

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 10-51. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

uSDHCx_MIX_CTRL field descriptions

Field	Description
31 -	Reserved. Always write as 1
30 -	Reserved. Always write as 0.
29 -	Reserved. Always write as 0.
28–27 Reserved	This read-only field is reserved and always has the value 0.
26 HS400_MODE	Enable HS400 Mode HS400 Enable
25 FBCLK_SEL	Feedback Clock Source Selection (Only used for SD3.0, SDR104 mode) 1 Feedback clock comes from the ipp_card_clk_out 0 Feedback clock comes from the loopback CLK
24 AUTO_TUNE_EN	Auto Tuning Enable (Only used for SD3.0, SDR104 mode) 1 Enable auto tuning 0 Disable auto tuning
23 SMP_CLK_SEL	When STD_TUNING_EN is 0, this bit is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode) 1 Tuned clock is used to sample data / cmd 0 Fixed clock is used to sample data / cmd
22 EXE_TUNE	Execute Tuning: (Only used for SD3.0, SDR104 mode) When STD_TUNING_EN is 0, this bit is set to 1 to indicate the Host Driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 1 Execute Tuning 0 Not Tuned or Tuning Completed
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 AC23EN	Auto CMD23 Enable When this bit is set to 1, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	In DDR 4-bit mode nibble position indication. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single Block Select This bit enables multiple block DATA line data transfers. For any other commands, this bit can be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Command Transfer Type (uSDHC_CMD_XFR_TYP)). 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select

Table continues on the next page...

uSDHCx_MIX_CTRL field descriptions (continued)

Field	Description
	<p>This bit defines the direction of DATA line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the uSDHC and is set to 0 for all other commands.</p> <p>1 Read (Card to Host) 0 Write (Host to Card)</p>
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	<p>Auto CMD12 Enable</p> <p>Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the uSDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the uSDHC will ignore this bit no matter it is set or not.</p> <p>1 Enable 0 Disable</p>
1 BCEN	<p>Block Count Enable</p> <p>This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer.</p> <p>1 Enable 0 Disable</p>
0 DMAEN	<p>DMA Enable</p> <p>This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA or the Advanced DMA is active depends on the DMA Select field of the Protocol Control register.</p> <p>1 Enable 0 Disable</p>

10.3.8.20 Force Event (uSDHCx_FORCE_EVENT)

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_FORCE_EVENT field descriptions

Field	Description
31 FEVTCINT	Force Event Card Interrupt Writing 1 to this bit generates a short low-level pulse on the internal DATA1 line, as if a self clearing interrupt was received from the external card. If enabled, the CINT bit will be set and the interrupt service routine may treat this interrupt as a normal interrupt from the external card.
30–29 Reserved	This read-only field is reserved and always has the value 0.
28 FEVTDMAE	Force Event DMA Error Forces the DMAE bit of Interrupt Status Register to be set.
27 Reserved	This read-only field is reserved and always has the value 0.
26 FEVTTNE	Force Tuning Error Forces the TNE bit of Interrupt Status Register to be set.
25 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_FORCE_EVENT field descriptions (continued)

Field	Description
24 FEVTAC12E	Force Event Auto Command 12 Error Forces the AC12E bit of Interrupt Status Register to be set.
23 Reserved	This read-only field is reserved and always has the value 0.
22 FEVTDEBE	Force Event Data End Bit Error Forces the DEBE bit of Interrupt Status Register to be set.
21 FEVTDCE	Force Event Data CRC Error Forces the DCE bit of Interrupt Status Register to be set.
20 FEVTDTOE	Force Event Data Time Out Error Force the DTOE bit of Interrupt Status Register to be set.
19 FEVTCIE	Force Event Command Index Error Forces the CCE bit of Interrupt Status Register to be set.
18 FEVTCEBE	Force Event Command End Bit Error Forces the CEBE bit of Interrupt Status Register to be set.
17 FEVTCCE	Force Event Command CRC Error Forces the CCE bit of Interrupt Status Register to be set.
16 FEVTCIOE	Force Event Command Time Out Error Forces the CIOE bit of Interrupt Status Register to be set.
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 FEVTCNIBAC12E	Force Event Command Not Executed By Auto Command 12 Error Forces the CNIBAC12E bit in the Auto Command12 Error Status Register to be set.
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 FEVTAC12IE	Force Event Auto Command 12 Index Error Forces the AC12IE bit in the Auto Command12 Error Status Register to be set.
3 FEVTAC12EBE	Force Event Auto Command 12 End Bit Error Forces the AC12EBE bit in the Auto Command12 Error Status Register to be set.
2 FEVTAC12CE	Force Event Auto Command 12 CRC Error Forces the AC12CE bit in the Auto Command12 Error Status Register to be set.
1 FEVTAC12TOE	Force Event Auto Command 12 Time Out Error Forces the AC12TOE bit in the Auto Command12 Error Status Register to be set.
0 FEVTAC12NE	Force Event Auto Command 12 Not Executed Forces the AC12NE bit in the Auto Command12 Error Status Register to be set.

10.3.8.21 ADMA Error Status Register (uSDHCx_ADMA_ERR_STATUS)

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- **ST_STOP:** Previous location set in the ADMA System Address register is the error descriptor address.
- **ST_FDS:** Current location set in the ADMA System Address register is the error descriptor address.
- **ST_CADR:** This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST_TFR:** Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

Table 10-52. ADMA Error State Coding

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

Ultra Secured Digital Host Controller (uSDHC)

Address: Base address + 54h offset

uSDHCx_ADMA_ERR_STATUS field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
3 ADMADCE	ADMA Descriptor Error This error occurs when invalid descriptor fetched by ADMA. 1 Error 0 No Error
2 ADMALME	ADMA Length Mismatch Error This error occurs in the following 2 cases: <ul style="list-style-type: none"> While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length. Total data length cannot be divided by the block length. 1 Error 0 No Error
ADMAES	ADMA Error State (when ADMA Error is occurred)

Table continues on the next page...

uSDHCx_ADMA_ERR_STATUS field descriptions (continued)

Field	Description
	This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to ADMA Error Status Register (uSDHC_ADMA_ERR_STATUS) for more details.

10.3.8.22 ADMA System Address (uSDHCx_ADMA_SYS_ADDR)

This register contains the physical system memory address used for ADMA transfers.

Address: Base address + 58h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADS_ADDR[31:0]																0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_ADMA_SYS_ADDR field descriptions

Field	Description
31–2 ADS_ ADDR[31:0]	<p>ADMA System Address</p> <p>This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.</p> <p>Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions .</p>
Reserved	This read-only field is reserved and always has the value 0.

10.3.8.23 DLL (Delay Line) Control (uSDHCx_DLL_CTRL)

This register contains control bits for DLL.

Address: Base address + 60h offset

uSDHCx_DLL_CTRL field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT[3:0]	DLL control loop update interval. The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop shall update every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 DLL_CTRL_SLV_UPDATE_INT[7:0]	Slave delay line update interval. If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 DLL_CTRL_SLV_DLY_TARGET1	Refer to DLL_CTRL_SLV_DLY_TARGET0 below.
15–9 DLL_CTRL_SLV_OVERRIDE_VAL[6:0]	When SLV_OVERRIDE = 1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.

Table continues on the next page...

uSDHCx_DLL_CTRL field descriptions (continued)

Field	Description
8 DLL_CTRL_ SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_ GATE_UPDATE	Set this bit to 1 to prevent the DLL from updating (since when clock_in exists, glitches may appear during DLL updates). This bit may be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_ SLV_DLY_ TARGET0	The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is $((DLL_CTRL_SLV_DLY_TARGET1 + 1) * REF_CLOCK / 2) / 16$ So the input read-clock can be delayed relative input data from $(REF_CLOCK / 2) / 16$ to $REF_CLOCK * 4$.
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_ RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

10.3.8.24 DLL Status (uSDHCx_DLL_STATUS)

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

Address: Base address + 64h offset

uSDHCx_DLL_STATUS field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–9 DLL_STS_REF_SEL[6:0]	Reference delay line select taps. This is encoded by 7 bits for 127 taps.
8–2 DLL_STS_SLV_SEL[6:0]	Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

10.3.8.25 CLK Tuning Control and Status (uSDHCx_CLK_TUNE_CTRL_STATUS)

This register contains the Clock Tuning Control status information. All bits are read only and will read the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PRE_ERR	TAP_SEL_PRE[6:0]						TAP_SEL_OUT[3:0]				TAP_SEL_POST[3:0]				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_CLK_TUNE_CTRL_STATUS field descriptions

Field	Description
31 PRE_ERR	PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.

Table continues on the next page...

uSDHCx_CLK_TUNE_CTRL_STATUS field descriptions (continued)

Field	Description
30–24 TAP_SEL_ PRE[6:0]	Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE will be updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23–20 TAP_SEL_ OUT[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19–16 TAP_SEL_ POST[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14–8 DLY_CELL_ SET_PRE[6:0]	Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7–4 DLY_CELL_ SET_OUT[6:0]	Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
DLY_CELL_ SET_POST[6:0]	Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

10.3.8.26 Strobe DLL Control (uSDHCx_STROBE_DLL_CTRL)

This register contains the strobe DLL Control information.

Address: Base address + 70h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

uSDHCx_STROBE_DLL_CTRL field descriptions (continued)

Field	Description
15–9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL[6:0]	Strobe DLL Control Slave Override Value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL Control Slave Override Set this bit to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this bit to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE_1	Strobe DLL Control Gate Update Set this bit to 1 to prevent the DLL from updating (since when STROBE_CLOCK_IN exists, glitches may appear during DLL updates). This bit can be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6 STROBE_DLL_CTRL_GATE_UPDATE_0	Strobe DLL Control Gate Update Set this bit to 1 to prevent the DLL from updating (since when STROBE_CLOCK_IN exists, glitches may appear during DLL updates). This bit can be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
5–3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is $((\text{STROBE_DLL_CTRL_SLV_DLY_TARGET} + 1) * \text{STROBE_REF_CLOCK} / 2) / 16$, So the input read-clock can be delayed relative input data from $(\text{STROBE_REF_CLOCK} / 2) / 16$ to $(\text{STROBE_REF_CLOCK} * 4) / 16$.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL Control Slave Force Updated Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL Control Reset Setting this bit to 1 to force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL Control Enable Set this bit to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. NOTE: Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

10.3.8.27 Strobe DLL Status (uSDHCx_STROBE_DLL_STATUS)

This register contains the strobe DLL status information. All bits are read only and read the same as the power-reset value.

Address: Base address + 74h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R								0								
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Ultra Secured Digital Host Controller (uSDHC)

uSDHCx_STROBE_DLL_STATUS field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–9 STROBE_DLL_ STS_REF_ SEL[6:0]	Strobe DLL Status Reference Select Reference delay line select taps. This is encoded by 7 bits for 127 taps.
8–2 STROBE_DLL_ STS_SLV_ SEL[6:0]	Strobe DLL Status Slave Select Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_ STS_REF_LOCK	Strobe DLL Status Reference Lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.

Table continues on the next page...

uSDHCx_STROBE_DLL_STATUS field descriptions (continued)

Field	Description
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL Status Slave Lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

10.3.8.28 Vendor Specific Register (uSDHCx_VEND_SPEC)

This register contains the vendor specific control / status register.

Address: Base address + C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3 AC12_WR_ CHKBUSY_EN	<p>Check busy enable after auto CMD12 for write data packet</p> <p>0 Do not check busy after auto CMD12 for write data packet</p> <p>1 Check busy after auto CMD12 for write data packet</p>
2 CONFLICT_ CHK_EN	<p>Conflict check enable.</p> <p>It is not implemented in uSDHC IP.</p> <p>0 Conflict check disable</p> <p>1 Conflict check enable</p>
1 VSELECT	<p>Voltage Selection</p> <p>Change the value of output signal VSELECT, to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads.</p> <p>1 Change the voltage to low voltage range, around 1.8 V</p> <p>0 Change the voltage to high voltage range, around 3.0 V</p>
0 EXT_DMA_EN	<p>External DMA Request Enable</p> <p>Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this bit is set, uSDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by Arm platform polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set.</p> <p>0 In any scenario, uSDHC does not send out external DMA request.</p> <p>1 When internal DMA is not active, the external DMA request will be sent out.</p>

10.3.8.29 MMC Boot Register (uSDHCx_MMC_BOOT)

This register contains the MMC Fast Boot control register.

Address: Base address + C4h offset

uSDHCx_MMC_BOOT field descriptions

Field	Description
31–16 BOOT_BLK_CNT[15:0]	The value defines the Stop At Block Gap value of automatic mode. When received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, bit31 - 16 of 0x04.
15–9 Reserved	This read-only field is reserved and always has the value 0.
8 DISABLE_TIME_OUT	Disable Time Out NOTE: When this bit is set, there is no timeout check no matter whether BOOT_EN is set or not. 0 Enable time out 1 Disable time out
7 AUTO_SABG_EN	During boot, enable auto stop at block gap function. This function will be triggered, and host will stop at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot mode enable 0 Fast boot disable 1 Fast boot enable
5 BOOT_MODE	Boot mode select

Table continues on the next page...

uSDHCx_VEND_SPEC2 field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11 HS400_RD_ CLK_STOP_EN	HS400 Read Clock Stop Enable Only stop clock at read block gap.
10 HS400_WR_ CLK_STOP_EN	HS400 Write Clock Stop Enable Only stop clock at write block gap.
9 Reserved	This read-only field is reserved and always has the value 0.
8 Reserved	This read-only field is reserved and always has the value 0.
7 CARD_INT_ AUTO_CLR_DIS	Disable the feature to clear the Card interrupt status bit when Card Interrupt status enable bit is cleared. Only for debug. 0 Card interrupt status bit (CINT) can be cleared when Card Interrupt status enable bit is 0. 1 Card interrupt status bit (CINT) can only be cleared by writing a 1 to CINT bit.
6 TUNING_CMD_ EN	Enable the auto tuning circuit to check the CMD line. 0 Auto tuning circuit does not check the CMD line. 1 Auto tuning circuit checks the CMD line.
5 TUNING_1bit_EN	Enable the auto tuning circuit to check the DATA0 only. It is used with the TUNING_8bit_EN together.
4 TUNING_8bit_EN	Enable the auto tuning circuit to check the DATA[7:0]. It is used with the TUNING_1bit_EN together. NOTE: The format of these two bits are [TUNNING_8bit_EN:TUNNING_1bit_EN]. 00 Tuning circuit only checks the DATA[3:0]. 01 Tuning circuit only checks the DATA0. 10 Tuning circuit checks the whole DATA[7:0]. 11 Invalid.
3 CARD_INT_D3_ TEST	Card Interrupt Detection Test This bit only uses for debugging. 0 Check the card interrupt only when DATA3 is high. 1 Check the card interrupt by ignoring the status of DATA3.
2 SDR104_NSD_ DIS	Interrupt window after abort command is sent. This bit only uses for debugging. 0 Enable the interrupt window 9 cycles later after the end of the I/O abort command (or CMD12) is sent. 1 Enable the interrupt window 5 cycles later after the end of the I/O abort command (or CMD12) is sent.
1 SDR104_OE_ DIS	CMD_OE / DATA_OE logic generation test. This bit only uses for debugging. 0 Drive the CMD_OE / DATA_OE for one more clock cycle after the end bit. 1 Stop to drive the CMD_OE / DATA_OE at once after driving the end bit.

Table continues on the next page...

uSDHCx_VEND_SPEC2 field descriptions (continued)

Field	Description
0 SDR104_ TIMING_DIS	Timeout counter test. This bit only uses for debugging. 0 The timeout counter for Ncr changes to 80, Ncrc changes to 21. 1 The timeout counter for Ncr changes to 72, Ncrc changes to 15.

10.3.8.31 Tuning Control Register (uSDHCx_TUNING_CTRL)

The register contains configuration of tuning circuit.

Address: Base address + CCh offset

uSDHCx_TUNING_CTRL field descriptions

Field	Description
31–25 -	Reserved

Table continues on the next page...

uSDHCx_TUNING_CTRL field descriptions (continued)

Field	Description
24 STD_TUNING_ EN	Standard tuning circuit and procedure enable: This bit is used to enable standard tuning circuit and procedure.
23 -	Reserved
22–20 TUNING_ WINDOW	Select data window value for auto tuning
19 -	Reserved
18–16 TUNING_STEP	The increasing delay cell steps in tuning procedure.
15–8 TUNING_ COUNTER	The MAX repeat CMD19 times in tuning procedure.
TUNING_ START_TAP	The start dealy cell point when send first CMD19 in tuning procedure.

Chapter 11

Connectivity

11.1 Ethernet MAC (ENET)

11.1.1 Introduction

The MAC-NET core, in conjunction with a 10/100/1000-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

11.1.2 Overview

The core implements a triple-speed 10/100/1000-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

11.1.2.1 Features

The MAC-NET core includes the following features.

11.1.2.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
 - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
 - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
 - a 2-bit Reduced MII (RMII) operating at 50 MHz.
 - a (double data rate) 4-bit Reduced GMII (RGMII) operating at 125 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
 - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
 - Pause quanta used to form pause frames — dynamically programmable
 - Pause frame generation additionally controllable by user application offering flexible traffic flow control
 - Optional forwarding of received pause frames to the user application
 - Implements standard flow-control mechanism

- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading
- Traffic-shaping bandwidth distribution supports credit-based and round-robin-based policies. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
 - Credit-based bandwidth distribution policy can be combined with time-based shaping
 - AVB endpoint talker and listener support
 - Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)

11.1.2.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols

- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

11.1.2.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

11.1.2.2 Block diagram

Figure 11-1. Ethernet MAC-NET core block diagram

11.1.3 External Signals

The table found here describes the external signals of ENET.

Table 11-1. ENET External Signals

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_1588_EVENT0_I N	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/ RGMII	UART3_RX D	ALT4	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
	the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.				
ENET1_1588_EVENT2_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA20	ALT2	O
ENET1_1588_EVENT3_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_ENABLE	ALT2	I
ENET1_1588_EVENT3_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA21	ALT2	O
ENET1_COL	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full duplex mode.	MII	ENET1_COLL	ALT0	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_CR_S	Carrier sense. When asserted, indicates transmit or receive medium is not idle.	MII	ENET1_CR_S	ALT0	I
ENET1_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	MII/RMII/RGMII	GPIO1_IO11	ALT2	O
			SD2_WP	ALT1	
			UART1_TXD	ALT6	
ENET1_MDIO	Transfers control information between the external PHY and the mediaaccess controller. Data is synchronous to MDC. This signal is an input after reset.	MII/RMII/RGMII	GPIO1_IO10	ALT2	IO
			SD2_CD_B	ALT1	
			UART1_RXD	ALT6	
ENET1_RX_CLK	In MII mode, provides a timing reference for RX_EN, RX_DATA[3:0], and RX_ER.	MII	ENET1_RX_CLK	ALT0	I
ENET1_RX_ER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	MII/RMII	ENET1_RX_C	ALT1	I
ENET1_TX_CLK	TX clock, which provides a timing reference for TX_EN, TX_DATA[3:0], and TX_ER.	MII	ENET1_TX_CLK	ALT0	O
ENET1_TX_ER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	MII	ENET1_TX_C	ALT1	O
RGMI1_RD0	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/RMII/MII	ENET1_RDATA0	ALT0	I
RGMI1_RD1	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/RMII/MII	ENET1_RDATA1	ALT0	I
RGMI1_RD2	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/MII	ENET1_RDATA2	ALT0	I
RGMI1_RD3	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMI/MII	ENET1_RDATA3	ALT0	I
RGMI1_RX_CTL	In RGMII mode, contains RX_EN on the rising edge of RGMII_RXC, and a logical derivative of RX_EN and RX_ER (RX_EN XOR RX_ER) on the falling edge of RGMII_RXC.	RGMI	ENET1_RX_CTL	ALT0	I
RGMI1_RXC	In RGMII mode, provides a timing reference for RX_DATA[3:0] and RX_CTL.	RGMI/MII	ENET1_RX_C	ALT0	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
RGMI1_TD0	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/RMII/MII	ENET1_TD ATA0	ALT0	O
RGMI1_TD1	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/RMII/MII	ENET1_TD ATA1	ALT0	O
RGMI1_TD2	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/MII	ENET1_TD ATA2	ALT0	O
RGMI1_TD3	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMI1/MII	ENET1_TD ATA3	ALT0	O
RGMI1_TX_CTL	In RGMI1 mode, contains TX_EN on the rising edge of RGMI1_TXC, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of RGMI1_TXC.	RGMI1	ENET1_TX_ CTL	ALT0	O
RGMI1_TXC	In RGMI1 mode, provides a timing reference for TX_DATA[3:0] and TX_CTL.	RGMI1	ENET1_TX C	ALT0	O
ENET2_1588_EVENT0_I N	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRN. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/ RGMI1	UART1_RX D	ALT4	I
ENET2_1588_EVENT0_O UT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRN register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRN. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set. NOTE: ENET_1588_EVENT0_OUT has programmable output width, see IOMUXC_GPR0[CLK_STRETCH] delayed one clock cycle in relation to all other EVENTx_OUT signals	MII/RMII/ RGMI1	UART1_TX D	ALT4	O
ENET2_1588_EVENT1_I N	Capture/compare block input/output event bus signal. When configured for	MII/RMII/ RGMI1	UART2_RX D	ALT4	I

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
	capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.				
ENET2_1588_EVENT1_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	UART2_TXD	ALT4	O
ENET2_1588_EVENT2_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_HSYNC	ALT2	I
ENET2_1588_EVENT2_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA22	ALT2	O

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET2_1588_EVENT3_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_VSYNC	ALT2	I
ENET2_1588_EVENT3_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	LCD1_DATA23	ALT2	O
ENET2_COL	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full duplex mode.	MII	EPDC1_PWRSTAT	ALT2	I
ENET2_CRS	Carrier sense. When asserted, indicates transmit or receive medium is not idle.	MII	EPDC1_PWRCOM	ALT2	I
ENET2_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	MII/RMII/RGMII	GPIO1_IO15	ALT2	O
			SD2_WP	ALT2	
			UART2_TXD	ALT6	
ENET2_MDIO	Transfers control information between the external PHY and the mediaaccess controller. Data is synchronous to MDC. This signal is an input after reset.	MII/RMII/RGMII	GPIO1_IO14	ALT2	IO
			SD2_CD_B	ALT2	
			UART2_RXD	ALT6	
ENET2_RX_CLK	In MII mode, provides a timing reference for RX_EN, RX_DATA[3:0], and RX_ER.	MII	EPDC1_BDR1	ALT2	I
ENET2_RX_ER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	MII/RMII	EPDC1_SDC1	ALT3	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET2_TX_CLK	Input clock, which provides a timing reference for TX_EN, TX_DATA[3:0], and TX_ER.	MII	EPDC1_BDR0	ALT2	O
ENET2_TX_ER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	MII/RMII	EPDC1_GDSP	ALT3	O
RGMI2_RD0	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RMII/RGMII	EPDC1_SDCCLK	ALT2	I
RGMI2_RD1	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RMII/RGMII	EPDC1_SDL	ALT2	I
RGMI2_RD2	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII	EPDC1_SDOE	ALT2	I
RGMI2_RD3	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII	EPDC1_SDSHR	ALT2	I
RGMI2_RX_CTL	In RGMII mode, contains RX_EN on the rising edge of RGMII_RXC, and a logical derivative of RX_EN and RX_ER (RX_EN XOR RX_ER) on the falling edge of RGMII_RXC.	RMII/RGMII	EPDC1_SDC0	ALT2	I
RGMI2_RXC	In RGMII mode, provides a timing reference for RX_DATA[3:0] and RX_CTL.	RMII/RGMII	EPDC1_SDC1	ALT2	I
RGMI2_TD0	Serial output Ethernet data. Only valid during TX_EN assertion.	RMII/RGMII	EPDC1_SDC2	ALT2	O
RGMI2_TD1	Serial output Ethernet data. Only valid during TX_EN assertion.	RMII/RGMII	EPDC1_SDC3	ALT2	O
RGMI2_TD2	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII	EPDC1_GDCCLK	ALT2	O
RGMI2_TD3	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII	EPDC1_GDOE	ALT2	O
RGMI2_TX_CTL	In RGMII mode, contains TX_EN on the rising edge of RGMII_TXC, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of RGMII_TXC.	RMII/RGMII	EPDC1_GDL	ALT2	O
RGMI2_TXC	In RGMII mode, provides a timing reference for TX_DATA[3:0] and TX_CTL.	RGMII	EPDC1_GDSP	ALT2	O

11.1.4 Clocks

The table found here describes the clock sources for ENET. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 11-2. ENET Clocks

Clock name	Clock Root	Description
ipg_clk	ENET_AXI_CLK_ROOT	Module clock
ipg_clk_mac0	ENET_AXI_CLK_ROOT	MAC peripheral clock
ipg_clk_mac0_s	ENET_AXI_CLK_ROOT	MAC peripheral access clock
ipg_clk_s	ENET_AXI_CLK_ROOT	Peripheral access clock
ipg_clk_time	ENET1_TIME_CLK_ROOT	Peripheral clock
mac0_rxmem_clk	ENET_AXI_CLK_ROOT	MAC receive memory clock
mac0_txmem_clk	ENET_AXI_CLK_ROOT	MAC transmit memory clock

11.1.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

Table 11-3. Register map summary

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

ENET memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
30BE_0004	Interrupt Event Register (ENET1_EIR)	32	w1c	0000_0000h	11.1.5.1/2929
30BE_0008	Interrupt Mask Register (ENET1_EIMR)	32	R/W	0000_0000h	11.1.5.2/2932
30BE_0010	Receive Descriptor Active Register - Ring 0 (ENET1_RDAR)	32	R/W	0000_0000h	11.1.5.3/2936
30BE_0014	Transmit Descriptor Active Register - Ring 0 (ENET1_TDAR)	32	R/W	0000_0000h	11.1.5.4/2937
30BE_0024	Ethernet Control Register (ENET1_ECR)	32	R/W	See section	11.1.5.5/2938
30BE_0040	MII Management Frame Register (ENET1_MMFR)	32	R/W	0000_0000h	11.1.5.6/2940
30BE_0044	MII Speed Control Register (ENET1_MSCR)	32	R/W	0000_0000h	11.1.5.7/2941
30BE_0064	MIB Control Register (ENET1_MIBC)	32	R/W	C000_0000h	11.1.5.8/2943
30BE_0084	Receive Control Register (ENET1_RCR)	32	R/W	05EE_0001h	11.1.5.9/2944
30BE_00C4	Transmit Control Register (ENET1_TCR)	32	R/W	0000_0000h	11.1.5.10/2947
30BE_00E4	Physical Address Lower Register (ENET1_PALR)	32	R/W	0000_0000h	11.1.5.11/2949
30BE_00E8	Physical Address Upper Register (ENET1_PAUR)	32	R/W	0000_8808h	11.1.5.12/2949
30BE_00EC	Opcode/Pause Duration Register (ENET1_OPD)	32	R/W	0001_0000h	11.1.5.13/2950
30BE_00F0	Transmit Interrupt Coalescing Register (ENET1_TXIC0)	32	R/W	0000_0000h	11.1.5.14/2950
30BE_00F4	Transmit Interrupt Coalescing Register (ENET1_TXIC1)	32	R/W	0000_0000h	11.1.5.14/2950
30BE_00F8	Transmit Interrupt Coalescing Register (ENET1_TXIC2)	32	R/W	0000_0000h	11.1.5.14/2950
30BE_0100	Receive Interrupt Coalescing Register (ENET1_RXIC0)	32	R/W	0000_0000h	11.1.5.15/2951
30BE_0104	Receive Interrupt Coalescing Register (ENET1_RXIC1)	32	R/W	0000_0000h	11.1.5.15/2951
30BE_0108	Receive Interrupt Coalescing Register (ENET1_RXIC2)	32	R/W	0000_0000h	11.1.5.15/2951
30BE_0118	Descriptor Individual Upper Address Register (ENET1_IAUR)	32	R/W	0000_0000h	11.1.5.16/2952
30BE_011C	Descriptor Individual Lower Address Register (ENET1_IALR)	32	R/W	0000_0000h	11.1.5.17/2953
30BE_0120	Descriptor Group Upper Address Register (ENET1_GAUR)	32	R/W	0000_0000h	11.1.5.18/2953

11.1.5.1 Interrupt Event Register (ENETx_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

NOTE

TxBD[INT] and RxBd[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

ENETx_EIR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. NOTE: The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
4 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
7 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
8 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
9 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.

Table continues on the next page...

ENETx_EIR field descriptions (continued)

Field	Description
10 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
12 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. NOTE: In situations where the device has various masters generating high traffic, a FIFO underrun can occur on the transmit FIFO. To avoid transmit FIFO underrun, store and forward can be enabled in ENET_TFWR[STRFWD]. See STRFWD. Also, a higher priority can be set for ENET traffic using available means on the central bus fabric connecting the ENET module.
13 PLR	Payload Receive Error Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
14 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
15 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
16 TS_TIMER	Timestamp Timer The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
17 RXFLUSH_2	RX DMA Ring 2 flush indication. This ring's RX frame has been flushed due to either RDAR2[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_2] is enabled.
18 RXFLUSH_1	RX DMA Ring 1 flush indication. This ring's RX frame has been flushed due to either RDAR1[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_1] is enabled.
19 RXFLUSH_0	RX DMA Ring 0 flush indication. . This ring's RX frame has been flushed due to either RDAR[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_0] is enabled.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 2).
25 TXB2	Transmit buffer interrupt, class 2 This field indicates that a transmit buffer descriptor has been updated (ring/class 2).

Table continues on the next page...

ENETx_EIR field descriptions (continued)

Field	Description
26 RXF2	Receive frame interrupt, class 2 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 2).
27 RXB2	Receive buffer interrupt, class 2 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 2).
28 TXF1	Transmit frame interrupt, class 1 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 1).
29 TXB1	Transmit buffer interrupt, class 1 This field indicates that a transmit buffer descriptor has been updated (ring/class 1).
30 RXF1	Receive frame interrupt, class 1 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 1).
31 RXB1	Receive buffer interrupt, class 1 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 1).

11.1.5.2 Interrupt Mask Register (ENETx_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

ENETx_EIMR field descriptions

Field	Description
0 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
1 BABR	BABR Interrupt Mask Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
2 BABT	BABT Interrupt Mask Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
3 GRA	GRA Interrupt Mask Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
4 TXF	TXF Interrupt Mask Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
5 TXB	TXB Interrupt Mask Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
6 RXF	RXF Interrupt Mask Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

Table continues on the next page...

ENETx_EIMR field descriptions (continued)

Field	Description
7 RXB	<p>RXB Interrupt Mask</p> <p>Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
8 MII	<p>MII Interrupt Mask</p> <p>Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
9 EBERR	<p>EBERR Interrupt Mask</p> <p>Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
10 LC	<p>LC Interrupt Mask</p> <p>Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
11 RL	<p>RL Interrupt Mask</p> <p>Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
12 UN	<p>UN Interrupt Mask</p> <p>Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
13 PLR	<p>PLR Interrupt Mask</p> <p>Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
14 WAKEUP	<p>WAKEUP Interrupt Mask</p> <p>Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.</p>
15 TS_AVAIL	<p>TS_AVAIL Interrupt Mask</p> <p>Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting</p>

Table continues on the next page...

ENETx_EIMR field descriptions (continued)

Field	Description
	source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 RXFLUSH_2	Corresponds to interrupt source EIR[RXFLUSH_2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
18 RXFLUSH_1	Corresponds to interrupt source EIR[RXFLUSH_1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 RXFLUSH_0	Corresponds to interrupt source EIR[RXFLUSH_0] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_0] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2 Corresponds to interrupt source EIR[TXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
25 TXB2	Transmit buffer interrupt, class 2 Corresponds to interrupt source EIR[TXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
26 RXF2	Receive frame interrupt, class 2 Corresponds to interrupt source EIR[RXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
27 RXB2	Receive buffer interrupt, class 2 Corresponds to interrupt source EIR[RXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
28 TXF1	Transmit frame interrupt, class 1 Corresponds to interrupt source EIR[TXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
29 TXB1	Transmit buffer interrupt, class 1

Table continues on the next page...

ENETx_EIMR field descriptions (continued)

Field	Description
	Corresponds to interrupt source EIR[TXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
30 RXF1	Receive frame interrupt, class 1 Corresponds to interrupt source EIR[RXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
31 RXB1	Receive buffer interrupt, class 1 Corresponds to interrupt source EIR[RXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

11.1.5.3 Receive Descriptor Active Register - Ring 0 (ENETx_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring 0 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: Base address + 10h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0							RDAR	0								
W	[Shaded]								[Shaded]								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0																
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

ENETx_RDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active

Table continues on the next page...

ENETx_RDAR field descriptions (continued)

Field	Description
	Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.4 Transmit Descriptor Active Register - Ring 0 (ENETx_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring 0 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: Base address + 14h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0							TDAR	0							
W	[Shaded]								[Shaded]

ENETx_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.5 Ethernet Control Register (ENETx_ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: Base address + 24h offset

ENETx_ECR field descriptions

Field	Description
0–13 Reserved	This field is reserved. Always write 0111000000000b to this field.
14–19 Reserved	This field is reserved. Always write 0 to this field.
20 SVLANDBL	S-VLAN double tag If enabled, S-VLAN detection requires a double-tagged frame to define a frame as being a VLAN frame. The following rules apply: <ul style="list-style-type: none"> • If the first tag is the S-VLAN type, it must be followed by a second tag with the C-VLAN type to declare the frame as VLAN frame. • If the first tag is the S-VLAN type but no 2nd tag follows, it is not considered a VLAN frame but instead treated as an untagged frame. • If the first tag is the C-VLAN type, it is considered a VLAN frame as normal. <p>NOTE: VLANUSE2ND can be used to determine from which tag the data should be extracted. This applies only if SVLAN_EN = 1, ignored otherwise.</p>
21 VLANUSE2ND	VLAN use second tag 0 Always extract data from the first VLAN tag if it exists. 1 When a double-tagged frame is detected, the data of the second tag is extracted for further processing. A double-tagged frame is defined as: <ul style="list-style-type: none"> • The first tag can be a C-VLAN or a S-VLAN (if SVLAN_ENA = 1) • The second tag must be a C-VLAN

Table continues on the next page...

ENETx_ECR field descriptions (continued)

Field	Description
22 SVLANEN	<p>S-VLAN enable</p> <p>Enable additional detection of S-VLAN tag according to IEEE802.1Q.</p> <p>0 Only the EtherType 0x8100 will be considered for VLAN detection. 1 The EtherType 0x88a8 will be considered in addition to 0x8100 (C-VLAN) to identify a VLAN frame in receive. When a VLAN frame is identified, the two bytes following the VLAN type are extracted and used by the classification match comparators, RCMRn.</p>
23 DBSWP	<p>Descriptor Byte Swapping Enable</p> <p>Swaps the byte locations of the buffer descriptors.</p> <p>NOTE: This field must be written to 1 after reset.</p> <p>0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.</p>
24 Reserved	<p>This field is reserved. Always write 0 to this field.</p>
25 DBGEN	<p>Debug Enable</p> <p>Enables the MAC to enter hardware freeze mode when the device enters debug mode.</p> <p>0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.</p>
26 SPEED	<p>Selects between 10/100-Mbit/s and 1000-Mbit/s modes of operation.</p> <p>0 10/100-Mbit/s mode 1 1000-Mbit/s mode</p>
27 EN1588	<p>EN1588 Enable</p> <p>Enables enhanced functionality of the MAC.</p> <p>0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.</p>
28 SLEEP	<p>Sleep Mode Enable</p> <p>0 Normal operating mode. 1 Sleep mode.</p>
29 MAGICEN	<p>Magic Packet Detection Enable</p> <p>Enables/disables magic packet detection.</p> <p>NOTE: MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection.</p> <p>NOTE: EIMR[WAKEUP] must be written to one if Magic packet wakeup is programmed to wake up the chip from low power mode.</p> <p>0 Magic detection logic disabled. 1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.</p>
30 ETHEREN	<p>Ethernet Enable</p>

Table continues on the next page...

ENETx_ECR field descriptions (continued)

Field	Description
	<p>Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.</p> <p>Hardware clears this field under the following conditions:</p> <ul style="list-style-type: none"> • RESET is set by software • An error condition causes the EBERR field to set. <p>NOTE:</p> <ul style="list-style-type: none"> • ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only <i>after</i> all other ENET-related registers have been configured. • If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts. <p>0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame.</p> <p>1 MAC is enabled, and reception and transmission are possible.</p>
31 RESET	<p>Ethernet MAC Reset</p> <p>When this field is set, it clears the ETHEREN field.</p>

11.1.5.6 MII Management Frame Register (ENETx_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: Base address + 40h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

	See Table 11-42 (Clause 22) or Table 11-44 (Clause 45) for correct value.
4–8 PA	PHY Address See Table 11-42 (Clause 22) or Table 11-44 (Clause 45) for correct value.
9–13 RA	Register Address See Table 11-42 (Clause 22) or Table 11-44 (Clause 45) for correct value.
14–15 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

11.1.5.7 MII Speed Control Register (ENETx_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (that is, peripheral bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

Table 11-4. Programming Examples for MSCR

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

Ethernet MAC (ENET)

Reset	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

ENETx_MSCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 HOLDTIME	Hold time On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
24 DIS_PRE	Disable Preamble Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
25–30 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: $1/((\text{MII_SPEED} + 1) \times 2)$ of the internal module clock frequency
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.8 MIB Control Register (ENETx_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

Address: Base address + 64h offset

ENETx_MIBC field descriptions

Field	Description
0 MIB_DIS	Disable MIB Logic If this control field is set, 0 MIB logic is enabled. 1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.
1 MIB_IDLE	MIB Idle

Table continues on the next page...

ENETx_MIBC field descriptions (continued)

Field	Description
	0 The MIB block is updating MIB counters. 1 The MIB block is not currently updating any MIB counters.
2 MIB_CLEAR	MIB Clear NOTE: This field is not self-clearing. To clear the MIB counters set and then clear this field. 0 See note above. 1 All statistics counters are reset to 0.
3–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.9 Receive Control Register (ENETx_RCR)

Address: Base address + 84h offset

ENETx_RCR field descriptions

Field	Description
0 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.
1 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLR] field.
2–15 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
17 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. NOTE: If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
18 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
19 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
20–21 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
22 RMII_10T	Enables 10-Mbit/s mode of the RMII or RGMII . 0 100-Mbit/s operation. 1 10-Mbit/s operation.

Table continues on the next page...

ENETx_RCR field descriptions (continued)

Field	Description
23 RMII_MODE	<p>RMII Mode Enable</p> <p>Specifies whether the MAC is configured for MII mode or RMII operation , when ECR[SPEED] is cleared .</p> <p>NOTE: Do not set both RCR[RGMIEN] and RCR[RMII_MODE].</p> <p>0 MAC configured for MII mode. 1 MAC configured for RMII operation.</p>
24 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
25 RGMII_EN	<p>RGMII Mode Enable</p> <p>NOTE: Do not set both RCR[RGMIEN] and RCR[RMII_MODE].</p> <p>0 MAC configured for non-RGMII operation 1 MAC configured for RGMII operation. If ECR[SPEED] is set, the MAC is in RGMII 1000-Mbit/s mode. If ECR[SPEED] is cleared, the MAC is in RGMII 10/100-Mbit/s mode.</p>
26 FCE	<p>Flow Control Enable</p> <p>If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.</p>
27 BC_REJ	<p>Broadcast Frame Reject</p> <p>If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.</p>
28 PROM	<p>Promiscuous Mode</p> <p>All frames are accepted regardless of address matching.</p> <p>0 Disabled. 1 Enabled.</p>
29 MII_MODE	<p>Media Independent Interface Mode</p> <p>This field must always be set.</p> <p>0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.</p>
30 DRT	<p>Disable Receive On Transmit</p> <p>0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)</p>
31 LOOP	<p>Internal Loopback</p> <p>This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0.</p> <p>0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.</p>

11.1.5.10 Transmit Control Register (ENETx_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: Base address + C4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0																
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0					Reserved	CRCFWD	ADDINS	ADDSEL				RFC_PAUSE	TFC_PAUSE	FDEN	[Shaded]	GTS
W	[Shaded]											[Shaded]			0		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

ENETx_TCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This field is read/write and must be set to 0.
22 CRCFWD	Forward Frame From Application With CRC 0 TxBD[TC] controls whether the frame has a CRC from the application. 1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.

Table continues on the next page...

ENETx_TCR field descriptions (continued)

Field	Description
23 ADDINS	Set MAC Address On Transmit 0 The source MAC address is not modified by the MAC. 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
24–26 ADDSEL	Source MAC Address Select On Transmit If ADDINS is set, indicates the MAC address that overwrites the source MAC address. 000 Node MAC address programmed on PADDR1/2 registers. 100 Reserved. 101 Reserved. 110 Reserved.
27 RFC_PAUSE	Receive Frame Control Pause This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit Frame Control Pause Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame. 0 No PAUSE frame transmitted. 1 The MAC stops transmission of data frames after the current transmission is complete.
29 FDEN	Full-Duplex Enable If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.
30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 GTS	Graceful Transmit Stop When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.

11.1.5.11 Physical Address Lower Register (ENETx_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: Base address + E4h offset

ENETx_PALR field descriptions

Field	Description
0–31 PADDR1	Pause Address Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

11.1.5.12 Physical Address Upper Register (ENETx_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: Base address + E8h offset

ENETx_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type Field In PAUSE Frames These fields have a constant value of 0x8808.

11.1.5.13 Opcode/Pause Duration Register (ENETx_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: Base address + ECh offset

ENETx_OPD field descriptions

Field	Description
0–15 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
16–31 PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

11.1.5.14 Transmit Interrupt Coalescing Register (ENETx_TXICn)

See [Interrupt coalescence](#) for more information.

Address: Base address + F0h offset + (4d × i), where i=0d to 2d

ENETx_TXICn field descriptions

Field	Description
0 ICEN	Interrupt Coalescing Enable

Table continues on the next page...

ENETx_TXICn field descriptions (continued)

Field	Description
	0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0. This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0. This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

11.1.5.15 Receive Interrupt Coalescing Register (ENETx_RXICn)

See [Interrupt coalescence](#) for more information.

Address: Base address + 100h offset + (4d × i), where i=0d to 2d

ENETx_RXICn field descriptions

Field	Description
0 ICEN	Interrupt Coalescing Enable 0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.

Table continues on the next page...

ENETx_RXICn field descriptions (continued)

Field	Description
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2-3 Reserved	This field must be set to 0. This field is reserved.
4-11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12-15 Reserved	This field must be set to 0. This field is reserved.
16-31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

11.1.5.16 Descriptor Individual Upper Address Register (ENETx_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: Base address + 118h offset

ENETx_IAUR field descriptions

Field	Description
0-31 IADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

11.1.5.17 Descriptor Individual Lower Address Register (ENETx_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: Base address + 11Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENETx_GAUR field descriptions

Field	Description
0–31 GADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

11.1.5.19 Descriptor Group Lower Address Register (ENETx_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: Base address + 124h offset

ENETx_GALR field descriptions

Field	Description
0–31 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

11.1.5.20 Transmit FIFO Watermark Register (ENETx_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to '0', the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to '1'. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: Base address + 144h offset

ENETx_TFWR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 STRFWD	Store And Forward Enable 0 Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 Enabled.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. NOTE: If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. 000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. 111111 4032 bytes written.

11.1.5.21 Receive Descriptor Ring 1 Start Register (ENETx_RDSR1)

RDSR1 points to the beginning of circular receive buffer descriptor queue 1 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

11.1.5.23 Maximum Receive Buffer Size Register - Ring 1 (ENETx_MRBR1)

MRBR1 is a user-programmable register that dictates the maximum size of all ring-1 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR1 must be set to RCR[MAX_FL] or larger.
- R_BUF_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR1 must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_SIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR1 greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: Base address + 168h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENETx_RSEM field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 STAT_SECTION_EMPTY	RX Status FIFO Section Empty Threshold Defines number of frames in the receive FIFO, independent of its size, that can be accepted. If the limit is reached, reception will continue normally, however a pause frame will be triggered to indicate a possible congestion to the remote device to avoid FIFO overflow. A value of 0 disables automatic pause frame generation
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 RX_SECTION_EMPTY	Value Of The Receive FIFO Section Empty Threshold Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued. A value of 0 disables automatic pause frame generation. When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client. NOTE: The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.

11.1.5.32 Receive FIFO Almost Empty Threshold (ENETx_RAEM)

Address: Base address + 198h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENETx_RAEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENETx_RAEM field descriptions (continued)

Field	Description
22–31 RX_ALMOST_EMPTY	Value Of The Receive FIFO Almost Empty Threshold Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

11.1.5.33 Receive FIFO Almost Full Threshold (ENETx_RAFL)

Address: Base address + 19Ch offset

ENETx_RAFL field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 RX_ALMOST_FULL	Value Of The Receive FIFO Almost Full Threshold Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

11.1.5.34 Transmit FIFO Section Empty Threshold (ENETx_TSEM)

Address: Base address + 1A0h offset

ENETx_TSEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_SECTION_EMPTY	Value Of The Transmit FIFO Section Empty Threshold Value, in 64-bit words, of the transmit FIFO section empty threshold. See Transmit FIFO for more information.

11.1.5.35 Transmit FIFO Almost Empty Threshold (ENETx_TAEM)

Address: Base address + 1A4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENETx_TAEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_ALMOST_EMPTY	Value of Transmit FIFO Almost Empty Threshold Value, in 64-bit words, of the transmit FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See Transmit FIFO for more information. A minimum value of 4 should be set.

11.1.5.36 Transmit FIFO Almost Full Threshold (ENETx_TAFL)

Address: Base address + 1A8h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															TX_ALMOST_FULL																	
W	0																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

ENETx_TAFL field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5). When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information. NOTE: A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

11.1.5.37 Transmit Inter-Packet Gap (ENETx_TIPG)

Address: Base address + 1ACh offset

ENETx_TIPG field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IPG	Transmit Inter-Packet Gap Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12. NOTE: The IPG value read will be the value that was written, even if it is out of range.

11.1.5.38 Frame Truncation Length (ENETx_FTRL)

Address: Base address + 1B0h offset

ENETx_FTRL field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 TRUNC_FL	Frame Truncation Length Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL]. NOTE: Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

11.1.5.39 Transmit Accelerator Function Configuration (ENETx_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: Base address + 1C0h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	[Reserved]															
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	[Reserved]											PROCHK	IPCHK	[Reserved]		SHIFT16
W	0											PROCHK	IPCHK	0	SHIFT16	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_TACC field descriptions

Field	Description
0–26 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
27 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
28 IPCHK	Enables insertion of IP header checksum. 0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
29–30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

11.1.5.40 Receive Accelerator Function Configuration (ENETx_RACC)

Address: Base address + 1C4h offset

ENETx_RACC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. NOTE: This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.
25 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.
26–28 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
29 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
30 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum

Table continues on the next page...

ENETx_RACC field descriptions (continued)

Field	Description
	0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
31 PADREM	Enable Padding Removal For Short IP Frames 0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.

11.1.5.41 Receive Classification Match Register for Class n (ENETx_RCMRn)

This match register allows specifying up to four priorities, which are tested (OR'ed) simultaneously. The match detection uses the extracted VLAN field according to the rules for VLAN detection configured through the ECR register. If both match registers, RCMR1 and RCMR2, report a match at the same time, only the class 1 match is indicated as the final result.

Address: Base address + 1C8h offset + (4d × i), where i=0d to 1d

ENETx_RCMRn field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 MATCHEN	Match Enable NOTE: A comparison is done only on incoming VLAN frames. If no VLAN frame is received no match will occur.

Table continues on the next page...

ENETx_RCMRn field descriptions (continued)

Field	Description
	<p>If both match registers have overlapping compare values and hence can match both on the same frame, only class 1 will be indicated and the class 2 match is ignored.</p> <p>0 Disabled (default): no compares will occur and the classification indicator for this class will never assert.</p> <p>1 The register contents are valid and a comparison with all compare values is done when a VLAN frame is received.</p>
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 CMP3	Compare 3 Fourth value to compare against. If unused it must be set to the same value as CMP0.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 CMP2	Compare 2 Third value to compare against. If unused it must be set to the same value as CMP0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 CMP1	Compare 1 Second value to compare against. If unused it must be set to the same value as CMP0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 CMP0	Compare 0 A three-bit value that will be compared with the frame's VLAN priority field (if a VLAN frame is received). All four compare values, CMP0..3, will be used in parallel. If any of the values match, a match for the class is reported (if MATCHEN is 1). NOTE: To implement a single priority match, all four compare values must be set to the same value.

11.1.5.42 DMA Class Based Configuration (ENETx_DMAnCFG)

The DMA class based configuration registers are used to configure the DMA controller interface to support the additional class 1 (buffer descriptor ring 1) and class 2 (buffer descriptor ring 2) traffic and define configuration options such as bandwidth allocation as needed.

NOTE

The registers are cleared when ECR[ETHEREN] becomes 0.

Address: Base address + 1D8h offset + (4d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								Reserved						CALC_NOIPG	DMA_CLASS_EN
W	[Shaded]								Reserved						CALC_NOIPG	DMA_CLASS_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	IDLE_SLOPE															
W	IDLE_SLOPE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_DMAnCFG field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–13 Reserved	This field is reserved. NOTE: Write only zeroes to this field.
14 CALC_NOIPG	Calculate no IPG Disable inclusion of IPG bytes for bandwidth calculations. 0 The traffic shaper function should consider 12 octets of IPG in addition to the frame data transferred for a frame when doing bandwidth calculations. This is the default. 1 Addition of 12 bytes for the IPG should be omitted when calculating the bandwidth (for traffic shaping, when writing a frame into the transmit FIFO, the shaper will usually consider 12 bytes of IPG for every frame as part of the bandwidth allocated by the frame. This addition can be suppressed, meaning short frames will become more bandwidth than large frames due to the relation of data to IPG overhead).
15 DMA_CLASS_EN	DMA class enable 0 The DMA controller's channel for the class is not used. NOTE: Disabling the DMA controller of a class also requires disabling the class match comparator for the class (see registers RCMRn). When class 1 and class 2 queues are disabled then their frames will be placed in queue 0. 1 Enable the DMA controller to support the corresponding descriptor ring for this class of traffic.
16–31 IDLE_SLOPE	Idle slope 16-bit value to define the per class idle slope setting used by the credit based shaper defining allocated bandwidth for the class. This value is used to calculate the BW (bandwidth) fraction, given by the equation, BW fraction = 1/(1+512/IDLE_SLOPE). Idle slope is restricted to certain values. For values less than 128, idle slope = 2 ⁿ , where n = 0, 1, 2, ...6. For values equal to or greater than 128, idle slope = 128×m, where m = 1, 2, 3, ...12.

Table continues on the next page...

ENETx_DMAnCFG field descriptions (continued)

Field	Description
	Example 1. BW fraction = $0.20 = 1/(1+(512/128))$; therefore idleslope = 128. Example 2. BW fraction = $0.33 = 1/(1+(512/256))$; therefore idleslope = 256. Example 3. BW fraction = $0.75 = 1/(1+(512/1536))$; therefore idleslope = 1536. NOTE: For AVB applications, the BW fraction of class 1 and class 2 combined must not exceed .75.

11.1.5.43 Receive Descriptor Active Register - Ring 1 (ENETx_RDAR1)

RDAR1 is a command register, written by the user, to indicate that the receive descriptor ring 1 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: Base address + 1E0h offset

ENETx_RDAR1 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.44 Transmit Descriptor Active Register - Ring 1 (ENETx_TDAR1)

TDAR1 is a command register that the user writes to indicate that transmit descriptor ring 1 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: Base address + 1E4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ENETx_TDAR1 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.45 Receive Descriptor Active Register - Ring 2 (ENETx_RDAR2)

RDAR2 is a command register, written by the user, to indicate that the receive descriptor ring 2 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: Base address + 1E8h offset

ENETx_RDAR2 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.46 Transmit Descriptor Active Register - Ring 2 (ENETx_TDAR2)

TDAR2 is a command register that the user writes to indicate that transmit descriptor ring 2 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

Address: Base address + 1ECh offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ENETx_IEEE_T_DROP field descriptions

Field	Description
0–31 Reserved	This read-only field always has the value 0. This field is reserved.

11.1.5.67 Frames Transmitted OK Statistic Register (ENETx_IEEE_T_FRAME_OK)

Address: Base address + 24Ch offset

ENETx_IEEE_T_FRAME_OK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted OK NOTE: Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

11.1.5.68 Frames Transmitted with Single Collision Statistic Register (ENETx_IEEE_T_1COL)

Address: Base address + 250h offset

ENETx_IEEE_T_1COL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with one collision

11.1.5.69 Frames Transmitted with Multiple Collisions Statistic Register (ENETx_IEEE_T_MCOL)

Address: Base address + 254h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]

ENETx_IEEE_T_MCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with multiple collisions

11.1.5.70 Frames Transmitted after Deferral Delay Statistic Register (ENETx_IEEE_T_DEF)

Address: Base address + 258h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_IEEE_T_DEF field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with deferral delay

11.1.5.71 Frames Transmitted with Late Collision Statistic Register (ENETx_IEEE_T_LCOL)

Address: Base address + 25Ch offset

ENETx_IEEE_T_LCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with late collision

11.1.5.72 Frames Transmitted with Excessive Collisions Statistic Register (ENETx_IEEE_T_EXCOL)

Address: Base address + 260h offset

ENETx_IEEE_T_EXCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with excessive collisions

11.1.5.73 Frames Transmitted with Tx FIFO Underrun Statistic Register (ENETx_IEEE_T_MACERR)

Address: Base address + 264h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_IEEE_T_MACERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with transmit FIFO underrun

11.1.5.74 Frames Transmitted with Carrier Sense Error Statistic Register (ENETx_IEEE_T_CSERR)

Address: Base address + 268h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]

W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_IEEE_T_SQE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	This read-only field is reserved and always has the value 0. NOTE: Counter not implemented as no SQE information is available.

11.1.5.76 Flow Control Pause Frames Transmitted Statistic Register (ENETx_IEEE_T_FDXFC)

Address: Base address + 270h offset

ENETx_IEEE_T_FDXFC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of flow-control pause frames transmitted

11.1.5.77 Octet Count for Frames Transmitted w/o Error Statistic Register (ENETx_IEEE_T_OCTETS_OK)

Address: Base address + 274h offset

ENETx_IEEE_T_OCTETS_OK field descriptions

Field	Description
0–31 COUNT	Octet count for frames transmitted without error NOTE Counts total octets (includes header and FCS fields).

11.1.5.78 Rx Packet Count Statistic Register (ENETx_RMON_R_PACKETS)

Address: Base address + 284h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]

ENETx_RMON_R_BC_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive broadcast packets

11.1.5.80 Rx Multicast Packets Statistic Register (ENETx_RMON_R_MC_PKT)

Address: Base address + 28Ch offset

ENETx_RMON_R_MC_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive multicast packets

11.1.5.81 Rx Packets with CRC/Align Error Statistic Register (ENETx_RMON_R_CRC_ALIGN)

Address: Base address + 290h offset

ENETx_RMON_R_CRC_ALIGN field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets with CRC or align error

11.1.5.82 Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register (ENETx_RMON_R_UNDERSIZE)

Address: Base address + 294h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENETx_RMON_R_OVERSIZE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets greater than MAX_FL and good CRC

11.1.5.84 Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENETx_RMON_R_FRAG)

Address: Base address + 29Ch offset

ENETx_RMON_R_FRAG field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets with less than 64 bytes and bad CRC

11.1.5.85 Rx Packets Greater Than MAX_FL Bytes and Bad CRC Statistic Register (ENETx_RMON_R_JAB)

Address: Base address + 2A0h offset

ENETx_RMON_R_JAB field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets greater than MAX_FL and bad CRC

11.1.5.86 Reserved Statistic Register (ENETx_RMON_R_RESVD_0)

Address: Base address + 2A4h offset

ENETx_RMON_R_RESVD_0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.87 Rx 64-Byte Packets Statistic Register (ENETx_RMON_R_P64)

Address: Base address + 2A8h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENETx_IEEE_R_MACERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Receive FIFO overflow count

11.1.5.100 Flow Control Pause Frames Received Statistic Register (ENETx_IEEE_R_FDXFC)

Address: Base address + 2DCh offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0															COUNT																	
W	[Shaded]																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENETx_IEEE_R_FDXFC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of flow-control pause frames received

11.1.5.101 Octet Count for Frames Received without Error Statistic Register (ENETx_IEEE_R_OCTETS_OK)

Address: Base address + 2E0h offset

ENETx_IEEE_R_OCTETS_OK field descriptions

Field	Description
0–31 COUNT	Number of octets for frames received without error NOTE: Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

11.1.5.102 Adjustable Timer Control Register (ENETx_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

NOTE

The CAPTURE and RESTART fields and bits 19 and 21 must be 0 in order to write to the other fields in this register.

Address: Base address + 400h offset

ENETx_ATCR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SLAVE	Enable Timer Slave Mode 0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
19 Reserved	This field is reserved. Always write 0 to this field.
20 CAPTURE	Capture Timer Value When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. NOTE: To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles. 0 No effect. 1 The current time is captured and can be read from the ATVR register.
21 Reserved	This field is reserved. Always write 0 to this field.
22 RESTART	Reset Timer Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. NOTE: The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.
23 Reserved	This field is reserved.
24 PINPER	Enables event signal output assertion on period event. NOTE: Not all devices contain the event signal output. See the chip configuration details. 0 Disable. 1 Enable.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved. NOTE: This field must be written always with one.
27 PEREN	Enable Periodical Event 0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit. NOTE: Not all devices contain the event signal output. See the chip configuration details.

Table continues on the next page...

ENETx_ATCR field descriptions (continued)

Field	Description
28 OFFRST	Reset Timer On Offset Event 0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
29 OFFEN	Enable One-Shot Offset Event 0 Disable. 1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
30 Reserved	This field is reserved.
31 EN	Enable Timer 0 The timer stops at the current value. 1 The timer starts incrementing.

11.1.5.103 Timer Value Register (ENETx_ATVR)

Address: Base address + 404h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENETx_ATPER field descriptions

Field	Description
0–31 PERIOD	<p>Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10⁹) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.</p> <p>NOTE: The value of PERIOD has the following constraint: $2^{32} - \text{ENET_ATINC}[\text{INC_COR}] - 3 \times \text{ENET_ATINC}[\text{INC}] \geq \text{PERIOD} > 0.$</p>

11.1.5.106 Timer Correction Register (ENETx_ATCOR)

ENETx_TCCRn field descriptions

Field	Description
0–31 TCC	Timer Capture Compare This register is double buffered between the module clock and 1588 clock domains. When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag. The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.

11.1.6 Functional description

This section provides a complete functional description of the MAC-NET core.

11.1.6.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)
- Extension field is defined only for Gigabit Ethernet half-duplex implementations and is not supported by the MAC core

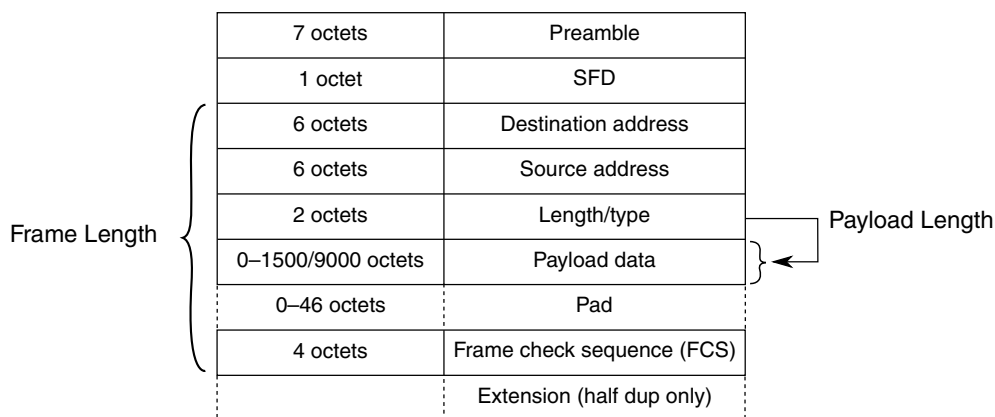

Figure 11-2. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

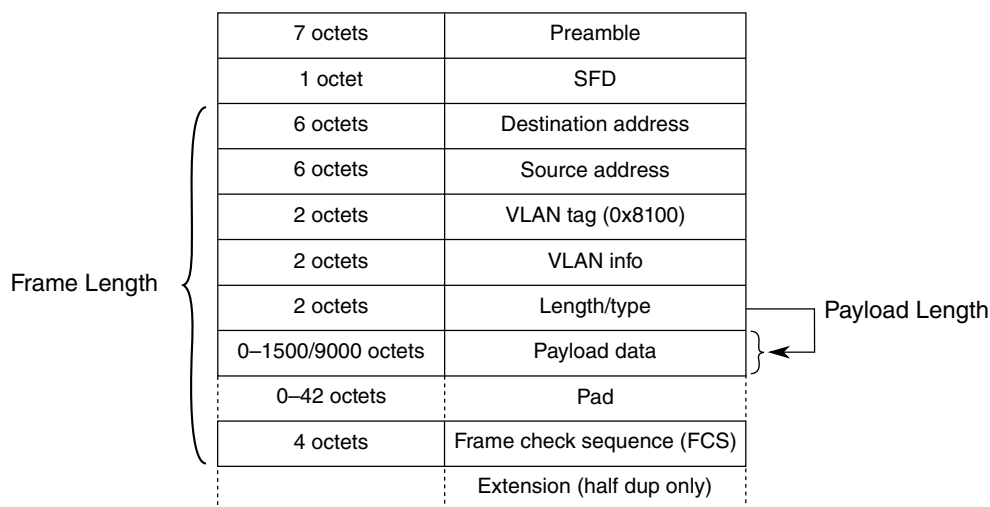

Figure 11-3. VLAN-tagged MAC frame format overview

Table 11-5. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. <ul style="list-style-type: none"> If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check .

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

11.1.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 11-6. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27–68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address							Type	Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

11.1.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in [Magic packet detection](#).

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

11.1.6.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

11.1.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 11-7. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

11.1.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 11-8. IPv4 header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Version				IHL				TOS				Length																			
Fragment ID								Flags				Fragment offset																			
TTL				Protocol				Header checksum																							
Source address																															
Destination address																															
Options																															

Table 11-9. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

11.1.6.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

Figure 11-4. IPv6 header format

Table 11-10. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

11.1.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 11-11. ICMP header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ICMP message data																															

Table 11-12. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

11.1.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 11-13. UDP header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source port												Destination port																			
Length												Checksum																			

Table 11-14. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

11.1.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

Table 11-15. TCP header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 11-16. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags

Table continues on the next page...

Table 11-16. TCP header fields (continued)

Field name	Description
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

11.1.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

11.1.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

11.1.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

[Table 11-17](#) shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 11-17. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 11-18. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

11.1.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 11-19. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

11.1.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

11.1.6.3.2.1 PTPv1 header

Table 11-20. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							

Table continues on the next page...

Table 11-20. Common PTPv1 message header (continued)

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in [Table 11-21](#) :

Table 11-21. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

11.1.6.3.2.2 PTPv2 header

Table 11-22. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved

8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field `messageId` as follows:

Table 11-23. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the `TWO_STEP` bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 11-24. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

11.1.6.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing

- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

Figure 11-5. MAC receive flow

11.1.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

11.1.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

11.1.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

11.1.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ($\text{RCR}[\text{PROM}] = 1$) no address checking is performed and all unicast frames are accepted.

11.1.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in $\text{ENET}_n_GAUR/GALR$ (group address hash match) or $\text{ENET}_n_IAUR/IALR$ (individual address hash match).

- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET n _GAUR (msb = 1) or ENET n _GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

If Promiscuous mode is enabled (ENET n _RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET n _GAUR/GALR and ENET n _IAUR/IALR settings.

11.1.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET n _RCR[PROM] is set. If PROM is cleared when ENET n _RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 11-25. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

11.1.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:
 - Node address (PALR[PADDR1] and PAUR[PADDR2])
 - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

11.1.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

11.1.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET_n_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

11.1.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

11.1.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET n _RCR[FCE] is cleared and are forwarded to the client interface when ENET n _RCR[PAUFWD] is set.

11.1.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET n _RCR[CRCFWD] is cleared and ENET n _RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $$FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: x^{31} , x^{30} , ..., x^1 , x^0 .

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

11.1.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of `ENETn_RCR[PADEN]`.

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

11.1.6.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see [Receive Classification Match Register for Class n \(ENET_RCMR_n\)](#)) and the following figure.

Figure 11-6. AVB frame classification

11.1.6.4.11 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's `RxBD[EMPTY]` is not set or `ENET_RDARn` is not set. When RX flushing is enabled, via [QoS Scheme \(ENET_QOS\)](#), the blocking frame will be flushed (discarded).

11.1.6.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET n _TCR[TFC_PAUSE] is set with ENET n _OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

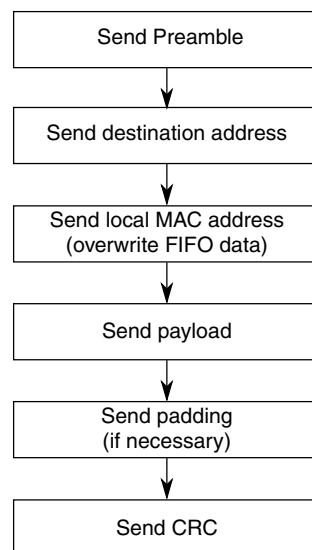

Figure 11-7. Frame transmit overview

11.1.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

11.1.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENETn_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENETn_TCR[ADDINS] = 0)

11.1.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31} , x^{30} , ..., x^1 , x^0 .

11.1.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENETn_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII_CRS de-assertion.

11.1.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

Figure 11-8. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$; where n is the number of retransmissions and $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by $N = 10$ as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET n _EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled, the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

11.1.6.5.6 Rate limiting / traffic shaping support

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

Figure 11-9. Transmit arbitration schemes

11.1.6.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue n has a frame to transmit, the queue transmits its frame. After queue n has transmitted its frame, or if queue n does not have a frame to transmit, queue $n+1$ is then allowed to transmit its frame, and so on.

11.1.6.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

Table 11-26. Bandwidth allocation example

AVB Class A	50%
AVB Class B	20%
non-AVB frames	30%
Total	100%

See [DMA Class Based Configuration \(ENET_DMA \$n\$ CFG\)](#) for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

11.1.6.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

11.1.6.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See [Timer Value Register \(ENET_ATVR\)](#) and [Adjustable Timer Control Register \(ENET_ATCR\)](#).
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See [Enhanced transmit buffer descriptor](#).
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must be not be greater than the current value of ENET_ATVR + (0.5 × ENET_ATPER). This means the application can not prepare frames with launch times beyond ENET_ATVR + (0.5 × ENET_ATPER). Because ENET_ATVR wraps, calculate TLT using the equation

$$(ENET_ATVR + (0.5 \times ENET_ATPER)) \text{ mod } ENET_ATPER$$

For example, if ENET_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET_ATVR).

As a specific example, if the current value of ENET_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on

11.1.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.

- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

11.1.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET n _RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET n _TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET n _RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET n _RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

11.1.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET n _TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.

- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENETn_OPD[PAUSE_DUR].

Figure 11-10. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

11.1.6.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

11.1.6.7.1 Sleep mode

To put the MAC in Sleep mode, set ENETn_ECR[SLEEP]. At the same time ENETn_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, if ENET is enabled, write 1 to ENET n _ECR[SLEEP] before entering into low power mode.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

11.1.6.7.2 Magic packet detection

The core is designed to detect magic packets (see [Magic packets](#)) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

11.1.6.7.3 Wakeup

When a magic packet is detected, indicated by ENET n _EIR[WAKEUP], ENET n _ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET n _ECR[MAGICEN], disabling magic packet detection.

11.1.6.8 IP accelerator functions

The following sections describe the IP accelerator functions.

11.1.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 11-27. IPv4 pseudo-header for checksum calculation

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
Zero				Protocol								TCP/UDP length																			

Table 11-28. IPv6 pseudo-header for checksum calculation

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
TCP/UDP length																															
Zero																Next header															

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

11.1.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

11.1.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET n _TACC and ENET n _RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 11-29](#).

Table 11-29. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

11.1.6.8.3.1 Receive processing

When ENET n _RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

11.1.6.8.3.2 Transmit processing

When ENET n _TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

11.1.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET n _RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
 - The frame has an invalid payload length
 - Frame length is greater than MAX_FL
 - Frame received with a CRC-32 error
 - Frame truncated due to receive FIFO overflow
 - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET n _RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

11.1.6.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBDFRAG) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBDPayload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

11.1.6.8.6 IPv6 support

The following sections describe the IPv6 support.

11.1.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see [32-bit Ethernet payload alignment](#)).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

11.1.6.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

11.1.6.9 Resets and stop controls

The following sections describe the resets and stop controls.

11.1.6.9.1 Hardware reset

To reset the Ethernet module, set ENET n _ECR[RESET].

11.1.6.9.2 Soft reset

When ENET n _ECR[ETHER_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting GMII/TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

11.1.6.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).

- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII/GMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

11.1.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

11.1.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET n _TCR[GTS] is set by software.
- ENET n _TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

11.1.6.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII/GMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
 - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
 - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

11.1.6.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

11.1.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

Figure 11-11. IEEE 1588 functions overview

11.1.6.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to $(1 \times 10^9) - 1$. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

11.1.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

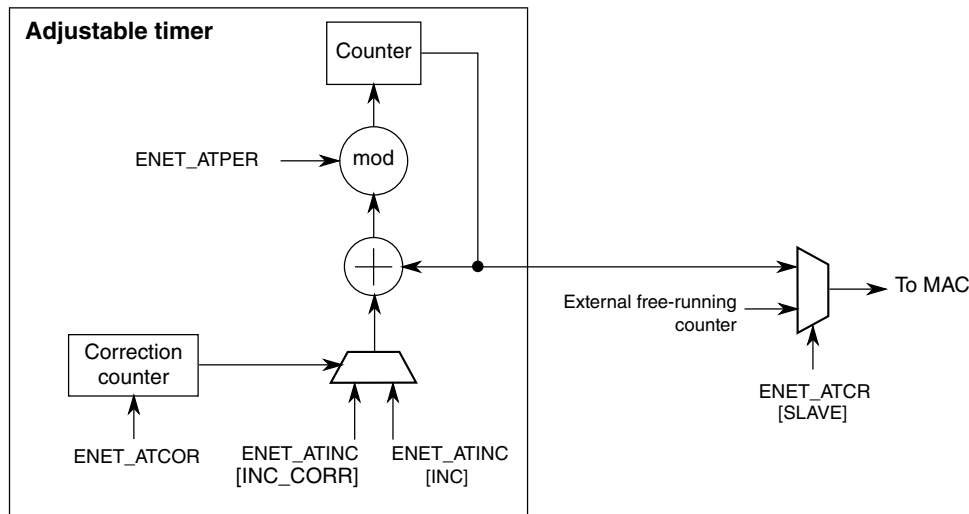

Figure 11-12. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in $ENET_n_ATINC$. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in $ENET_n_ATPER$, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value $(Current + Inc - (1 \times 10^9))$, assuming the period is set to 1×10^9 .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in `ENET n _ATCOR`, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in `ENET n _ATINC`. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (`ENET n _ATCR[SLAVE] = 1`), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer. When slave mode is enabled, you still must set `ENET n _ATINC[INC]` to the value of the master, since it is used for internal comparisons.

11.1.6.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENET n _ATSTMP`. `ENET n _EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENET n _EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENET n _ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

11.1.6.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

11.1.6.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to $(1 \times 10^9) - 1$. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9 .

11.1.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

11.1.6.10.5.1 Input capture

The $TCCR_n$ capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR_n signals. An event will cause the corresponding $TCSR_n[TF]$ timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the $TCSR_n[TIE]$ field, an interrupt can be generated.

11.1.6.10.5.2 Output compare

The $TCCR_n$ compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the $TCCR_n$ register, the corresponding flag, $TCSR_n[TF]$, is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by $TCSR_n[TIE]$, will be generated. The corresponding 1588_TMR_n output signal will be asserted according to $TCSR_n[TMODE]$.

11.1.6.10.5.3 DMA requests

A DMA request can be enabled by setting $TCSR_n[TDRE]$. The corresponding DMA request is generated when the $TCSR_n[TF]$ timer flag is set. When the DMA has completed, the corresponding $TCSR_n[TF]$ flag is cleared.

11.1.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 1024 words.

11.1.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

Table 11-30. Receive FIFO thresholds definition

Register	Description
ENET $_n$ _RSFL [RX_SECTION_F ULL]	<p>When the FIFO level reaches the ENET$_n$_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET$_n$_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENET$_n$_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENET$_n$_RSFL (cut-through operation) it should be greater than ENET$_n$_RAEM.</p>
ENET $_n$ _RAEM [RX_ALMOST_E MPTY]	<p>When the FIFO level reaches the ENET$_n$_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p> <p>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</p> <p>Set ENET$_n$_RAEM to a minimum of six.</p>
ENET $_n$ _RAFL	<p>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET$_n$_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</p>

Table continues on the next page...

Table 11-30. Receive FIFO thresholds definition (continued)

Register	Description
[RX_ALMOST_FULL]	The corresponding error status is set when the frame is delivered to the application. Set ENET _n _RAFL to a minimum of 4.
ENET _n _RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET _n _RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET _n _RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET _n _RSEM disables any pause frame generation.

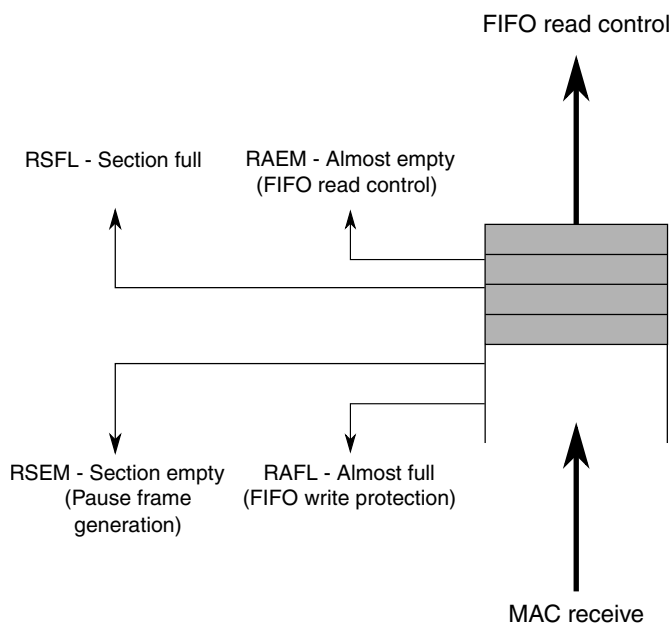

Figure 11-13. Receive FIFO overview

11.1.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 11-31. Transmit FIFO thresholds definition

Register	Description
ENET _n _TAEM [TX_ALMOST_EMPTY]	When the FIFO level reaches the ENET _n _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET _n _TAEM to a minimum of 4.
ENET _n _TAFL [TX_ALMOST]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET _n _TAFL number of words, the MAC deasserts its control signal to the application.

Table continues on the next page...

Table 11-31. Transmit FIFO thresholds definition (continued)

Register	Description
_FULL]	<p>If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication.</p> <p>Set ENET_n_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.</p>
ENET _n _TSEM [TX_SECTION _EMPTY]	<p>When the FIFO level reaches the ENET_n_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.</p> <p>When ENET_n_TSEM is 0, the signal is never deasserted.</p>
ENET _n _TFWR	<p>When the FIFO level reaches the ENET_n_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).</p> <p>If a complete frame has a size smaller than the ENET_n_TFWR threshold, the MAC also transmits the frame to the line.</p> <p>To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.</p>

**Figure 11-14. Transmit FIFO overview**

11.1.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET_n_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET_n_RCR register fields:

Table 11-32. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces. In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s)

Figure 11-15. Loopback options

11.1.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET_n_ECR[1588EN].

NOTE

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA_nCFG[DMA_CLASS_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for little-endian chips. **DBSWP** must be set to 1 after reset to enable little-endian mode.

11.1.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. [Table 11-36](#) contains the descriptions for each field.

Table 11-33. Legacy FEC receive buffer descriptor (RxBD)

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer — low halfword															
Offset + 6	Rx data buffer pointer — high halfword															

11.1.6.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. [Table 11-38](#) contains the descriptions for each field.

Table 11-34. Legacy FEC transmit buffer descriptor (TxBD)

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Offset + 0	Data Length															
Offset + 2	R	TO1	W	TO2	L	TC	ABC ¹	—	—	—	—	—	—	—	—	—
Offset + 4	Tx Data Buffer Pointer — low halfword															
Offset + 6	Tx Data Buffer Pointer — high halfword															

1. This field is not supported by the uDMA.

11.1.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET $_n$ _ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

11.1.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 11-36](#) contains the descriptions for each field.

Table 11-35. Enhanced uDMA receive buffer descriptor (RxBD)

	Byte 1							Byte 0								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Offset + 0	Data length															
Offset + 2	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 4	Rx data buffer pointer – low halfword															
Offset + 6	Rx data buffer pointer – high halfword

Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 11-36. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	0–15 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	0 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	2 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET _n _RDSR.
Offset + 2	3 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	4 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 2	5–6	Reserved, must be cleared.

Table continues on the next page...

Table 11-36. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 2	7 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 2	8 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 2	9 MC	Set if the DA is multicast and not BC.
Offset + 2	10 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 2	11 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 2	12	Reserved, must be cleared.
Offset + 2	13 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 2	14 OV	Overrun. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 2	15 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 4	0–15 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 6	0–15 Data buffer pointer high	Receive data buffer pointer, high halfword ¹
Offset + 8	0–2 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + 8	3–9	Reserved, must be cleared.
Offset + 8	10 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + 8	11 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.

Table continues on the next page...

Table 11-36. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	12	Reserved, must be cleared.
Offset + 8	13 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + 8	14 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + 8	15 FRAG	IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + A	0 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + A	1–4	Reserved, must be cleared.
Offset + A	5 PE	PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + A	6 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + A	7 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + A	8 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb / dma_int_rxfevent</i> .
Offset + A	9–15	Reserved, must be cleared.
Offset + C	0–15 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + E	0–4 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + E	5–7	Reserved, must be cleared.
Offset + E	8–15 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + 10	0–15	Reserved, must be cleared.
Offset + 12	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).

Table continues on the next page...

Table 11-36. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 12	1–15	Reserved, must be cleared.
Offset + 14	0–15	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16	1588 timestamp	
Offset + 18	0–15	Reserved, must be cleared.
–		
Offset + 1E		

- The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

11.1.6.14.2 Enhanced transmit buffer descriptor

Table 11-37. Enhanced transmit buffer descriptor (TxBD)

Table 11-38. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	0–15	Data length, written by user.
	Data Length	Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 2	0	Ready. Written by the MAC and you.

Table continues on the next page...

Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
	R	0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 2	1 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 2	3 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	4 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 2	5 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 2	6 ABC	Append bad CRC. Note: This field is not supported by the uDMA and is ignored.
Offset + 2	7–15	Reserved, must be cleared.
Offset + 4	0–15 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 6	0–15 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. NOTE: For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 8	0 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + 8	1	Reserved, must be cleared.
Offset + 8	2 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + 8	3 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.

Table continues on the next page...

Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	4 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + 8	5 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + 8	6 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + 8	7 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.
Offset + 8	8–15	Reserved, must be cleared.
Offset + A	0	Reserved, must be cleared.
Offset + A	1 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + A	2 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + A	3 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	4 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	5–6	Reserved, must be cleared.
Offset + A	7 UTLT	Use transmit launch time. If set to 1, TLT high and low values are used to determine if frame can be transmitted. This field must only be set in the <i>first</i> BD of a frame. TLT is always used in combination with either the round-robin scheme or the credit-based shaper. TLT can be used with a single BD queue. However, at least one DMA class, <code>DMAnCFG[DMA_CLASS_EN]</code> must be enabled. For example, to use TLT with only queue 0, enable one of the <code>DMAnCFG[DMA_CLASS_EN]</code> fields and clear both TDAR1 and TDAR2. Although this enables multi-queue, only the single queue 0 is used.
Offset + A	8–11 FTYPE	Type of frame to be transmitted. If a credit-based scheme is used, this field must match the BD ring queue. 0x0 – Non-AVB. Corresponds to ENET_TDSR. 0x1 – AVB Class A. Corresponds to ENET_TDSR1. 0x2 – AVB Class B. Corresponds to ENET_TDSR2.

Table continues on the next page...

Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
		All other values are reserved.
Offset + A	12–15	Reserved, must be cleared.
Offset + C	0–15 TLT low	Transmit launch time low. Low two bytes of time value that specifies when frame can be transmitted.
Offset + E	0–15 TLT high	Transmit launch time high. High two bytes of time value that specifies when frame can be transmitted.
Offset + 10	0–15	Reserved, must be cleared.
Offset + 12	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	1–15	Reserved, must be cleared.
Offset + 14	0–15	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16	1588 timestamp	
Offset + 18–Offset + 1E	0–15	Reserved, must be cleared.

11.1.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

11.1.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 11-39. FIFO interface data structure

	63	56 55	48 47	40 39	32 31	24 23	16 15	8 7	0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	
...	...								

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if `ENETn_TCR[ADDINS]` is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the `ENETn_PAUR` and `ENETn_PALR` registers.

Table 11-40. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 11-41. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

11.1.6.15.2 Data structure examples

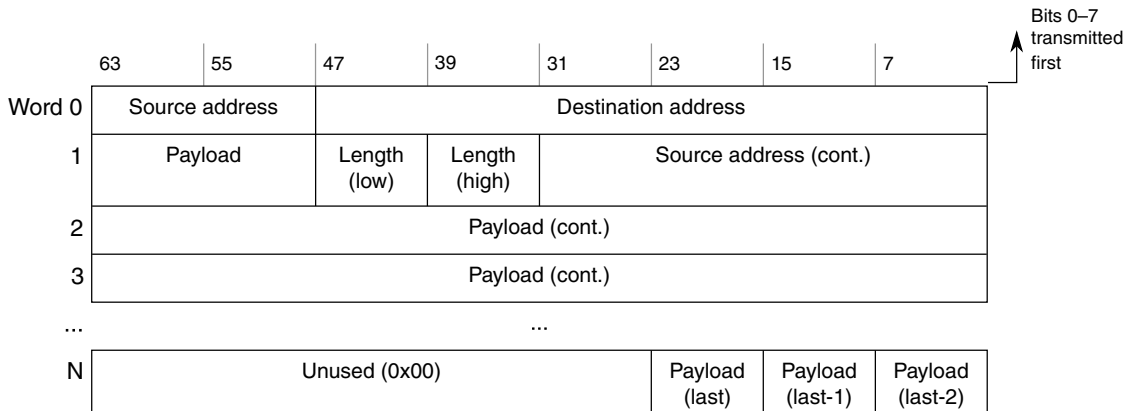

Figure 11-16. Normal Ethernet frame 64-bit mapping example

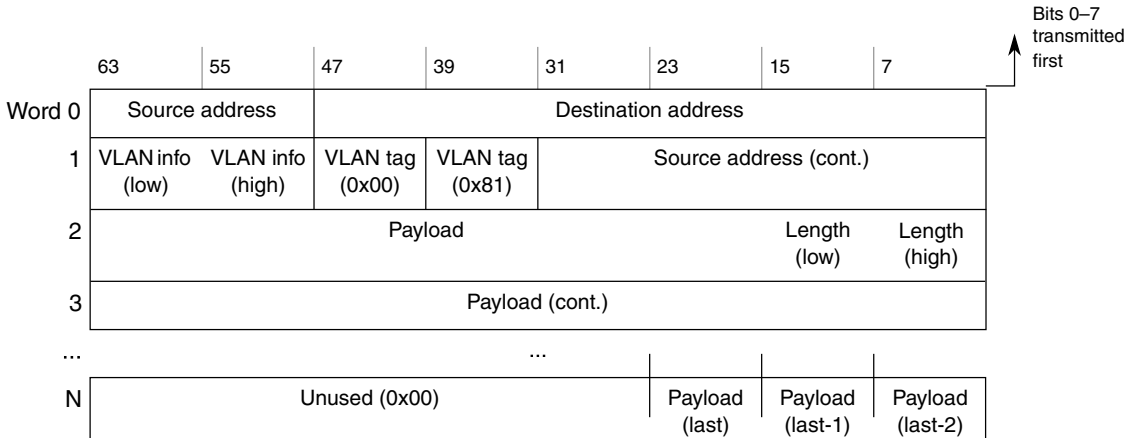

Figure 11-17. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

11.1.6.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See [Enhanced buffer descriptors](#) for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

11.1.6.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

11.1.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in [Figure 11-18](#)) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 11-18. Transmit FIFO underflow protection

11.1.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET $_n$ _ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

11.1.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

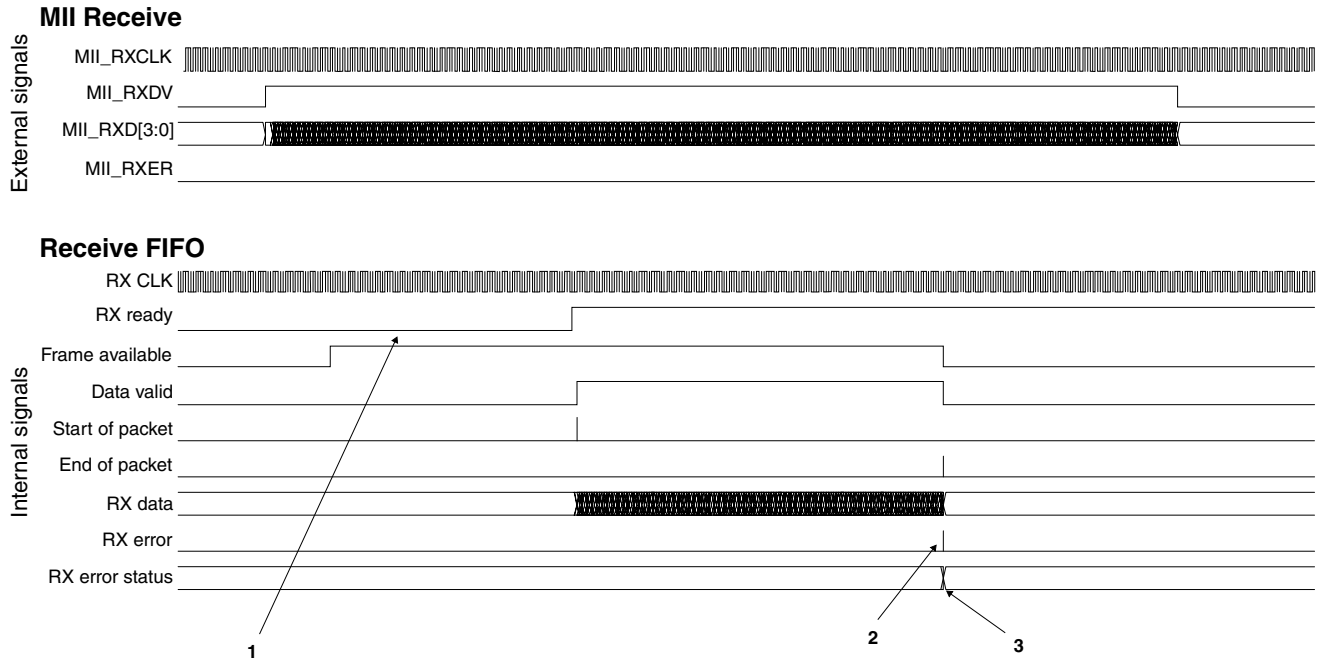

Figure 11-19. Receive FIFO overflow protection

11.1.6.17 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

11.1.6.17.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

Table 11-42. MDIO clause 22 frame structure

ST	OP	PHYADR	REGADR	TA	DATA
----	----	--------	--------	----	------

Table 11-43. MDIO frame field descriptions

Field	Description
ST (2 bits)	Start indication field, programmed with ENET _n _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET _n _MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET _n _MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET _n _MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET _n _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET _n _MMFR[DATA]. Written to or read from the PHY

11.1.6.17.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 11-44. MDIO clause 45 frame structure

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA
----	----	-------	-------	----	-----------

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 11-45. MDIO clause 45 frame field descriptions

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET n _MMFR[OP]. See Table 11-46 for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET n _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENET n _MMFR[DATA], written to or read from the PHY.

Table 11-46. MDIO Clause 45 Transactions

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

11.1.6.17.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET n _MSCR[MII_SPEED].

11.1.6.17.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET n _MMFR) according to the description provided in MII Management Frame Register (ENET n _MMFR).

To check when the programmed access completes, read the ENET n _EIR[MII] field.

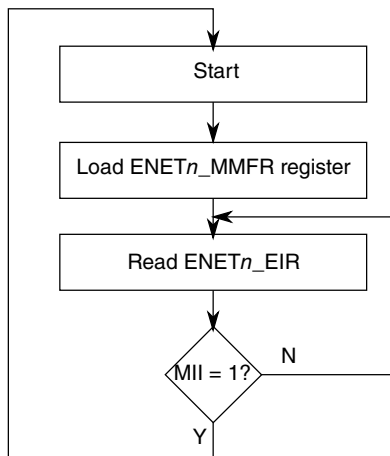

Figure 11-20. MDIO access overview

11.1.6.18 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets
- RGMII 10/100/1000 by way of interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]	RCR[RGMIIE_EN]
MII - 10 Mbit/s	0	—	0	0
MII - 100 Mbit/s	0	—	0	0
RMII - 10 Mbit/s	0	1	1	0
RMII - 100 Mbit/s	0	0	1	0
RGMII - 10 Mbit/s	0	1	0	1
RGMII - 100 Mbit/s	0	0	0	1
RGMII - 1000 Mbit/s	1	—	0	1

11.1.6.18.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

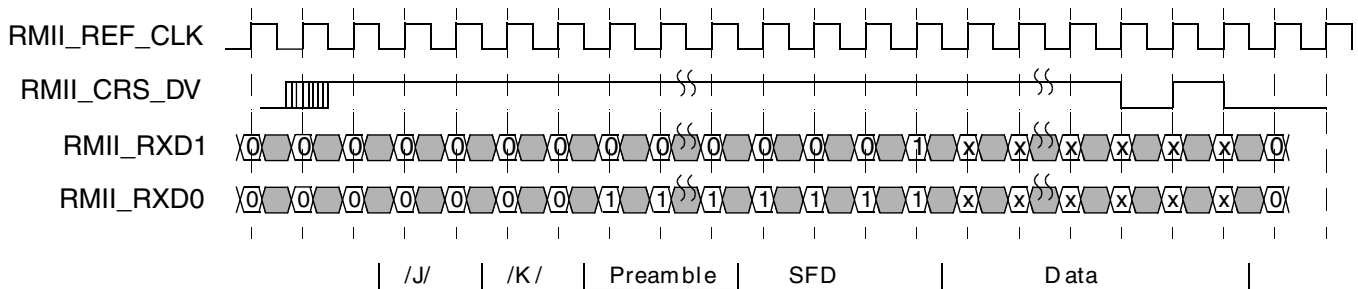

Figure 11-21. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

Figure 11-22. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

Figure 11-23. RMII transmit operation

11.1.6.18.2 RGMII interface

In RGMII modes, the data and control information is multiplexed by taking advantage of both edges of the reference clocks.

The data signals contain the lower four data bits on the rising edge and the upper four bits on the falling edge. The control signals are multiplexed into a single clock cycle using the same technique.

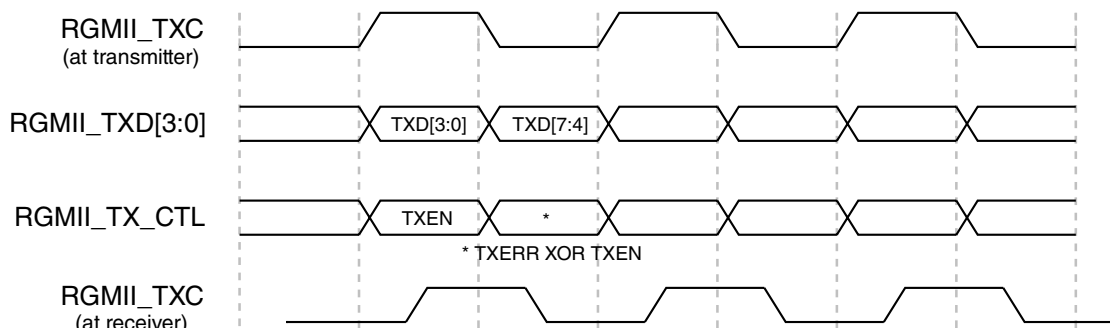

Figure 11-24. RGMII transmit operation

Figure 11-25. RGMII receive operation

11.1.6.18.3 MII Interface — transmit

On transmit, all data transfers are synchronous to MII_TXCLK rising edge. The MII data enable signal MII_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII_TXD[3:0] bus.

Between frames, MII_TXEN remains deasserted.

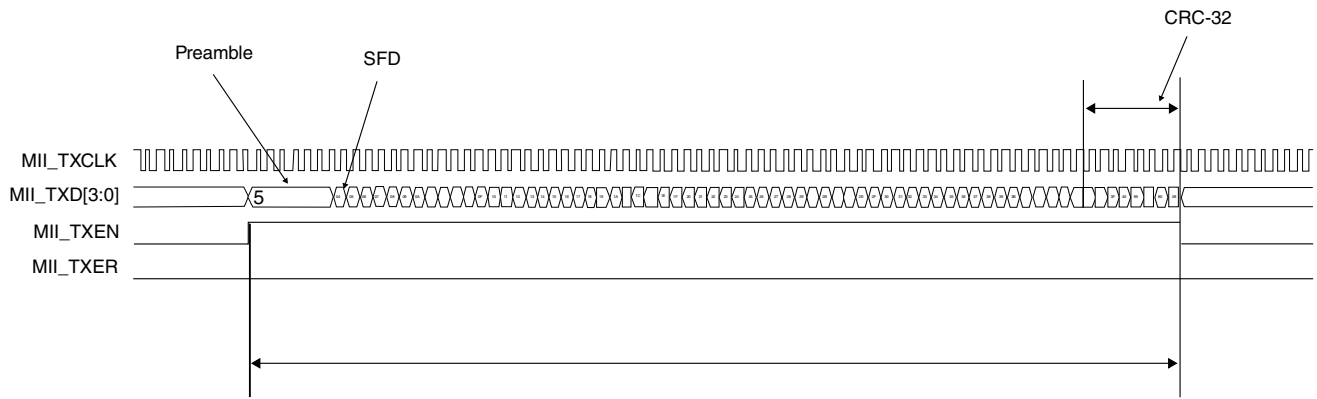

Figure 11-26. MII transmit operation

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII_TXER error signal for one clock cycle at any time during the packet transfer.

Figure 11-27. MII transmit operation — errored frame

11.1.6.18.3.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See [Collision detection in half-duplex mode](#) for details)

Figure 11-28. MII transmit operation — transmission with collision

11.1.6.18.4 MII interface — receive

On receive, all signals are sampled on the MII_RXCLK rising edge. The MII data enable signal, MII_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII_RXD[3:0] bus.

Between frames, MII_RXDV remains deasserted.

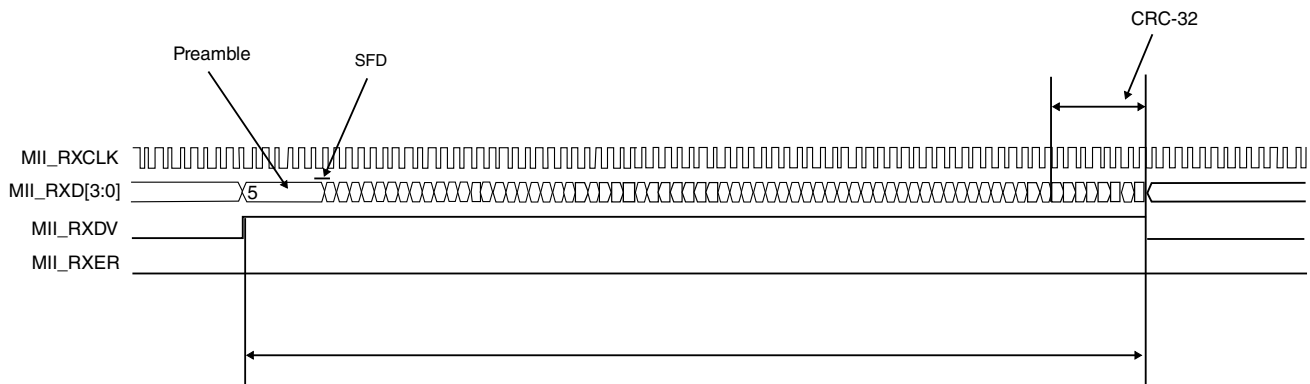

Figure 11-29. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII_RXER, for at least one clock cycle at any time during the packet transfer.

Figure 11-30. MII receive operation — errored frame

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

11.1.6.19 AVB configuration

The following steps give an example of how to initialize the ENET module for AVB.

1. Set up ENET_QOS:
 - Set TX_SCHEME to 000b, credit-based scheme.
 - Set RX_FLUSH0 to 1, enable RX flush for ring 0.
2. Set up TX BD ring and RX BD ring for each queue, 0-2.
 - Program ENET_MRBR, ENET_TDSR, and ENET_RDSR.
 - Program ENET_MRBR1, ENET_TDSR1, and ENET_RDSR1.
 - Program ENET_MRBR2, ENET_TDSR2, and ENET_RDSR2.
 - Program each TX and RX BD ring queue for all classes used in memory.

NOTE

If using credit-based scheme, ensure that enhanced transmit buffer descriptor FTYPE field matches BD ring queue, for example:

- FTYPE = 0h corresponds to ENET_TDSR
 - FTYPE = 1h corresponds to ENET_TDSR1
 - FTYPE = 2h corresponds to ENET_TDSR2
3. Program ENET_DMA1CFG and ENET_DMA2CFG for class 1 and class 2 corresponding to BD ring queue 1 and 2. DMA_CLASS_EN must be set to one for

that class to be enabled. See [DMA Class Based Configuration \(ENET_DMA \$n\$ CFG\)](#) for information on how to program IDLE_SLOPE.

4. Program ENET_RCMR1 and ENET_RCMR2 for class 1 and class 2 matching for receive.

NOTE

Even if a match occurs, if ENET_DMA n CFG[DMA_CLASS_EN] is zero for the corresponding class, the RX frame will be automatically forwarded to BD ring queue 0.

5. Program the other ENET registers according to application requirements.
6. Program ENET_RDAR, ENET_RDAR1, ENET_RDAR2, ENET_TDAR, ENET_TDAR1, and ENET_TDAR2 to 0100_0000h according to the classes used.
7. Set ENET_ECR[ETHEREN] to one.

11.1.6.20 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing for each queue, these registers are available with the same control and configuration fields.

- [Transmit Interrupt Coalescing Register \(ENET_TXIC \$n\$ \)](#) where $n=0,1,2$ for queue/class 0,1,2.
- [Receive Interrupt Coalescing Register \(ENET_RXIC \$n\$ \)](#) where $n=0,1,2$ for queue/class 0,1,2.

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

11.1.6.20.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
 - Set the INT bit in the enhanced received buffer descriptor to one.
 - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the RXB, RXB1, and RXB2 fields in the EIMR register.
- Clear the TXB, TXB1, and TXB2 fields in the EIMR register.

11.1.6.20.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC n and TXIC n registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

11.1.6.20.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC n and TXIC n registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

11.2 Subscriber Identification Module (SIM)

11.2.1 SIM Overview

The Subscriber Identification Module (SIM) is designed to facilitate communication to SIM cards or Eurochip pre-paid phone cards, and compatible with ISO/IEC 7816-3 standards. See the SIM block diagram in the figure below. The SIM module has one port that can be used to interface with the various cards. The interface with the Micro Controller Unit (MCU) is a 32-bit connection as described in the reference document IP Bus Specification.

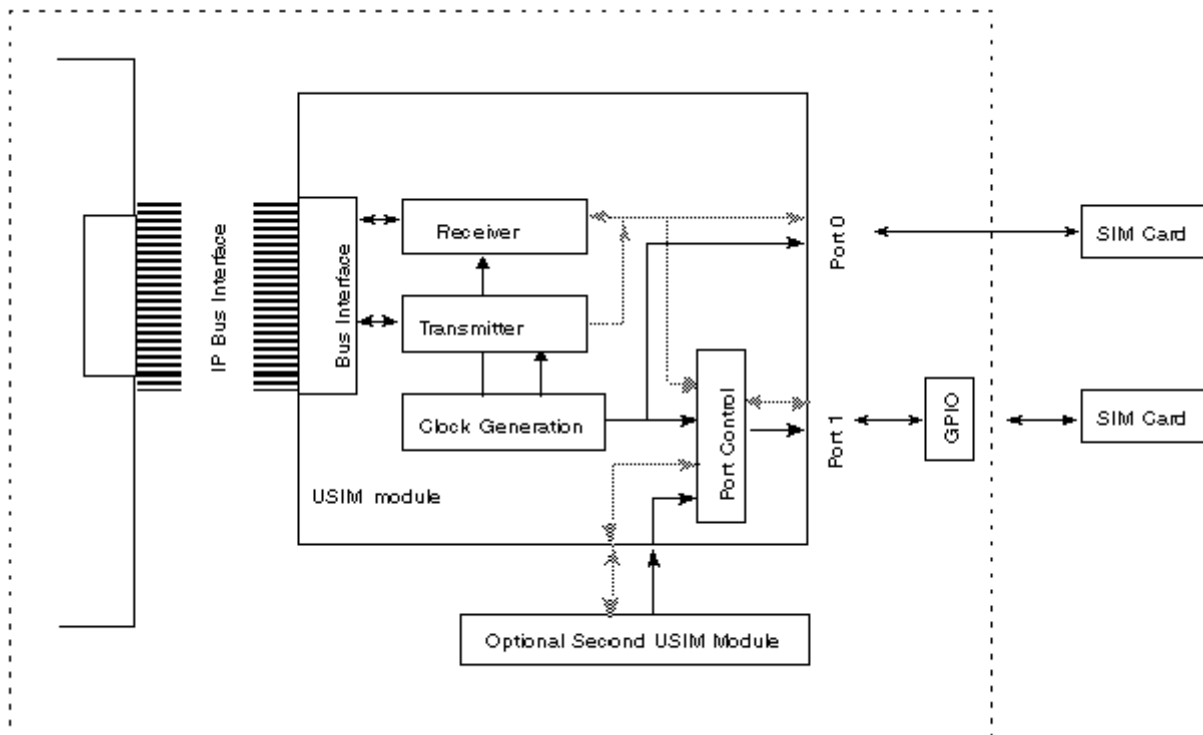

Figure 11-31. SIM Block Diagram

11.2.1.1 Features

The SIM design is summarized in the following sections:

- [SIM Bus Interface Overview](#)
- [SIM Clock Generator Overview](#)
- [SIM Transmitter Overview](#)

- [SIM Receiver Overview](#)
- [SIM Port Control Overview](#)
- [SIM General Purpose Counter Overview](#)
- [SIM LRC Block Overview](#)
- [SIM CRC Block Overview](#)

11.2.1.2 Modes of Operation

The SIM module I/O interface can be operated in one of three modes of operation summarized below.

- Two wire interface. In this mode both the IC pin RX and TX are used to interface to the SmartCard. This is activated by resetting the 3VOLT_x bit in the port control register to a "0".
- External one wire interface. In this mode the IC pins RX and TX are tied together external to the IC and routed to the SmartCard. The 3VOLT bit in the port control register is reset to a "0" and the OD_P_x bit in the OD_CONFIG register is set to a "1". For this interface to work properly the IC pin (RX-TX) must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.
- Internal one wire interface. In this mode the IC pin TX is routed to the SmartCard. The receive pin RX is connected to the TX pin internal to the IC. The 3VOLT_x bit in the port control register is reset to a "1" and the OD_P_x bit in the OD_CONFIG register is set to a "1". For this interface to work properly the IC pin TX must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.

NOTE

For the internal one wire interface to work, the bond pad must be capable of simultaneous input and output. (The input path should not be disabled when the output is enabled.)

11.2.1.3 SIM Bus Interface Overview

The SIM module is designed with a separate block that encompasses the interface to the IP bus. The bus interface is built in such a way as to be easily modified to other bus definitions. The SIM module is to be considered a 32-bit peripheral. To avoid endian issues with register access, all read/writes should be done as word access (32-bit). The bus interface has the following features:

- Peripheral Address/chip select decoding

- Illegal Address generation
- Dynamic wait state generation (tied inactive)
- Register organization
- Register bit implementations

See the table below for a summary of SIM top level interrupts.

Table 11-47. SIM Top Level Interrupt Summary

Flag	Interrupt Sources	Interrupt Masks	Description
SIMIRQ_N	XTE, OEF, SDI0, SDI1, TFO, GPCNT, BWT, BGT, CWT, RTE	XTM, OIM, SDIM0, SDIM1, TFOM, GPCNTM, BWTM, BGTM, CWTM, RTM	SIM General Interrupt
SIMDAT_N	TC, ETC, TFE, RDRF, TDTF, RFE	TCIM, ETCIM, TFEIM, RIM, TDTFM, RFEM	SIM Data Interrupt

11.2.1.4 SIM Clock Generator Overview

The SIM module contains a block designed specifically for generating the clocks used internal to the SIM module, and the clocks provided to the SIM cards. The clock generator has the following features:

- Programmable Divisor (CLK_PRESCALER[7:0]) for SIM card clock generation (45-55% duty cycle except for divider by 3, 5, 7, 9)
- Receive clock generation (/1, /2, /4, /8, /16, /32, /31) from first stage
- Transmit clock generation (/12, /8) from second stage
- Programmable divisor for receive clock generation
- There are no interrupt sources generated by the SIM clock generator block

11.2.1.5 SIM Transmitter Overview

The SIM transmitter block contains the transmit state machine, transmit shift register, and transmit FIFO. The transmitter has the following features.

- 16 bytes deep transmit FIFO
- Automatic NACK generation on parity and overrun errors
- Hardware data format support (inverse convention or direct convention)
- Retransmission of data upon SIM card NACK request with programmable maximum threshold of retransmissions
- Programmable guard time between transmitted bytes
- Six interrupt sources (see the table below)

Table 11-48. SIM Transmitter Interrupt Summary

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill Error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag

11.2.1.6 SIM Receiver Overview

The SIM receiver block contains the receive state machine, receive FIFO, and control logic. The receiver has the following features.

- 288 bytes deep receive FIFO
- Decoding of initial character mode for setting data format
- Hardware data format support (inverse convention or direct convention)
- NACK detection
- Eleven ETU character support
- Character Wait Time Counter
- Six interrupt sources (see the table below)

Table 11-49. SIM Receiver Interrupt Summary

Flag	Flag register	Mask	Mask register	Description
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive Nack threshold
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time flag
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive Data Register Full
RFE	RCV_STATUS	RFEM	INT_MASK	Receive Fifo Empty

11.2.1.7 SIM Port Control Overview

The SIM module supports numerous port control functions necessary for SIM card interaction. Each of the two SIM card ports has the following I/O: CLK, \overline{RST} , DATA_RCV, DATA_XMT, SIMPD (SIM presence detect), and SVEN (SIM V_{CC} enable). The following list gives a number of the important features of the port logic.

- Open-drain or push pull DATA_XMT pin
- Port 1, port 0, ore alternate port selection
- SIM card presence detect with interrupt capability
- Sleep mode wake-up via SIM card presence detect interrupt
- Manual control of all SIM card interface signals
- Automatic power down of port logic on SIM card presence detect
- Two interrupt sources. See [Table 11-50](#).

Table 11-50. SIM Card Detect Interrupts

Flag	Flag register	Mask	Mask Register	Description
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT	SIM Detect Interrupt for port 0

11.2.1.8 SIM General Purpose Counter Overview

The SIM module provides a 16-bit counter that can be configured to count using clock sources from the card clock, receive clock, or transmitter clock (ETU Clock). A programmable 16-bit register is provided to compare with the counter for interrupt generation:

- Selectable clock source
- 16-bit counter and comparator
- One Interrupt source (see the table below)

Table 11-51. SIM General Purpose Counter Interrupts

Flag	Flag Register	Mask	Mask Register	Description
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	GPCNT Comparator Interrupt

11.2.1.9 SIM LRC Block Overview

The SIM module contains a block designed to generate Linear Redundancy Checking (LRC) information for both received and transmitted characters. The LRC block has the following features:

- 8-bit LRC value
- Valid LRC Detector
- There are no interrupt sources generated by the SIM LRC block

11.2.1.10 SIM CRC Block Overview

The SIM module contains a block designed to generate Cyclic Redundancy Checking (CRC) information for both received and transmitted characters. The CRC block has the following features:

- 16-bit CRC value
- 16-bit CRC Polynomial Generator
- Valid CRC Detector
- There are no interrupt sources generated by the >SIM CRC block

11.2.2 External Signal Description

11.2.2.1 External Signals Overview

See the table below for summary of the SIM module signals.

Table 11-52. Signal Properties

Name	Port	Function	Reset State	Pull-up
External Signals				
SIM_CLK	O	Clock for the smartcard on port0	0	Active
SIM_RST_B	O	Reset signal for port0	0	Active
SIM_SVEN	O	Vcc enable signal for port0	0	Active
SIM_TRXD	O	Transmit/receive data signal for port0	0	Active/Passive
SIM_PD	I	Card insertion detect signal for port0	-	-
sim_pin_sclk1	O	Clock for the smartcard on port1	0	Active
sim_pin_srst1	O	Reset signal for port1	0	Active
sim_pin_sven1	O	Vcc enable signal for port1	0	Active
sim_pin_data1_tx_out	O	Transmit/receive data signal for port1	0	Active/Passive
pin_sim_simpd1	I	Card insertion detect signal for port1	-	-
sim_rcvd1_io	I	I/O Receive data signal for port1	-	-
Module Interrupts				
ipi_int_sim_ipb_int	O	Active high SIM Interrupt. Composed of OEF, XTE, SDI1, and SDI0.	0	-
ipi_int_sim_data_irq	O	Active high SIM Data Interrupt. Composed of TC, ETC, TFE, and RDRF.	0	-
Module DMA Requests				
ipd_sim_tx_dmareq_b	O	Active low. Transmitter DMA request.	1	-
ipd_sim_rx_dmareq_b	O	Active low. Receiver DMA request.	1	-

11.2.2.2 Detailed Signal Descriptions

11.2.2.2.1 SIM_CLK

The SIM_CLK is an output from the chip to the SmartCard. This signal is the clock that the SIM module provides for the SmartCard. Typical frequencies are 1 MHz to 5 MHz. This clock is 372 times the data rate that is on pin SIM_TRXD. There is no required timing relationship between this clock signal and any of the other data signals. This is because of the asynchronous nature of the protocol.

11.2.2.2.2 SIM_RST_B

The SIM_RST_B is the reset signal from the SIM to the SmartCard.

11.2.2.2.3 SIM_SVEN

The SIM_SVEN is the SmartCard power supply enable control signal.

11.2.2.2.4 SIM_TRXD

The SIM_TRXD is the data transmitted/received from the SIM module to the SmartCard. In a 1-wire mode of operating, this output port must be bidirectional with a pull-up resistor off chip.

11.2.2.2.5 SIM_PD

The SIM_PD is the SmartCard insertion detect.

11.2.3 SIM Functional Description

To best describe the organization of the SIM module from a user's point of view, it is instructive to view the SIM at a number of different levels of hierarchy. See [Figure 11-31](#) for illustration of the organization of SIM and connection of the signals to the available serial port.

The SIM module is essentially a standard UART with some special provisions made for SIM card communication. The SIM consists of the following main parts:

- IP bus interface
- Bus interface

- Clock generator
- Transmitter
- Receiver
- General purpose counter
- LRC blocks
- CRC blocks

See the figure below for an illustration of the block diagram in detail, specifically the main parts.

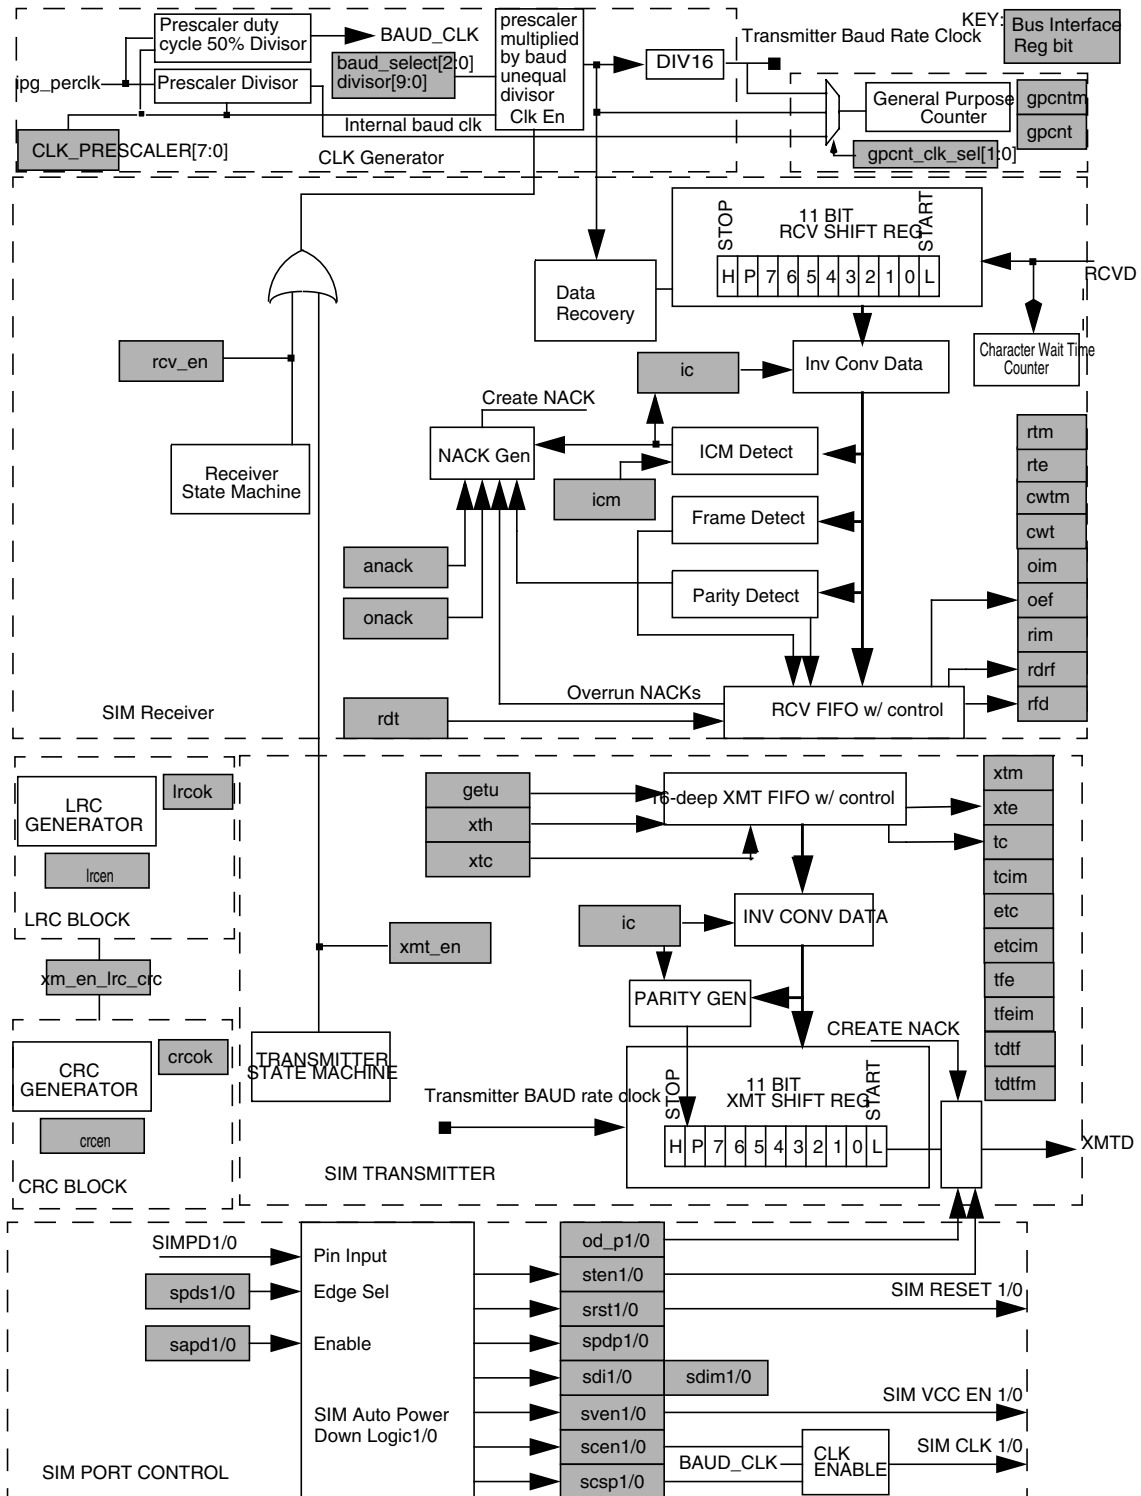

Figure 11-32. SIM Detailed Block Diagram

11.2.3.1 SIM Bus Interface

The IM Bus interface block has been designed to enable the SIM module to be easily ported to other MCU cores. The bus interface block contains all of the logic that uses the bus interface signals. See the figure below.

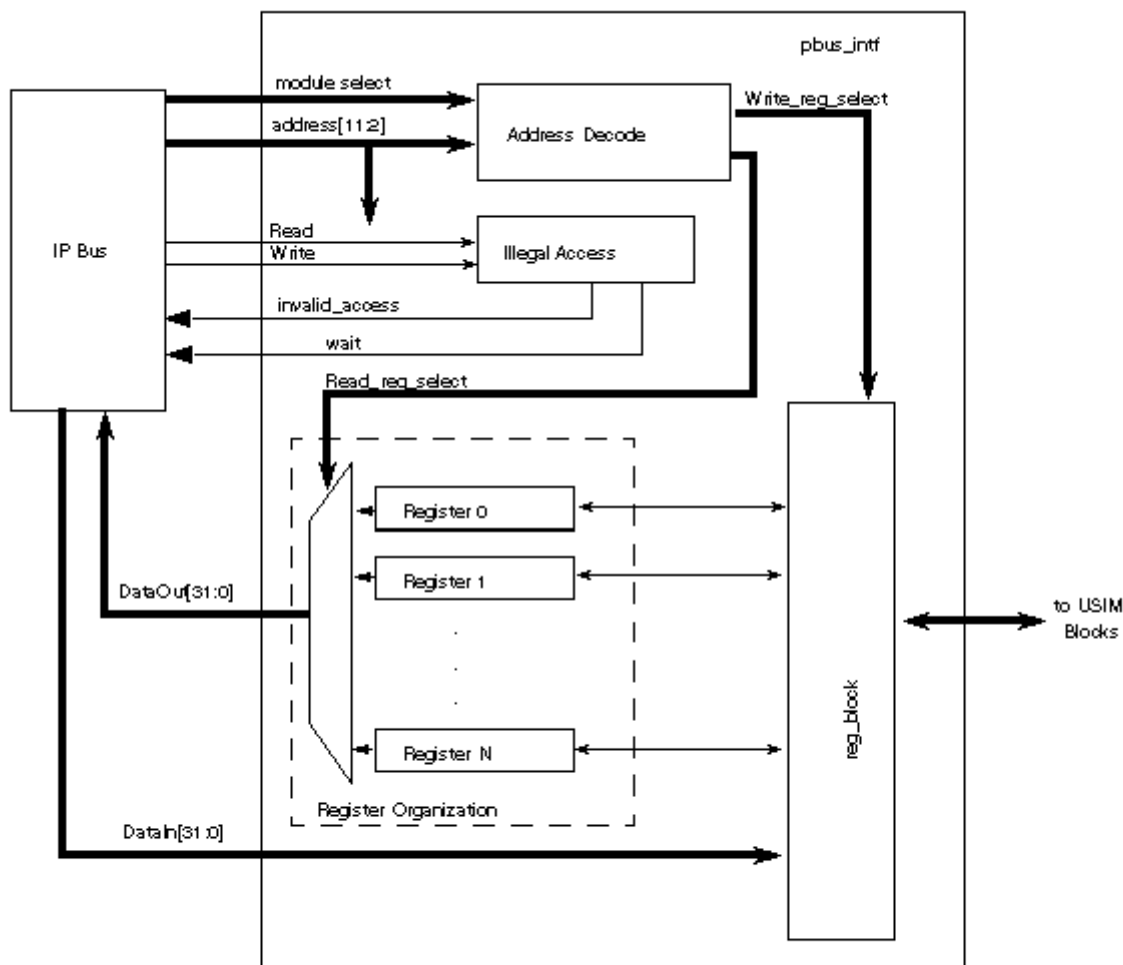

Figure 11-33. SIM Bus Interface

The bus interface block is responsible for peripheral bus address decoding, illegal access detection, dynamic wait-state requests, register organization, and register bit implementations. The address decoding uses the module address bus input along with the module select output of the IP bus to decode if the SIM module is being addressed. This decoding of these signals is done asynchronously. The output of the address decode is used with the read/write signals from the IP bus to determine the action requested by the bus master. If the read signal is active, the data_out bus will be driven with the register

selected by the address decoding. If the write signal is active, the data_in bus will be latched into the register selected by the address decoder at the rising edge of the data_strobe signal.

The illegal access detection is implemented similarly to the address decoding. If the module_select signal becomes active while the address inputs are pointing to an unimplemented address, the invalid signal is asserted asynchronously to the bus master. The invalid signal can also be generated under certain register access conditions such as writing to a full transmit FIFO, or writing to a read-only register. See the figure below.

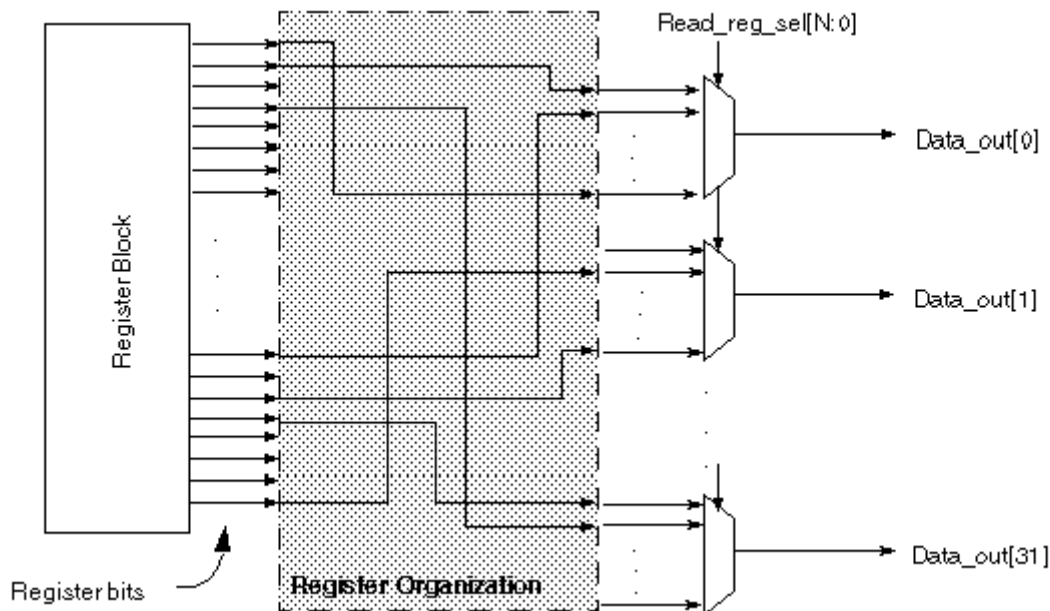

Figure 11-34. SIM Read Registers

The register bit implementations are done inside the reg_block sub-module. This block accepts the decoded read and write signals for the register bits generated in the address decoder. The data_strobe output is used as the clock input to the register bits in order to clock in the new data during a write access. The write_reg_sel signals are used to gate the write action with the address decoding. The clearing mechanisms for status bits are implemented as write-one-to-clear. See the figure below.

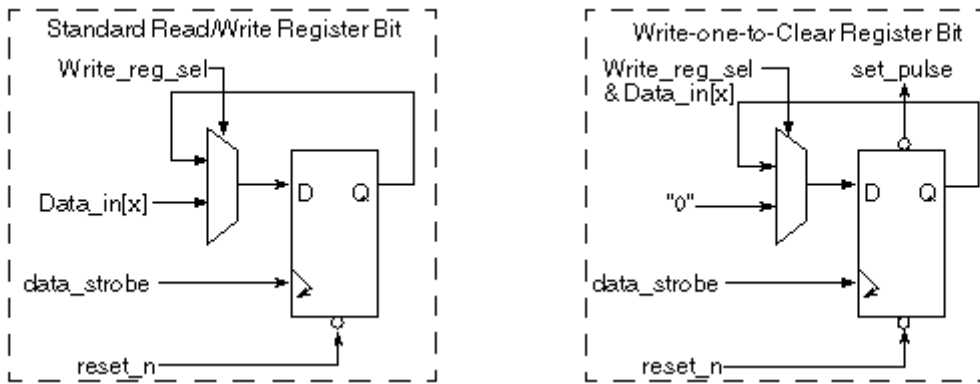

Figure 11-35. Register Bit Diagram

In the "write-one-to-clear" register bit example, "set_pulse" represents a pulsed signal generated in the data_strobe clock domain to set the register output.

11.2.3.2 SIM Clocking

The SIM has three clock inputs:

- ipg_clk-read/write clock; the frequency is half of platform_clk
- ipg_per_clk-reference frequency input clock to generate the SIM card clock and other internal clocks; the frequency is platform_clk divided by 8
- ckil-low frequency clock (32 KHz) used by the auto power down hardware circuit in the SIM. It is generated by dividing the platform_clk by a division factor which is programmed in the SIMCLKCR register in the global utilities. The default value of the divider is 0x3D09, which gives a 32 KHz clock from a platform_clk of 500 MHz.

Figure 11-36. SIM Clock Generator

Figure 11-37. SIM Clocking Diagram

11.2.3.3 SIM Clock Generator

The clock generator is responsible for implementing clock tree synthesis constructs, scan clock muxing, baud rate clock (BAUD_CLK) generation, and providing clocks to the transmitter, receiver, and port controller sections of the SIM module. See the figure below for the schematic of the SIM clock generator. The dividers outlined in bold, generate a pulsed (gated) clock of the desired frequency. The pulse is equal in duration to one half the ipg_per_clk period. This clock is used internal to the SIM module to drive the transmit and receive sections of the module.

The dividers outline in normal, generate a clock of 45-55% duty cycle to drive the clock pin of the SmartCard. This clock is not used internal to the SIM module.

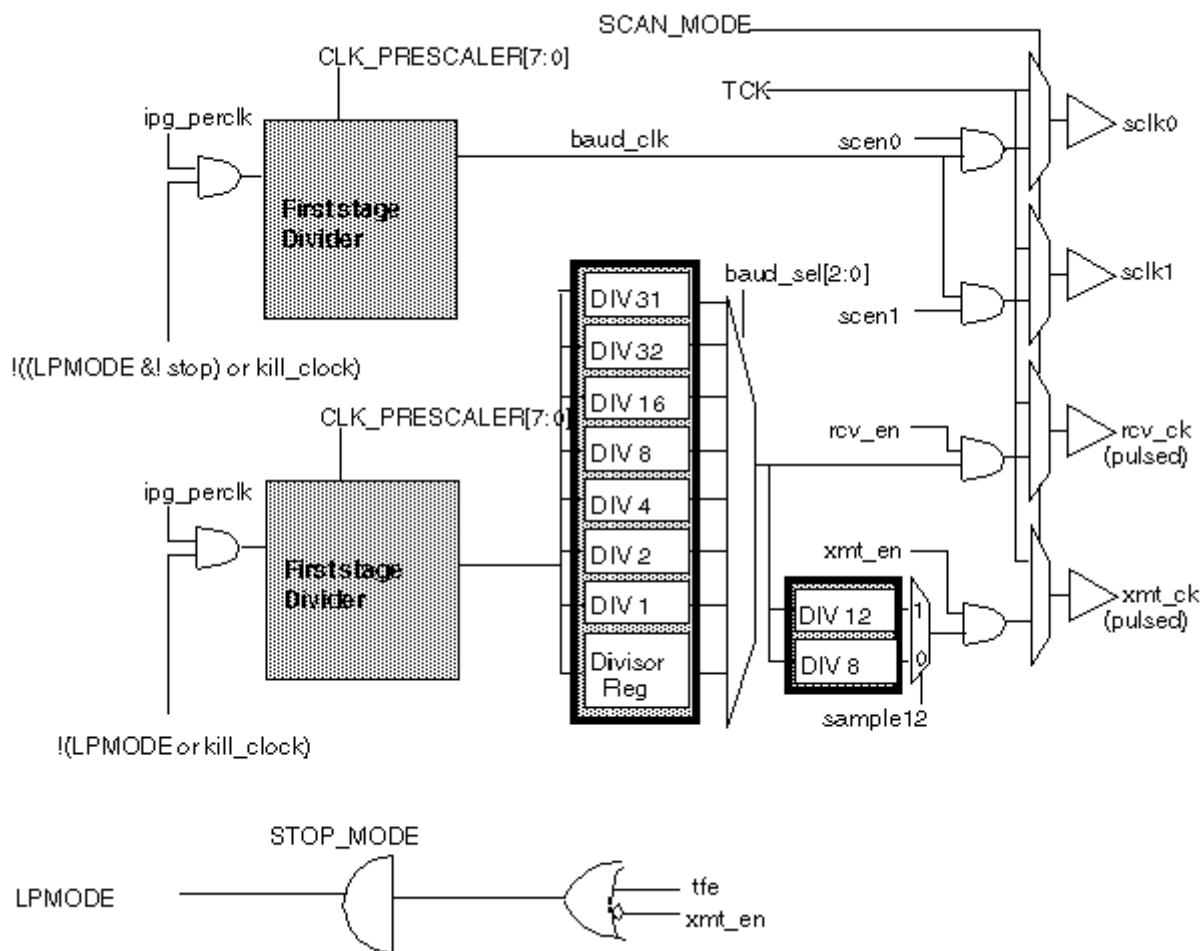

Figure 11-38. SIM Clock Generator

11.2.3.3.1 Scan Test

The scan clock muxing is implemented according to the design for testability rules.

11.2.3.3.2 Baud Clock Generation

The baud rate clock generation performed by the clock generator results in different frequencies. The default frequency is a divide by two of the `ipg_perclk` input. The baud rate can be programmed to be `ipg_perclk` divided by the even value using the `CLK_PRESCALER[7:0]` bits as shown in the `CLK_PRESCALER` register. The baud rate clock is generated in two forms in the design. The `BAUD_CLK` that is used by the SIM cards (`SCLK0`) is generated so that it must be 45-55% duty at the divide values. This is necessary to meet the requirements of the ISO 7816 specification. The `BAUD_CLK` that is used internal to the SIM module is generated as a gated version of the `ipg_perclk` clock. The resultant clock will be a pulse of one-half `ipg_perclk` period in width with the

expected frequency. The gated baud clock complies with the clock methodology initiative. The 50% duty cycle clock does not comply with the clock methodology initiative but this clock is not used as a clock internal to the SIM module. It is only used as a data path.

11.2.3.3.3 Transmitter Clock Generation

The transmitter clock (`xmt_clk`) is generated by the clock generator based on the values passed to it for the baud rate select (`baud_sel[2:0]`) and `sample12`. The transmit clock is gated by the transmit enable (`XMT_EN`) register bit. When the transmitter is enabled, the clock generator counts the appropriate number of receive clock (`rcv_clk`) positive edges to determine when to toggle the transmitter clock output. The transmitter clock is always based upon the receive clock.

11.2.3.3.4 Receiver Clock Generation

The receiver clock (`rcv_clk`) is generated by the clock generator based on the value passed to it for the baud rate select (`baud_sel[2:0]`). The receiver clock is gated by the receiver enable (`RCV_EN`) register bit. When the receiver is enabled, the clock generator counts the appropriate number of `BAUD_CLK` positive edges to determine when to toggle the receiver clock output. The number of `BAUD_CLK` positive edges is determined by the value of the baud rate select input (`baud_sel[2:0]`) and is programmable to these divisors: 31 (slowest because used with the 372/1 Fi/Di rate), 32, 16, 8, 4, 2, 1, and `divisor[7:0]`. The programmable divisor (`divisor[7:0]`) is programmable via the `DIVISOR_REG` register.

11.2.3.3.5 Port Control Clock Generation

The port controller clocks are provided by the clock generator for use on the SIM card ports. These clocks are equivalent in frequency to the `BAUD_CLK` and are gated by the SIM clock enable (`scen0`, `scen1`) signals. The level at which the card clocks (`SCLK0`, `SCLK1`) are stopped when disabled is determined by the SIM clock select polarity (`SCSP0`, `SCSP1`) inputs to the clock generator. Synchronizers are implemented to ensure glitch free operation of the card clocks when enabling/disabling, or changing the clock stopped polarity.

11.2.3.3.6 Low Power Mode Clock Control

The clock generator block is responsible for gating the clocks to the SIM module appropriately whenever a low power mode instruction is decoded. The IP interface provides two signals that encode the two available low-power states of the processor. These states are: `STOP` and `DOZE`. The response to the `DOZE` instruction is controlled

through the use of the DOZE bit in the RESET_CNTL register. See the RESET_CNTL register description. The response to the STOP instruction is controlled through the use of the STOP bit in the RESET_CNTL register. See the RESET_CNTL description

11.2.3.4 SIM Transmitter

The SIM Transmitter block has been designed to localize all transmit related circuitry into one section of hierarchy. The Transmitter block comprises the following sections of logic: transmit state machine, transmit shift register, transmit FIFO, guard time generator, transmit NACK control, and transmit data convention.

11.2.3.4.1 Transmit State Machine

The Transmit state machine is the heart of the transmitter block. The state machine is responsible for sequencing through a transmit operation while reacting to inputs from the receiver, the transmit FIFO, and the guard time circuit. See the figure below for flow diagram of the transmit state machine.

Figure 11-39. Transmit State Machine

The functions performed by each state are:

- **IDLE**
 - This is the initial state. The state machine waits here until it detects XMT_EN is set and a write to the transmit FIFO has occurred. The data pointed to by the transmit read pointer is loaded into the shift register, and the state machine

transitions to the MAIN_XMIT state. Any time XMT_EN is cleared, the state machine returns to this state.

- MAIN_XMIT
 - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the LAST_XMIT state.
- LAST_XMIT
 - This state transmits the last bit of the current transmission and determines the next operation. One of the following will occur.
 - If GETU[7:0] is non-zero, jump to the GUARD_WAIT state.
 - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to MAIN_XMIT state to retransmit the current byte.
 - If no transmit NACK, and GETU[7:0] is zero, load the shift register, jump to MAIN_XMIT to transmit the next byte
 - If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.
- GUARD_WAIT
 - The state machine remains in this state until the Guard time counter has expired.
 - If a transmit NACK error occurred on last transmission, jump to RTX_MAIN_XMIT and re-transmit
 - If no transmit NACK and the FIFO is not empty, load the shift register, jump to MAIN_XMIT to transmit the next byte.
 - If no transmit NACK and the FIFO is empty, return to the IDLE state.
 - If transmit NACK threshold is detected, stop transmitter, set XTE flag, and jump to the IDLE state.
- RTX_MAIN_XMIT
 - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the RTX_LAST_XMIT state. This state is identical to the MAIN_XMIT state except that it retransmits the previously NACKed byte.
- RTX_LAST_XMIT
 - This state transmits the last bit of the current re-transmission and determines the next operation. One of the following will occur.
 - If GETU[7:0] is non-zero, jump to the GUARD_WAIT state.
 - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to GUARD_WAIT state to check Transmit NACK threshold.

- If no transmit NACK, GETU[7:0] is zero, and the FIFO is not empty, load the shift register, jump to MAIN_XMIT to transmit the next byte
- If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.

11.2.3.4.2 Transmit Shift Register

The transmit shift register is 11 bits wide and controlled by the transmit state machine described previously. The shift register shifts out data at the transmit clock frequency (xmt_ck).

11.2.3.4.3 Transmit FIFO

The transmit FIFO is implemented inside the transmitter block. The FIFO depth is 16 bytes. The FIFO block is shared by both SIM module ports. The transmit FIFO cannot be accessed by the alternate SIM module through the alternate port. Each write to the transmit FIFO increases the transmit FIFO write pointer. Each time the transmit shift register is loaded from the transmit FIFO, the transmit FIFO read pointer is increased. When the read and write pointers are equal, the transmit FIFO empty flag (TFE) is set. Software has no visibility of the transmit FIFO pointers, but a transmit FIFO threshold value can be set to alert the software when the number of bytes in the FIFO has reached a specified level. A read of the transmit FIFO register (XMT_BUF) will return the last byte written to the FIFO. Writes to the transmit FIFO can occur at any time.

The transmit FIFO can be flushed by setting the XMT_FLUSH bit in the RESET_CNTL register. A transmit NACK threshold error (XTE) will halt the transmitter, and flush the transmit FIFO. The flush operation resets the transmit read and write pointers to equal values. Everything in the transmitter block is reset by the transmit flush operation. This does not include the control registers associated with the transmitter. The Transmit data threshold flag (TDTF) does not get cleared by the XMT_FLUSH operation.

11.2.3.4.4 Transmit Guard Time Generator

The guard time generator is simply a counter that is clocked by the transmit clock in order to delay the beginning of the next transmission and the setting of the transmit complete interrupt flag (TC) by a programmable amount of transmit bit widths (ETU's). The duration of the count is controlled by the GUARD_CNTL register (GETU[7:0]). See the figure below for depiction of three transmit operations in order to show the effect of the guard time generator logic

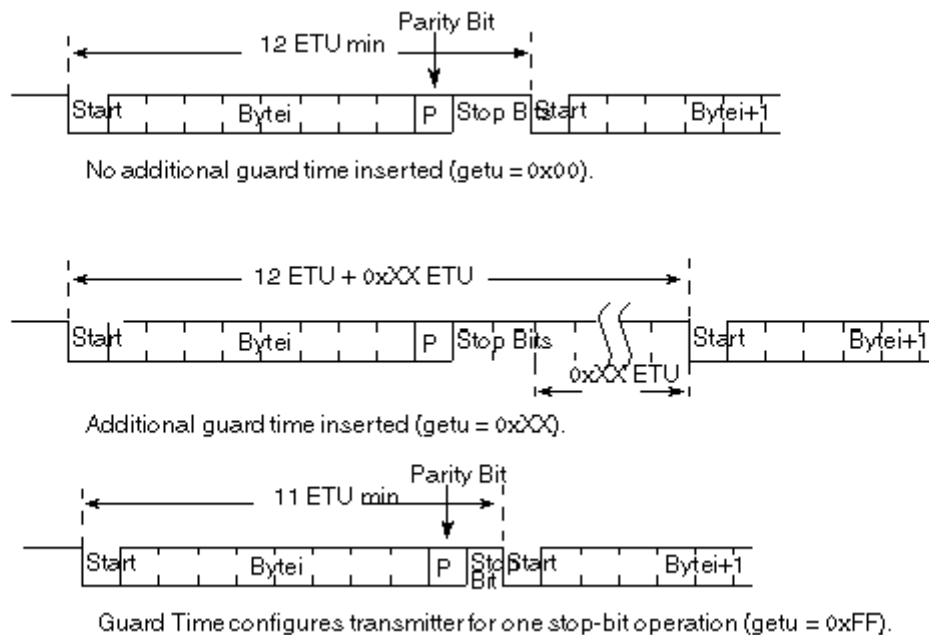

Figure 11-40. Transmit Guard Time

11.2.3.4.5 Transmit NACK Generator

The transmit NACK generator is responsible for driving the transmitter output low during the STOP bit time to signify an error was detected in the received data from the SIM card. This logic responds to a NACK request generated by the receiver block. The figure below shows a typical SIM transaction with the NACK pulse inserted.

Figure 11-41. Transmit NACK Generator

The transmit NACK generator is also responsible for keeping track of the number of NACKs received during a transmit operation. The SIM receive state machine detects NACKs generated by the SIM card, and reports them to the transmit NACK logic. Once the number of detected NACKs has reached the programmed threshold (XTH[3:0]), an interrupt flag is generated, the transmit FIFO is flushed, and the transmitter is disabled.

11.2.3.4.6 Transmit Data Convention Logic

The transmit data convention logic provides the support for the two different data conventions available in SIM cards. See the figure below for an illustration of SIM data conventions.

Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even
 if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd
 When configured for inverse convention, the parity bit is inverted by USIM before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.
 Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.
 Both the data bits and parity bit are logically inverted by hardware.

Figure 11-42. SIM Data Conventions

The direct data convention is the default. If the inverse convention bit (IC) in the DATA_FORMAT register is set, then the transmit data convention logic will convert the output of the transmit FIFO to the inverse convention before sending it to the transmit shift register.

11.2.3.5 SIM Receiver

The SIM Receiver block has been designed to localize all receive related circuitry into one section of hierarchy. The receiver block is comprised of the following functions: receive state machine and the receive FIFO.

11.2.3.5.1 Receive State Machine

The receive state machine is responsible for sampling the receive data pin and capturing the bit value into the receive shift register. Additionally, the receive state machine can detect the START bit, parity errors, framing errors, and initial character when operating in initial character mode.

Once enabled by the RCV_EN bit in the ENABLE register, the receive state machine sequences through the states as shown in the figure below.

Figure 11-43. Receive State Machine

The states identified with a "8x" are used when operating in a 8x oversampling mode. The states identified with a "12x" are used when operating in a 12x oversampling mode. This mode is only used when sample12 is set to "1". The number following the oversampling mode identifier represents the state number in the current mode. There are 12 states in "12x" mode, and 8 states in "8x" mode. Some states simply implement a one RCV_CK delay. States that perform additional functions are:

- RCV8x_1, RCV12x_1

- This is the initial state of the receive state machine. If the first bit has not been received, the state machine remains in this state until a valid START bit is detected. For every subsequent bit, this state is simply a one RCV_CK cycle delay.
- RCV8x_2, RCV12x_2
 - This state captures the first sample of the current receive data input.
- RCV12x_3
 - This state captures the second sample of the current receive data input.
- RCV12x_4
 - This state captures the third sample of the current receive data input.
- RCV8x_3, RCV12x_5
 - This state checks if we are receiving a correct START Bit. If not, Then we return to state 1.
- RCV8x_4, RCV12x_6
 - If we are in the 11th Bit, We check for Parity or Initial Character errors and send NACK if needed.
- RCV8x_5, RCV12x_7
 - Store current Bit value in Shift Register. If this is the first bit and the value is not 0, restart the State Machine.
- RCV8x_6, RCV12x_8
 - If the current bit is the last bit of the transfer, Set flag to transfer Shift Register to Receive Buffer.
- RCV8x_7, RCV12x_9
 - Clear flag for transferring Shift Register to Receive Buffer.
- RCV12x_10
 - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV12x_11
 - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV8x_8, RCV12x_12
 - This state represents the end of the current receive input bit. Several operations occur during this state, including:
 - Increment bit counter
 - Perform a majority vote on the NACK samples and notify the transmitter if a NACK pulse was detected.

11.2.3.5.2 Data Sampling / Voting

The receive state machine runs at the receive clock rate (RCV_CK). This clock is used to oversample the received data at either a 8X or 12X sample rate. For each input bit, the receive state machine captures 3 samples. A majority voting algorithm is then applied to determine the value of the bit received. The value common to 2 or more of the samples is determined to be the bit value in the receive shift register.

11.2.3.5.3 Start Bit Detection

The SIM receive input is defined to be high when not active. The data transmission is defined to begin with a low pulse for a bit duration. This is called the START bit. The receive state machine is responsible for detecting and validating the START bit. The receive state machine samples the START bit three times using a majority voting scheme to determine if the START bit is valid. This will effectively filter out any low receive inputs shorter than one RCV_CK period. See the figure below for an illustration of a typical SIM data transaction with the START bit identified.

Figure 11-44. Start Bit Diagram

11.2.3.5.4 Parity Error Detection

The receive state machine is responsible for detecting parity errors in the received data. Data is always transmitted with even parity, except when in inverse convention mode. In inverse convention mode, all data bits and the parity bit are complemented making the data appear to be odd parity. The parity bit is defined as the 10th bit of the received data. The parity of the 2nd through 10th received bits is calculated by the receiver parity logic. This logic determines if the parity of the 9 received bits is correct. See the figure below for an illustration of a typical SIM data transaction with the parity bit identified.

Figure 11-45. Parity Bit Diagram

When a parity error is detected on a given byte, the RCV_PF bit for that byte is set in the receive FIFO if NACK generation on errors is disabled (ANACK = 0 in the CNTL register). A parity error cannot cause an interrupt, but when NACK generation is enabled (ANACK = 1), it can signal the SIM transmitter to create a NACK pulse to the SIM card asking for a retransmission of the corrupted data.

11.2.3.5.5 Framing Error Detection

The receive state machine is responsible for detecting framing errors in the received data. A SIM data transaction is defined as 11 or 12 bits long consisting of the START bit, 8 data bits, 1 parity bit and 1 or 2 STOP bits. A framing error occurs when the STOP bit is not detected during the 11th bit time of a data transaction. The STOP bit is generally defined as two bit times (ETU's) of a high pulse following the parity bit. When the GUARD_CNTL register is programmed to 0xFF, the STOP bit is defined as one bit time. A framing error can only occur when the parity bit of the current byte is low, and the STOP bit arrives late. See the figure below for an illustration of a typical SIM data transaction with the STOP bits identified. Also, shown is a SIM data transaction with a late arriving STOP bit indicating a framing error.

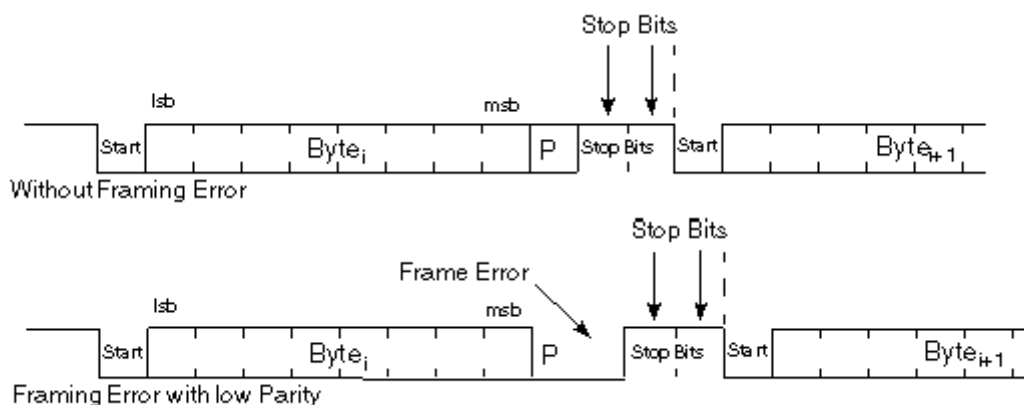

Figure 11-46. Framing Error Diagram

When a framing error is detected on a given byte, the RCV_FE bit for that byte is set in the receive FIFO. A framing error cannot cause an interrupt, nor can it create a NACK pulse to the SIM card asking for a retransmission of the corrupted data.

11.2.3.5.6 NACK Detection

The existence of the NACK pulse is sampled by the receive state machine at 11 Elementary Time Units (ETUs) after the falling edge of the START bit. An ETU is equivalent in time to 1 transmit clock period. Once the receiver detects a NACK, it signals the transmitter that an error occurred. The transmitter will not initiate retransmission for at least another two ETU times as required by the ISO 7816 specification.

11.2.3.5.7 Initial Character Detection

The SIM receive state machine supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential characters that it will use to set the data format control bit, IC, in the DATA_FORMAT register.

The two possible data formats are inverse convention and direct convention. The following figures illustrate the differences between the two formats. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

Figure 11-47. Valid Initial Characters

Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even
 if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd
 When configured for inverse convention, the parity bit is inverted by SIM card before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.
 Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.
 Both the data bits and parity bit are logically inverted by SIM card.

Figure 11-48. Inverse Convention versus Direct Convention

11.2.3.5.8 Receive FIFO

The receive FIFO is implemented inside a sub-block of the receiver block. The FIFO depth is 288 bytes. The FIFO block is shared by both SIM module ports. The receive FIFO cannot be accessed by another SIM module through the alternate port. Only the port1 IO pins can be accessed through the alternate port. The secondary SIM would then uses its own internal FIFO while using the primary SIM IO ports. This is only done if it is required to control two SIM cards at the same time. If the two SIM card access only occurs one at a time, then a single SIM module can control both SIM cards (one on port0 and one on port1). The receive FIFO is accessed through the RCV_BUF register.

The receive FIFO is loaded from the receive shift register after the final bit of the current SIM card transmission has been received. The FIFO contains 10 bits per transmission. The lower eight bits contain the received data byte. Bits 8 and 9 contain the parity and framing status for the received byte.

Each read from the receive FIFO increases the receive FIFO read pointer. Each time the receive shift register is transferred to the receive FIFO, the receive FIFO write pointer is increased. When the difference between the read and write pointers equals the programmed threshold value (RDT), the receive data register full flag (RDRF) will be set. An interrupt can be generated by the RDRF flag if the RIM bit in the INT_MASK register is cleared. Software has no visibility of the receive FIFO pointers. A write to the receive FIFO register (RCV_BUF) will generate an invalid access exception to the processor.

The receive FIFO can be flushed by setting the RCV_FLUSH bit in the RESET_CNTL register. The flush operation resets the receive read and write pointers to equal values. All logic associated with the receiver will be reset by the flush operation except for receiver control registers.

11.2.3.5.9 Overrun Detection

The receive FIFO logic is responsible for detecting an overrun condition. When a received byte is transferred from the receive shift register to a receive FIFO that contains 288 unread bytes, the SIM receiver will flag an overrun condition. This condition will always set the overrun error flag, OEF in the RCV_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered. The SIM module will generate a NACK to the SIM card on an overrun condition if the ONACK bit in the CNTL register is set. The SIM module will continually NACK SIM card transmissions until a read of the receive FIFO occurs.

11.2.3.5.10 Character Wait Time Counter

The SIM receiver block includes a 16-bit counter that counts the number of bit times (ETUs) between received characters. When enabled, the Character Wait Time Counter (CWT) will not start counting until after the START bit(s) of a valid character has been received. The counter is synchronized to the receive character bit positions so that an accurate count of the number of ETUs between characters can be made. The Character Wait Time Counter has a 16-bit programmable comparator. Software can write the expected number of ETUs between characters to the comparator. If the time between characters exceeds this value, an interrupt flag will be set and an interrupt generated if the mask is clear.

11.2.3.6 SIM Port Control

The SIM Port Control block has been designed to localize all port related circuitry into one section of hierarchy. The port control block comprises the following functions: SIM card interface, SIM Card presence detect, and SIM card auto-power down.

11.2.3.6.1 SIM Card Interface

The SIM module allows for direct control of two separate SIM cards. The SIM module does not support simultaneous communication with two SIM cards. To achieve simultaneous communication with two SIM cards, a second SIM module must be used. The SIM module can relinquish control of the inactive port to a secondary SIM module by setting the AMODE bit in the SETUP register. When alternate SIM Card Mode enable, output signals in port1 is directly from the secondary SIM module and input signals in port1 will pass through to the secondary SIM module.

The SIM card clock is generated in the SIM clock generator. The SIM card reset is controlled by software through the PORT0_CNTL register. Since the SIM module does not support a separate transmit data and receive data port, the 3VOLT0 bit should be set to 1.

11.2.3.6.2 SIM Card Presence Detect

The SIMPD_x input allows for detection of the insertion or removal of a SIM card. The SPDS_x control bit in the PORT_x_DETECT register allows the software to configure which edge of the SIMPD_x pin will cause a presence detect event. A maskable interrupt can be generated when a SIMPD_x event occurs.

An internal pull-down device is present on the SIMPD_x pins. This will provide for a high to low transition on the SIMPD_x pin when a SIM card is removed.

11.2.3.6.3 SIM Card Automatic Power Down

When interfacing to the SIM cards, it is necessary to follow a particular sequence when powering them up and down. The SIM port control block contains hardware that provides the correct sequence to power down a SIM card (see the figure below). The power up sequence must be done manually by the software using the pin control bits supplied in the PORT_x_CNTL registers.

The power down sequence is specified in ISO 7816 as:

1. RST transitions from high to low
2. CLK is turned off to a low
3. I/O transitions from high impedance to low
4. SIM V_{CC} is turned off

Figure 11-49. Auto Power Down Sequence

11.2.3.7 SIM General Purpose Counter

The SIM module provides a 16-bit counter for use when timing events during SIM card communication. The clock source for the counter is selectable between three sources: BAUD_CLK, RCV_CLK, or XMT_CK (ETU clock). The GPCNT_CLKSEL[1:0] bits in the CNTL register are used to select the clock input. The counter is enabled as soon as the input clock is selected. The starting of the counter is immediate once the input clock is running. Software can control the three input clock sources by using the KILL_CLOCK, RCV_EN and XMT_EN bits provided in the RESET_CNTL and ENABLE registers.

To run the counter from the card clock source the following conditions must be met:

1. 'KILL_CLOCK = 0' in the RESET_CNTL register.
2. 'GPCNT_CLKSET[1:0] = 01' in the CNTL register

The counter will begin to count at the card clock rate as soon as these conditions are met.

To run the counter from the receive clock source the following conditions must be met:

1. 'KILL_CLOCK = 0' in the RESET_CNTL register.
2. 'RCV_EN = 1' or XMT_EN = 1 in the ENABLE register
3. 'GPCNT_CLKSET[1:0] = 10' in the CNTL register

The counter will begin to count at the receive clock rate as soon as these conditions are met.

To run the counter from the ETU (transmit) clock source the following conditions must be met:

1. 'KILL_CLOCK = 0' in the RESET_CNTL register.
2. Either one of the following:
3. "RCV_EN = 1' in the ENABLE register and 'CWT_EN = 1' in the CNTL register
'XMT_EN = 1' in the ENABLE register
4. 'GPCNT_CLKSET[1:0] = 11' in the CNTL register

The counter will begin to count at the ETU clock rate as soon as these conditions are met.

The counter can be reset by setting GPCNT_CLKSEL[1:0] to 00. A 16-bit comparator value is provided that allows the software to select a count value at which an interrupt flag can be set and an interrupt generated if the mask is clear.

11.2.3.8 SIM LRC Block

The SIM module provides an 8-bit Linear Redundancy Check (LRC) generator / checker. The block is provided for use with T=1 SIM cards that support LRC. This block can be enabled through the LRCEN bit in the CNTL register. This block performs an 8-bit exclusive-OR on all received or transmitted characters. At the end of the reception of a block of characters, the result is expected to be 00. If so, the LRCOK bit is set in the RCV_STAT register. During transmission, the LRC block Exclusive-ORs each character that is transmitted with the current value of the LRC. If the XMT_CRC_LRC bit in the CNTL register is set, the LRC value will automatically be sent by the SIM transmitter as the final character when the transmit FIFO empties.

The LRC value can be reset in multiple ways. Clearing the LCREN bit in the CNTL register will reset the LRC value. At the end of a transmission (either after the LRC byte is transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the LRC value is automatically reset by the SIM hardware. Finally, when setting the XMT_EN bit, the SIM hardware resets the LRC value.

11.2.3.9 SIM CRC Block

The SIM module provides an 16-bit Cyclic Redundancy Check (CRC) generator / checker. The block is provided for use with T=1 SIM cards that support CRC. This block can be enabled through the CRCEN bit in the CNTL register. This block performs a polynomial based check on all received or transmitted characters. The polynomial description is shown in Figure 4-17. The polynomial used is the standard CRC-CCITT

where $g(x) = x^{16} + x^{12} + x^5 + 1$. The CRC register is initialized to all "1" before the data is shifted in. Before transmission the resulting CRC is inverted. For example, transmitting a 0xFA results in the following:

- Data = 0x5F (bit reversal of 0xFA)
- crc = 0x4AEA
- invert the crc = 0xB515 (bit reversal of 0xADA8)
- data transmitted = 0xFA, 0xAD, 0xA8

See the figure below for an illustration of the SIM CRC block.

Figure 11-50. CRC Block Diagram

At the end of the reception of a block of characters, the residual from the CRC calculation is compared to 0x1D0F. If so, the CRCOK bit is set in the RCV_STAT register. During transmission, the CRC block updates the current value of the CRC residual using each character. If the XMT_CRC_LRC bit in the CNTL register is set, the CRC value will automatically be inverted and sent by the SIM transmitter as the final two characters when the transmit FIFO empties.

The CRC value can be reset in multiple ways. Clearing the CRCEN bit in the CNTL register will reset the CRC value. At the end of a transmission (either after the CRC characters are transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the CRC value is automatically reset by the SIM hardware. Finally, when setting the XMT_EN bit, the SIM hardware resets the CRC value.

11.2.3.10 Module Interrupts

See the table below for the list of all possible interrupt sources and their corresponding mask bits. All SIM interrupts are logically ORed to create the active low irq_n and data_irq_n signals that go to the ITC module. All mask bits are such that a logic 1 implies that the corresponding interrupt is disabled (masked), whereas a 0 implies that the interrupt enabled (unmasked). All of these mask bits are logic 1 out of reset (all interrupts are masked).

Table 11-53. SIM Module Interrupts

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS)	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	General Purpose Counter Comparator Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive data register full (FIFO threshold level reached)
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time Counter Comparator Flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time Counter Comparator Flag
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time Counter Comparator Flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive NACK Threshold Error
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT)	SIM Detect Interrupt for port 0

11.2.4 Initialization/Application Information

This section describes the intended programming model for using the SIM module. The section describes how to begin a typical mode of operation using the registers.

11.2.4.1 Configuring SIM for Operation

The following is a list of items that need to be performed in order to configure the SIM module for operation:

1. Port selection in the SETUP register.
 - a. Select which SIM module port is active by writing the SPS bit.
 - b. Select whether the second SIM module port is active at the same time under the control of an alternate SIM module by writing the AMODE bit.
2. Enable the selected port (for port 1, see PORT1_CNTL register; for port 0, see PORT0_CNTL) following the SIM power up procedure specified in ISO 7816.
 - a. Program 3VOLT0 pin of PORT0_CNTRL register to 1.
 - b. Enable power to the SIM card using the SVEN1 or SVEN0 bit.
 - c. Enable SIM module transmit data output using the STEN1 or STEN0 bit. This is required to allow the SIM receiver to create NACK pulses.
 - d. Enable SIM card clock using the SCEN1 or SCEN0 bit.
 - e. Release the SIM card reset using the SRST1 or SRST0 bit (assert SRSTx high).
3. Select XMT port driver type (open-drain or push-pull) in the OD_CONFIG register.
 - a. Configure the selected port to be open drain or push-pull by using the OD_P1 or OD_P0 bit.
4. Choose the port baud rate in the CNTL register.
 - a. Select the SIM card clock rate by using the CLK_PRESCALER[7:0] register.
 - b. Select the SIM card baud rate by using the BAUD_SEL[2:0] bits and SAMPLE12.

NOTE

Follow the ISO 7816 spec with regards to card clock frequencies to ensure the maximum frequency specification is not violated.

5. Select Data format type, or place SIM receiver in initial character mode.
 - a. Select inverse convention or direct convention by using the IC bit in the DATA_FORMAT register, or
 - b. Enable initial character mode by using the ICM bit in the CNTL register.

11.2.4.1.1 Configuring SIM Receiver

The following is a list of items that need to be performed in order to configure the SIM receiver for operation:

1. Enable NACK capability in CNTL register.
 - a. Select NACK generation on parity errors, or invalid initial character by using the ANACK bit.
 - b. Select NACK generation on overrun conditions by using the ONACK bit.
2. Select the desired Receive NACK threshold and receive FIFO threshold in RCV_THRESHOLD register.
 - a. Program the threshold at which the RDRF flag will be set by using the RDT bits.
 - b. Program the threshold at which the RTE flag will be set by writing to the RTH[3:0] bits. If an auto power down after RTE flag is set, is desired, then enable the SIM card auto power down by setting the SAPD0,1 bits in the port0,1_cntl register.
3. Configure the Character Wait Time Counter, the Block Wait Timer Counter and the Block Guard Time Counter.
4. Enable interrupts in the INT_MASK register.
 - a. Enable the receive data register full interrupt by using the RIM bit
 - b. Enable the receive threshold error interrupt by using the RTM bit.
 - c. Enable the overrun condition interrupt by using the OIM bit.
 - d. Enable the Character Wait Time interrupt by using the CWTM bit
5. Enable enforce reception early stop function in ENABLE register.
 - a. Enable the enforce reception early stop enable by using the ESTOP_EN bit.
 - b. Enable the enforce reception early stop execution by using the ESTOP_EXE bit.

11.2.4.1.2 Configuring SIM Transmitter

The following is a list of items that need to be performed to configure the SIM transmitter for operation:

1. Select desired re-transmission threshold for NACKed characters in XMT_THRESHOLD register.
 - a. Program the threshold at which the XTE flag will be set by using the XTH[3:0] bits.
2. Select the guard time between transmissions in the GUARD_CNTL register.
 - a. Program the desired guard time between characters transmitted by the SIM module by using the GETU[7:0] bits.
3. Select the desired Transmit FIFO threshold level in the XMT_THRESHOLD register.
 - a. Program the desired threshold using the TDT[3:0] bits.
4. Enable interrupts in the INT_MASK register.

- a. Enable the transmit complete interrupt by using the TCIM BIT.
 - b. Enable the early transmit complete interrupt by using the ETCIM bit.
 - c. Enable the transmit FIFO empty interrupt by using the TFEIM bit.
 - d. Enable the transmit threshold error interrupt by using the XTM bit.
 - e. Enable the transmit FIFO threshold interrupt by using the TDTFM bit.
 - f. Enable the transmit FIFO overflow interrupt by using the TFOM bit.
5. Enable NACK delay detection in ENABLE register.
 - a. Enable the NACK delay detection enable by using the NACK_DD_EN bit.

11.2.4.1.3 Configuring SIM General Purpose Counter

The following is a list of items that need to be performed in order to configure the SIM General Purpose Counter for operation:

1. Select desired clock source for the General Purpose Counter using the CNTL register.
 - a. Use the GPCNT_CLKSEL[1:0] bits to select the desired clock source for the counter
2. Program counter comparator using the GPCNT register.
 - a. Use the GPCNT[15:0] bits to select the desired count value at which the GPCNT interrupt flag will be set.
3. Enable the selected clock source for the General Purpose Counter using either the RESET_CNTL or ENABLE registers.
 - a. If the GP Counter is configured for the card clock, enable the clock by clearing the KILL_CLOCK bit in the RESET_CNTL register.
 - b. If the GP Counter is configured for the receive oversample clock, enable this clock by setting the RCV_EN bit or XMT_EN bit in the ENABLE register.
 - c. If the GP Counter is configured for the transmit oversample clock, enable this clock by setting the XMT_EN bit in the ENABLE register.
4. Enable interrupts in the INT_MASK register.
 - a. Enable the general purpose counter interrupt by using the GPCNTM bit.

11.2.4.1.4 Configuring SIM to Measure WWT (Work Wait Time) for Type=0 Smartcards

The following is a list of items that need to be performed in order to configure the SIM to measure work wait time. This is intended for type=0 SmartCards. Work wait time is a combination of BWT and CWT. The CWT timer is to measure the time between the start bits of two consecutive characters in the block received from the SmartCard. If this time is larger than the value programmed in the cwt[15:0] register, then a flag will be set and an interrupt generated. This timer can be used for both type=0 and type=1 SmartCards. The BWT and BGT timer are used to measure the delay between the leading edge of the

last character of the block received by the card and the leading edge of the first character of the next block sent by the card. If you want the SIM to enforce a WWT of 100 bits. Then, you must activate both the CWT and BWT, and program both of them for a value of 100 bits. When measuring WWT, the BGT timer will not be used so it will be masked (inactive) by the BGTM bit. Below is the sequence to program the SIM to send and receive data while checking WWT.

1. Program both the CWT and the BWT (low and high) registers to the WWT (work wait time) value that needs to be enforced. Set BGT register to 0 (this is the default value).
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT and BWT interrupts by clearing the CWTM and BWTM bits in the INT_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT_EN and RCV_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should consider that a WWT violation. The software should clear the CWT or BWT interrupt by writing a "1" to the BWT or CWT bit in the RCV_STATUS register.

11.2.4.1.5 Configuring SIM to measure CWT, BWT, BGT for type=1 SmartCards

The following is a list of items that need to be performed in order to configure the SIM to measure CWT, BWT, BGT. This is intended for type=1 SmartCards. The CWT timer is to measure the time between start bits in the consecutive characters received from the SmartCard. If this time is larger than the value programmed in the CWT[15:0] register, then a flag will be set and an interrupt generated. This timer can be used for both type=0 and type=1 SmartCards. The BWT, BGT timer is used to measure the delay between the leading edge of the last character of the block received by the card and the leading edge

of the first character of the next block sent by the card. If this time is larger than the value in the both BWT registers (BWT and BWT_H), then the BWT flag will be set and an interrupt generated. If the time is less than the value in the BGT register, then the BGT flag will be set and an interrupt generated.

1. Program the CWT, BWT, BWT_H and BGT registers to the value that needs to be enforced.
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT, BWT, BGT interrupts by clearing the CWTM, BWTM, BGTM bits in the INT_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT_EN and RCV_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should read the RCV_STATUS register to determine if the error was caused by a CWT, BWT, or a BGT violation. The software should clear the CWT, BWT, BGT interrupt by writing a "1" to the CWT, BWT, BGT bit in the RCV_STATUS register.

11.2.4.1.6 Configuring SIM Linear Redundancy Check (LRC) Block

The following is a list of items that need to be performed in order to configure the SIM Linear Redundancy Check Block for operation:

1. Enable the LRC block by using the CNTL register.
 - a. Use the LRCEN bit to enable the LRC block.
 - b. Use the XMT_CRC_LRC bit to enable the transmission of the LRC Character after the last character in the Transmit FIFO is sent. Refer to the T=1 programming model for more details.

11.2.4.1.7 Configuring SIM Cyclic Redundancy Check (CRC) Block

The following is a list of items that must be performed to configure the SIM Cyclic Redundancy Check Block for operation:

1. Enable the CRC block by using the CNTL register.
 - a. Use the CRCEN bit to enable the CRC block.
 - b. Use the XMT_CRC_LRC bit to enable the transmission of the CRC Characters after the last character in the Transmit FIFO is sent. Refer to the T=1 Programming model for more details.

11.2.4.2 Using the SIM Receiver

Once the SIM has been properly configured (such as correct baud rate and correct data format), SIM receptions can be enabled by setting the receive enable bit, RCV_EN, in the ENABLE register. As bytes are received, they will be placed in the 288 byte deep receive data FIFO. Unread bytes can be accessed from this FIFO at any time. There is no need to disable the receiver to access the FIFO. The FIFO should only be read when the receive FIFO data flag, RFD, in the RCV_STATUS register is set. The RFD flag, which cannot create an interrupt, is high any time there is at least one unread byte in the receive FIFO. If the receive FIFO is read when RFD is low, it will simply produce the last byte read.

The receive data register full flag, RDRF, in the RCV_STATUS register can be used to determine when the receive FIFO has reached a given threshold value. This flag will create an interrupt if the RIM bit in the INT_MASK register is clear. To control at which point RDRF is set, program the receive data threshold, RDT, in the RCV_THRESHOLD register. If the number of unread bytes in the receive FIFO is equal to or greater than the value set by RDT, RDRF will be set.

NOTE

A value of 0x0 in RDT implies that there must be 288 unread bytes in the receive FIFO to trigger RDRF.

The standard flow for receiving bytes from the SIM card is to set RDT to the appropriate value, wait for RDRF to cause an interrupt (RIM clear), and then read bytes out of the receive FIFO as long as RFD is high. In addition to checking RFD between every byte, it is also recommended that software check for the existence of a set OEF flag as well.

11.2.4.2.1 Receive Parity Errors and Parity NACK Generation

The SIM receiver checks every byte received for proper parity. The IC control bit in the DATA_FORMAT register controls whether it checks for odd parity or even parity. When checking for odd parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be odd. Likewise, when checking for even parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be even.

If NACK generation on errors is disabled (ANACK = 0 in the CNTL register), the PORTx_PE bit will be set when the SIM receiver detects a parity error, the received data byte and its PORTx_PE bit are placed into FIFO. There is no need to clear the parity error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A parity error cannot cause an interrupt, and it is up to the software to discard data bytes with parity errors.

If NACK generation on errors is enabled (ANACK = 1), the SIM can automatically request the SIM card to re-send a byte that has a parity error by generating a NACK pulse on the SIM XMT pin. In this case, Bytes with parity errors are discarded and will not be placed into the FIFO.

To control NACK generation by the SIM receiver use the RTH[3:0], Receive NACK threshold, in the RCV_THRESHOLD register. This set of bits specifies the number of consecutive NACK's generated by the SIM module on a received byte, before generating an RTE (receive threshold interrupt flag) in the RCV_STATUS register. The RTE flag would also force the SIM port to power down the card if the SAPD0,1 bit is set in the PORT0,1_CNTL register.

NOTE

The ANACK bit must be set in the CNTL register to enable this feature. The control bit ANACK is also used in initial character mode to enable the retransmission of initial characters in the event that an invalid initial character is received.

When a valid character has been received by the SIM, the internal counter keeping track of the number of NACK's transmitted on the current byte resets to zero. Clearing the receive threshold error (RTE) bit would also clear that counter.

When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

11.2.4.2.2 Receive Frame Errors

The SIM receiver checks every byte received for a proper stop bit. A stop bit should exist during at least the first half of the 11th ETU time after the start of the character. If this is not true, a frame error is flagged. When a frame error is detected on a given byte, the

PORTx_FE bit for that byte is set in the FIFO. The PORTx_FE flag for each byte is read out of the FIFO when the data itself is read. There is no need to clear the frame error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A frame error cannot cause an interrupt, nor can it create a NACK pulse to the receiver asking for a retransmission of the corrupted data.

11.2.4.2.3 Receive Overrun Errors and Overrun NACK Generation

When there already exists 288 unread bytes in the FIFO, a received character will cause the SIM receiver to flag an overrun condition. This condition will always set the overrun error flag, OEF in the RCV_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered.

It is possible for the SIM to automatically request that the SIM card re-send the byte that caused the overrun condition by generating a NACK pulse on the SIM XMT pin. The SIM will generate a NACK pulse for the byte that caused the overrun condition if the control bit ONACK in the CNTL register is set. In this case, the existence of an OEF flag does not indicate the loss of data, but rather a NACK (that is, retransmission request) due to a full receive FIFO. As opposed to transmit NACK generation, there is no limit to the number of times an overrun condition will cause a NACK other than to disable ONACK itself. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

If the control bit ONACK is clear, the existence of a high OEF flag indicates the loss of data. The OEF flag can create an interrupt if the OIM bit in the INT_MASK register is clear.

To clear the OEF flag, software must simply write a "one" to the OEF bit position in the RCV_STATUS register. A high OEF flag has no effect on the operation of the SIM receiver other than to create an interrupt if OIM is clear.

11.2.4.2.4 Using Initial Character Mode and Resulting Receive Data Formats

The SIM receiver supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential values that it will use to set the data format control bit, IC, in the DATA_FORMAT register.

The two possible data formats are inverse convention and direct convention. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb, and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

To place the SIM into initial character mode, set the ICM bit in the CNTL register. Once a valid initial character is received, the IC bit in the DATA_FORMAT register will be set accordingly by the hardware, and the ICM bit will be cleared. Software can read the state of the IC bit to determine which mode the SIM is currently using.

The 0x3B (as decoded by direct convention) with parity bit high will cause direct convention to be used (IC set to logic 0), whereas a 0x3F (as decoded by inverse convention) with parity bit high will cause inverse convention to be used (IC set to logic 1).

When the receiver is in initial character mode, all received bytes will continue to be placed into the receive FIFO whether they be valid initial characters or not. If a valid initial character is received that causes the data format being used to change, all subsequent bytes will be decoded with that format before being placed into the FIFO, including the initial character byte itself. That is, if the IC bit is low, and the correct initial character for setting inverse convention is received, that character and all subsequently received characters will be stored in the FIFO after having been decoded using inverse convention (for example, the initial character will be stored as 0x3F).

If the receiver is in initial character mode (ICM is high), and an invalid initial character is received, the SIM can be configured to automatically request that the initial character be retransmitted by setting the ANACK control bit in the CNTL register. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETUs. The invalid initial character will be placed into the receive FIFO and marked with a parity error to signify that this is an invalid initial character.

11.2.4.2.5 Initial Character Mode Programming Notes

The usage of the initial character mode requires close attention to the programming model. There is a condition where a parity error in the initial byte for direct convention (0x3B) could be decoded as what appears to be a valid initial character for inverse convention (that is, 0x3F). The SIM module will not recognize this as a valid initial character for inverse convention and will mark the character by setting the parity error flag. The software must look for the existence of a parity error before recognizing a character as a valid initial character.

11.2.4.2.6 Automatic Receiver Mode

The SIM module has an automatic receive mode that inhibits the data being transmitted by the SIM module from entering the SIM receive buffer through the feedback path of the SIM data pin. The SIM module receiver should normally be enabled while the transmitter is operational. Automatic receive mode saves the software from having to actively manage the transition from transmitter to receiver. The auto receive mode is always active whenever the receiver is enabled.

11.2.4.2.7 Using the SIM Receiver with "T=1" SIM Cards

The SIM module provides hardware support for "T=1" type SIM cards. These type of cards present several requirements above and beyond the standard "T=0" cards. The features provided to meet the requirements that pertain to the SIM receiver are as follows:

- 11 ETU Characters
 - "T=1" cards can transmit with character lengths of 11 ETUs (that is, one STOP bit). The SIM module provides the RCVR11 bit in the GUARD_CNTL register in order to configure the receiver state machine to accept 11 ETU characters.
- Character Wait Time Counter
 - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters received from the SmartCard. The value of CWT can range from 12 ETU to 32779 ETU. The SIM module provides a 16-bit counter with programmable comparator clocked at the ETU bit rate to identify when the CWT has been exceeded by the SIM card.
- Block Waiting Time
 - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The block wait time must not exceed a value that is programmable. The SIM module provides a 32-bit Block Wait Timer that can be used to identify when the BWT has been violated (divided in two registers).
- Block Guard Time
 - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The block guard must be greater than a value that is programmable. The SIM module provides a 16-bit Block Guard Timer that can be used to identify when the BGT has been violated.
- Error Detection Code
 - "T=1" cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operations.

11.2.4.3 Using the SIM Transmitter

Once the SIM has been properly configured (such as data XMT enabled, correct baud rate, and correct data format), the transmitter can be enabled by setting the XMT_EN bit in the ENABLE register. If data had been previously written to the transmit FIFO, the transmitter will begin to send the first character. If no data is written to the transmit FIFO before enabling the transmitter, then the transmitter will wait until the first character is written before beginning transmission. Clearing the XMT_EN bit while the transmitter is in operation, will halt any transmission in progress, flush the transmit FIFO, and reset the transmit state machine.

Data can be written to the transmit FIFO at any time.

The transmit data threshold flag, TDTF, in the XMT_STATUS register can be used to determine when the transmit FIFO has reached a given threshold value. This flag will create an interrupt if the TDTFM bit in the INT_MASK register is clear. To control at which point TDTF is set, program the transmit data threshold, TDT[3:0], in the XMT_THRESHOLD register. If the number of bytes remaining in the transmit FIFO is equal to or less than the value set by TDT[4:0], TDTF will be set.

NOTE

A value of 0x0 in TDT[3:0] implies that the transmit FIFO must be empty to trigger TDTF.

The value in TDT[3:0] can be changed at any time to alter this threshold level. The comparison between the number of remaining bytes in the transmit FIFO and the value set by TDT[3:0] is continuously updated so that any change in either will be immediately reflected in the state of TDTF. Unlike the RDRF flag for the receive FIFO, TDTF is latched and remains set until the software writes a 1 to the TDTF bit location in the XMT_STATUS register. For instance, if TDT[3:0] is set to 5, and there are 6 bytes remaining in the FIFO, changing TDT[3:0] to 6 will immediately cause TDTF to be set. However, setting TDT[3:0] back to 5 will not cause TDTF to clear.

The standard flow for transmitting bytes from the SIM card is to set TDT[3:0] to the appropriate value, write up to 16 bytes to the transmit FIFO, enable the transmitter, wait for TDTF to cause an interrupt (TDTFM clear), and then write additional bytes to the transmit FIFO.

NOTE

For the SIM module to transmit successfully, the transmit pin must be connected to the receive pin of the same port. This connection is necessary for the SIM to decode transmit NACKs sent to it by the SIM card. Without this connection, all transmissions will appear to have a NACK thereby causing the first byte to be transmitted continuously. When operating in

external one wire interface mode (3VOLT0 or 3VOLT1), this connection is made internal to the SoC.

11.2.4.3.1 Transmit Data Formats

There are two possible data formats that the SIM module uses when transferring data to the SIM: card - inverse convention or direct convention. The format used depends on the state of inverse convention bit (IC in the DATA_FORMAT register). Software can set the IC bit, or it can be set automatically by hardware when using the initial character mode.

11.2.4.3.2 Transmit NACK

The SIM transmitter can respond to NACKs created by the SIM card. A NACK will be decoded if the SIM card creates a logic low level on the SIM receive pin during the STOP bit time at the end of a transmitted byte. To prevent a situation where the SIM interface is stalled by an infinite number of NACK pulses on a given byte, the SIM module can be configured to limit the number of times it will respond to NACKs. The XTH[3:0] control field in the XMT_THRESHOLD register allows software to set a threshold on the number of times a given byte will be retransmitted. If the threshold is reached, a transmit threshold error, XTE in the XMT_STATUS register, is asserted.

When XTE is set, the SIM transmitter is halted, and all pending transfers are aborted, and the TC, ETC, AND TFE flags are set. All bytes remaining in the transmit FIFO are lost. There is no way to restart the transmission on the next byte in the FIFO. The transmitter remains frozen until XTE is cleared by software. The only way to clear XTE is to write a 1 to the XTE bit in the XMT_THRESHOLD register. The XTE flag can create an interrupt if the XTM mask in the XMT_THRESHOLD register is clear.

It is possible to disable the detection of NACKs from the SIM card by setting XTH[3:0] to 0x0. By setting XTH[3:0] to 0x1, it is possible to disable all retransmissions while still setting XTE on the first NACK received. In general, XTE is set on the NACK that causes the threshold set by XTH[3:0] to be reached. This final NACK will not cause a retransmission, whereas all previous NACKs will cause a retransmission.

11.2.4.3.3 Transmit Guard Time

The time between data bytes sent from the SIM transmitter can be altered using the transmit guard time control. By default, the minimum time between start bits of successive transmitted bytes is 12 ETUs (Elementary Time Units). An ETU is equivalent in time to 1 bit time. Therefore, the amount of time an ETU consumes is determined by the baud rate chosen. The 12 ETUs that form the default character transmission time consist of a start bit, 8 data bits, a parity bit and two stop bits. The number of stop bits (idle bits) can be extended by an integer number of ETUs. The number of additional

ETUs can be programmed directly into the GETU[7:0] bits of the GUARD_CNTL register. Programming the GETU[7:0] bits to 0xFF will configure the SIM transmitter to use only one stop bit for each character transmission.

11.2.4.3.4 Using SIM Transmit with "T=1" SIM Cards

The SIM module provides hardware support for "T=1" type SIM cards. These type of cards present several requirements above and beyond the standard "T=0" cards. The features provided to meet the requirements that pertain to the SIM transmitter are as follows:

- 11 ETU Characters
 - The SIM module transmitter has a programmable guard time register that allows the programmer to specify the number of ETUs between character transmissions. Programming a value of 255 (0xFF) in the GETU[7:0] bits in the GUARD_CNTL register will set the number of ETUs per character transmitted to 11.
- Character Waiting Time
 - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters. The value of CWT can range from 12 ETU to 32779 ETU. The time between transmitted characters is controlled by the programmable guard time in the GUARD_CNTL register. However, the time between the last byte in the transmit FIFO, and the next transmitted byte can be largely affected by software response time to the transmit interrupts. The SIM transmitter provides a Transmit FIFO threshold (TDTF) interrupt to signal the system when the expected number of characters have been transmitted from the transmit FIFO. The minimum CWT is achieved only if the software can respond to the TDTF interrupt and write new data to the transmit FIFO before the last character in the Transmit FIFO has been sent.
- Block Waiting Time
 - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BWT is always greater than 1800 ETU. The SIM transmitter provides a General Purpose Counter that can be used to track the BWT. The BWT is purely determined by software response time to the transmit interrupts.
- Block Guard Time
 - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BGT is 22 ETU. The SIM module supports the BGT by providing the ability to generate an interrupt when the last byte is received, and transmitting within 2 ETU after the XMT_EN bit is set. The BGT

will be determined by the speed at which the software can react to an interrupt and enable the transmitter.

- Error Detection Code
 - "T=1" cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operation.

11.2.4.4 Suggested "T=1" Compliant Programming Model

This section describes the suggested programming model for supporting "T=1", "T=0", and known "special" cards using the SIM module on the device. This should be used as a rough guide for how to configure the SIM module for use with SIM cards specified by ISO 7816-3 and EMV. Some details are not addressed. Other uses for some of the SIM features are not included (for example, GP Counter uses for some ISO timing requirements).

11.2.4.4.1 Answer To Reset (ATR) Detection

The first step to communicating with a SIM card is to provide power and a clock signal to the card. Once the card is detected as present (using the presence detect features, or some other method), the SIM card should be powered up according to the power up sequence specified in the ISO 7816-3 specification.

1. Apply voltage to the SIM card by setting the SVEN0 or SVEN1 bit in the PORTx_CNTL register
2. Select the appropriate clock frequency for the SIM card by programming the CLK_PRESCALER[7:0] register.
3. Enable the clock to the SIM card by setting the SCEN0 or SCEN1 bit in the PORTx_CNTL register.
4. Remove the card from reset by setting the SRST0 or SRST1 bit in the PORTx_CNTL register.

The first communication between the SIM card and the SIM module will be a block of data sent from the SIM card to the SIM module after the card is powered and the card reset is removed. This block is called the Answer To Reset (ATR). To receive the ATR, the SIM module should be configured for 12 ETU character reception. According to the ISO 7816-3 spec, both "T=0" and "T=1" cards will communicate initially using 12 ETU character durations.

NOTE

We are aware of some card manufacturers that communicate at 11.5 ETU character durations (Geldkarte).

This will complicate the initial card detection sequence shown below.

5. Clear RCVR11 bit in the GUARD_CNTL register

The next item to configure for ATR reception is the NACK capability of the SIM module. The ISO 7816-3 spec allows the SIM module to NACK any communication errors that occur during the initial communication at 12 ETU.

NOTE

The Europay Mastercard and VISA (EMV) cards are similar to "T=1", but do not allow the SIM module to NACK during the initial communication. This will again complicate the initial card detection sequence shown below.

6. Set ANACK bit in the CNTL register to enable NACK generation

In order for the SIM module to notify when characters are received, the receive interrupt(s) can be enabled. A threshold can be set for the number of characters to receive before generating an interrupt.

7. Enable RDRF and OEF interrupts by setting RIM and OIM bits in INT_MASK register

8. Set desired threshold for received characters by writing RDT in RCV_THRESHOLD register.

The SIM should be setup to perform in initial character mode. This will cause the hardware to identify the first valid character sent during the ATR as an initial character. This character will automatically configure the hardware for the data convention used by the SIM card.

9. Set Initial Character Mode by setting the ICM bit in the CNTL register

The ISO 7816-3 spec requires that SIM cards meet certain timing restrictions. One of these is the time from the deassertion of the card reset to the beginning of the ATR sequence. The SIM module General Purpose Counter can be used to verify that the SIM card begins its ATR within the 400 to 40,000 clock cycle range.

1. Set General Purpose Counter Comparator to 0x9C40 using GPCNT register.

2. Enable General Purpose Counter Interrupt by clearing GPCNTM in INT_MASK register.

3. Enable General Purpose Counter by programming the GPCNT_CLKSEL[1:0] bits to 01 so the card clock is used for counting.

The ISO7816-3 spec states that the maximum allowed time between two characters during the ATR is 9600 ETUs (Initial Waiting Time). The Character Wait Time Counter should be setup to detect any errors for this condition.

1. Set Character Wait Time Counter Comparator to 9600 using the CHAR_WAIT register
2. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT_MASK register
3. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register

The last step in preparing for ATR reception is to enable the receiver.

4. Set RCV_EN bit in ENABLE register

The SIM module will generate interrupts once a threshold number of characters is received. The software should react to these interrupts and read the characters from the receive FIFO (RCV_BUF) until the complete ATR has been received. If a General Purpose Counter interrupt occurs before the final ATR character is received, then the card should be deactivated according to the ISO 7816-3 spec. Otherwise, once a valid ATR is received, the software will know from the ATR information the specific characteristics for this card (refer to the ISO 7816-3 spec for details).

11.2.4.4.2 Programming Considerations for Geldkarte Cards

There is at least one manufacturer of SIM cards (Geldkarte) that we know of that does not send the ATR in 12 ETU mode or support NACKs. This creates an issue with detecting a valid ATR from a SIM card. Since any kind of card can be attached to the SIM module, the software and hardware do not know how to begin communication. Basically, if the card fails to send a valid ATR on the first try, disable NACKs, configure the SIM module for 11 ETU and try again. The software should toggle between 12 and 11 ETU modes with and without NACKs enabled until a valid ATR is received, or the number of attempts to communicate passes a predetermined error threshold. The figure below shows the flow chart for the suggested Geldkarte Compliant SIM Initialization.

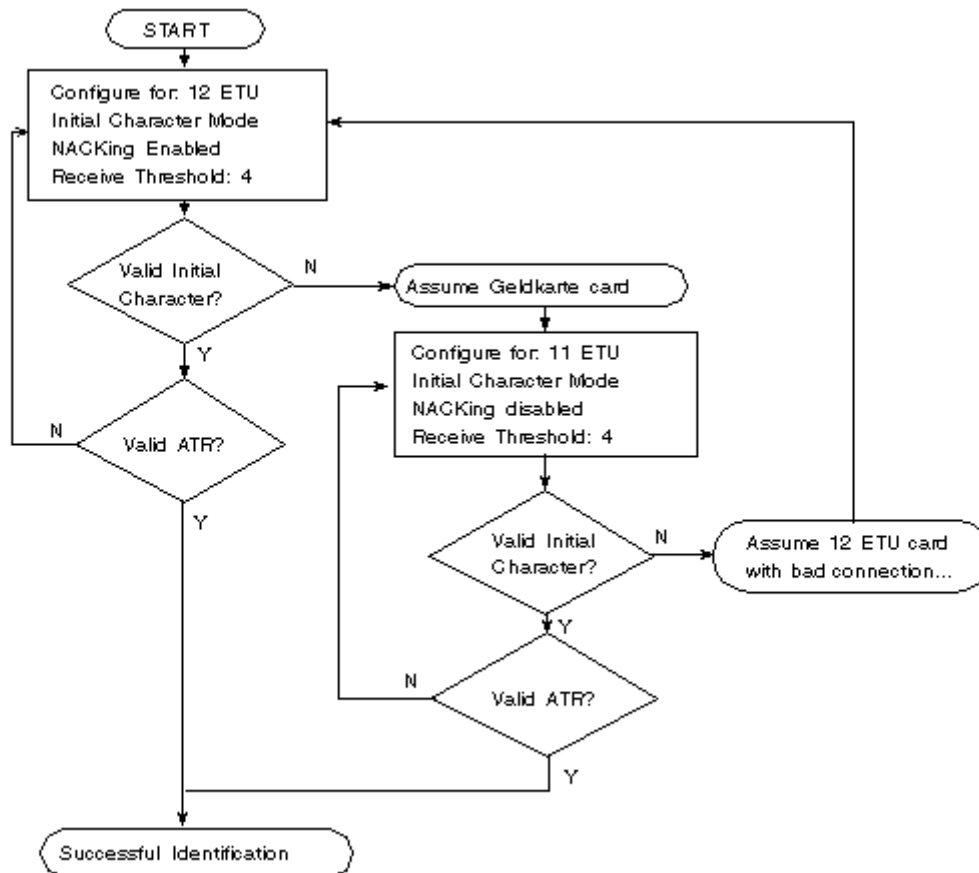

Figure 11-51. Suggested "T=1", EMV, Geldkarte Compliant SIM Initialization

11.2.4.4.3 Programming Considerations for T=0 SIM Cards

If the card is of type T=0, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD_CNTL register
3. Adjust NACK capability by modifying the values of the ONACK and ANACK bits in the CNTL register
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx_CNTL register
5. Adjust the level of transmit NACK re-transmissions allowed by modifying the value of the XTH[3:0] bits in the XMT_THRESHOLD register
6. Adjust the level for the Receive NACK threshold by modifying the RTH[3:0] bits in the RCV_THRESHOLD register.

If a negotiation with the SIM card is desired, the software sends a PPS response to the SIM card. To send the response, the following steps should be performed:

1. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT_THRESHOLD register
2. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT_BUF register
3. Clear all transmit interrupt flags in the XMT_STAT register by writing a one to them
4. Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
5. Enable the transmitter by setting the XMT_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=0 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

11.2.4.4.4 Programming Considerations for T=1 SIM Cards

If the card is of type T=1, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD_CNTL register. Setting GETU[7:0] to 0xFF configures the SIM transmitter for 11 ETU transmissions
3. Disable NACK capability by clearing the ONACK and ANACK bits in the CNTL register. T=1 cards do not allow NACKs.
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx_CNTL register
5. Set Character Wait Time Counter Comparator to value specified in the ATR by using the CHAR_WAIT register
6. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT_MASK register

7. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register
8. Enable CRC or LRC error checking according to the ATR information by setting either the CRCEN or LRCEN bit in the CNTL register. These bits will never be set at the same time!

For T=1 cards, the ATR is sent using a T=0 type of structure (12 ETU, no LRC or CRC). If a negotiation with the SIM card is desired, the software will send a PPS response to the SIM card. Otherwise, the protocol is initiated with a block transfer from the SIM module. In order to send the response or the first block, the following steps should be performed:

9. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT_THRESHOLD register
10. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT_BUF register
11. Clear all transmit interrupt flags in the XMT_STAT register by writing a 1 to them
12. Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
13. Enable the transmission of the error checking characters (LRC or CRC) by setting the XMT_CRC_LRC bit in the CNTL register.

NOTE

If the card supports PPS, the software may not be allowed to send the LRC/CRC information until the PPS exchange is completed. If so, do not set the XMT_CRC_LRC bit during the PPS exchange.

14. Enable the transmitter by setting the XMT_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=1 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

11.2.5 SIM Memory Map/Register Definition

SIM memory map

11.2.5.1 SIM Port1 Control Register (SIMx_PORT1_CNTL)

See the figure below for illustration of valid bits in the SIM Port1 Control Register and the table below for description of the bit fields.

Address: Base address + 0h offset

SIMx_PORT1_CNTL field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 SFPD1	Auto Power Down port1. Writing a "1" to this location will start the auto power down sequence for port 1. This bit will autoclear. A read of this bit will give a "0". 0 No effect 1 Start Auto Power down
6 VOLT3_1	External one wire interface for SIM Card port1. Used to configure the Port 1 transmit pin as bi-directional. This allows the Port 1 Receive pin to be re-used as General Purpose I/O. This operation is restricted to bi-directional data SIM cards only. This bit should not be changed while the receiver or transmitter is enabled! 0 Port1 uses both rcv and xmt pins 1 Port1 XMT pin bidirectional. Port1 RCV PIN unused

Table continues on the next page...

SIMx_PORT1_CNTL field descriptions (continued)

Field	Description
5 SCSP1	SIM Card Clock Stop Polarity Port1. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN1. It will be forced low by hardware during the auto power down sequence. This forces the clock be a logic 0 when stopped by auto power down as required by ISO 7816 spec. 0 Clock is logic 0 when stopped by SCEN1 1 Clock is logic 1 when stopped by SCEN1
4 SCEN1	SIM card Clock Enable Port 1. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 SIM Card Clock Disabled Port1 1 SIM Card Clock Enabled Port1
3 SRST1	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low. 0 SIM Card reset Port1 inactive (default) 1 SIM Card reset Port1 active
2 STEN1	SIM card Transmit Enable Port 1. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 Port1 Transmit Data is forced to zero (default) 1 Port 1 Transmit Data controlled by SIM module
1 SVEN1	SIM card Vcc Enable Port 1. Used to control the state of the SVEN1 pin on SIM card port 1. The SVEN1 pin controls the SIM card V _{CC} enable in the power management chip. It can be forced low by hardware during the auto power down sequence. 0 SIM card Voltage Port 1 disabled (default) 1 SIM card Voltage Port 1 enabled
0 SAPD1	SIM card Auto Power Down Port 1. Used to enable/disable the auto power down function for port 1. It will be forced low at the end of the auto power down sequence. 0 Auto power down Port 1 disabled (default) 1 Auto power down Port 1 enabled

11.2.5.2 SIM Setup Register (SIMx_SETUP)

See the figure below for illustration of valid bits in the SIM Setup Register and the table below for description of the bit fields.

Address: Base address + 4h offset

SIMx_SETUP field descriptions

Field	Description
31–2 -	This field is reserved. Reserved
1 SPS	SIM card Port Select. Controls which port the SIM interface uses. NOTE: The AMODE bit must be zero when the SPS bit is set to 1. 0 Port 0 Enabled (default) 1 Port 1 Enabled
0 AMODE	Alternate SIM Card Mode enable. Enables an alternate SIM module to control SIM card Port 1. NOTE: The SPS bit must be 0 to give the alternate SIM module control. 0 Alternate Port Disabled (default) 1 Alternate Port Enabled

11.2.5.3 SIM Port 1 Detect Register (SIMx_PORT1_DETECT)

See the figure below for illustration of valid bits in the SIM Port1 Detect Register and the table below for description of the bit fields.

Summary:

spds1 determines which edge transition of the SIMPD1 pin is used for SIM card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the SIMPD1 edge specified by spds1 will cause the following: sdi1 to be set; if the sdim1 mask is clear, an interrupt on SIMIRQ_N; and if sapd1 in the PORT1_CNTL register is set, an auto power down sequence to begin. If SIM card insertion is expected, sapd1 can be set low to avoid the auto power down sequence. There is no auto power up sequence. The bit spdp1 can be used to determine the current state of the SIMPD1 pin.

Address: Base address + 8h offset

SIMx_RCV_BUF field descriptions

Field	Description
31–11 -	This field is reserved. Reserved
10 CWT	CWT flag. The CWT indicates that this byte was late. It is not necessary to clear the byte since it is overwritten by the next byte received into that location of the FIFO. 0 Byte was on time 1 Byte was late
9 FE	Frame Error flag. The FE flag indicates whether a frame error was detected during the reception of the corresponding byte read in the RCV field. The FE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO. 0 Byte contains no framing error (default) 1 Byte contains a framing error
8 PE	Parity Error flag. The PE flag indicates whether a parity error was detected during the reception of the corresponding byte read in the RCV field. The PE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO. A parity error can create a NACK pulse. 0 Byte contains no parity error (default) 1 Byte contains a parity error
RCV	Receive buffer. Read from the next location in the receive buffer.

11.2.5.6 SIM Port0 Control Register (SIMx_PORT0_CNTL)

See the figure below for illustration of valid bits in the SIM Port0 Control Register and the table below for description of the bit fields.

Address: Base address + 14h offset

SIMx_PORT0_CNTL field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 SFPD0	Auto Power Down port0. Writing a "1" to this location will start the auto power down sequence for port 0. This bit will autoclear. A read of this bit will give a "0". 0 No effect 1 Start Auto Power down
6 VOLT3_0	External one wire interface for SIM Card port0. Used to configure the Port 0 transmit pin as bi-directional. Only bi-directional data SIM cards are supported. Hence user should program this bit to 1. This bit should not be changed while the receiver or transmitter is enabled! Port0 uses both RCV and XMT pins 1 Port0 XMT pin bidirectional. Port0 rcv pin unused

Table continues on the next page...

SIMx_PORT0_CNTL field descriptions (continued)

Field	Description
5 SCSP0	SIM Card Clock Stop Polarity port0. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN0. It will be forced low by hardware during the auto power down sequence. This forces the clock to be a logic 0 when stopped by auto power down as required by ISO 7816 spec. 0 Clock is logic 0 when stopped by scen0 1 Clock is logic 1 when stopped by scen0
4 SCEN0	SIM card Clock Enable Port 0. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 SIM Card Clock Disabled Port 0 1 SIM Card Clock Enabled Port 0
3 SRST0	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low. 0 SIM Card reset Port0 inactive (default) 1 SIM Card reset Port0 active
2 STEN0	SIM card Transmit Enable Port 0. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 Port0 Transmit Data is forced to zero (default) 1 Port 0 Transmit Data controlled by SIM module
1 SVEN0	SIM card V _{CC} Enable Port 0. Used to control the state of the SVEN0 pin on SIM card port 0. The SVEN0 pin controls the SIM card V _{CC} enable in the power management chip. It can be forced low by hardware during the auto power down sequence. 0 SIM card Voltage Port 0 disabled (default) 1 SIM card Voltage Port 0 enabled
0 SAPD0	SIM card Auto Power Down Port 0. Used to enable/disable the auto power down function for port 0. It will be forced low at the end of the auto power down sequence. 0 Auto power down Port 0 disabled (default) 1 Auto power down Port 0 enabled

11.2.5.7 SIM Control Register (SIMx_CNTL)

See the figure below for illustration of valid bits in the SIM Control Register and the table below for description of the bit fields.

Address: Base address + 18h offset

SIMx_CNTL field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 BWTEN	Block wait time enable. Writing a "1" to this bit will enable the bwt and bgt functions. The bwt and bgt functions can then be individually selected using the interrupt mask. 0 Disable BWT, BGT 1 Enable BWT, BGT
14 xmt_crc_lrc	Transmit CRC or LRC. This bit specifies whether or not to transmit the redundancy checking data at the end of a transmission (that is, when the FIFO becomes empty). 0 No Redundancy check info transmitted (default) 1 Transmit LRC or CRC info when FIFO empties (whichever is enabled)
13 CRCEN	CRC Enable. This bit enables the calculation of the 16-bit CRC value for both receiver and transmitter. The result of the calculation is continuously compared to the expected remainder and reflected in the

Table continues on the next page...

SIMx_CNTL field descriptions (continued)

Field	Description
	<p>crcook bit in the RCV_STAT register. Clearing this bit resets the current CRC residual value in the SIM hardware.</p> <p>0 16-bit Cyclic Redundancy Checking disabled (default) 1 16-bit Cyclic Redundancy Checking enabled</p>
12 LRCEN	<p>LRC Enable. This bit enables the calculation of the 8-bit LRC value for both receiver and transmitter. The result of the calculation is continuously compared to zero and reflected in the lrcok bit in the RCV_STAT register. Clearing this bit resets the current LRC value in the SIM hardware.</p> <p>0 8-bit Linear Redundancy Checking disabled (default) 1 8-bit Linear Redundancy Checking enabled</p>
11 CWTEN	<p>Character Wait Time Counter Enable. Enables the character wait time counter. Clearing this bit resets the counter to zero.</p> <p>0 Character Wait time Counter off (default) 1 Character Wait time counter on</p>
10–9 gpcnt_clk_sel	<p>General Purpose Counter Clock Select. Selects which clock source is used by SIM Module general purpose counter. The only way to reset the counter is to set these bits to zero. The counter will begin counting as soon as the clock input is selected and the clocks are enabled. These input clocks are enabled through other register bits of the SIM module (KILL_CLOCK, RCV_EN, and XMT_EN respectively).</p> <p>00 Disabled / Reset 01 Card Clock 10 Receive Clock 11 ETU Clock (transmit clock)</p>
8–6 baud_sel[2:0]	<p>SIM Baud Rate Select. Selects the asynchronous baud rate divisor of the clock. When set to "111", the divisor is set to the value programmed in the DIVISOR register. This allows for more flexible baud rate determination.</p> <p>000 31 (512/1 Fi/Di) 001 32 (512/2 Fi/Di) 010 16 (512/4 Fi/Di) 011 8 (512/8 Fi/Di) 100 4 (512/16 Fi/Di) 101 2 (512/32 Fi/Di) 110 1 (512/64 Fi/Di) 111 DIVISOR Reg</p>
5 Sample12	<p>Sample12. Set the third stage divider. This sets the corresponding sample rate which is the number of times a bit being received is sampled.</p> <p>0 divide by 8(default) 1 divide by 12</p>
4 -	<p>This field is reserved. Reserved</p>
3 ONACK	<p>Overrun NACK Enable. Enables overrun NACK generation.</p> <p>0 NACK generation on overrun is disabled (default) 1 NACK generation on overrun is enabled</p>

Table continues on the next page...

SIMx_CNTL field descriptions (continued)

Field	Description
2 ANACK	Automatic NACK Enable. Enables nack generation for parity errors or invalid initial characters when in ICM mode. 0 NACK generation on errors disabled 1 NACK generation on errors enabled (default)
1 ICM	Initial Character Mode. Enables initial character mode. Will be automatically cleared by hardware once a valid initial character is received. 0 Initial Character Mode disabled 1 Initial Character Mode enabled (default)
0 -	This field is reserved. Reserved

11.2.5.8 SIM Clock Prescaler Register (SIMx_CLK_PRESCALER)

See the figure below for illustration of valid bits in the SIM Clock Prescaler Register and the table below for description of the bit fields.

Address: Base address + 1Ch offset

SIMx_CLK_PRESCALER field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
CLK_ PRESCALER	Clock prescaler divisor register. The value written to this register will determine the first stage divider setting. If the ipg_perclk is 66Mhz, a typical setting would be 0x0e. This would set the SIM card clock to 66Mhz/14 = 4.7Mhz. The duty cycle of divided clock will be between 45% and 55% according to ISO7816 requirement. For the odd divider factor (2K+1), the duty cycle will be K/(2K+1) and (K+1)/(2k+1). So for 0x03, the duty cycle is 33%-66%. For 0x05, the duty cycle is 40%-60%. For 0x07, the duty cycle is 43%-57%, and for 0x09, the duty cycle is 44%-56%. For all other values, the clock duty cycle can meet the ISO7816 requirement. NOTE: Not all values are listed 0x00 ~0x02 ipg_perclk / 2 0x03 ipg_perclk / 3 0x04 ipg_perclk / 4 0x05 ipg_perclk / 5 0x06 ipg_perclk / 6 0xFD ipg_perclk / 253

Table continues on the next page...

SIMx_CLK_PRESCALER field descriptions (continued)

Field	Description
0xFE	ipg_perclk / 254
0xFF	ipg_perclk / 255

11.2.5.9 SIM Receive Threshold Register (SIMx_RCV_THRESHOLD)

See the figure below for illustration of valid bits in the SIM Receive Threshold Register and the table below for description of the bit fields.

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																RTH[3:0]			RDT[8:0]												
W	Reserved																RTH[3:0]			RDT[8:0]												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

SIMx_RCV_THRESHOLD field descriptions

Field	Description
31–13 -	This field is reserved. Reserved
12–9 RTH[3:0]	Receive Nack Threshold. Used to specify the number of consecutive NACK's transmitted by the SIM module, for a given character, before the receive threshold error (RTE) flag is triggered. A value of 0 indicates that RTE is never set. When a valid character is received by the SIM, the internal counter keeping track of the NACK count resets to zero for the subsequent byte being received. If the ANACK bit is clear in the CNTL register, RTH has no effect.
RDT[8:0]	Receive Data Threshold. Determines the number of unread bytes that must exist in the FIFO to trigger the receive data register full (RDRF) interrupt flag. If the number of unread bytes in the receive FIFO is greater than or equal to the value in RDT, the RDRF flag in the RCV_STATUS register will be set. A value of zero indicates that there must be 288 unread bytes in the FIFO to trigger RDRF. If a value of more than 288 is entered in this register, the register value will remain 288.

11.2.5.10 SIM Enable Register (SIMx_ENABLE)

See the figure below for illustration of valid bits in the SIM Enable Register and the table below for description of the bit fields.

Address: Base address + 24h offset

SIMx_ENABLE field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 RXCL	Reception data latch disable. Used to disable/enable the cross clock domain synchronization operation of reception data in SIM receive state machine. 0 Enable the synchronization operation. 1 Disable the synchronization operation.
6 ESTOP_EXE	Enforce reception early stop execution. Used to execute the function of enforce reception early stop when ESTOP_EN bit set to 1. If this bit is 0 the early stop function can't be executed when NACK signal occur. 0 Enforce reception early stop function will be executed without NACK. 1 Enforce reception early stop function will be executed at all times.
5 ESTOP_EN	Enforce reception early stop enable. Used to early stop the SIM receive state machine. The state machine will stop earliey than 10.8 ETUs when 11 ETUs mode or earlier than 11.8 ETUs when non 11 ETUs mode, if enable this bit. This function is used for the test case transmission stop at 10.8 ETUs from the falling edge of start signal. NOTE: This bit should be set to 1 when receive data, and set to 0 when transmit data. 0 Disable the enforce reception early stop function. 1 Enable the enforce reception early stop function.
4 NACK_DD_EN	NACK delay detection enable. Used to enable/disable the function of NACK delay detection. The SIM receive state machine will detect the NACK signal at the 16th phase and use the values of 12th, 14th and

Table continues on the next page...

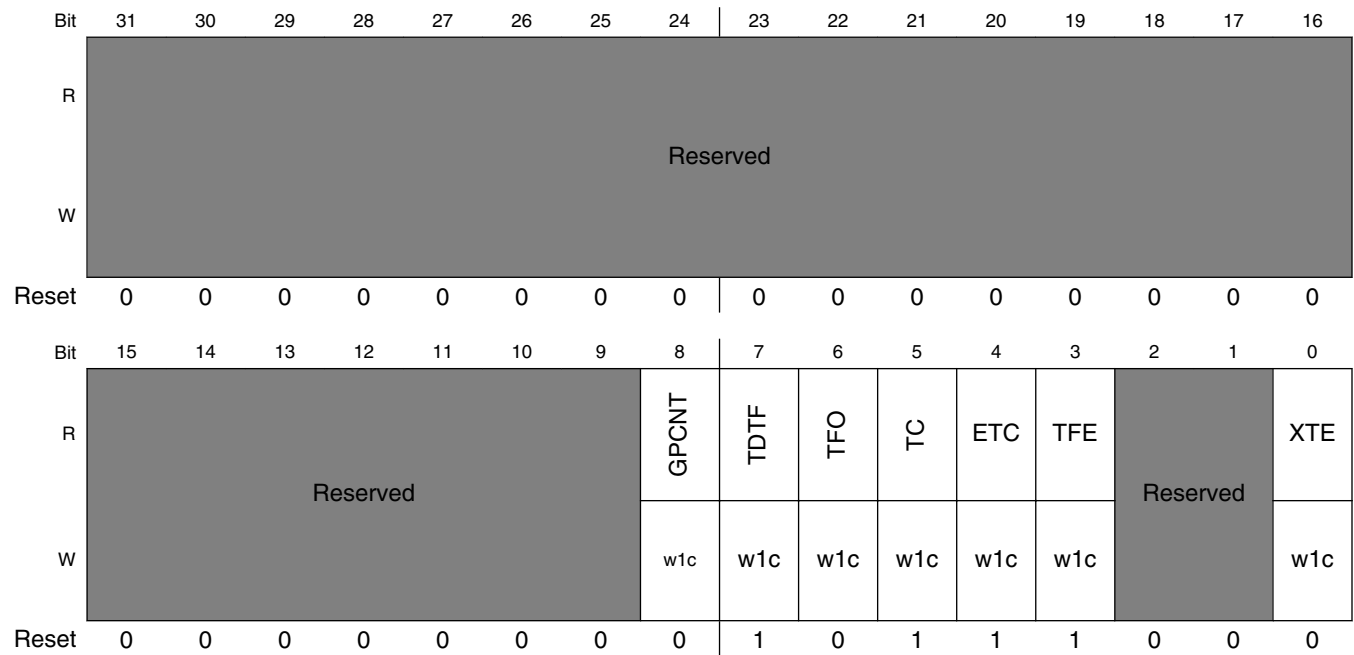

SIMx_ENABLE field descriptions (continued)

Field	Description
	15th sample point, if enable this bit. This function is used for the test case NACK signal send at 10.7 ETUs from the falling edge of start signal. 0 Disable the delay detection function. 1 Enable the delay detection function.
3 TXDMA_EN	Transmitter DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the tdt[3:0] bits in the XMT_THRESHOLD register and XMT_EN is set. 0 SIM Transmitter DMA requests disabled. 1 SIM Transmitter DMA requests enabled.
2 RXDMA_EN	Receiver DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when the number of bytes in the receive FIFO is more than or equal to the value programmed in the RDT[8:0] in the RCV_THRESHOLD register and RCV_EN is set 0 SIM Receiver DMA request disabled. 1 SIM Receiver DMA request enabled.
1 XMT_EN	SIM Transmit Enable. Used to enable/disable the SIM transmit state machine. When the SIM is being used to receive data, XMT_EN should be deasserted. This bit also enables the xmt_clk and rcv_clk inputs to the General Purpose Counter. NOTE: Setting this bit (transition from 0 to 1) will reset the CRC and LRC values. 0 SIM Transmitter disabled (default) 1 SIM Transmitter enabled
0 RCV_EN	SIM Receiver Enable. Used to enable/disable the SIM receive state machine. The RCV_EN bit should be left high whenever the SIM module is in use. The SIM module has an automatic receive mode operation that disables the reception of characters when the transmitter is operational. Once the transmitter has completed sending the last character, the receiver is automatically enabled. This bit also enables the RCV_CLK input to the General Purpose Counter. 0 SIM Receiver disabled (default) 1 SIM Receiver enabled

11.2.5.11 SIM Transmit Status Register (SIMx_XMT_STATUS)

See the figure below for illustration of valid bits in the SIM Transmit Status Register and the table below for description of the bit fields.

Address: Base address + 28h offset

SIMx_XMT_STATUS field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
8 GPCNT	General purpose Counter Flag. Used to indicate when the General purpose counter has reached the value in the GPCNT register. 0 GPCNT time not reached, or bit has been cleared. (default). 1 General Purpose counter has reached the GPCNT value.
7 TDTF	Transmit Data Threshold Flag. Used to indicate when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the tdt[3:0] bits in the XMT_THRESHOLD register. 0 Number of bytes in FIFO is greater than tdt[3:0], or bit has been cleared. 1 Number of bytes in FIFO is less than or equal to tdt[3:0] (default)
6 TFO	Transmit FIFO Overfill Error. Used to indicate when the Transmit FIFO has been written with more than 16 bytes. The tfo bit can only be cleared by setting the flush_xmt or soft_reset bit in the RESET_CNTL register. 0 No transmit FIFO overfill error has occurred (default). 1 A Transmit FIFO overfill error has occurred.

Table continues on the next page...

SIMx_XMT_STATUS field descriptions (continued)

Field	Description
5 TC	<p>Transmit Complete. Used to indicate whether the SIM transmitter is ready for a new transmission. The tc flag becomes set after the guard time has expired for the last byte in the transmit FIFO. The tc flag will create an interrupt if tcim in the INT_MASK register is low. The tc bit is a write-one-to-clear bit.</p> <p>0 Transmit pending or in progress 1 Transmit complete (default)</p>
4 ETC	<p>Early Transmit Complete. Used to indicate that the SIM transmitter has finished sending the current byte and the transmit FIFO is empty. This bit differs from the tc bit in that it is set before the guard time of the last byte has elapsed. The ETC flag will create an interrupt if ETCIM in the INT_MASK register is low. The ETC bit is a write-one-to-clear bit.</p> <p>0 Transmit pending or in progress 1 Transmit complete (default)</p>
3 TFE	<p>Transmit FIFO Empty. Used to indicate that the SIM transmit FIFO has emptied. This bit will be set when the last byte in the transmit FIFO has been transferred to the SIM transmitter shift register. The TFE flag will create an interrupt if TFEIM in the INT_MASK register is low. The TFE bit is a write-one-to-clear bit.</p> <p>0 Transmit FIFO is not empty 1 Transmit FIFO is empty (default)</p>
2-1 -	<p>This field is reserved. Reserved</p>
0 XTE	<p>Transmit NACK Threshold Error. Used to indicate the transmit NACK threshold has been reached. When XTE is high, no further transmissions will be done until the XTE flag is cleared. Any data transmissions still pending in the transmit FIFO will be aborted, and the TC, ETC, and TFE flags will be set. The XTE flag will create an interrupt if XTEIM in the INT_MASK register is low. The XTE bit is a write-one-to-clear bit.</p> <p>0 Transmit NACK threshold has not been reached (default) 1 Transmit NACK threshold reached; transmitter frozen</p>

11.2.5.12 SIM Receive Status Register (SIMx_RCV_STATUS)

See the figure below for illustration of valid bits in the SIM Receive Status Register and the table below for description of the bit fields.

Address: Base address + 2Ch offset

SIMx_RCV_STATUS field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11 BGT	Block guard time error flag. Used to indicate if the block guard time was too small. The threshold is set by the block guard time register. 0 Block guard time was sufficient. 1 Block guard time was too small.
10 BWT	Block wait time error flag. Used to indicate if the block wait time has been exceeded. The threshold is set by the block wait time registers. 0 Block wait time not exceeded. 1 Block wait time was exceeded.
9 RTE	Receive NACK threshold error flag. Used to indicate whether the number of consecutive NACKs generated by the SIM module in response to receive parity errors, for the byte being received, equals the

Table continues on the next page...

SIMx_RCV_STATUS field descriptions (continued)

Field	Description
	<p>value programmed in the RTH[3:0] in the RCV_THRESHOLD register. This bit would never be set unless the ANACK bit is set in the CNTL register. The SAPDx bit in the PORTx_CNTL register must be set to enable the threshold error to trigger the auto power down sequence. RTE is a write-one-to-clear bit. Clearing this bit also resets the internal counter for consecutive NACKs being transmitted for a given byte.</p> <p>0 Number of NACKs generated by the receiver is less than the value programmed in RTH[3:0] 1 Number of NACKs generated by the receiver is equal to the value programmed in RTH[3:0]</p>
8 CWT	<p>Character Wait Time Counter Flag. Used to indicate when the time between received characters is equal to or greater than the value programmed in the CHAR_WAIT register.</p> <p>0 No CWT violation has occurred (default). 1 Time between two consecutive characters exceeded the value in CHAR_WAIT.</p>
7 CRCOK	<p>Cyclic Redundancy Check Okay flag. Used to indicate when the calculated 16-bit CRC value matches the expected value for the current input data stream. The value is calculated across all received characters from the point the CRCEN bit is set in the CNTL register. The current CRC residual can be reset by three mechanisms:</p> <p>Clear CRCEN bit in CNTL register Set XMT_EN bit in ENABLE register Automatically by hardware when ETC flag is set at the end of a transmission.</p> <p>0 Current CRC value does not match remainder. 1 Current calculated CRC value matches the expected result.</p>
6 LRCOK	<p>Linear Redundancy Check Okay flag. Used to indicate when the calculated 8-bit LRC value is zero value for the current input data stream. The value is calculated across all received characters from the point the LRCEN bit is set in the CNTL register. The current LRC residual can be reset by three mechanisms:</p> <p>Clear LRCEN bit in CNTL register Set XMT_EN bit in ENABLE register Automatically by hardware when ETC flag is set at the end of a transmission.</p> <p>0 Current LRC value does not match remainder. 1 Current calculated LRC value matches the expected result (that is, zero).</p>
5 RDRF	<p>Receive Data Register Full. Used to indicate when the number of bytes in the receive FIFO is more than or equal to the value programmed in the RDT[8:0] in the RCV_THRESHOLD register.</p> <p>0 Number of unread bytes in receive buffer < value set by RDT[8:0] (default), or bit has been cleared. 1 Number of unread bytes in receive buffer >= value set by RDT[8:0].</p>
4 RFD	<p>Receive FIFO has unread Data. Used to indicate that there is at least one unread byte in the receive data FIFO. Can only be cleared by reading all bytes out of the receive FIFO. The RFD bit cannot be used to create an interrupt. Normally, the SIM triggers the interrupt with RDRF and software uses rfd to read all of the bytes out of the receive FIFO.</p> <p>0 There are no unread bytes in the receive FIFO (default). 1 There is at least one unread byte in the receiver FIFO.</p>
3–2 -	<p>This field is reserved. Reserved</p>
1 RFE	<p>Receive FIFO Empty. Used to indicate that the SIM receive FIFO has emptied. This bit will be set when the last byte in the receive FIFO has been transferred to the IPS bus. The RFE flag will create an interrupt if RFEIM in the INT_MASK register is low. The RFE bit is a write-one-to-clear bit.</p>

Table continues on the next page...

SIMx_RCV_STATUS field descriptions (continued)

Field	Description
	0 Receive FIFO is not empty 1 Receive FIFO is empty (default)
0 OEF	Overflow Error Flag. Used to indicate that the SIM was unable to store received data due to already having 288 unread bytes in the FIFO. It does not necessarily indicate that data has been lost. If the ONACK control bit in the CNTL register is set, there will be a NACK pulse generated on bytes that would otherwise cause a loss of data due to a full FIFO. These bytes should be retransmitted by the SIM card which implies that no data has actually been lost. In this case, the OEF flag is just an indicator that this situation has occurred which may be helpful in system debug. For the case where ONACK is not set, a set OEF flag does indicate a loss of data since all bytes received with the OEF flag set will indeed be lost (including the byte that caused the bit to be set). The OEF flag will cause an interrupt if the oim bit in the INT_MASK register. The OEF flag is a write-one-to-clear bit. 0 No overrun error has occurred (default). 1 A byte was received when the received FIFO was already full.

11.2.5.13 SIM Interrupt Mask Register (SIMx_INT_MASK)

See the figure below for illustration of valid bits in the SIM Interrupt Mask Register and the table below for description of the bit fields.

Address: Base address + 30h offset

SIMx_INT_MASK field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
13 RFEM	Receive fifo empty interrupt mask. Used to enable/disable the ability of the RFE flag in the RCV_STATUS register to generate SIM interrupts.

Table continues on the next page...

SIMx_INT_MASK field descriptions (continued)

Field	Description
	0 RFE interrupt enabled 1 RFE interrupt masked (default)
12 BGTM	Block guard time interrupt mask. Used to enable/disable the ability of the bgt flag in the RCV_STATUS register to generate SIM interrupts. 0 BGT interrupt enabled 1 BGT interrupt masked (default)
11 BWTM	Block wait time interrupt mask. Used to enable/disable the ability of the bwt flag in the RCV_STATUS register to generate SIM interrupts. 0 BWT interrupt enabled 1 BWT interrupt masked (default)
10 RTM	Receive Nack threshold interrupt mask. Used to enable/disable the ability of the RTE flag in the RCV_STATUS register to generate SIM interrupts. 0 RTE interrupt enabled 1 RTE interrupt masked (default)
9 CWTM	Character Wait Time Interrupt Mask. Used to enable/disable the ability of the CWT flag in the RCV_STATUS register to generate SIM interrupts. 0 CWT interrupt enabled 1 CWT interrupt masked (default)
8 GPCNTM	General Purpose Counter Interrupt Mask. Used to enable/disable the ability of the GPCNT flag in the XMT_STATUS register to generate SIM interrupts. 0 GPCNT interrupt enabled 1 GPCNT interrupt masked (default)
7 TDTFM	Transmit Data Threshold Interrupt Mask. Used to enable/disable the ability of the TDTF flag in the XMT_STATUS register to generate SIM interrupts. 0 TDTF interrupt enabled 1 TDTF interrupt masked (default)
6 TFOM	Transmit FIFO Overfill Error Interrupt Mask. Used to enable/disable the ability of the TFO flag in the XMT_STATUS register to generate SIM interrupts. 0 TFO interrupt enabled 1 TFO interrupt masked (default)
5 XTM	Transmit Threshold Interrupt Mask. Used to enable/disable the ability of the XTE flag in the XMT_STATUS register to generate SIM interrupts 0 XTE interrupt enabled 1 XTE interrupt masked (default)
4 TFEIM	Transmit FIFO Empty Interrupt Mask. Used to enable/disable the ability of the TFE flag in the XMT_STATUS register to generate SIM interrupts. 0 TFE interrupt enabled 1 TFE interrupt masked (default)
3 ETCIM	Early Transmit Complete Interrupt Mask. Used to enable/disable the ability of the ETC flag in the XMT_STATUS register to generate SIM interrupts.

Table continues on the next page...

SIMx_INT_MASK field descriptions (continued)

Field	Description
	0 ETC interrupt enabled 1 ETC interrupt masked (default)
2 OIM	Overrun Interrupt Mask. Used to enable/disable the ability of the OEF flag in the RCV_STATUS register to generate SIM interrupts. 0 OEF interrupt enabled 1 OEF interrupt masked (default)
1 TCIM	Transmit Complete Interrupt Mask. Used to enable/disable the ability of the TC flag in the XMT_STATUS register to generate SIM interrupts. 0 TC interrupt enabled 1 TC interrupt masked (default)
0 RIM	Receive Interrupt Mask. Used to enable/disable the ability of the RDRF flag in the RCV_STATUS register to generate SIM interrupts. 0 RDRF interrupt enabled 1 RDRF interrupt masked (default)

11.2.5.14 SIM Port0 Detect Register (SIMx_PORT0_DETECT)

See the figure below for illustration of valid bits in the SIM Port0 Detect Register and the table below for description of the bit fields.

SPDS0 determines which edge transition of the SIMPD0 pin is used for SIM card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the SIMPD0 edge, specified by SPDS0, will cause the following:

- SDI0 to be set
- If the SDIM0 mask is clear, an interrupt to occur on SIMIRQ_N
- If SAPD0 in the PORT0_CNTL register is set, auto power down sequence will begin

If a SIM card insertion is expected, SAPD0 can be set low to avoid the auto power down sequence. There is no auto power up sequence. SPDP0 can be used to determine the current state of the SIMPD0 pin.

Address: Base address + 3Ch offset

SIMx_PORT0_DETECT field descriptions

Field	Description
31–4 -	This field is reserved. Reserved
3 SPDS0	SIM Presence Detect Select Port 0. Controls which edge of the SIMPD0 pin is used to detect the presence of the SIM card. 0 Falling edge of SIMPD0 Input (default) 1 Rising edge of SIMPD0 Input
2 SPDP0	SIMPDP0 input pin status. This bit reflects the state of the SIMPD0 pin. It is not a latched register bit, but instead a synchronized version of the state of the SIMPD0 pin itself. 0 SIMPD0 pin is logic low 1 SIMPD0 pin is logic high
1 SDI0	SIM Detect Interrupt flag Port 0. Status flag to indicate the insertion or removal of a SIM card has been detected on port 0. Can create an interrupt to the MCU if SDIM0 is low. Write a "1" to this bit to clear. 0 No insertion or removal of SIM card detected on Port 0 (default) 1 Insertion or removal of SIM card detected on Port 0
0 SDIM0	SIM Detect Interrupt Mask Port 0. Interrupt mask for the SDI0 interrupt flag. 0 sdi0 enabled 1 sdi0 masked (default)

11.2.5.15 SIM Data Format Register (SIMx_DATA_FORMAT)

See the figure below for illustration of valid bits in the SIM Data Format Register and the table below for description of the bit fields.

Address: Base address + 40h offset

SIMx_DATA_FORMAT field descriptions

Field	Description
31–1 -	This field is reserved. Reserved
0 IC	Inverse Convention. Used to configure the SIM to use either inverse convention or direct convention for its data format. The IC bit can be controlled by software, but it is normally set by hardware as a result of the interpretation of the initial character when in ICM mode. 0 Direction convention transfers enabled (default). 1 Inverse convention transfers enabled.

11.2.5.16 SIM Transmit Threshold Register (SIMx_XMT_THRESHOLD)

See the figure below for illustration of valid bits in the SIM Transmit Threshold Register and the table below for description of the bit fields.

Address: Base address + 44h offset

SIMx_XMT_THRESHOLD field descriptions

Field	Description
31–8 -	This field is reserved. Reserved

Table continues on the next page...

SIMx_XMT_THRESHOLD field descriptions (continued)

Field	Description
7–4 XTH	<p>XTH[3:0] Transmit NACK Threshold. Used to set the NACK threshold for the transmitter. Once the threshold number set by XTH has been reached for the current byte being transmitted, the error flag XTE in the XMT_STATUS register will be set. Setting of XTE causes the remaining transmissions queued in the transmit FIFO to be aborted and no more transmissions to occur until software clears XTE. To trigger XTE, a given byte being transmitted must reach the XTH threshold itself. Transmit NACKs accumulated on one byte are not carried over to the next.</p> <p>0x0 XTE will never be set; retransmission after NACK reception is disabled. 0x1 XTE will be set after 1 nack is received; 0 retransmissions occurs. 0x2 XTE will be set after 2 nacks are received; at most 1 retransmission occurs. 0x3 XTE will be set after 3 nacks are received; at most 2 retransmissions occurs. 0xX XTE will be set after X nacks are received; at most (X - 1) retransmissions occurs. 0xF XTE will be set after 15 nacks are received; at most 14 retransmissions occurs.</p>
TDT	<p>Transmit Data Threshold. Used to set the threshold value for the Transmit FIFO at which the TDTF bit in the XMT_STATUS register will be set. When the number of bytes in the Transmit FIFO is less than or equal to TDT[3:0], TDTF will be set.</p>

11.2.5.17 SIM Transmit Guard Control Register (SIMx_GUARD_CNTL)

See the figure below for illustration of valid bits in the SIM Transmit Guard Control Register and the table below for description of the bit fields.

Address: Base address + 48h offset

Table continues on the next page...

SIMx_GUARD_CNTL field descriptions (continued)

Field	Description
8 RCVR11	Receiver use 11 ETUs. Used to configure the SIM module receiver for 11 ETU operation (that is, 1 Stop bit). This bit is provided for support of T=1 cards. 0 Receiver configured for 12 ETU operation (default) 1 Receiver configured for 11 ETU operation
GETU	Transmit Guard ETUs. Used to control the number of additional Elementary Time Units (ETUs) inserted between bytes transmitted by the SIM transmitter. An ETU is equivalent to one bit time at the given baud rate (for example, the length of a START bit). The guard time has no effect on the SIM receiver. A value of 0x00 inserts no additional ETUs, while a value of 0xFE inserts 254 additional ETUs. A value of 0xFF subtracts one ETU by reducing the number of STOP bits from two to one.

11.2.5.18 SIM Open Drain Configuration Control Register (SIMx_OD_CONFIG)

See the figure below for illustration of valid bits in the SIM Open Drain Configuration Control Register and the table below for description of the bit fields.

Address: Base address + 4Ch offset

SIMx_OD_CONFIG field descriptions

Field	Description
31–2 -	This field is reserved. Reserved
1 OD_P1	Open Drain control for Port 1. Used to control whether the XMT data line on port 1 is open-drain. If AMODE bit in SETUP register is set, this bit will have no effect. 0 XMT pin on port 1 is push-pull (default). 1 XMT pin on port 1 is open-drain.

Table continues on the next page...

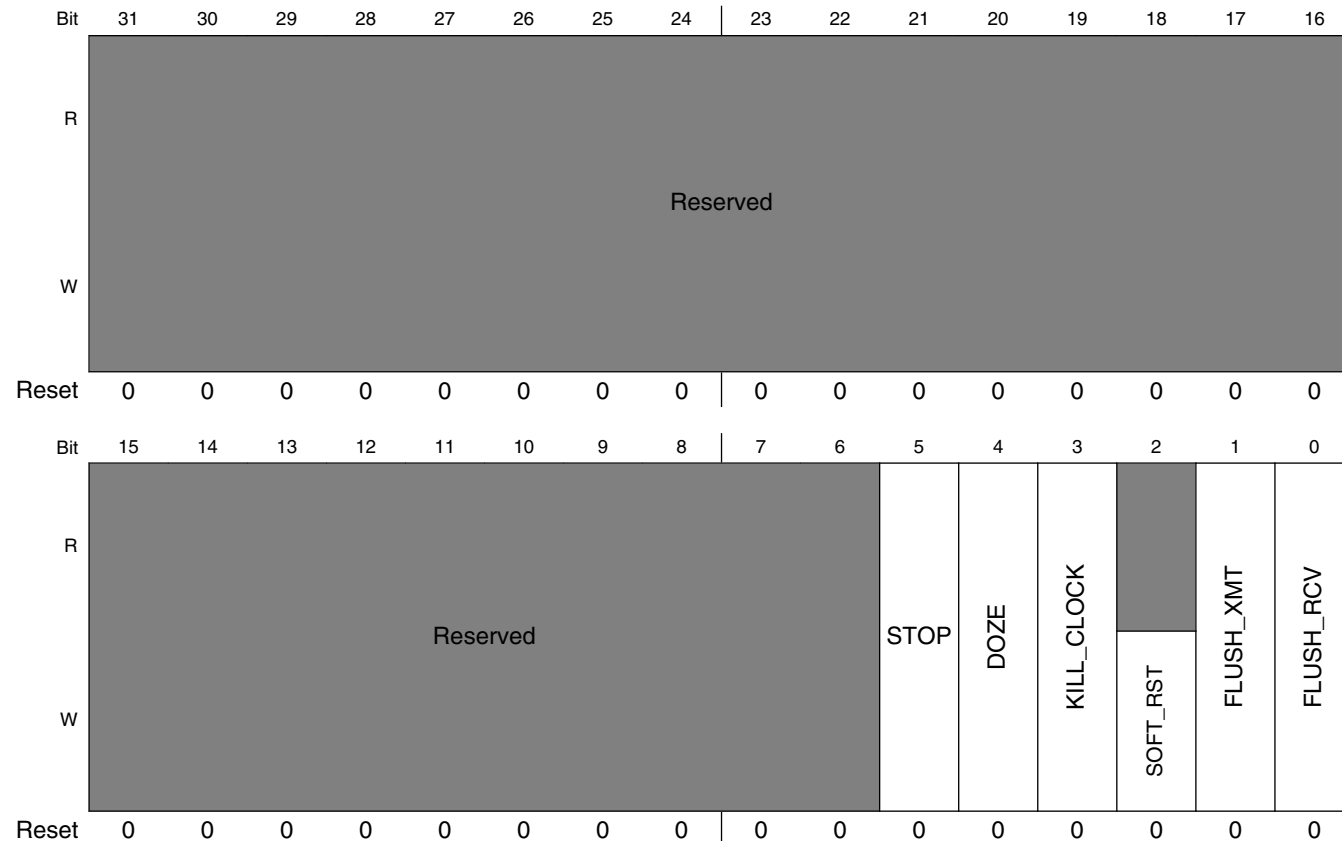

SIMx_OD_CONFIG field descriptions (continued)

Field	Description
0 OD_P0	Open Drain control for Port 0. Used to control whether the XMT data line on port 0 is open-drain. 0 XMT pin on port 0 is push-pull (default). 1 XMT pin on port 0 is open-drain.

11.2.5.19 SIM Reset Control Register (SIMx_RESET_CNTL)

See the figure below for illustration of valid bits in the SIM Reset Control Register and the table below for description of the bit fields.

Address: Base address + 50h offset

SIMx_RESET_CNTL field descriptions

Field	Description
31–6 -	This field is reserved. Reserved

Table continues on the next page...

SIMx_RESET_CNTL field descriptions (continued)

Field	Description
5 STOP	<p>STOP. Used to configure the operation of the SIM module when a processor STOP instruction is executed. This bit is added to provide support for SIM cards that do not allow the SIM Card clock to be stopped while power is applied.</p> <p>0 STOP instruction shuts down all SIM clocks (default). 1 STOP instruction shuts down all clocks except for the BAUD_CLK (clock provided to SIM Card).</p>
4 DOZE	<p>DOZE. Used to configure the operation of the SIM module when a processor DOZE instruction is executed.</p> <p>0 DOZE instruction has no effect on SIM module (default). 1 DOZE instruction will cause SIM module to gate SIM clocks when the transmit FIFO is empty.</p>
3 KILL_CLOCK	<p>Kill SIM Clock. Used to enable/disable the SIM clock input to the SIM module. This bit will gate all SIM clocks including the SIM card clock regardless of the state of the STOP bit described above.</p> <p>0 SIM input clock enabled (default). 1 SIM input clock disabled.</p>
2 SOFT_RST	<p>Software Reset. Used to reset the entire SIM module. This acts the same as a hardware reset for the SIM module. This bit is self-clearing.</p> <p>NOTE: Software should allow a minimum of 4 reference clock cycles (CKIH) before attempting to access the SIM module after a software reset.</p> <p>0 SIM Normal operation (default). 1 SIM held in Reset.</p>
1 FLUSH_XMT	<p>Flush Transmitter. This bit operates as a SIM transmitter reset. The receive portion of the SIM module is not affected. The software must clear this bit before the SIM transmitter can operate.</p> <p>0 SIM Transmitter normal operation (default). 1 SIM Transmitter held in Reset.</p>
0 FLUSH_RCV	<p>Flush Receiver. This bit operates as a SIM receiver reset. The transmit portion of the SIM module is not affected. The software must clear this bit before the SIM receiver can operate.</p> <p>0 SIM Receiver normal operation (default). 1 SIM Receiver held in Reset.</p>

11.2.5.20 SIM Character Wait Time Register (SIMx_CHAR_WAIT)

See the figure below for illustration of valid bits in the SIM Character Wait Time Register and the table below for description of the bit fields.

Address: Base address + 54h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	

SIMx_CHAR_WAIT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
CWT	Character Wait Time. The value written to this register will specify the number of ETU times allowed between characters. Default is 0xFFFF

11.2.5.21 SIM General Purpose Counter Register (SIMx_GPCNT)

See the figure below for illustration of valid bits in the SIM General Purpose Counter Register and the table below for description of the bit fields.

Address: Base address + 58h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																GPCNT															
W	Reserved																GPCNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

SIMx_GPCNT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
GPCNT	General Purpose Counter. The value written to this register will be used to compare to the general purpose counter in the SIM module. Once the General purpose counter reaches this value, the GPCNT flag in the XMT_STATUS register will be set. This counter is intended to be used for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration. Default is 0xFFFF

11.2.5.22 SIM Divisor Register (SIMx_DIVISOR)

See the figure below for illustration of valid bits in the SIM Divisor Register and the table below for description of the bit fields.

Address: Base address + 5Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																DIVISOR															
W	Reserved																DIVISOR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1

SIMx_DIVISOR field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
DIVISOR	DIVISOR Register. The value written to this register will be used to generate the SIM Receive clock. The BAUD_SEL[2:0] bits in the CNTL register must be set to '111' in order to control the divisor value using the DIVISOR register. Default is 0xFF

11.2.5.23 SIM Block Wait Time Register (SIMx_BWT)

See the figure below for illustration of valid bits in the SIM Block Wait Time Register and the table below for description of the bit fields.

Address: Base address + 60h offset

SIMx_BWT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
BWT	BWT Register 16 LSB. The value in this register is the block wait time 16 LSB. The time from START bit of last byte sent from the SIM module to the START bit of the first byte sent from the SmartCard must be less than the value formed by the 32-bit register composed by BWT_H and BWT registers. If it is not, then the BWT flag will be set. Default is 0xFFFF

11.2.5.24 SIM Block Guard Time Register (SIMx_BGT)

See the figure below for illustration of valid bits in the SIM Block Guard Time Register and the table below for description of the bit fields.

Address: Base address + 64h offset

SIMx_BGT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
BGT	BGT Register. The value in this register is the block guard time. Time from START bit of last byte sent from the SIM module to the START bit of the first byte sent from the SmartCard must be greater than this value. If it is not, then the BGT flag will be set. Default is 0x0000

11.2.5.25 SIM Block Wait Time Register HIGH (SIMx_BWT_H)

See the figure below for illustration of valid bits in the SIM Block Wait Time Register HIGH and the table below for description of the bit fields.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																BWT_H															
W	Reserved																BWT_H															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

SIMx_BWT_H field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
BWT_H	BWT Register 16 MSB. The value in this register is the block wait time 16 MSB. The time from START bit of last byte sent from the SIM module to the START bit of the first byte sent from the SmartCard must be less than the value formed by the 32-bit register composed by BWT_H and BWT registers. If it is not, then the BWT flag is set. Default is 0xFFFF

11.2.5.26 SIM Transmit FIFO Status Register (SIMx_XMT_FIFO_STAT)

See the figure below for illustration of valid bits in the SIM Transmit FIFO Status Register and the table below for description of the bit fields.

Address: Base address + 6Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	Reserved																XMT_CNT				XMT_WPTR				XMT_RPTR							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIMx_XMT_FIFO_STAT field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11–8 XMT_CNT	These bits indicate the number of Bytes in the transmit FIFO. '0' value means FIFO is empty or full.
7–4 XMT_WPTR	These bits indicate the transmit FIFO Write Pointer.
XMT_RPTR	These bits indicate the transmit FIFO Read Pointer.

11.2.5.27 SIM Receive FIFO Counter Register (SIMx_RCV_FIFO_CNT)

See the figure below for illustration of valid bits in the SIM Receiver FIFO Counter Register and the table below for description of the bit fields.

Address: Base address + 70h offset

SIMx_RCV_FIFO_CNT field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
RCV_CNT	These bits indicate the number of Byte can be written into the receive FIFO. 0 value means FIFO is empty or full.

11.2.5.28 SIM Receive FIFO Write Pointer Register (SIMx_RCV_FIFO_WPTR)

See the figure below for illustration of valid bits in the SIM Receive FIFO Write Pointer Register and the table below for description of the bit fields.

Address: Base address + 74h offset

SIMx_RCV_FIFO_WPTR field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
RCV_WPTR	These bits indicate the receive FIFO Write pointer.

11.2.5.29 SIM Receive FIFO Read Pointer Register (SIMx_RCV_FIFO_RPTR)

See the figure below for illustration of valid bits in the SIM Receive FIFO Read Pointer Register and the table below for description of the bit fields.

Address: Base address + 78h offset

SIMx_RCV_FIFO_RPTR field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
RCV_RPTR	These bits indicate the receiver FIFO read pointer.

11.3 PCI Express Controller (PCIe)

11.3.1 Product Overview

This section gives an overview of the PCI Express controller

11.3.1.1 Overview

This PCI Express dual mode (DM) controller provides a solution to implement a PCI Express port for a PCI Express root complex or endpoint application.

A complete PCI Express port solution includes the controller, an analog PHY macro, and application logic to source and sink data. The physical layer is split across the PIPE and controller such that the MAC functionality (LTSSM, lane-to-lane deskew) is in the controller and the PHY functionality is implemented in the PIPE-compliant PHY. The PHY is outside of the controller, interfacing through the standard PIPE interface.

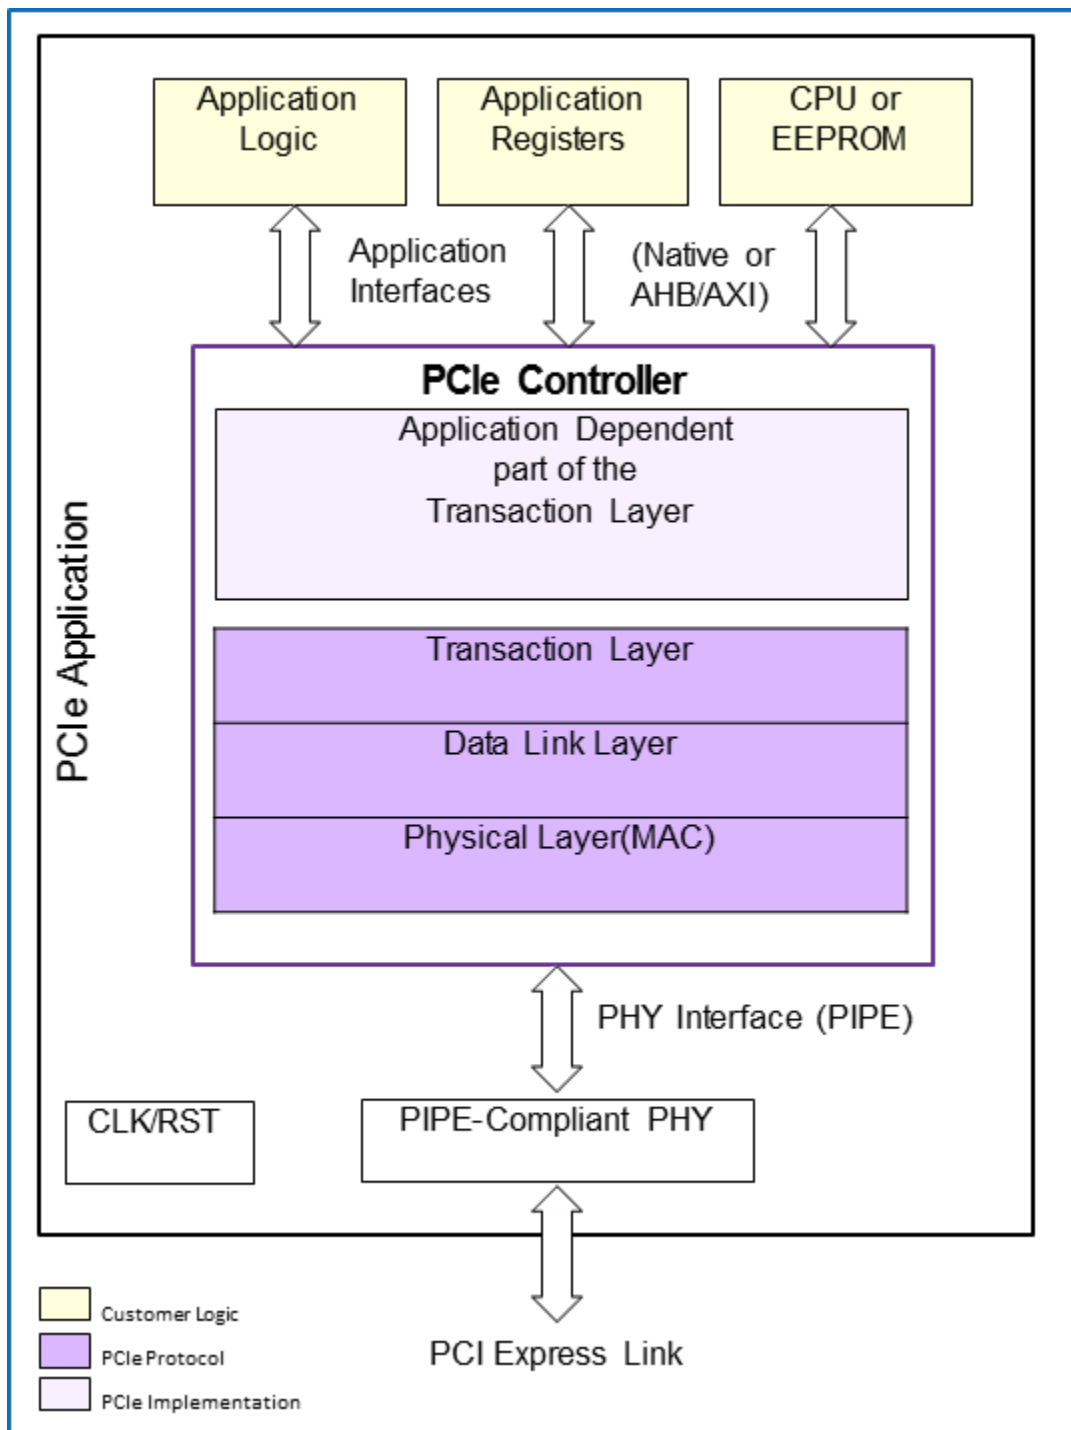

Figure 11-52. PCIe Application

11.3.1.2 Applications

Typical applications for a PCI Express component built with the controller include:

- Motherboard components for desktop and mobile computers

- Graphics devices
- Add-in
- cards for desktop and mobile computers
- Components and add-in cards in server applications
- Embedded applications
- Data communications equipment
- Telecommunications equipment
- Storage devices
- Wireless devices
- Other applications

Note: The DM controller is not intended for use in a PCI Express switch or as a root complex integrated endpoint.

11.3.1.3 Features

The PCI Express DM controller supports:

- Single Root I/O Virtualization (SR-IOV)
- Latency Tolerance Reporting (LTR)
- Alternative Routing-ID Interpretation (ARI)
- Address Translation Services (ATS) by your application
- Page Request Services (PRS) by your application
- Completion Timeout Ranges
- Function Level Reset (FLR)
- ID-Based Ordering (IDO) by your application
- TLP Processing Hints (TPH)
- Atomic Operations
- M-PCIe
- TLP Prefix
- PASID
- Dynamic Power Allocation (DPA)
- L1 Substates (L1SS)
- Extended Tag Support
- Resizable BAR (RBAR) with Expanded RBAR support
- Optimized Buffer Fill and Flush (OBFF)
- Separate Refclk with Independent Spread Spectrum Clocking (SRIS)

- Gen3 Receiver Impedance
- Lightweight Notifications (LN)
- Readiness Notifications (RN)
- PCI Express Active State Power Management (ASPM)
- PCI Express Advanced Error Reporting (AER) with Multiple Header Logging
- PCI Express Advanced Error Reporting (AER)
- Vital Product Data (VPD)
- Precision Time Measurement (PTM)
- Up to x16 Gen1, Gen2, Gen3, or Gen4 lanes (x1, x2, x4, x8, or x16)
- 32, 64, 128, or 256-bit Internal Datapath Operating at 62.5, 125, 250, 500, or 1000 MHz
- Automatic Integration With Most PHY types (8-bit, 16-bit, 32-bit, and 64-bit PIPE Width per Lane)
- Power Gating (UPF) Support
- Advanced Power and Clock Management
- Internal Address Translation Unit
- Internal MSI-X Generation Module
- AXI3/AXI4/ACE-Lite bridge
- Embedded DMA
- Automatic Lane Reversal
- Upconfigure Support
- Multiple Functions. Up to 32 Functions with ARI or SR-IOV, and up to 8 Functions otherwise.
- RAS DES (Debug, Error Injection, and Statistics)
- RAS DP (Data Protection) for Datapath and RAMs using ECC or Parity
- ECRC Generation and Checking
- Configuration Intercept Controller to allow your application modify CFG access from wire
- Multiple Virtual Channels (VCs)¹ and Traffic Classes (TCs)
- Bypass, Cut-through, and Store-and-forward Queue Modes for Rx TLPs
- Configurable Receive and Retry Buffer sizes
- Configurable Max_Payload_Size size (128 bytes to 4 KB)
- Configurable Filtering Rules for Posted, Non-posted, and Completion Traffic
- Configurable BAR Filtering, I/O Filtering, Configuration Filtering and Completion Lookup/Timeout
- Three Application Transmit Clients
- MSI and MSI-X with Per-Vector Masking (PVM), Extended message data for MSI
- Type 1 Configuration Space
- Application-initiated Manual Lane Reversal/flip for situations where controller does not detect Lane 0
- Type 0 Configuration space

Attention: Some features are not available or might have limitations, when you are using the AXI bridge. For more details see "AXI Features and Limitations" or "AHB Features and Limitations"

1. The AXI bridge supports multi-VC operation but it does not support QOS.

11.3.1.3.1 Gen2/Gen3/Gen4 Modes

The controller supports Dynamic frequency, width, and pacing configurations for Gen2/Gen3/Gen4 modes.

■ **Dynamic Frequency (DF):** For DF configurations, the number of active symbols on the PIPE is constant; the frequency of the controller doubles each time as the controller transitions from Gen1 -> Gen2 -> Gen3 -> Gen4 rates.

■ **Dynamic Width (DW):** For DW configurations, the frequency of the controller is constant; the number of active symbols on the PIPE doubles each time as the controller transitions from Gen1 -> Gen2 -> Gen3 -> Gen4 rates.

■ **Dynamic Pacing (DP):** DP is a rate reduction mode for the PIPE interface that allows for a higher clock rate to be used at a slower data rate. It uses the `mac_phy_txdatavalid` and `phy_mac_rxdatavalid` Gen3 signals to obtain the slower effective rate by toggling them every other clock (2:1 DP) or every fourth clock (4:1 DP). This controls the number of valid symbols per one, two, or four clock cycles. When DP is not used in a lower speed mode, these signals must be held high. At Gen3 rate these signals are also used for regular de-assertion for 128b/130b encoding and decoding. The `mac_` - `phy_txdatavalid` and `phy_mac_rxdatavalid` signals are present on all Gen3 and Gen4 configurations. However, DP is only enabled for some controller/PHY combinations as indicated in Table 1-3. For more details on the usage of the `mac_phy_txdatavalid` and `phy_mac_rxdatavalid` signals, see "Signal Interfaces".

Note: The controller and PHY can have different Gen2 modes. For example, you can configure the controller for Dynamic Frequency and the PHY for Dynamic Width. This is also true for Gen3 and Gen4.

For more information, see "Gen2/3/4 Speed Modes", "Gen3 8.0 GT/s Operation", and "Gen4 16.0 GT/s Operation".

Table 1-1 Supported Controller Configurations

Gen3 Speed Mode

Gen4 Speed Mode

- a. The value in each cell indicates the maximum link width supported. You can configure the controller with a link width up to this value, and coreConsultant automatically calculates the datapath width
- b. For license scheme details, see the Checking License Requirements section in the PCI Express Controller Installation Guide.
- c. The actual physical PIPE interface I/O width is CX_NB bytes per lane. The coreConsultant tool automatically calculates this from CX_GEN2_MODE, CX_GEN3_MODE, and CX_FREQ
- d. 512-bit is an early code drop release for simulation purposes; do not tape out a 512-bit configuration. The receive queue RAM requirements for the 512-bit feature are not optimized. Future releases will resolve this limitation by reducing the size of the receive queues.
- e. The g value indicates the speed mode. The s value indicates the number of 8-bit symbols processed per clock cycle per lane by the controller PIPE I/F, in the indicated speed mode. The dw/df value indicates how the speed change to that mode is achieved
- f. The 1GHz code in this release is for early access for simulation purposes and not for tape-out; timing is not guaranteed.

0.0.1 Controller-PHY Compatibility

The following tables indicate which combinations of controller configurations from Table 1-1 and PHYs are supported. In Table 1-3, the triplet of values for each row indicates how the controller moves from Gen1 to Gen2 speed mode and from Gen2 to Gen3 speed mode. The triplet of values also identifies the particular controller configuration in Table 1-1. The controller always uses the same mechanism (DF or DW) to go from Gen1 to Gen2 and from Gen2 to Gen3. However, some Gen3 PHYs use a mix of mechanisms (for example the Virtex7 PHY in the fourth column in "Gen3 Controller-PHY Combinations Supported")

) and others support Dynamic Pacing (DP) which is indicated by the dp_ postfix in the first and second columns in Table 1-3

Table 1-2 Gen4 Controller-PHY Combinations Supported

	PHY

c. DP PHY: doing Gen1 and Gen2 with 2:1 DP, Gen3 with no DP.

Frequency Step Module (CX_FREQ_STEP_EN=1)

When the controller PIPE lane width (CX_NB) and PHY PIPE lane width (CX_PHY_NB) are different, or when the controller and the PHY have different Gen2 speed modes, then the derived CX_FREQ_STEP_EN parameter is defined, and a PIPE adapter module is added between the controller PIPE and the PHY PIPE. If the controller clock frequency is slower than the pipe clock frequency, the derived parameter CX_FREQ_STEP_DOWN_EN is defined. If the core_clk frequency is faster than the pipe_clk frequency, the derived CX_FREQ_STEP_UP_EN parameter is defined. In typical configurations (CX_FREQ_STEP_EN=0), the pipe_clk input is not present.

Figure 1-3 Location of freq_step PIPE Adapter Module

This module steps up/down the signals at the PIPE interface and adjusts the controller PIPE width according to the PHY PIPE width if the core_clk frequency is slower or faster than the pipe_clk frequency.

11.3.1.4 Standards

The PCIe controller implements the following standards:

- *PCI Express Base Specification, Revision 4.0, Version 0.7*

Access to this specification requires membership in PCI-SIG.

- *PIPE Specification for PCI Express, Version 4.3, Intel Corporation*

- *PCI Local Bus Specification, Revision 3.0*

Access to this specification requires membership in PCI-SIG.

- *PCI Bus Power Management Specification, Revision 1.2* Access to this specification requires membership in PCI-SIG.

- *PCI Express Card Electromechanical Specification, Revision 1.1* Access to this specification requires membership in PCI-SIG.

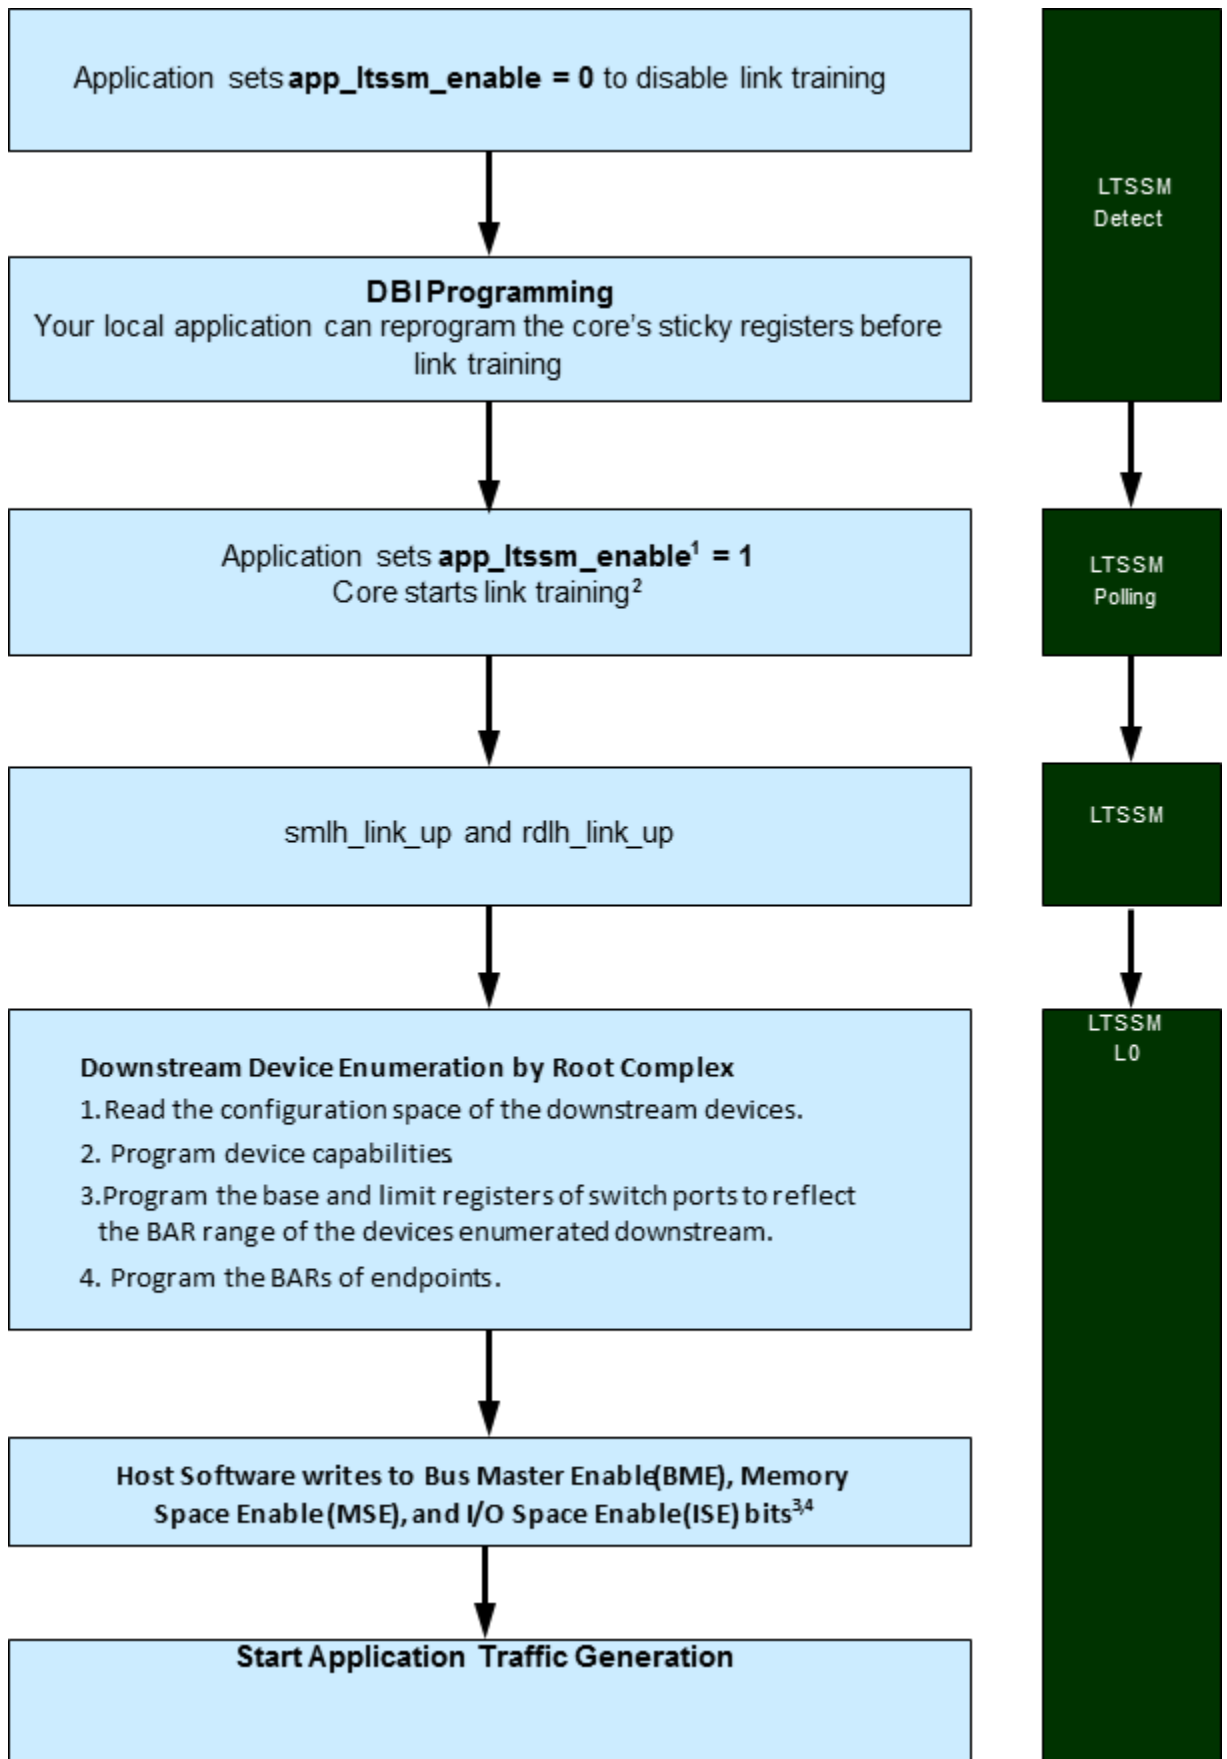

11.3.2 Controller Operations

This section describes the operations of the PCI Express controller.

11.3.2.1 Initialization

Immediately upon powerup the DM controller goes into either EP mode or RC mode, depending on the state of the device_type input. If you have enabled crosslink (CX_CROSSLINK_ENABLE =1), then the determination of the device type is different.

Figure 3-1PCIe Initialization Steps

1. Your application can use the `app_req_retry_en` input to program the controller (through the DBI) after the link is up. When `app_req_retry_en = 1`, the controller completes incoming CFG requests with a configuration request retry status (CRS). Other incoming requests complete normally.
2. For multiple VC configurations, only VC0 should be enabled before the link is up. Other VCs should be enabled after `rdlh_link_up` is asserted.
3. The application logic must not generate any MEM or I/O requests until the host software has

enabled the BME. The controller does not check this bit before transmitting requests. Therefore, your application logic must monitor the status of the BME on the `cfg_bus_master_en` output (or

read it over the DBI).

4. RC application logic must not generate any MEM or I/O requests until the host has enabled the MSE and ISE bits. The RC controller does not check these bits before transmitting requests.

Therefore, your application should monitor the status of the MSE on the `cfg_mem_space_enable` output. There is no corresponding ISE output, so the RC application must be aware of when the host software writes to this bit. Your application could also read these bits over the DBI.

11.3.3 Link Establishment

The controller implements the LTSSM function according to the *PCI Express Base Specification, Revision 4.0, Version 0.7*. When you have unused lanes in your system, you must tie them off using the hardware and software procedures. The controller supports link widths of x1, x2, x4, x8, and x16. It does not support x12.

11.3.3.1 Lane Resizing

Initially, the controller tries to linkup at maximum width; you can restrict the maximum width as follows:

1. Program the `LINK_CAPABLE` field of `PORT_LINK_CTRL_OFF`.
2. Program the `NUM_OF_LANES` field of `GEN2_CTRL`.

To conserve power, your PHY should ignore any signaling on the non-operational lanes. The controller supports the PIPE turn off feature by using the TxElecIdle and TxCompliance signals.

The link partners can change the link width after the link is up. Resizing options are shown in Table 3-1.

Table 3-1 Link Resizing Options

	Remote Partner Initiates Link Remains Up L0 -> Recovery -> Configuration	Software Initiates Locally Link Remains Up L0 -> Recovery -> Configuration
Upsizing	Yes	Yes
Downsizing	Yes	Yes

a. Previous versions of the databook described a method of link resizing by taking the link down, and transitioning the LTSSM from L0 -> Recovery -> Loopback -> Detect. The controller still supports that method for legacy designs (see previous version of databook for details), but new designs should use the method described here.

b. Called UpConfigure in the PCI Express Specification.

c. If the lanes are reversed, your application must manually flip the lanes to achieve downsizing for some configurations. For more details, see "Link Down-sizing with Non-reversed/Reversed Lanes; and Wide/Narrow Ports".

The following steps show how you can initiate link resizing:

1. Ensure the link is in the L0 LTSSM state.
2. Program the TARGET_LINK_WIDTH[5:0] field of the MULTI_LANE_CONTROL_OFF register.
3. Program the DIRECT_LINK_WIDTH_CHANGE2 field of the MULTI_LANE_CONTROL_OFF register. It is assumed that the PCIE_CAP_HW_AUTO_WIDTH_DISABLE field in the LINK_CONTROL_LINK_STATUS_REG register is 0.

Note: If your system has reversed lanes in Gen3 or Gen4 mode, then you should perform upsizing at Gen1 or Gen2 speed only. Otherwise, there is a risk of link-down caused by LFSR mismatching.

1. Resizing (up or down) only occurs if both link partners advertised the Upconfigure Capability bit. In cases of link reliability, the PCIe specification permits the remote partner to initiate downsizing regardless of the value of this bit. You must set the

UPCONFIGURE_SUPPORT field in MULTI_LANE_CONTROL_OFF so that the controller advertises 1 in the Upconfigure Capability bit of the TS2 OS. Default for this field comes from DEFAULT_UPCONFIGURE_SUPPORT parameter.

2. The controller clears the contents of this register after it has accepted the request.

11.3.3.2 Lane Reversal and Flipping

The controller supports lane reversal and lane flipping. Depending on the configuration of the link partners and the topology of the link between them, the controller will attempt to reverse and/or flip lanes to form a link in any of the following scenarios:

- The lanes are reversed by the physical layout of the PCIe link or chip package pinning.
- When connecting a narrower link partner into upper lanes of a wider controller.
- A lane is non-operational (broken).
- A lane is said to be non-operational if it cannot be detected in Detect LTSSM state or it cannot receive in Polling LTSSM state. This might be caused by any of (i) break on PCB (ii) electrical fault in transmitter (iii) electrical fault in receiver.

Lane auto flip occurs in Detect and is useful to connect physical lane CX_NL-1 (or CX_NL/2-1 or CX_NL/4-1) to logical Lane0 of the controller to form a link when physical Lane0 cannot be detected.

Lane auto reverse occurs in Configuration and is useful to form a link when logical Lane0 receives TS Ordered Sets from the link partner with the Lane Number field different from '0'.

Note: To enable lane auto flip and reverse support:

- You must set configuration parameters CX_LANE_FLIP_CTRL_EN =1 and CX_AUTO_LANE_FLIP_CTRL_EN =1
- You must set GEN2_CTRL_OFF register fields AUTO_LANE_FLIP_CTRL_EN =1 and PRE_DET_LANE =0

Figure 3-2 to 3-4 show the muxing logic implemented in the controller as a function of parameters

CX_LANE_FLIP_CTRL_EN and CX_AUTO_LANE_FLIP_CTRL_EN.

Figure 3-2 Muxing Logic when CX_LANE_FLIP_CTRL_EN = 1 and CX_AUTO_LANE_FLIP_CTRL_EN = 1

Figure 3-3 Muxing Logic when CX_LANE_FLIP_CTRL_EN = 1 and CX_AUTO_LANE_FLIP_CTRL_EN = 0

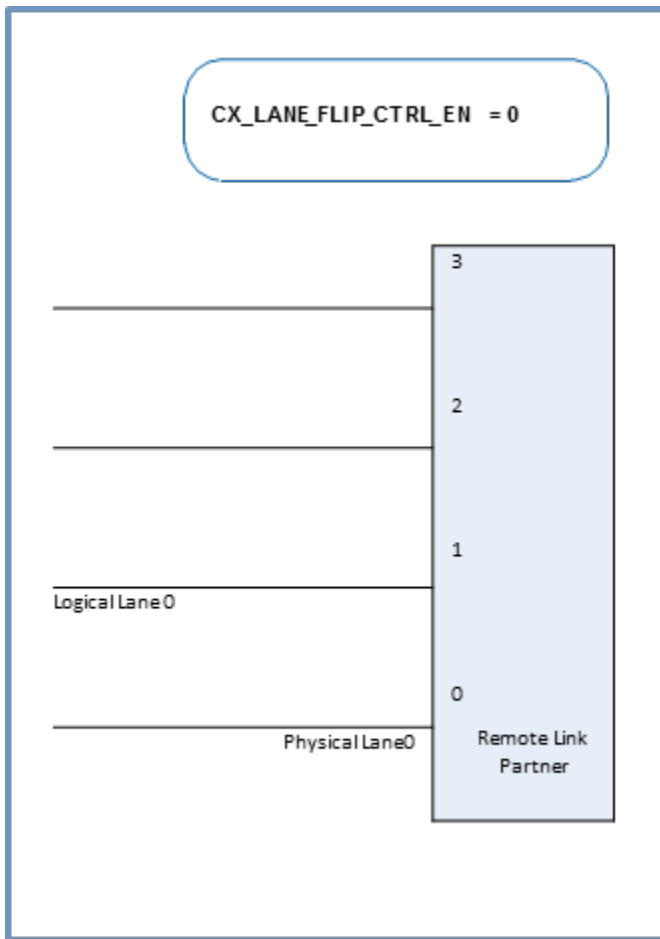

Figure 3-4 Muxing Logic when CX_LANE_FLIP_CTRL_EN = 0

11.3.3.3 Transmit TLP Processing

The following section describe the flow of transmit TLPs through the controller.

Note: The controller does not check the TLP for errors.

The native PCIe controller does not check that the TLP payload size is less than the Maximum Payload Size limit. However, the AXI/AHB bridge module (if present) does guarantee that this limit is not exceeded.

The native PCIe controller does not check that the TLP payload size is less than CX_MAX_MTU limit. Exceeding this limit overflows the retry buffer, resulting in data corruption. However the AXI/AHB bridge module does guarantee that this limit is not exceeded.

11.3.3.3.1 Transmit TLP Arbitration

TLPs and DLLPs have equal priorities during transmit arbitration as shown in Core Operations Figure 3-5. The priority of TLP types and DLLP types are shown in Table 3-2 and Table 3-3, respectively.

Figure 3-5 Transmit TLP/DLLP Arbitration

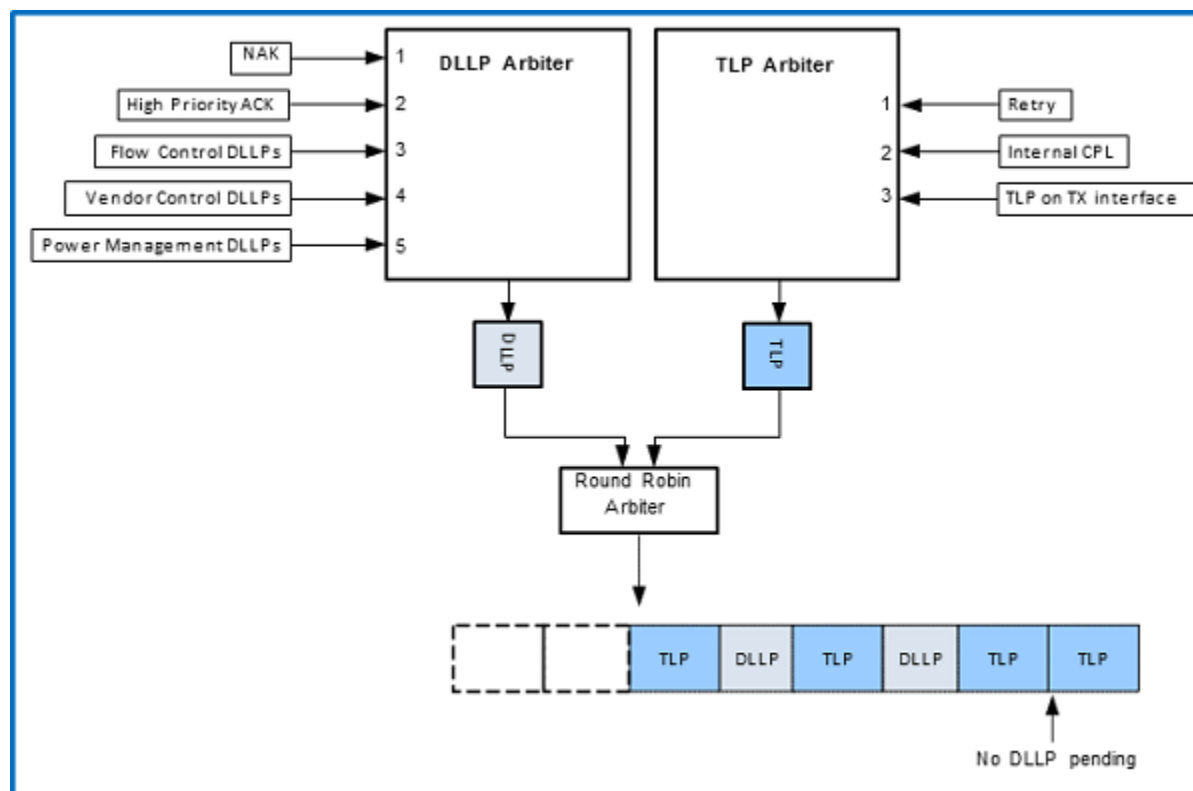

Table 3-2 TLP Arbitration Priority (1= Highest, 4= Lowest)

Priority	TLP Type
1	Completion of any TLP currently in progress
2	Retry buffer retransmissions
3	TLPs from the transaction layer (in the following order of priority): <ul style="list-style-type: none"> • Messages generated by the controller (including by your application through the MSI interface) • Upstream ports: Completions generated by the controller (including memory or I/O mapped application register space) for Type 0 configuration read and write requests, or responses to error conditions (unsupported requests) • Downstream ports: Completions generated by the controller for unsupported requests or completer aborts
4	TLPs on the transmit client interface (XALI0/1/2), or on the AXI Master/Slave interface if the AXI bridge is being used.

Table 3-3DLLP Arbitration Priority (1= Highest, 6 = Lowest)

Priority	DLLP Type
1	Completion of any DLLP currently in progress
2	NAK DLLP
3	High Priority ACK DLLP
4	Flow Control DLLP
5	Vendor Specific Message DLLP
6	Power management or any other Low Priority DLLP

11.3.3.3.1.1 Selecting Transmit Client Arbitration Scheme (No AXI Bridge)

All transmit client interfaces XALI0/1/2 are served using one of the three arbitration schemes when credit is available, regardless of the type of transaction. You can change the arbitration scheme using the CX_XADM_ARB_MODE configuration parameter when CX_NVC >1.

■ **0: VC Based.** Provides a VC-based programmable weighted round robin arbitration (WRR) using two different arbitration methods for the two groups of VCs:

□ Strict Priority for the High-Priority VC (HPVC) group

□ RR or WRR for the Low-Priority VC (LPVC) group Between the two groups of VCs, arbitration is as follows:

■ The HPVC group is always the highest priority. Within the HPVC group, priority order is by VC ID. The highest VC ID has the highest priority. Ties within the HPVC are resolved by client-based Strict Priority arbitration; XALI0 has lowest, XALI1 higher, and XALI2 (if implemented) highest priority.

■ The LPVC group is of lower priority than the HPVC group. Within the LPVC group, priority is determined by RR or WRR arbitration as described later. Ties within the LPVC group are resolved by client-based RR arbitration.

■ **1: Round Robin (RR).** Provides round robin arbitration between the three transmit clients. This is the default method.

■ **2: Strict Priority.** Provides strict priority between the three transmit clients. XALI0 is lowest, XALI1 is higher, XALI2 (if implemented) is highest.

11.3.3.3.1.2 Effects of Flow Control Credits On Transmit Client Arbitration

The controller checks that enough flow control (FC) credits are available in the remote device for the specific type of transaction (posted, non-posted, completion) before allowing a transmission of a TLP. TLPs that passed the credit check are arbitrated according to the supported arbitration method. Internally generated completions and messages are also gated by the arbitration logic, though at highest priority, and must also pass the FC credit test before they are accepted for transmission.

For example when using the RR scheme, when a posted (P) transaction is presented onto XALI1 followed by a completion (CPL) on XALI0, and when credits permit, then the P is transmitted onto the wire before the CPL. When the credit is not available then the CPL on XALI0 can pass the P on XALI1 and be sent onto the wire. However, any non-posted (NP) or CPL TLPs on XALI1 (behind the blocked P) are blocked by the halted P. It is the responsibility of your application to make appropriate use of the three interfaces. There is no guarantee that order is preserved among client interfaces.

When your application is using a single transmit client interface for more than one TLP type (for example, posted and non-posted), and the current request (for example, a posted request) is being blocked due to lack of available FC credits, then that client interface is effectively blocked from sending other requests (for example, non-posted) even though credits might be available for that type. To avoid this situation, your application can use different transmit client interfaces for different request types (for example, XALI0 for posted requests, XALI1 for non-posted requests, and XALI2 for completions). Another way your application can avoid this situation is to monitor the current FC credit availability on the `xadm_*_cdts` outputs from the controller and only generate requests for which FC credits are available.

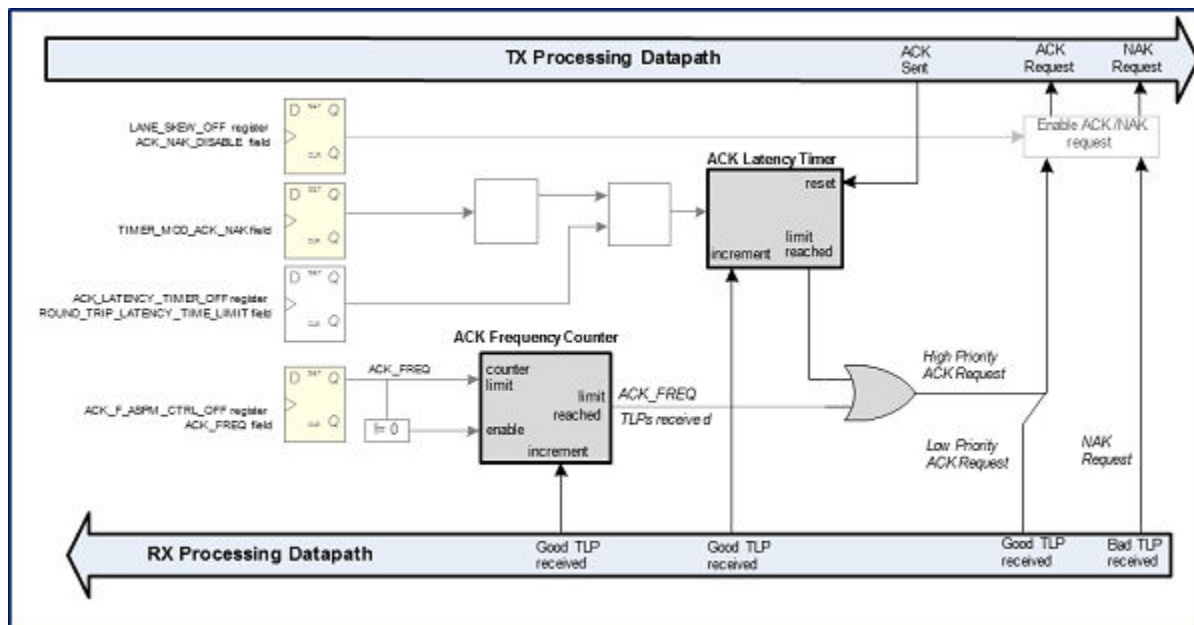

When using `xadm_*_cdts` to monitor credit availability, your application must consider that it is possible that the controller might generate a message or completion TLP (which would change the number of credits available), between the time your application samples `xadm_*_cdts` and when your application generates the request. For more details, see "Flow Control" .

Note: The DMA or AXI bridge modules when present, manage these interfaces.

11.3.3.3.2 ACK/NAK Scheduling

Figure 3-6 shows how you can reprogram the controller to influence the sending of ACK and NAK DLLPs. When the link is idle, the controller sends an ACK DLLP every time it receives a good TLP. For a typical system, you do not have to modify the defaults, unless the remote device is executing unexpected replays.

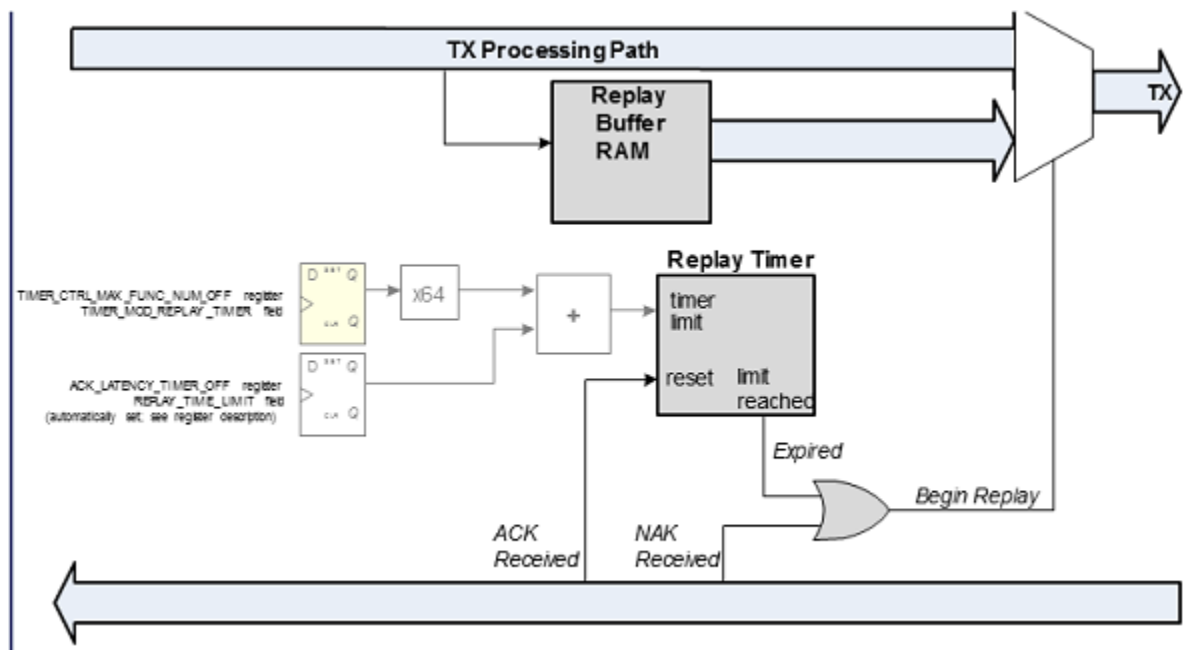

Figure 3-6 Ack Frequency and Latency Timers Operation (Representative)

11.3.3.3 Transmit Replay

You can modify the time-out value of the replay buffer as shown in Figure 3-6. For a typical system, you do not have to modify the default settings, unless the remote device is executing unexpected replays.

Figure 3-7 Replay Buffer And Time (Representative)

11.3.3.4 Receive TLP Processing

This section describes the flow of received TLPs through the controller.

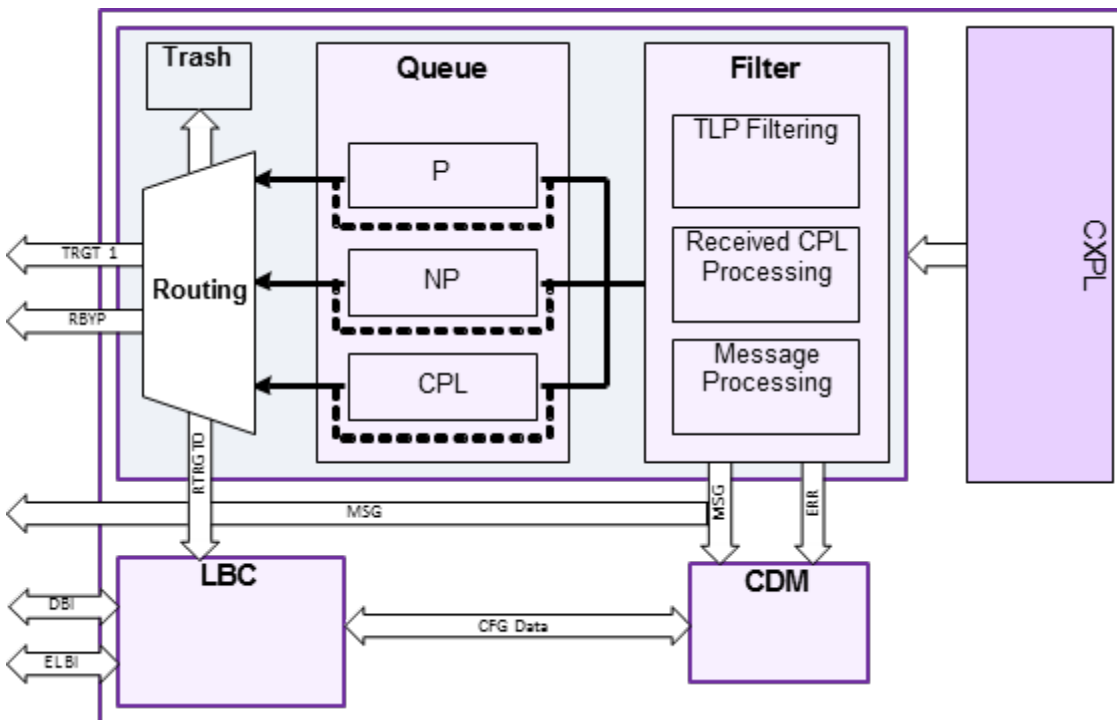

11.3.3.4.1 Receive Filtering

The controller contains a filter module that is responsible for the following tasks:

- Determine the status of a received TLP using filtering rules.
- Determine the destination of a received TLP based on the filtering status.
- Indicate the status of the received TLP using outputs.
- Report Errors to AER registers based on filter results. When more than one type of error is detected, Section 6.2.3.2.3, Error Pollution, of the *PCI Express Base Specification, Revision 4.0, Version 0.7* is followed.

The controller filters and routes received TLPs according to a set of rules determined by the TLP type based on the *PCI Express Base Specification, Revision 4.0, Version 0.7* and user-configurable filtering options. The filtering rules for a received TLP are affected by the configuration parameters (compile-time options), I/O signals (runtime options) and register values (runtime options).

Figure 3-8RADM Block Diagram

The following general rules apply to all incoming TLPs that are not malformed. For details on what happens to malformed TLPs, see "Error Detection for Received TLPs" By default:

■ For a function in device power states D1, D2, and D3hot, the controller only accepts CFG and MSG requests TLPs for that function. All other incoming request types for that function are treated as unsupported requests (UR).

■ When the controller detects an error in a received TLP, it normally performs the following:

- Discards the TLP
- Generates a completion (for non-posted requests) with the completion status set to CA or UR
- Sets the status in the PCI-compatible Status register
- Sets the status in the AER registers (when you enable AER)
- Generates an error message (upstream port only)

All error-free MSG requests are decoded internally, signaled on the SII interface and then dropped. When you want to have the decoded message also sent to the application interface, then see “Routing of Received Messages”.

11.3.3.4.2 Receive Routing

This section discusses how the RADM routes different TLP types to different receive interfaces depending on TLP type and filter result. When you are using the AXI bridge, then TRGT1 is replaced by the AXI bridge interfaces. TRGT0 refers to the internal interface used to access the CDM registers or the ELBI in an upstream port.

Note: For information on BAR operation, see "Register Configuration Space" .

11.3.3.4.2.1 EP Mode Routing Overview

The possible destinations of a posted or non-posted request TLP are TRGT1 interface, TRGT0 interface and Discard1. By default:

- CFG requests are routed to TRGT0 and then to CDM through the LBC.
- BAR-matched MEM and I/O requests are routed to TRGT1.
- MSG requests are decoded internally, signaled on the SII interface, and then terminated.

Figure 3-9

1. Serviced internally, and then not passed to the application but dropped.

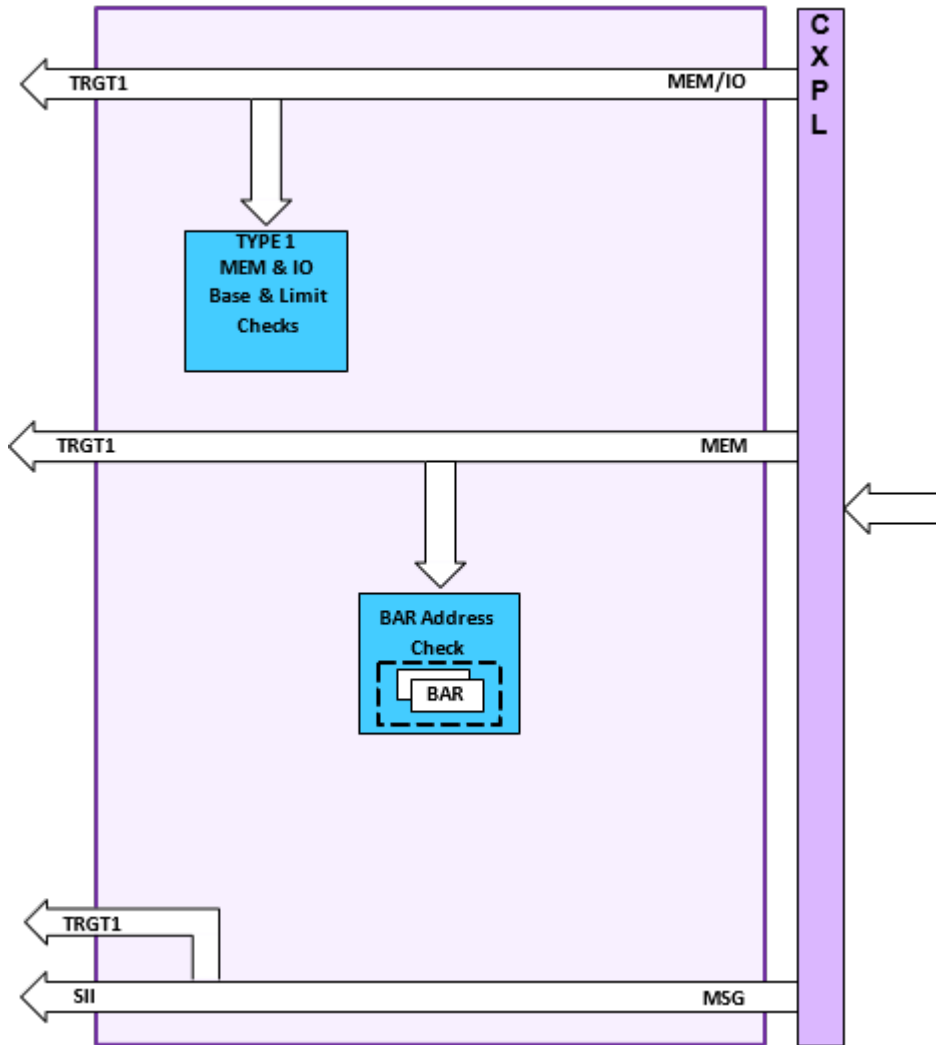

11.3.3.4.2.2 RC Mode Routing Overview

The possible destinations of a posted or non-posted request are TRGT1 and Discard1. By default:

- MEM requests outside of the memory range and prefetchable memory range as determined by the corresponding Base and Limit fields in the Type-1 header are routed to TRGT1.
- MSG requests are decoded internally, signaled on the SII interface, and then terminated.
- An RC does not expect to receive CFG or I/O requests.
- BARs should be disabled and not used.

The possible destinations of a completion TLP are TRGT1 and Discard.

Figure 3-10 Default Request TLP Routing (Assuming no TLPs with CA/CRS/UR Error Status).

11.3.3.4.3 Error Handling

The controller supports the Baseline Capabilities, AER capabilities, and Advisory Non-Fatal Error Messaging as specified in Section 6.2, Error Signaling and Logging of the *PCI Express Base Specification, Revision 4.0, Version 0.7*. These include Correctable and Uncorrectable (Fatal and Non-Fatal) errors. For an RC port, the reporting of most errors is internal to the root port. No external error notifications are generated. One exception to this (for example) is unsupported request (UR) completion status.

11.3.3.4.3.1 Error Detection for Received TLPs

The controller performs all mandatory error detections, the error reporting mechanism based on the PCI Express Base Specification, Revision 4.0, Version 0.7, and some optional error detections (using the `ENABLE_OPTIONAL_CHECKS` parameter). When the controller detects an error in a received TLP, it normally performs the following:

- Discards the TLP
- Generates a completion (for non-posted requests) with the completion status set to CA or UR
- Sets the status in the PCI-compatible status register
- Sets the status in the AER registers (when you enable AER)
- Generates an error MSG (upstream port only)

11.3.3.4.3.2 AER Multiple Header Logging

The controller supports the AER multiple header logging as specified in Section 6.2.4.2, "Multiple Error Handling (Advanced Error Reporting Capability)" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

11.3.3.4.3.3 Physical Functions

By default, each physical function only logs the first header that caused an error. You can now individually per physical function, set the number of logged headers for each physical function using the `CX_HDR_LOG_DEPTH_i` parameter. Per physical function, the controller implements a FIFO queue of depth (`CX_HDR_LOG_DEPTH_i`) that interfaces with the AER Header Log registers (`HDR_LOG_i_OFF`). A valid queue entry is never overwritten. When the queue is full and your software does not read the header log registers fast enough, new header log information will be missed.

11.3.3.4.3.4 Virtual Functions

By default, each virtual function only logs the first header that caused an error. You can now set the number of logged headers for each VF using the `VF_HDR_LOG_DEPTH` parameter. Each VF in each physical function has the exact same header log queue depth. Per VF, the controller implements a queue of depth (`VF_HDR_LOG_DEPTH`) that interfaces with the AER Header Log registers (`VF_HDR_LOG_i_OFF`). A valid queue entry is never overwritten. When the queue is full and your software does not read the header log registers fast enough, new header log information will be missed.

When you set VF_HDR_LOG_SHARED=1, the controller implements a shared queue per PF for all the VFs in that physical function. The depth of each shared queue is identical for all PFs and is set by the VF_HDR_LOG_SHARED_DEPTH parameter. The queue is not a FIFO, it is just a resource-saving mechanism, and each VF can randomly access it's own header logs independently of other VFs.

Table 3-4 Shared VF Header Log Full Behavior

VF First Error Pointer Status	VF Shared Header Log Status	Core Actions
Invalid	Full	<ul style="list-style-type: none"> • A read to the Header Log returns all 1's. • A read to the "TLP Prefix Log Present" bit indicates '0'. • The controller sets the Uncorrectable Error Status Register according to the First Error Pointer.

VF First Error Pointer Status	VF Shared Header Log Status	Core Actions
Valid	Full	<ul style="list-style-type: none"> • The controller sets the Uncorrectable Error Status Register according to the First Error Pointer that is associated with the rejected TLP. • The Header log can be cleared or updated to the next stored header log, if one exists, by writing to the bit of the Uncorrectable Status Error Register pointed to by the First Error Pointer. • This applies to both when a normally displayed TLP Header is present in the Header Log Register or when an overflow condition is shown on the Uncorrectable Status Error Register.

11.3.3.5 Register Module and Data Bus Interface (DBI)

11.3.3.5.1 Overview

The Local Bus Controller (LBC) module provides a mechanism for a link partner (in upstream mode) or a local CPU (through the DBI) to access:

- Internal registers (in the CDM)
- External application registers connected externally to the ELBI

In RC mode:

- There is no PCIe wire access to the CDM registers and ELBI.
- There is full DBI access to the CDM registers and ELBI.

The controller has 4096 bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. The controller register space is fully accessible from the DBI without any restrictions.

Table 3-5EP Mode Port Region Access

Register Location		CDM					ELBI
		PCI-SIG		Port Logic			User
Register Type		Normal	Shadow	Misc	IATU	DMA	User
Access Details	CDM/ELBI Selector Bita Value	0	0	0	1	1	1
	CS2 Selector Bit Value	0	1	0	1	1	0
DBI/Wire Access Allowed							
DBI		Y	Y	Y	Y	Y	Y
Wire	CFG Request	Y	-	Y	-	-	Y
	BAR Matched MEM Request	-	-	Yb	Y	Y	Yc

- a. Selector bit locations are configuration-dependent.
- b. IO request also supported.
- c. IO request also supported.

Figure 3-11LBC Context

PCI Express Controller (PCIe)

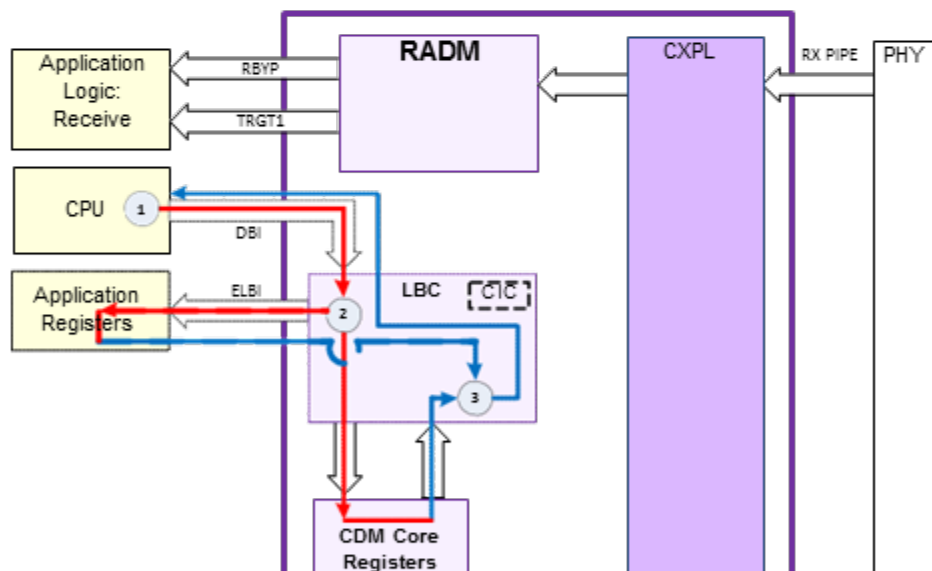

Note: For DSP there is no wire access to CDM or ELBI

— Request flow
— Response flow

PCIe Wire Access to CDM Registers or ELB(USP)

- ① Incoming request from PCIe remote link partner
- ② Request is filtered and routed by RADM through TRGT0 to LBC
- ③ LBC forwards the request to external registers (through ELBI) or internal registers in CDM
- ④ LBC forms completion TLPs with response received from ELBI or internal registers in CDM
- ⑤ PCIe controller transmits response completion to remote link partner

11.3.3.5.2 CDM Register Space Layout

11.3.3.5.2.1 Overview

The controller has 4096(0xFFF)1 bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. The controller register space is fully accessible from the DBI without any restrictions.

Table 3-6Port Region Access

Register Location		CDM					ELBI
Register Type		PCI-SIG		Port Logic			User
		Normal	Shadow	Misc	IATU	DMA	User
Access Details	CDM/ELBI Selector Bita Value	0	0	0	1	1	1
	CS2 Selector Bit Value	0	1	0	1	1	0
DBI/Wire Access Allowed							
DBI		Y	Y	Y	Y	Y	Y
Wire	CFG Request	Y	-	Y	-	-	Y
	BAR Matched MEM Request	-	-	Yb	Y	Y	Yc

- a. Selector bit locations are configuration-dependent.
- b. IO request also supported.
- c. IO request also supported.

Figure 3-12Controller Configuration Space Layout (EP Mode)

PCI Express Controller (PCIe)

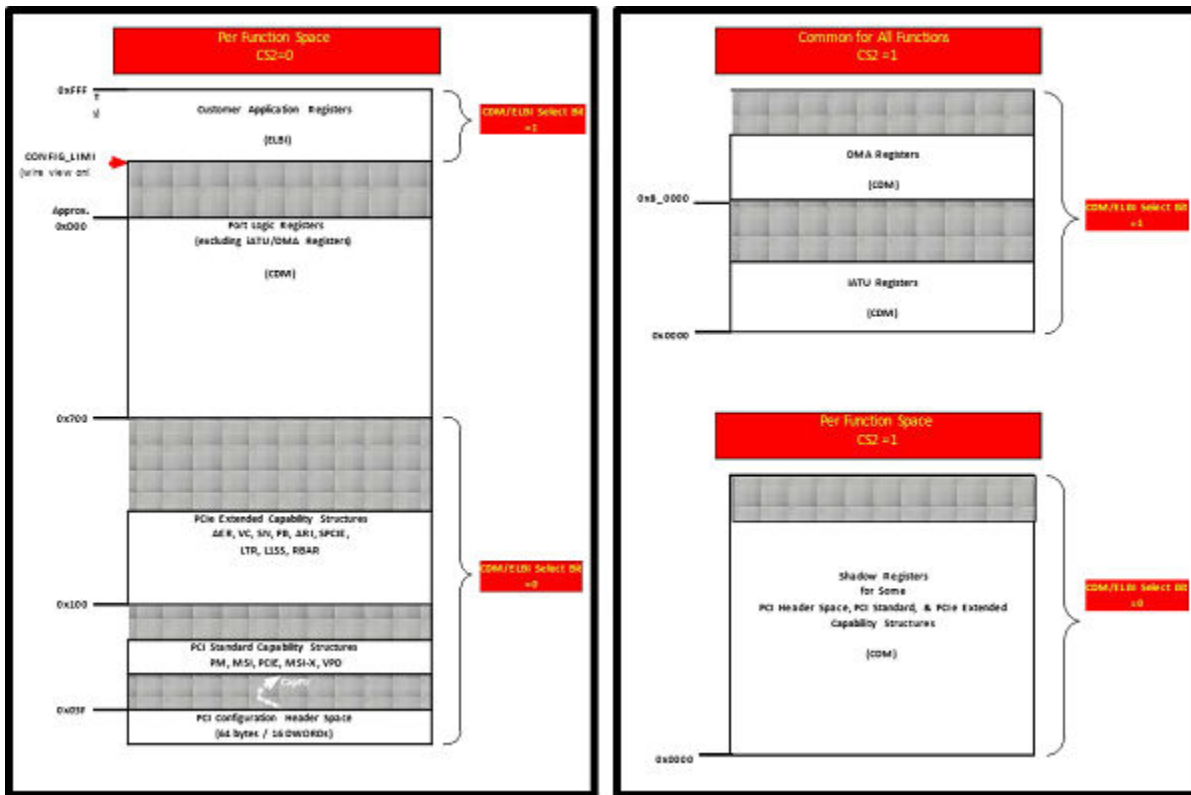

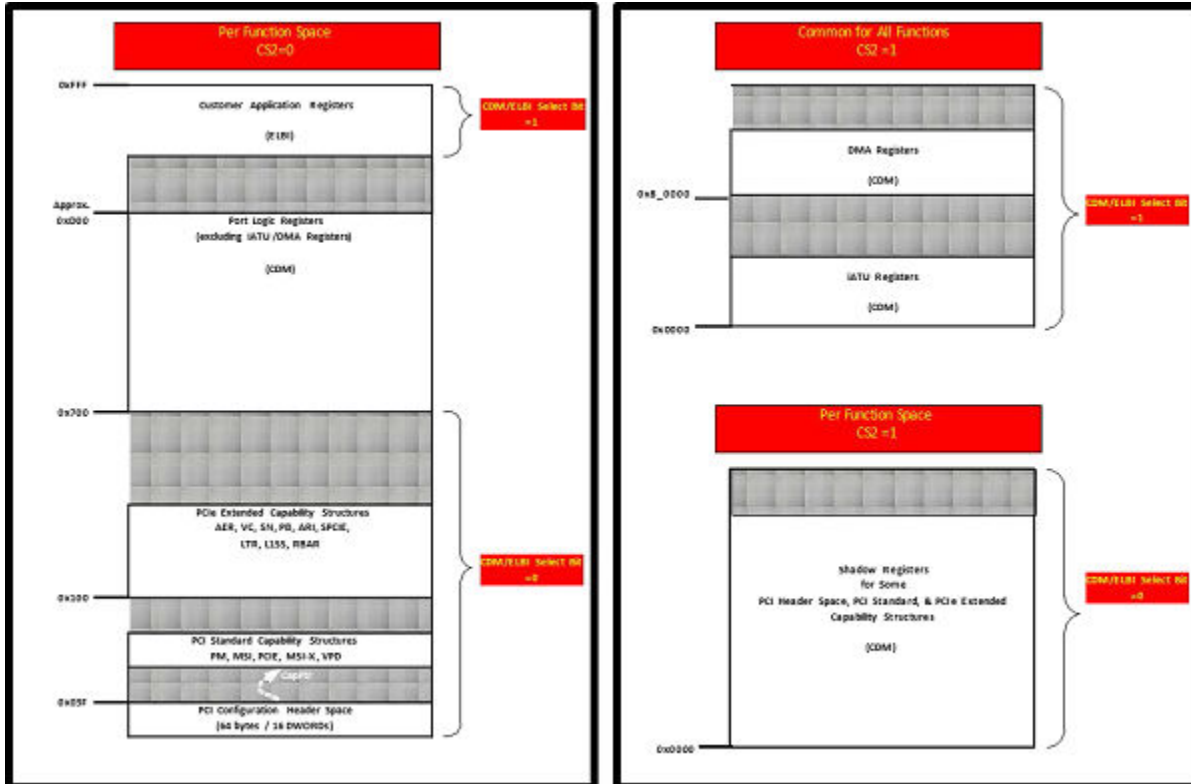

Figure 3-13 Controller Configuration Space Layout: (RC Mode)

Wire Access (Upstream Ports Only):

- Any CFG > CONFIG_LIMIT goes to TRGT1 or ELBI
- Any MEM/IO captured by a BAR whose interface target is TRGT0 goes to ELBI
- Any MEM captured by BAR_n ($n = \text{UNROLL_BAR_NUM}$) when ENABLE_MEM_MAP_UNROLL_{DMA|ATU}_REG=1, whose interface target is TRGT0, and whose address falls into the range defined in "Memory Mapping iATU and DMA Port Logic Registers" goes to the IATU/DMA registers.

DBI Access (Upstream and Downstream Ports):

- No concept of MEM/IO/CFG
- Uses the specified address bit to route the access to ELBI or CDM
- No restrictions regarding what spaces can be accessed or not
 - a. The CONFIG_LIMIT parameter specifies a DWORD limit above which incoming CFG requests are routed to the destination defined by TARGET_ABOVE_CONFIG_LIMIT which can be ELBI or TRGT1 (default). The CONFIG_LIMIT parameter is normally set to a limit that divides the controller's configuration space registers in CDM from your application's external configuration space registers on ELBI. The default setting of 0x3FF corresponds to the 4K upper limit of configuration space and so the cores CDM will consume all CFG transactions by default. CONFIG_LIMIT must be set to a value lower than this to have an effect. Normally, you would never set this to less than 0xD00 which is the top of the Port Logic register space.

11.3.3.5.2.2 Core Configuration Space Registers

- CDM Registers
- PCI Configuration Header and Capability Registers

The *PCI configuration header and capability registers* in the previous diagrams are PCIe controller configuration registers specified by the *PCI Express Base Specification, Revision 4.0, Version 0.7*. Access from the PCIe wire is possible with CFG requests (upstream ports). These registers are fully accessible from the DBI without any restrictions.

- In EP mode, from the PCIe wire:
 - You can memory-map the port logic (PL) register space.
 - You cannot memory-map the PCI and PCIe configuration register spaces. You must always access them with a CFG request

- In RC mode, access to the CDM registers is not possible from the PCIe wire.
- From the DBI, you can access the CDM without any restrictions.

□ Port Logic Registers

The port logic (PL) registers are configuration registers which are not specified by the *PCI Express Base Specification, Revision 4.0, Version 0.7*. Access from the PCIe wire is normally with CFG requests. There is no access from the PCIe wire in a DSP. These registers are fully accessible from the DBI without any restrictions.

iATU and DMA Port Logic Registers

This memory space is dedicated for iATU and DMA configuration registers. Access from the PCIe wire is with specific BAR matched MEM requests; for details, see "Memory Mapping iATU and DMA Port Logic Registers". There is no access from the PCIe wire in a DSP. These registers are fully accessible from the DBI without any restrictions. These registers can be accessed using a configuration of CS2 and CDM/ELBI selection signals as described in "Data Bus Interface (DBI)".

Attention

For releases previous to 4.80a, the iATU and DMA registers were programmed through an indirect addressing scheme using an index register (iATU_VIEWPORT_OFF/DMA_VIEWPORT_OFF), to reduce the address footprint in the PCI Express extended configuration space.

■ External Register Access (ELBI)

Your application registers are external to the controller and are connected to the ELBI. Access from the PCIe wire is with CFG, MEM, or I/O requests. There is no access from the PCIe wire in a DSP. These registers are fully accessible from the DBI without any restrictions.

□ For ELBI access with features and limitations, see "Features and Limitations".

□ The ELBI can support up to 4 GB1 of application register space for each of the CX_NFUNC functions through a 32-bit ELBI address bus.

For more details, see "External Local Bus Interface (ELBI)".

11.3.3.5.2.3 PCIe Wire Access (EP Mode)

For wire access to:

- ELBI space with I/O or MEM requests, set MEM_FUNCN_BARn_TARGET_MAP to 0

- ELBI space with CFG requests, use CONFIG_LIMIT and TARGET_ABOVE_CONFIG_LIMIT
- Port logic with MEM requests, use the ENABLE_MEM_MAP_PL_REG mechanism
- iATU Configuration registers with MEM requests, use the ENABLE_MEM_MAP_ATU_REG mechanism
- DMA Configuration registers with MEM requests, use the ENABLE_MEM_MAP_DMA_REG mechanism

For more details, see "Memory Mapping iATU and DMA Port Logic Registers"

By default² all requests to the standard PCI configuration space or to the port logic registers (except iATU and DMA registers) are routed to TRGT0 and then to the CDM through the LBC. By default there is no ELBI/TRGT1 access because CONFIG_LIMIT defaults to 0x3FF (top of the CFG register address space). To access the iATU/DMA registers, you must use MEM requests that target the BAR you have setup to capture these addresses. For more details, "Memory Mapping iATU and DMA Port Logic Registers" The "Configuration Intercept Controller (CIC) for USP" enables your application to detect the occurrence of; and to modify the behavior of Rx CFG requests (from the remote link partner) that are accessing the controller's internal registers.

Figure 3-14 Request TLP Routing: Typical Use Model

1. 4 KB for PCIe TRGT0 access and 4 GB for DBI native controller access.
2. To see all routing possibilities, see "Receive Routing".

11.3.3.5.2.4 PCIe Wire Access (RC Mode)

RC Mode Access

- Your application must access the CDM registers or ELBI by using the DBI.
- PCIe wire access (through TRGT0) to the CDM registers or ELBI is not possible.

11.3.3.5.3 Data Bus Interface (DBI)

11.3.3.5.3.1 Overview

The DBI can access all 4096 bytes (1024 DWORDs) of the PCI Express configuration space per function. DBI can also access iATU and DMA configuration space. This address space is fully accessible from the DBI without any restrictions. When you are using the AHB or AXI bridge module, then you can choose to access the DBI through the AXI slave DBI interface or through the native DBI interface (which is not connected to your AXI bus).

11.3.3.5.3.1.1 Native Core DBI Access

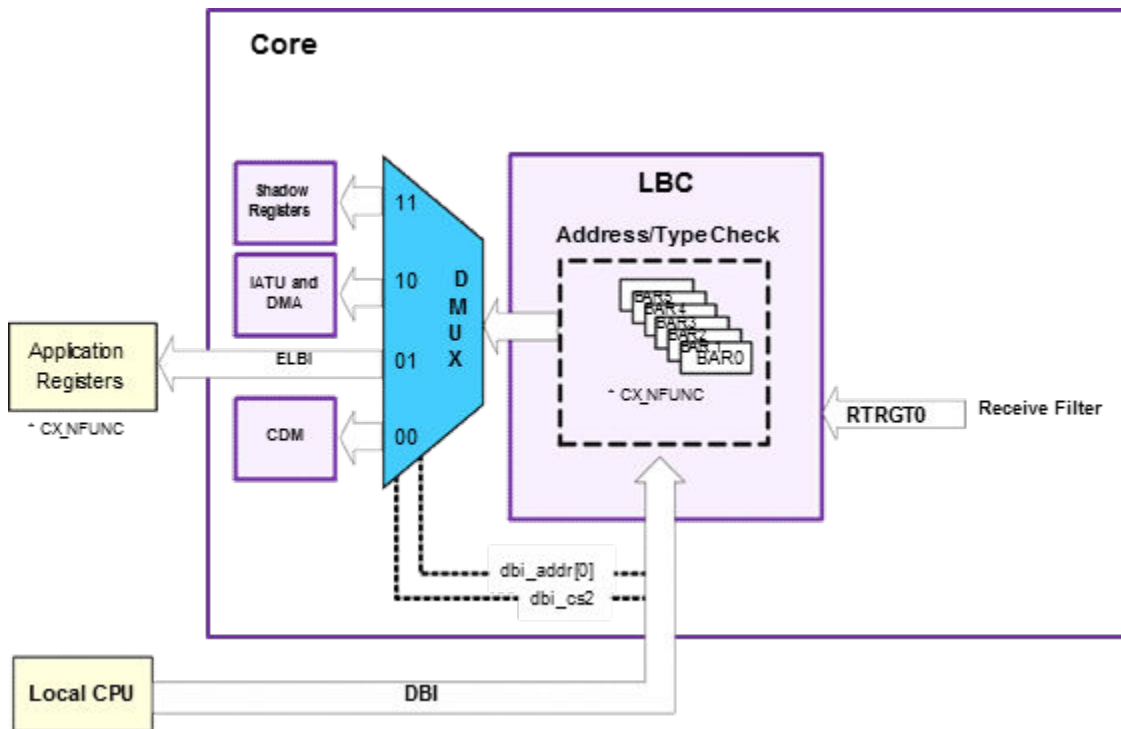

When you are not using the AXI DBI slave, bit 0 of the DBI address input (dbi_addr) and chip select signal (dbi_cs2) determines the target of a DBI transaction as follows:

Table 3-7 Native Core DBI Address Bus Layout for Accessing CDM

	Register Location			CDM			ELBI
	Register Type	PCI-SIG		Port Logic			User
		Normal Shadow		Misc	IATU	DMA	User
Access Details	CDM/ELBI Selector Bit Value	0	0	0	1	1	1
	CS2 Selector Bit Value	0	1	0	1	1	0

- a. Selector bit locations are configuration-dependent.

Figure 3-15 DBI Access Using Native DBI Interface (Not Using AXI DBI Slave)

11.3.3.5.3.2 AXI Dedicated DBI Access

When you are using the AXI DBI slave, then the DBI interface is not directly available to your application but is accessed through an AXI bridge slave interface. To enable DBI access through a dedicated AXI bridge slave interface, you must set the `DBI_4SLAVE_POPULATED` configuration parameter. You select the target of the DBI transaction using a bit of the AXI DBI slave address signal, whose position moves around. For more information, see "AXI Bridge DBI to CDM/ELBI Access Details"

11.3.3.5.3.3 AXI Shared DBI Access

To enable sharing of the existing slave interface (AXI only), you must enable the `SHARED_DBI_ENABLED` configuration parameter. You select the target of the DBI transaction using a bit of the AXI DBI slave address signal whose position moves around. For more information, see "AXI Bridge DBI to CDM/ELBI Access Details". When `slv_armisc_info[21]/slv_awmisc_info[21]=1`, the shared slave interface routes transactions to the LBC, instead of to the outbound PCIe transmit path at XALI1. Your application AXI master could possibly decode an address range, or bits of the slave ID, to drive this bit.

Figure 3-16 AXI DBI Access with a Dedicated Slave Interface
(`SHARED_DBI_ENABLED = 0`, `DBI_4SLAVE_POPULATED = 1`)

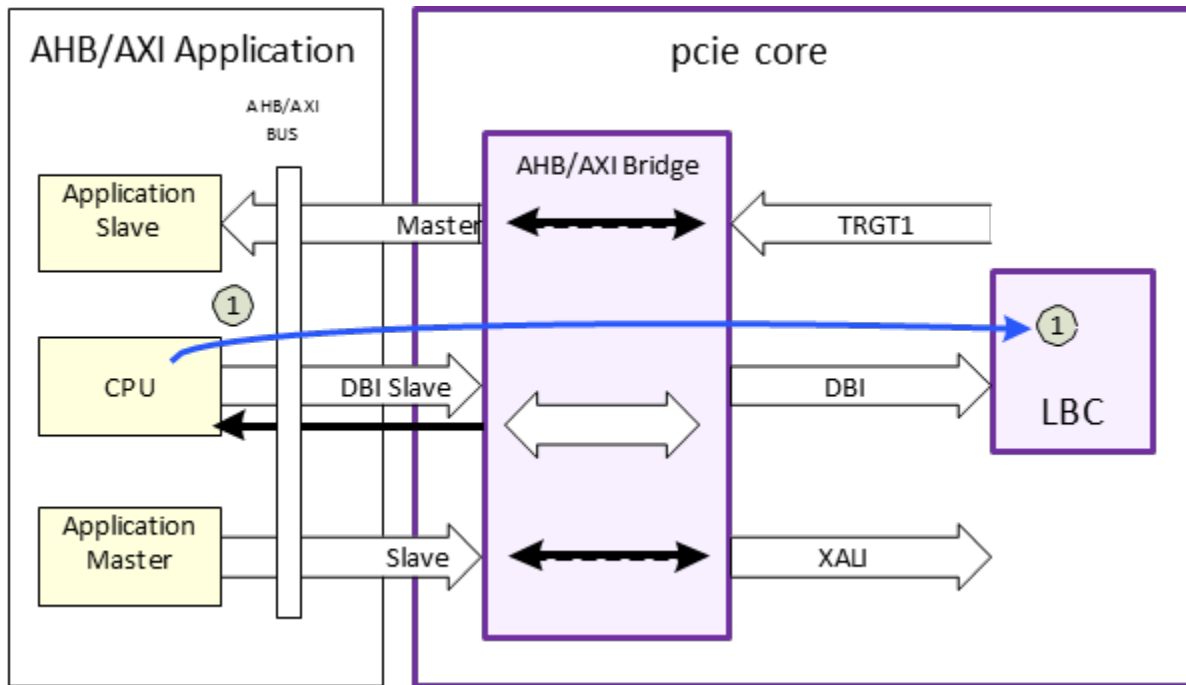

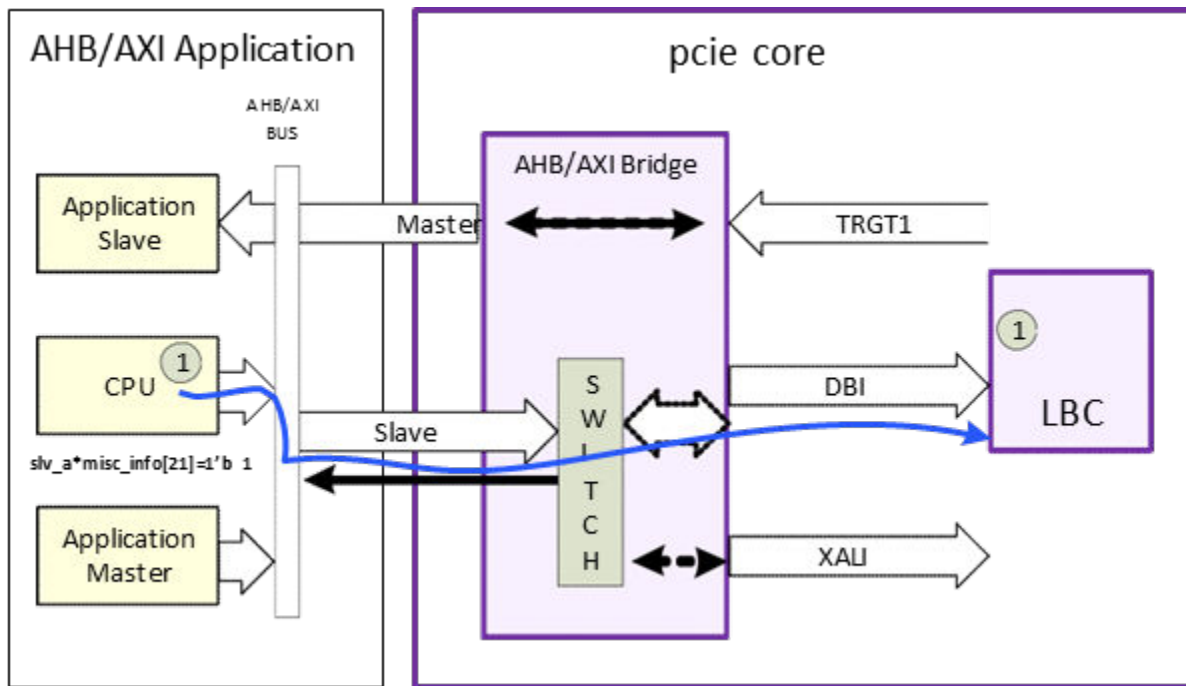

Figure 3-17 AXI DBI Access with a Shared Slave Interface (SHARED_DBI_ENABLED =1, DBI_4SLAVE_POPULATED =0)

■ When you are using the AXI bridge module, you do not have to use the AXI DBI slave interface because it is optional. You can alternatively access the DBI through the native DBI interface (which is not connected to your AXI bus). To disable DBI access through the AXI/AHB slave, disable SHARED_DBI_ENABLED and DBI_4SLAVE_POPULATED) and use the native DBI access instead.

■ You cannot share the AXI slave I/F when `CX_SRIOV_ENABLE` or `CX_ARI_ENABLE = 1`.

■ You must not enable both parameters (`SHARED_DBI_ENABLED` and `DBI_4SLAVE_POPULATED`) at the same time.

11.3.3.5.3.4 Native Core DBI to CDM/ELBI Access Details

■ The DBI address must be a DWORD address with `dbi_addr[1]=1b0`.

■ Byte access within a DWORD for write requests is possible using `dbi_wr[3:0]`.

■ The `dbi_wr[3:0]` bus also identifies the type of access as a write or read (4h0).

Table 3-8 Native Core DBI Address Bus Layout for Accessing CDM (`dbi_cs2=0`)

31-19	18-16	15-12	11-2	1	0
Not used	Function1 #0x0	Not used	1 K-DWORD Register Address	0	0

The lower 12 bits are used to access the 4KB (1K DWORDs) of the PCI Express configuration space per function.

Table 3-9 Native Core DBI Address Bus Layout for Accessing ELBI (`dbi_cs2=0`)

31-19	18-16	15-2	1	0
Not used	Functiona #0x0	16 K-DWORD Register Address	0	1

The lower 16 bits are used to access the 64KB (16K DWORDs) of the ELBI space per function.

a. When SR-IOV is enabled (`CX_SRIOV_ENABLE = 1`), this field does not exist. For an access to a physical function, the function number is indicated on `dbi_func_num`. For an access to a virtual function, the function number is indicated on `dbi_vfunc_num`.

Table 3-10 Native Core DBI Address Bus Layout for Accessing iATU and DMA Configuration Registers(`dbi_cs2=1`)

Access Type	31-20	19	18-17	16-9	8	7-2	1	0
iATU	Not used	0	Reserved	Region Number Select	0: Outbound Region	Register Address	0	1
	Not used	0	Reserved	Region Number Select	1: Inbound Region	Register Address	0	1

Table continues on the next page...

PCI Express Controller (PCIe)

DMA	Not used	1	Reserved	Channel Number Select	0:Write Channel	Register Address	0	1
	Not used	1	Reserved	Channel Number Select	1:Read Channel	Register Address	0	1

Note: If DBI_MULTI_FUNC_BAR_EN=1, refer to “DBI_MULTI_FUNC_BAR_EN Parameter (EP Mode)”

11.3.3.5.3.5 AXI Bridge DBI to CDM/ELBI Access Details

■ The DBI address must be a DWORD address (*addr[1:0]=2b00) with the CDM/ELBI selection bit of the address set to CDM(0) or ELBI(1).

■ The position of the CDM/ELBI selection bit within the address bus moves around (see Table 3-11). If DBI_MULTI_FUNC_BAR_EN =1, refer to "DBI_MULTI_FUNC_BAR_EN Parameter (EP Mode)" for CDM/ELBI selection bit position.

■ In the AXI Shared DBI slave mode, you must set sly_armisc_info[21] or sly_awmisc_info[21] =1 to indicate that the request is for the DBI, and that is not a normal PCIe outbound request.

11.3.3.5.3.6 iATU or DMA Enabled (CC_DMA_ENABLE = 1 or CX_INTERNAL_ATU_ENABLE = 1)

Table 3-11 Position of CDM/ELBI Select Bit when DMA or iATU is Enabled

Parameters	CDM/ELBI Select Bit Position
CX_ARI_ENABLE = 0 and CX_SRIOV_ENABLE = 0	21
CX_ARI_ENABLE = 1 or CX_SRIOV_ENABLE = 1	32

Table 3-12 AXI DBI Address Bus Layout (CX_ARI_ENABLE = 0 and CX_SRIOV_ENABLE = 0)

Access Type	31-22	21	20	19	18-16	15-12	11-2	1	0

11.3.3.5.3.7 iATU and DMA Disabled (CC_DMA_ENABLE = 0 and CX_INTERNAL_ATU_ENABLE = 0)

Table 3-14 Position of CDM/ELBI Select Bit when DMA and iATU Disabled

Parameters	CDM/ELBI Select Bit Position
CX_NFUNC =1 and CX_ARI_ENABLE =0 and CX_SRIOV_ENABLE =0	13
CX_NFUNCa >1 and CX_ARI_ENABLE =0 and CX_SRIOV_ENABLE =0	20
CX_NFUNCa >1 and CX_ARI_ENABLE =0 and CX_SRIOV_ENABLE =0 and DBI_MULTI_FUNC_BAR_EN=1	21
CX_ARI_ENABLE =1 or CX_SRIOV_ENABLE =1	32

PCI Express Controller (PCIe)

a. Bit position is based on CX_NFUNC and not on device_type, so a DM controller with CX_NFUNC > 1 uses bit 20 (not bit 13) in RC mode.

Table 3-15 AXI DBI Address Bus Layout (CX_NFUNC =1; CX_ARI_ENABLE =0; CX_SRIOV_ENABLE =0)

ELBI	1	0	ROM	VF#	VF Active	PF#	Reserved	1 K-DWORD Register Address	0	0

Note: If DBI_MULTI_FUNC_BAR_EN=1, refer to "DBI_MULTI_FUNC_BAR_EN Parameter (EP Mode)"

11.3.3.5.4 Features and Limitations

The following limitations exist for the LBC.

■ CDM Access Restrictions:

- Maximum payload Length =1 DWORD.
- PCIe MEM requests with Length > 1 are processed as completer abort.
- PCIe MEM requests with Length =0 are processed as completer abort.
- PCIe IO or CFG requests with Length !=1 are processed as malformed TLPs.

■ ELBI Access Restrictions:

- CS2 bit must be 1'b0.
- Maximum payload Length = CX_LBC_NW (1 or 2 DWORDs).
- PCIe MEM requests with Length > CX_LBC_NW are processed as completer abort.
- PCIe MEM requests with Length =0 are processed as completer abort.
- PCIe IO or CFG requests with Length !=1 are processed as malformed TLPs.
- Address must be CX_LBC_NW aligned.
- Does not support "Atomic Operations (AtomicOps)"
- Does not support TPH. Core does not forward the TPH bits to the ELBI.

■ ELBI Data/Address Port Width Restrictions:

- Data (Write): CX_LBC_NW= 1 or 2 DWORDs.
- Data (Read): CX_LBC_NW = 1 or 2 DWORDs per function.

■ DBI Data/Address Port Widths (with no AXI bridge):

- Data: 32 bit
- Address: 32 bit

11.3.3.5.4.1 Additional AXI DBI Limitations

The following limitations exist when you configure the controller to use the AXI bridge module.

■ The supported DBI data and address port sizes are as follow:

Table 3-19 Supported AHB DBI Slave Port Widths

Data	Address
For more details, see Table 83 on page 802.	32, 33a

a. When CX_SRIOV_ENABLE = 1 or CX_ARI_ENABLE = 1

Table 3-20 Supported AXI Dedicated-DBI Slave Port Widths

Data	Address
32	32, 33a

a. When CX_SRIOV_ENABLE = 1 or CX_ARI_ENABLE = 1

Table 3-21 Supported AXI Shared-DBI Slave Port Widths

Data	Address
32, 64, 128, 256	32, 64

■ You cannot share the normal AXI slave interface for DBI access (SHARED_DBI_ENABLED) when CX_SRIOV_ENABLE = 1 or CX_ARI_ENABLE = 1.

■ The DBI address must be a DWORD address.

■ AXI transfer widths of 8, 16, and 32 bits are supported. The AXI dedicated/shared DBI interface returns an error response to requests with width greater than 32 bits. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register 1.

- For AHB you get an error response whenever the size is not equal to 32 bits (that is, when $slv_hsize \neq 2b10$).
- The CDM only supports 32-bit data access. The AXI dedicated/shared DBI interface returns an error response to multi beat requests. The type of error response is programmable through AMBA_ER- ROR_RESPONSE_DEFAULT_OFF register1.
- No support for CC_RESPONSE_MODE =SPLIT_RETRY in AHB.
- Byte access within a DWORD for DBI requests is not possible for AHB.
- Byte access within a DWORD for DBI WRITE requests is possible for AXI (not for AHB).
- Dedicated DBI: The write strobes $dbi_wstrb[3:0]$ are sent to the LBC.
- Shared DBI: The relevant four strobes from slv_wstrb are sent to the LBC. For example on a 64-bit data bus:
 - $slv_waddr=0x0000$ and $slv_wstrb[7:0]=0x03$ results in $lbc_wr[3:0]=0x3$.
 - $slv_waddr=0x0004$ and $slv_wstrb[7:0]=0x30$ results in $lbc_wr[3:0]=0x3$.

A zero-byte write over DBI is processed as a read and should never be issued. The AXI dedicated/shared DBI slave drops a zero-byte write before it reaches the internal (native controller) DBI and returns an error response. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register1.

The type of error response returned by the AXI dedicated/shared DBI slave is the same as that programmed for UR completions in the AMBA_ERROR_RESPONSE_DEFAULT_OFF register.

11.3.3.6 Reliability, Availability, and Serviceability (RAS)

This section discusses how the controller maintains the integrity of the link using different methods at different points. It also discusses error injection and traffic, error, and state logging.

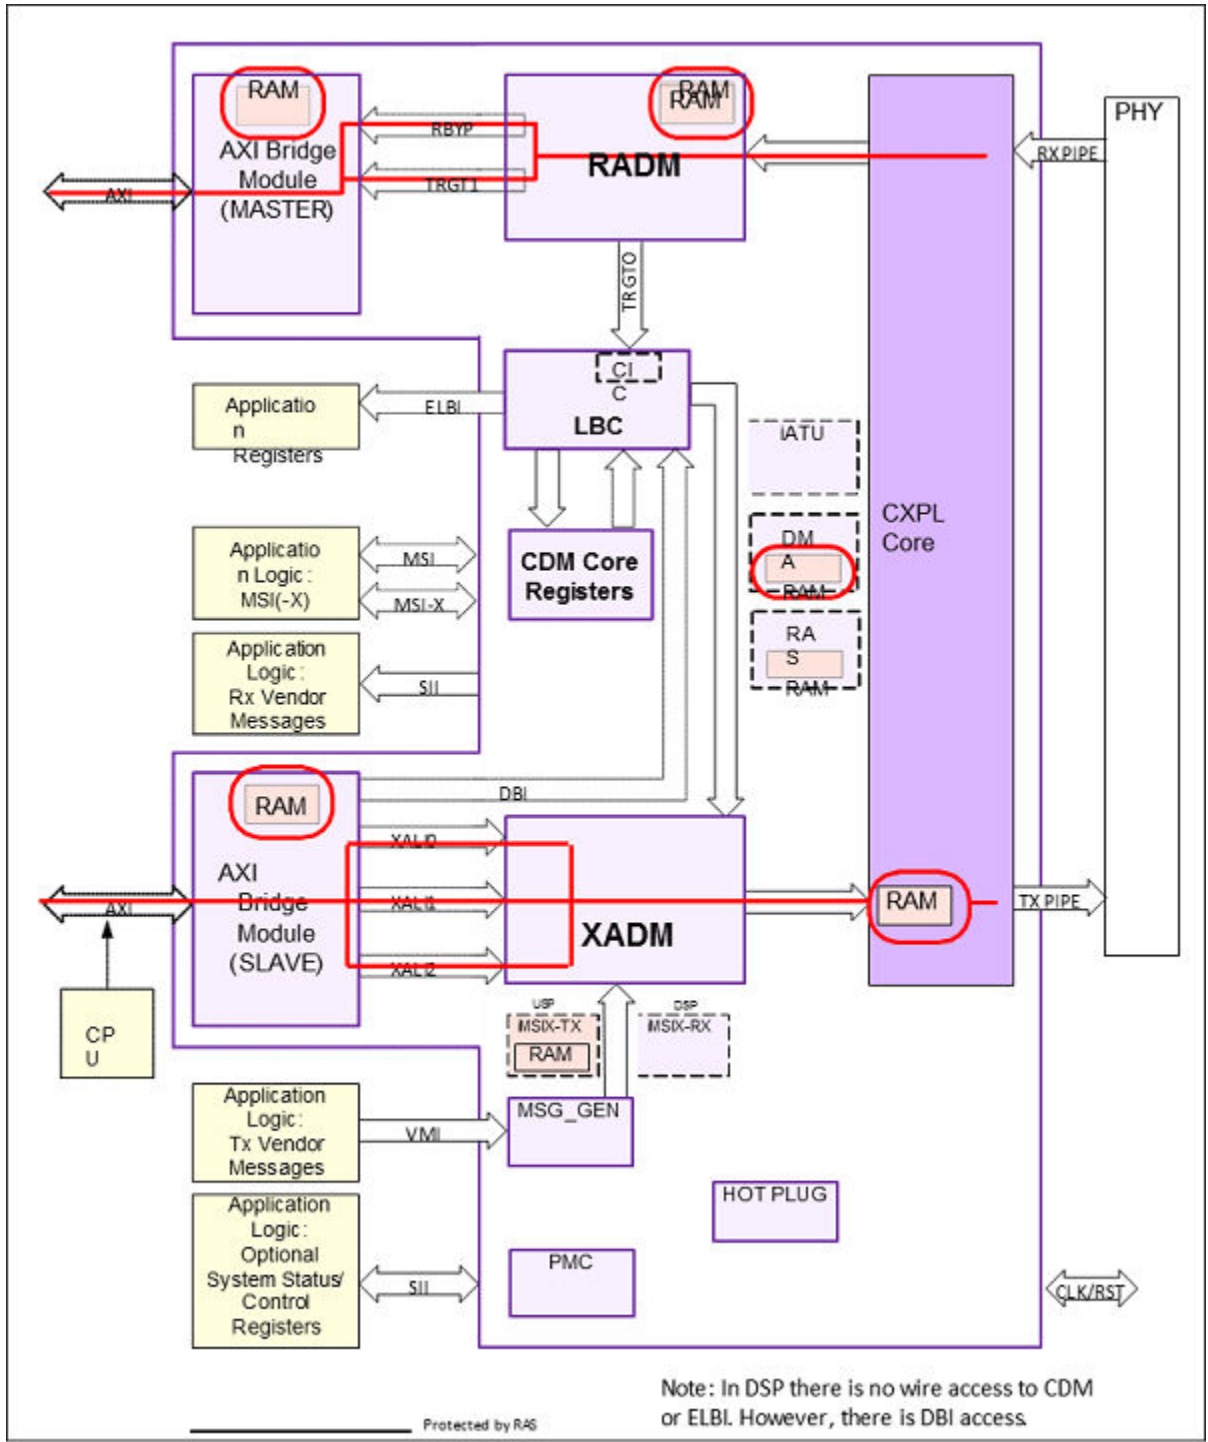

11.3.3.6.1 Overview

PCIe system Reliability, Availability, and Serviceability (RAS) ensures that failures in the underlying processes and hardware components do not cause any interruptions in the overall system operation. PCIe RAS consists of four fundamental components:

- Reliable protocol architecture involving LCRC, ECRC, ACK/NAK handshake, and Replay mechanisms.

- Internal device-level Datapath and RAM protection (RAS DP) of data, header, and RAM control signals from application I/F to LCRC extraction/generation points.
- Debug, Error Injection, and Statistic gathering (RAS DES).
- Hot-plug usage to swap out components with uncorrectable errors.

Figure 3-18 RAS DP Protection Coverage

11.3.3.6.2 RAS Wire Protection (ECRC)

The controller uses the optional ECRC checksum, as defined in the PCIe specification, to protect the wire part of the link. The controller inserts the ECRC in the transmit logic and checks it in the receive logic.

11.3.3.6.2.1 Generation

It is expected that the ECRC is not present in traffic that your application is presenting on the transmit interfaces of the controller. The controller generates and inserts the ECRC. When you are not using the AXI bridge, then you should set `client0_tlp_td=0`. To enable ECRC insertion:

- Set `CX_ECRC_ENABLE = AER_ENABLE = 1`
- Set the `ECRC_GEN_EN` field of the `ADV_ERR_CAP_CTRL_OFF` register.

When you select the address alignment feature (`GLOB_ADDR_ALIGN_EN = 1`) and you are not using the AXI bridge, your application must set `clientN_addr_align_en=0` for those TLPs that contain ECRC (TD bit

=1). For more details, see "Address Alignment and ECRC".

11.3.3.6.2.2 Checking

When the ECRC is present, the controller checks it and removes it from the TLP. To enable ECRC checking:

- Set `CX_ECRC_ENABLE = AER_ENABLE = CX_ECRC_STRIP_ENABLE = 1`
- Set the `ECRC_CHECK_EN` field of the `ADV_ERR_CAP_CTRL_OFF` AER register.

By default, when the controller detects a TLP with an ECRC error, it performs the following:

- Discards the TLP
- Generates a completion (for non-posted requests) with the completion status set to CA or UR
- Sets the status in the PCI-compatible status register
- Sets the status in the AER registers (when you enable AER)
- Generates an error message (upstream port only)

1. The controller does not remove the ECRC when CX_P2P_ENABLE =1. For more details, see the CX_ECRC_STRIP_ENABLE parameter.
2. You can program the controller to forward the TLP.

11.3.3.6.3 RAS Data Protection (DP)

For the parts of the controller outside of ECRC/LCRC protection, you can use the RAS DP feature consisting of Data Path protection and RAM Protection.

- ❑ The MSBs on radm_trgt1_tlp_ptfx and radm_bypass_tlp_prfx for the TLP prefixes.
- d. The controller pulses app_parity_err[2:0] output bus. Your application can OR the bus bits and drive the Uncorrectable Error bit of the app_err_bus input. This is not required when RASDP error mode is enabled because the controller handles the parity error as an uncorrectable error in this mode.
- a. The controller might drop TLPs that were received prior to the bad TLP.

Statistics and Error Injection Features	
Error Injection (Per TLP)	✓✓✓✓
Programmable 1-bit or 2-bit Injection	
Programmable Continuous or Fixed-Number (n) Injection Modes Programmable Global Enable/Disable	
Programmable Selectable Location Where Injection Occurs	
Error Statistics	✓✓✓✓
Counts # Correctable Errors Counts # Uncorrectable Errors	
Reports Location of First and Last Errors (Correctable and Uncorrectable) Reports RAM Addresses of Detected Errors (Correctable and Uncorrectable)	

- b. 2-bit ECC and all parity errors.
- a. A single RASDP error might increment more than one counter.
- c. RASDP_RAM_ADDR_UNCORR_ERROR_OFF and RASDP_RAM_ADDR_UNCORR_ERROR_OFF registers.

Limitations

radm_trgt1_hdr_prot and radm_bypass_hdr_prot for the TLP header.

b. Using the RASDP_ERROR_PROT_CTRL_OFF register.

c. In RASDP error mode, TLPs are not guaranteed to be correct. You must discard all TLPs when this signal is high.

d. 1-bit ECC errors.

a. When an uncorrectable RAS.DP error is detected by the AXI logic, the following scenarios apply:-

The controller has a set of RAS DP registers as defined in Table 3-23.

Note: There is one set of common capability registers shared across all physical functions which can be accessed through each function. The exception is the NEXT_OFFSET field in the capability header register.

Table 3-23 RAS DP Vendor Specific Extended Capability (VSEC Registers)

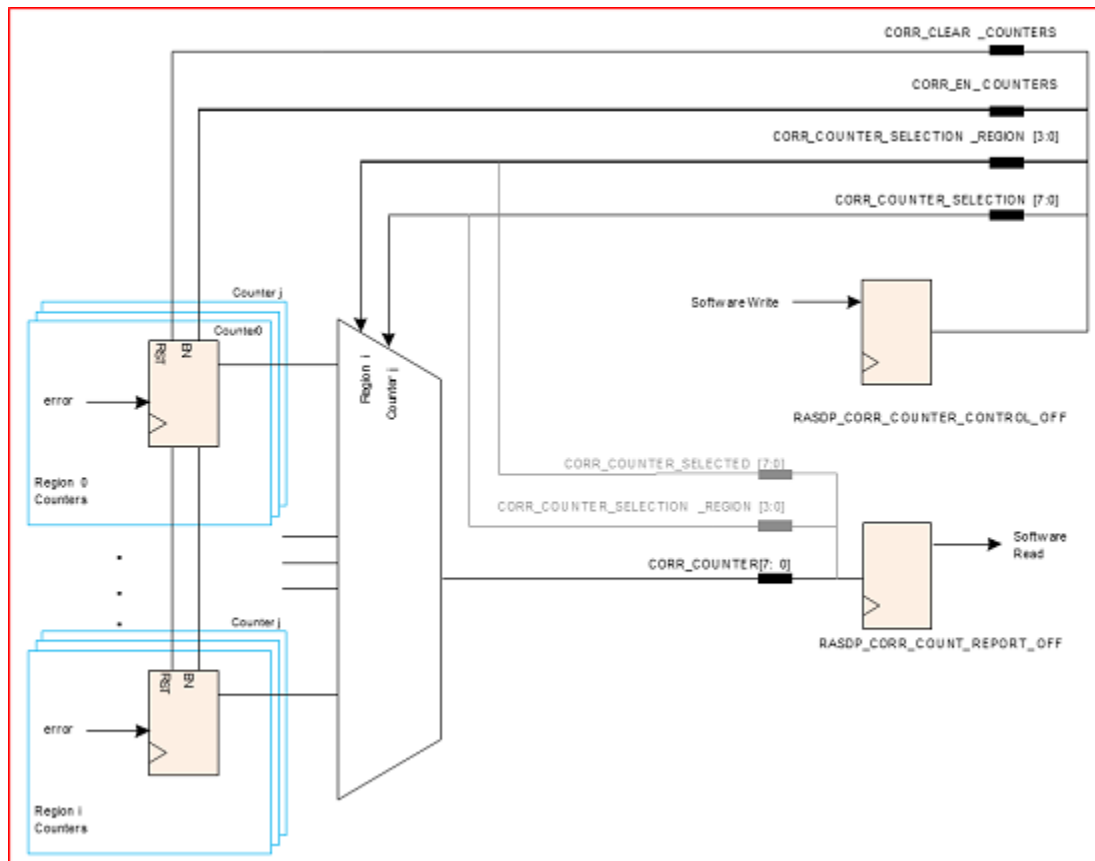

Register	Description
RASDP_EXT_CAP_HDR_OFF	Vendor-Specific Extended Capability Header.
RASDP_VENDOR_SPECIFIC_HDR_OFF	Vendor Specific Header.
RASDP_ERROR_PROT_CTRL_OFF	Error Protection Control.

RASDP_CORR_COUNT_REPORT_OFF	Corrected error (1-bit ECC) counter data.

Table continues on the next page...

PCI Express Controller (PCIe)

RASDP_UNCORR_COUNTER_CTRL_OFF	Uncorrected error (2-bit ECC and parity) counter selection and control.
RASDP_UNCORR_COUNT_REPORT_OFF	Uncorrected error (2-bit ECC and parity) counter data.
RASDP_ERROR_INJ_CTRL_OFF	Error injection control.
RASDP_CORR_ERROR_LOCATION_OFF	Corrected errors locations.
RASDP_UNCORR_ERROR_LOCATION_OFF	Uncorrectable errors locations.
RASDP_ERROR_MODE_EN_OFF	RASDP error mode enable.
RASDP_ERROR_MODE_CLEAR_OFF	RASDP error mode clear.
RASDP_RAM_ADDR_CORR_ERROR_OFF	RAM Address where a corrected error (1-bit ECC) has been detected.
RASDP_RAM_ADDR_UNCORR_ERROR_OFF	RAM Address where an uncorrected error (2-bit ECC) has been detected.

Figure 3-19 RAS DP Register Access to Error Counters (Same Method Applies to Uncorrectable Errors)

■ Silicon Debug Support (Control and Status of PIPE, Deskew, Ack/Nak, Reversal, FC, EQ, LTSSM, Replay)

□ Additional MSBs on client0_tlp_data and client1_tlp_data for the TLP data.

11.3.3.6.3.1 Datapath Protection (ECC or Parity)

For Tx traffic, your local application logic must add ECC or parity protection codes¹ to traffic using:

- client0_tlp_hdr_prot and client1_tlp_hdr_prot for the TLP header.
- For AXI configurations: mstr_awaddrp, mstr_araddrp, mstr_wdatap, and mstr_rdatap.

For Rx traffic, your local application must check the protection codes on:

- radm_trgt1_hdr_prot and radm_bypass_hdr_prot for the TLP header.
- The MSBs on radm_trgt1_tlp_data and radm_bypass_tlp_data for the TLP data.
- The MSBs on radm_trgt1_tlp_ptfx and radm_bypass_tlp_prfx for the TLP prefixes.
- For AXI configurations: mstr_awaddrp, mstr_araddrp, mstr_wdatap, and mstr_rdatap.

11.3.3.6.3.2 RAM Protection (ECC on data and Parity on address)

An ECC checksum is calculated and added to data that is written to the RAM. When the data is read from the RAM, then the controller recalculates the ECC and compares it against the value read from RAM. RAM ECC protection is provided for all of the RAMs in the controller, except for the RAS-DES RAM. ECC corrects single-bit errors and reports (without correction) multi-bit errors.

Table 3-22 RAS Data Protection Features and Limitations

PCI Express Controller (PCIe)

<p>■ Subsequent Replays are Silently Dropped Credits Accuracy Retained</p> <p>Uncorrectable Error is Logged</p> <p>Uncorrectable Internal Error Reported (AER)</p> <p>Instruct Core to Exit Error Mode by Writing to RASDP_ERROR_MODE_CLEAR_OFF Register Through DBI</p> <p>Uncorrectable Errors Propagate and Cause an Error in Some Subsequent Check Points (Error Pollution)</p>	
<p>Note: The controller attempts a best-effort recovery in RASDP Error Mode (after detection of an uncorrectable error). For more information, see footnotes j, k, l, and m.</p>	
<p>Correctable Error Handling</p> <p>Correctable Error is Logged</p> <p>Correctable Internal Error Reported (AER) TLP is Modified/Corrected.</p> <p>Errors Reported When Detected (Immediately)</p> <p>Error Correction Enable/Disable Control (Per TX/RX Direction and Per-Layer)</p>	<p>✓✓✓✓✓</p>

- a. You can disable RASDP error mode by writing to the to RASDP_ERROR_MODE_EN_OFF register. This is not recommended.
- b. In RASDP error mode, TLPs are not guaranteed to be correct. You must discard all TLPs when this signal is high.
- c. The controller might nullify TLPs that were received prior to the bad TLP.
- d. The controller might drop TLPs that were received prior to the bad TLP.
- e. The controller implements a best-effort approach in accounting for credits under uncorrectable error conditions. However, credit inaccuracies are unavoidable in such conditions. This might result in performance degradation or triggering of overflow protection mechanisms.
- f. 2-bit ECC and all parity errors.
- g. The core only reports uncorrectable errors when it exits RASDP error mode.
- h. 1-bit ECC errors. i. If the controller is capable of single bit error correction, disabling ECC error correction does not change the nature of the errors and their reporting. A single-bit error is reported as a correctable error although correction might be disabled.

- a. When RAS is enabled RTRGT1 address width (FLT_Q_ADDR_WIDTH) can be either 32 or 64, other values are not supported by the controller.
- b. When an uncorrectable RAS.DP error is detected by the AXI logic, the following scenarios apply:- If the payload data is corrupted but the bridge is functional, no reset is required to resume normal operation. -If the header is corrupted and bridge is in an inconsistent state a hot/cold reset is required to resume normal operation.

- c. RAM protection cannot be enabled without datapath protection.
- d. The complete TLP payload data is protected, but only the address part of the header is fully protected inside the AXI bridge. The remainder of the header (carried on the *_misc_info_* signals) is not protected everywhere inside the AXI bridge and is routed without parity or ECC. It is however fully protected in the rest (native part) of the controller.
- e. A single RASDP error might increment more than one counter.

Table 3-23 RAS DP Vendor Specific Extended Capability (VSEC Registers)

Register	Description

RASDP_RAM_ADDR_UNCORR_ERROR_OFF	RAM Address where an uncorrected error (2-bit ECC) has been detected.

Figure 3-19 RAS DP Register Access to Error Counters (Same Method Applies to Uncorrectable Errors)

11.3.3.6.4 RAS Debug, Error Injection, and Statistics (DES)

The RAS DES feature consists of:

- General Diagnostic Support (Legacy Internal Probe Points).
- Event Counter Support (Error and Non-Error).
- Error Injection Support (ECRC, LCRC, SEQ#, Nullify, Header, Ack/Nak block, Ksymbol, FC Update)
- Time-based Analysis Support (RX/TX data throughput and time spent in each low-power LTSSM state)
- Silicon Debug Support (Control and Status of PIPE, Deskew, Ack/Nak, Reversal, FC, EQ, LTSSM, Replay)

11.3.3.6.4.1 General Diagnostic Support

You enable the basic DES operation with the `CX_RAS_DES_ENABLE` parameter. Your application can use the signals in Table 3-24.

Table 3-24 General Diagnostic Signals

Signal Name
diag_ctrl_bus
diag_status_bus

11.3.3.6.4.2 Event Counter Support

You enable this feature with the CX_RAS_DES_EC_ENABLE parameter. Your application can use the outputs in Table 3-25 and registers in Table 3-27.

Table 3-25Event Counter Signals

Output
cdm_ras_des_ec_info_common
cdm_ras_des_ec_info_i (for i = 0; i <= 15)

Register	Description
RAS_DES_CAP_HEADER_REG	Vendor-Specific Extended Capability Header.
VENDOR_SPECIFIC_HEADER_REG	Vendor-Specific Header.
EVENT_COUNTER_CONTROL_REG	Event Counter Control.
EVENT_COUNTER_DATA_REG	Event Counter Data.

Figure 3-20Event Counter Register Access

11.3.3.6.4.3 Event Counter Data Details

The following tables provide the Group/Event numbers which are required when using the EVENT_COUNTER_CONTROL_REG viewport control register to read each of the event counters. Some of the event counters only exist for specific configurations. Groups 5-7 are implemented in RAM as indicated. The group # is set by EVENT_COUNTER_EVENT_SELECTION[11:8] and the event # is set by EVENT_COUNTER_EVENT_SELECTION[7:0]

Table 3-28 Event Counter Group #0 (4-bit Layer1 Error Counter Per-Lane)

Event #	Description	Note
0x00	EBUF Overflow	-
0x01	EBUF Under-run	-
0x02	Decode Error	-
0x03	Running Disparity Error	-
0x04	SKP OS Parity Error	Gen3

Table continues on the next page...

PCI Express Controller (PCIe)

0x05	SYNC Header Error	Gen3
0x06	Rx Valid de-assertion	RxValid de-assertion without EIOS(s).

Note: There is one set of common capability registers shared across all physical functions which can be accessed through each function. The exception is the NEXT_OFFSET field in the capability header register.

11.3.3.7 Messages

This section describes the processing of messages through the controller.

For a proper understanding of messages you should be familiar with Section 2.2.8, "Message Request Rules" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

- Messages (Msg/MsgD1) are posted transactions.
- Vendor Defined and PTM messages are Msg / MsgD.
- Set Slot Power Limit messages are MsgD.
- All other messages are Msg. For more details, see "Interrupts".

11.3.3.7.1 Message Generation

Messages that are transmitted by the controller are derived from the following sources:

- the controller (automatically)
- the controller (under the control of your application)
- your application
- the host/client software

Figure 3-22 Message Transmission: EP Mode

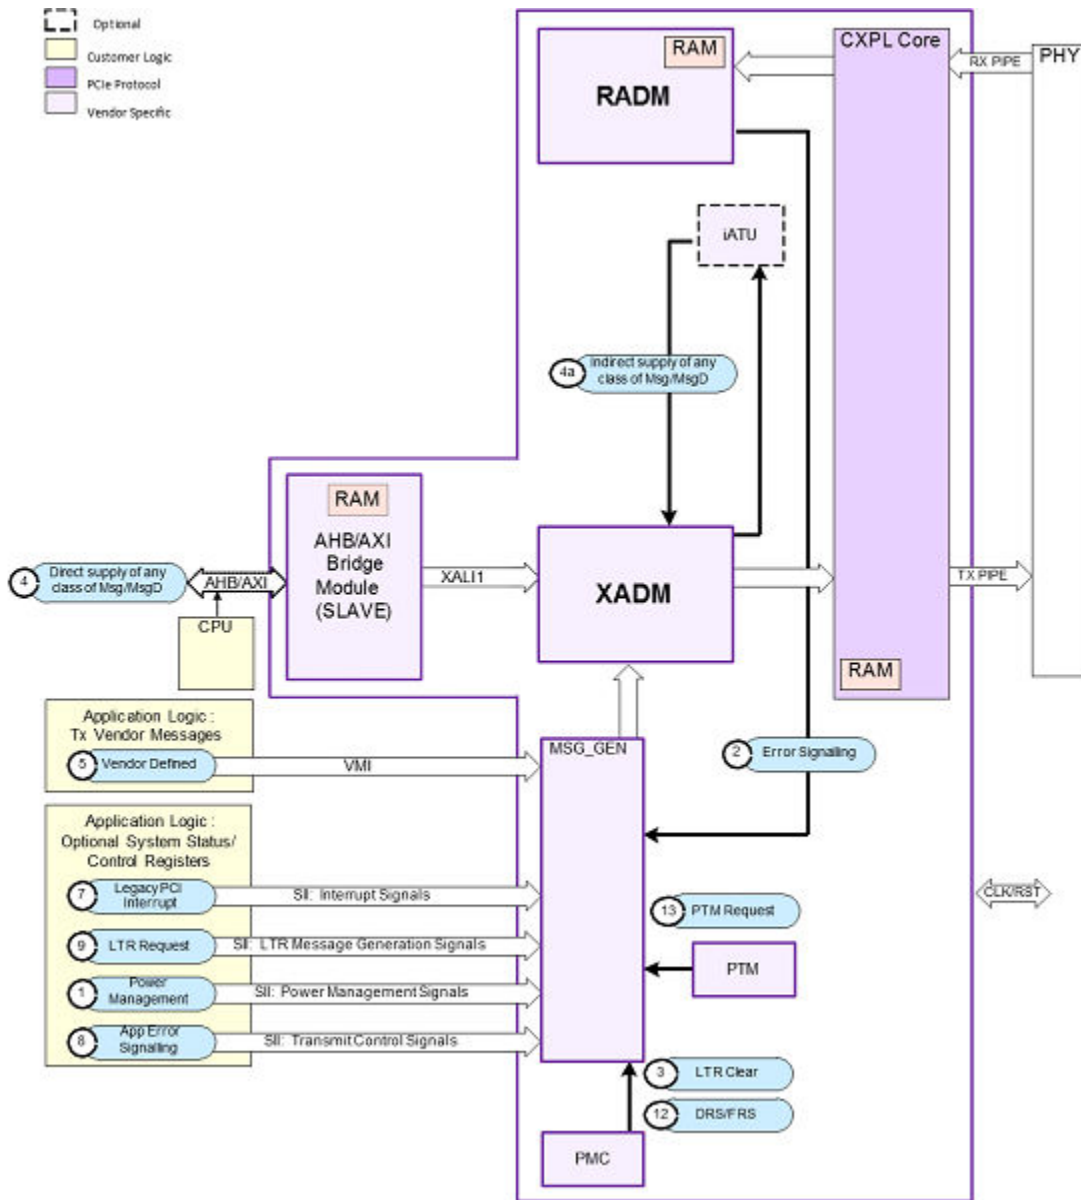

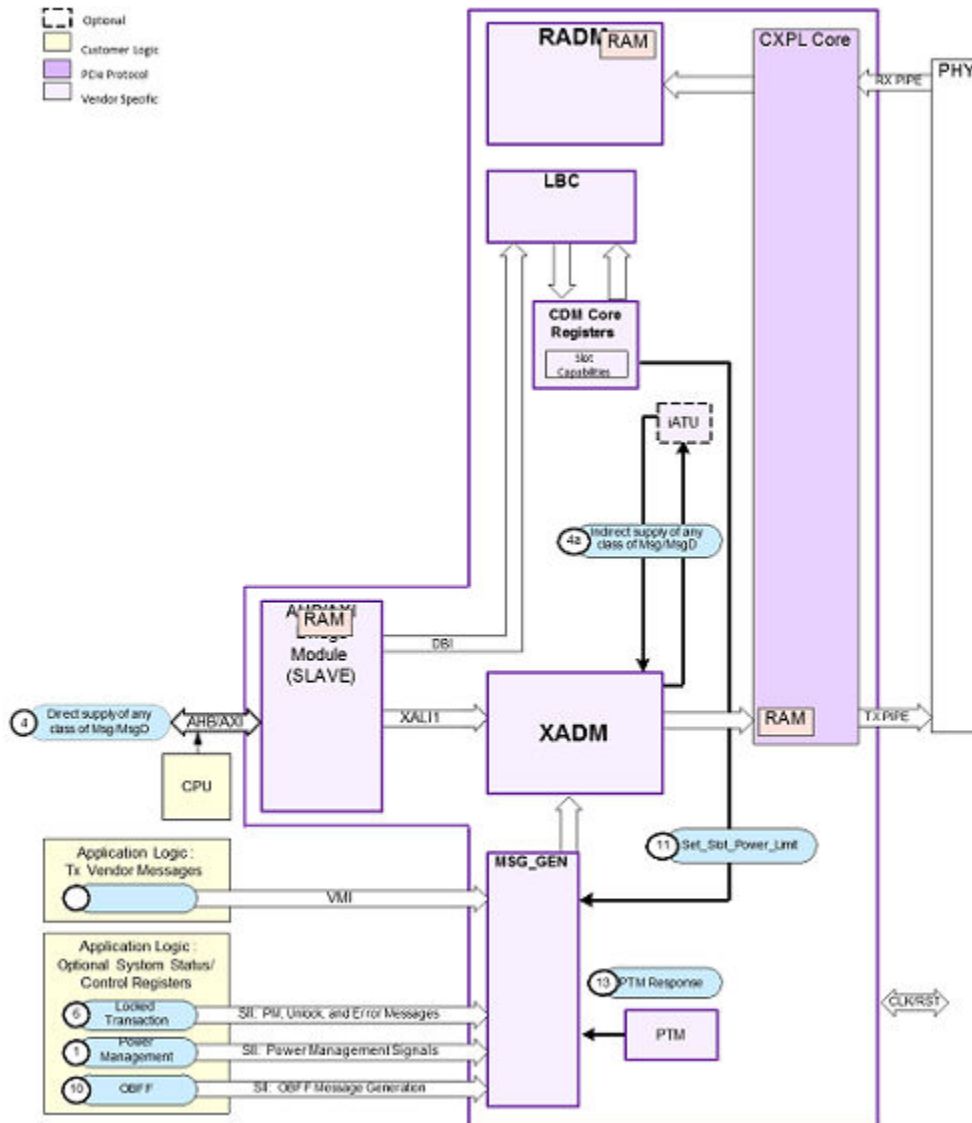

Figure 3-23 Message Transmission: RC Mode

PCI Express Controller (PCIe)

For definitions of acronyms used for block and interface names, see "Terms and Descriptions".

Table 3-46 Types of Transmitted Messages

Index	Message Source (Type)	EP Mode	RC Mode
1	Power Management interface (Msg)	For more details, see "Power Management" .	For more details, see "Power Management"
2	Error Signaling inside the controller (Msg)	COR_ERR / ERR_NONFATAL / ERR_FATAL. For more details, see "Reliability, Availability, and Serviceability (RAS)" for more details	n/a

Table continues on the next page...

3	LTR Clear (Msg)	For more details, see "Latency Tolerance Reporting (LTR) Message Generation [EP Mode]" .	n/a
4	Direct Supply of any class of message (Msg/MsgD)	XALI0/1/2 or AXI For details on how to generate a message at the XALI0/1/2 (or AXI) interface, see "Transmit Client Interface Protocol Rules" transmit Client Interface Protocol Rules on page235 and "Application Msg/MsgD Programming Examples" .	
4a	Indirect Supply of any class of message (Msg/MsgD)	For more details on generating Msg/MsgD from MWr/IOWr using an internal address translation unit (ATU), see "iATU Outbound MSG Handling" For more details on the supported methods of Msg/MsgD generation, see Table 3-48 and Table 3-49.	
5	Vendor Defined (Msga)	The controller generates Vendor Defined messages in response to requests on the VMI (see "Vendor Message Interface (VMI)").	
6	Locked Transaction (Msg)	n/a	Unlock message, triggered by root complex application logic through the app_unlock_msg pin in.
7	Legacy PCI Interrupt (Msg)	SII interrupt signals sys_int.	n/a
8	Error Signaling from the application (Msg)	The controller generates Error Signaling messages in response to application requests on the SII app_err* I/O. It is also possible to generate Error messages through the client interfaces. For more details, see items 4and 4a in this table.	n/a
9	LTR Request (Msg)	For more details, see "Latency Tolerance Reporting (LTR) Message Generation [EP Mode]" .	n/a

Table continues on the next page...

Index	Message Source (Type)	EP Mode	RC Mode
10	Optimized Buffer Flush Fill (OBFF) (Msg)	n/a	OBFF messages, triggered by your application logic through the app_obff_obff_msg_req/ app_obff_idl e_msg_req/ app_obff_cpu_active_msg_r eq inputs. For more details, see "OBFF Message Generation [RC Mode]" .

PCI Express Controller (PCIe)

11	Set_Slot_Power_Limit (MsgD)	n/a	Set_Slot_Power_Limit message, triggered by writing to the Slot Capabilities register through the DBI, or when LTSSM enters L0
12	DRS/FRS (Msg)	For more details, see "FRS Qu n/a	
13	PTM	PTM Request (Msg)	PTM Response (Msg/MsgD)

Formore details, see "Precision Time Measurement"

a. MsgD transmission not possible on Vendor Message Interface (VMI). For more details, see "Vendor Defined Message (VDM) Generation". However, it is possible through (4).

11.3.3.7.1.1 Vendor Defined Message (VDM) Generation

VDMs can be generated by your application using any of the following methods:

- The controller generates VDMs in response to requests on the VMI.
- The VMI can be used to send Msg only. It does not support message with payload (MsgD).
- The inputs `ven_msg_fmt[1:0]` and `ven_msg_len[9:0]` should be set to 0x1 and 0x0 respectively to indicate 4-DWORD header and no payload.
- VDMs created by you at the VMI are always subject to translation by the “Internal Address Translation Unit (iATU)”

NOTE

It is preferable to use the SII interface to send a VDM. The AXI bridge slave can also support message transmission of a VDM without any modifications.

A full set of limitations for the AXI bridge is available at “AXI Bridge Limitations” and “AHB Bridge Limitations”.

- Direct supply of I/O and MEM TLPs at XALI0/1/2 (or AXI bridge slave when present) to be converted to LTR messages. The iATU can convert I/O and MEM TLPs to Msg TLPs. For more details, see "iATU Outbound MSG Handling".
- Direct supply of Msg and MsgD TLPs at XALI0/1/2 (or AXI bridge slave when present).

Note: You must use 64-bit addressing when using the Direct supply method of VDM generation. For more details, see figure 3-27 and 3-28.

11.3.3.7.1.2 Latency Tolerance Reporting (LTR) Message Generation [EP Mode]

You can enable LTR message generation by setting `CX_LTR_M_ENABLE = 1`. The LTR feature is not supported for Virtual functions (VF). You can generate LTR messages using any of the following methods:

- The controller generates LTR messages in response to requests made by your application logic on the SII input see `app_ltr_msg_req`.
- Direct supply of Msg TLPs at XALI0/1/2 (or AXI bridge slave when present).

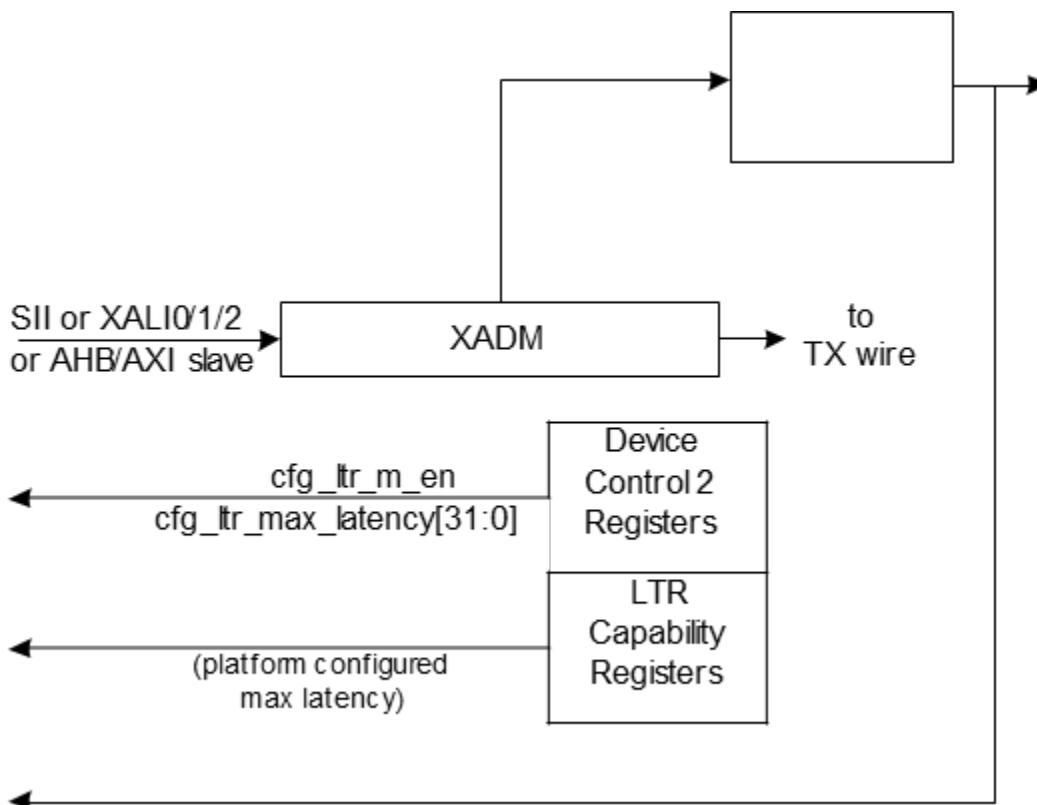

■ Direct supply of I/O and MEM TLPs at XALI0/1/2 (or AXI bridge slave when present) to be converted to LTR messages. The iATU can convert I/O and MEM TLPs to Msg TLPs. For more details, see “iATU Outbound MSG Handling”.

When the LTR is changing fast and dynamically with the data stream, the LTR message should be synchronized with the data stream and transmitted over the cores XALI0/1/2 interfaces (or AXI bridge slave when present). For applications where the LTR is changing slowly or is static, then you can transmit the LTR message over the SII message interface. In that case, it is assumed that the LTR message is guided by software and the SII message interface is externally stimulated by software (by writing to a memory mapped application register whose outputs are driving the SII inputs). When you are using the SII interface you should drive the contents of the LTR message header on the `app_ltr_msg_latency[31:0]` input. It has the same format as LTR messages described in the PCIe specification.

The actual values in the LTR message transmitted by this upstream port are captured in the port logic LTR Latency Register (`LTR_LATENCY_OFF`). They are also reflected on the `app_ltr_latency[31:0]` output.

The values in the PF Latency Tolerance Reporting (LTR) Capability Registers (`LTR_LATENCY_OFF`) are reflected on the `cfg_ltr_max_latency` output.

Figure 3-24 LTR Registers

The controller automatically generates a new LTR message with the Requirement bits set to 0 for both Snoop and No-Snoop latencies when:

- A function is directed to a non-D0 state through a write to the Power State field of the Power Management Control and Status register, and the LTR mechanism is active since the last DL_Down to DL_Up transition. or
- The LTR mechanism is disabled by clearing the LTR Mechanism Enable field of the Device Control 2 register. This field is cleared through a CFG write or a function level reset (FLR).

You must not send an LTR message when the LTR Mechanism Enable bit of the Device Control 2 Register is 1. When this bit is 0, the controller does not block transmission of LTR messages that you generate. The value of the LTR Mechanism Enable bit is reflected on the `cfg_ltr_m_en` output.

- It is preferable to use the SII interface to send LTR messages. The AXI bridge slave can also support message transmission of LTR messages without any modifications.
- A full set of limitations for the AXI bridge is available at “AXI Bridge Limitations” and “AHB Bridge Limitations” .
- It is preferable to use the SII interface to send OBFF messages. The bridge AXI slave can also support message transmission of OBFF messages without any modifications.

b. When the "payload inhibit" feature of the iATU is used, then `slv_wstrb` does not need to be set. Similarly, for iATU header and tag substitution; the iATU can be set up to fill these fields in the outgoing TLP.

11.3.3.7.1.3 OBFF Message Generation [RC Mode]

You can enable OBFF message generation by setting `CX_OBFF_SUPPORT`. You can generate OBFF messages using any of the following methods:

- The controller generates OBFF messages in response to requests made by your application logic on the SII `app_obff_*_msg_req` inputs.
- Direct supply of Msg TLPs at XALI0/1/2 (or AXI bridge slave when present).
- Direct supply of I/O and MEM TLPs at XALI0/1/2 (or AXI bridge slave when present) to be converted to OBFF messages. The optional iATU can convert I/O and MEM TLPs to Msg TLPs. For more details, see “iATU Inbound MSG Handling” .

You must not send an OBFF message when the OBFF Enable field of the Device Control 2 Register (DEVICE_CONTROL2_DEVICE_STATUS2_REG) is 00. When this field is 00, the controller does not block transmission of OBFF messages that you generate. The value of the OBFF Enable field is reflected on the `cfg_obff_en[1:0]` output.

When you configure the controller to support either variation (A or B) of OBFF messages (through the OBFF Enable field of the Device Control 2 Register (DEVICE_CONTROL2_DEVICE_STATUS2_REG), and your application sends an OBFF message when the controller is in the L0s or L1 TX states, then the controller transitions to the L0 state and transmits the message. According to the PCI Express Base Specification, Revision 4.0, Version 0.7, the controller should drop a Variation A message in this scenario. Therefore, your application must not send Variation A OBFF messages when the controller is in the L0s or L1 TX states.

Your application must monitor the `pm_linkst_in_l0s`, `pm_linkst_in_l1sub`, and `pm_linkst_in_l1` outputs. For the purpose of controller optimization the controller does not do this check; your application must do the check.

- It is preferable to use the SII interface to send OBFF messages. The bridge AXI slave can also support message transmission of OBFF messages without any modifications.
- A full set of limitations for the AXI bridge is available at “AXI Bridge Limitations” and “AHB Bridge Limitations” .

11.3.3.7.1.4 OBFF Wake Signal Encoder Reference Design

Figure 3-25 Encoder Example Design in (DSP)

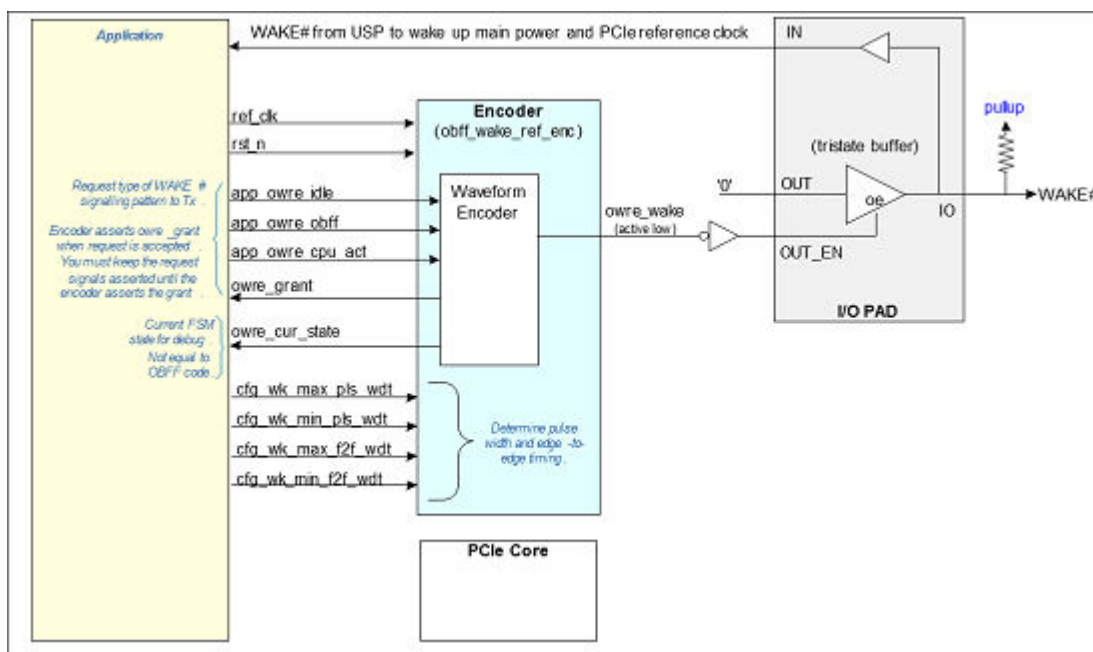

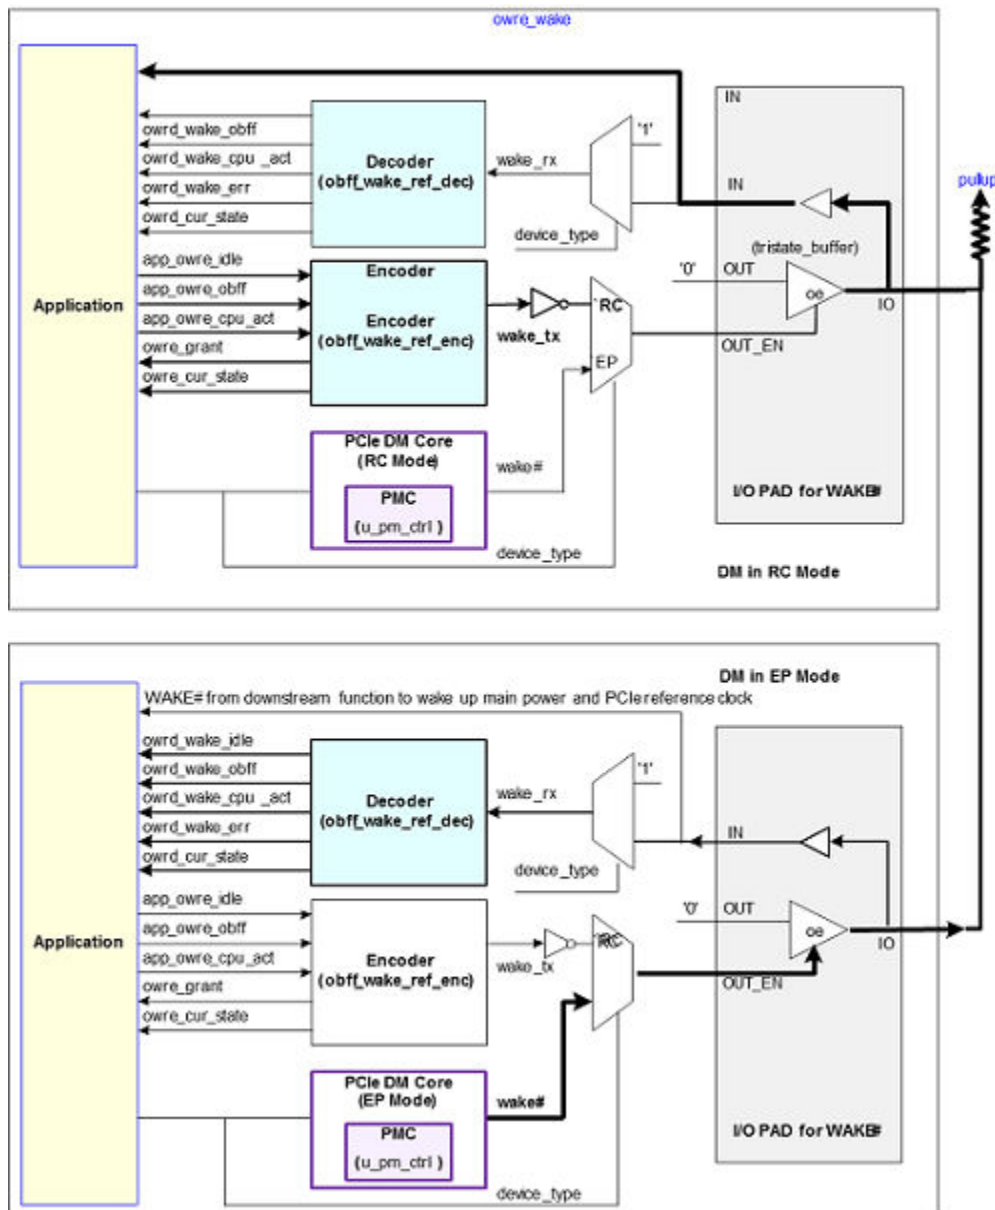

Table 3-47 OBFF WAKE# AC Specification (Table 2.6.2 of PCIe Specification)

Symbol	Parameter	Min	Max	Unit	Relationship to Timing Inputs
TWKRF	WAKE# rise-fall time		100	ns	n/a
TWAKE-TX-MIN-PULSE	Minimum WAKE# pulse width; applies to both active-inactive-active and inactive-active-inactive cases.	300		ns	$cfg_wk_min_pls_wdt * Ta$ CK_PERIOD
N/A	Maximum WAKE# pulse width; applies to both active-inactive-active and inactive-active-inactive Set to less than 50% of { $cfg_wk_max_f2f_wdt * TCK_PERIOD$ }		500	ns	$cfg_wk_max_pls_wdt * TCK_PERIOD$
TWAKE-FALL-FALL-CPU-ACTIVE	Time between two falling WAKE# edges when signalling CPU Active.	700	1000	ns	min = $cfg_wk_min_f2f_wdt * TCK_PERIOD$ max = $cfg_wk_max_f2f_wdt * TCK_PERIOD$

11.3.3.7.1.5 Application Msg/MsgD Programming Examples

The following tables enumerate the different ways that your application can generate Msg and MsgD TLPs.

Table 3-48Msg Without Payload Transmission Methods

Application Interface	Description	Application I/O Signals
AHB	Direct Supply using a Msg transaction.	slv_req_misc_info[4:0] =MSG slv_req_misc_info[25:22] =0000

Table continues on the next page...

	Indirect Supply (iATU) using a MWra transaction. The iATUb needs to be configured to translate MWr to Msg TLPs.	slv_req_misc_info[4:0] =MEM slv_req_misc_info[25:22] =0000
AXI	Direct Supply using a Msg transaction.	slv_awmisc_info[4:0] =MSG slv_wstrb[3:0] =0000 slv_awmisc_info[20:13] = message code slv_awmisc_info_p_tag[5:0] = tag slv_awmisc_info_hdr_34dw[63:32] = 3rd TLP header DWORD slv_awmisc_info_hdr_34dw[31:0] = 4th TLP header DWORD
	Indirect Supply (iATU) using a MWra transaction. The iATUc needs to be configured to translate MWr to Msg TLPs.	slv_awmisc_info[4:0] =MEM slv_wstrb[3:0] =0000 slv_awmisc_info_hdr_34dw[63:32] = 3rd TLP header DWORD slv_awmisc_info_hdr_34dw[31:0] = 4th TLP header DWORD
XALI0/1/2 (Native controller)	Direct Supply using a Msg transaction.	client1_tlp_type =MSG client1_tlp_fmt[1:0] =01 client1_tlp_byte_len =0 client1_tlp_byte_en =message Code client1_tlp_addr[31:0] =header bytes 12-15 client1_tlp_addr[63:32] =header bytes 8-11
	Indirect Supply (iATU) using an MWra transaction. The iATU needs to be configured to translate MWr to Msg TLPs. A MWr with an "effective length of 0"d is converted to Msg and all other MWr TLPs are converted to MsgD.	client1_tlp_type =MSG client1_tlp_byte_len =0 client1_tlp_byte_en =00000000
VMI	The controller generates Vendor Defined messages in response to requests on the VMI (see "Vendor Message Interface (VMI)")	

a. For AXI, the determination of effective length takes the first and last byte enables into account using slv_wstrb for AXI and slv_req_misc_info[25:22] for AHB. When not using the AXI bridge, an effective length of "0" is determined by looking for a "0" at client_tlp_fmt[1]. When you are only translating the address of MSG TLPs then use client0_tlp_byte_en to provide the message code.

Table 3-49Msg With Payload Transmission Methods

Application Interface	Description	Application I/O Signals
AHB	Direct supply using a MsgD transaction.	slv_req_misc_info[4:0] =MSG

VMI	MsgD is not supported.	

a. Or IOWr

b. When the “payload inhibit” feature of the iATU is used, then slv_wstrb does not need to be set. Similarly, for iATU header and tag substitution; the iATU can be set up to fill these fields in the outgoing TLP.

c. When the “payload inhibit” feature of the iATU is used, then slv_wstrb does not need to be set. Similarly, for iATU header and tag substitution; the iATU can be set up to fill these fields in the outgoing TLP.

11.3.3.7.1.6 Byte Mapping of Third and Fourth Message Header Dwords At I/O Interfaces

Figure 3-27 and Figure 3-28 indicate the byte mapping between the message generation interfaces and the third and fourth DWORDs of the message TLP header. For more details, see:

■ Descriptions of client0_tlp_addr and client0_tlp_data at “Transmit Interfaces (XALI0/1/2)” .

■ Description of ven_msg_data at “Vendor Message Interface (VMI)” .

Figure 3-27 Transmitted 3rd and 4th DWORD Message Header Byte Mapping at Interfaces (without AXI Bridge)

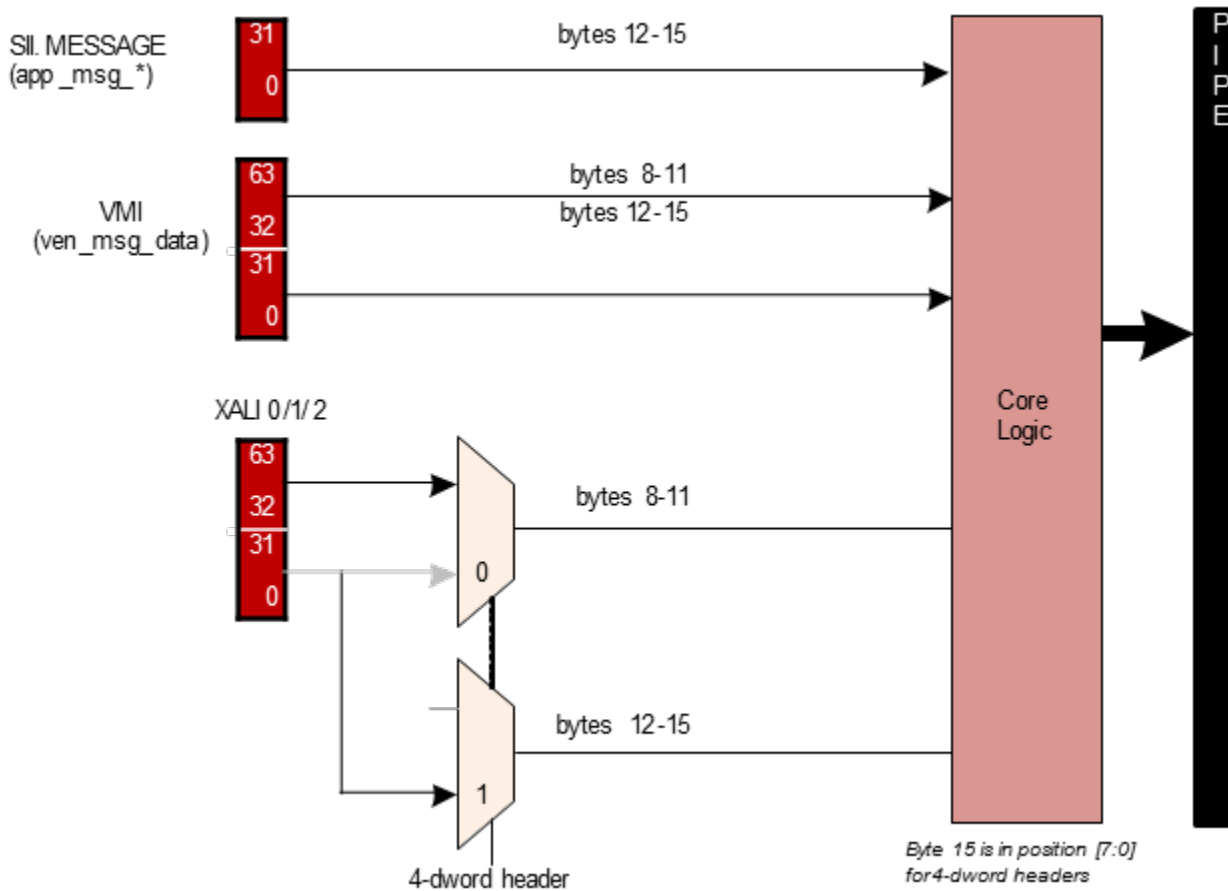

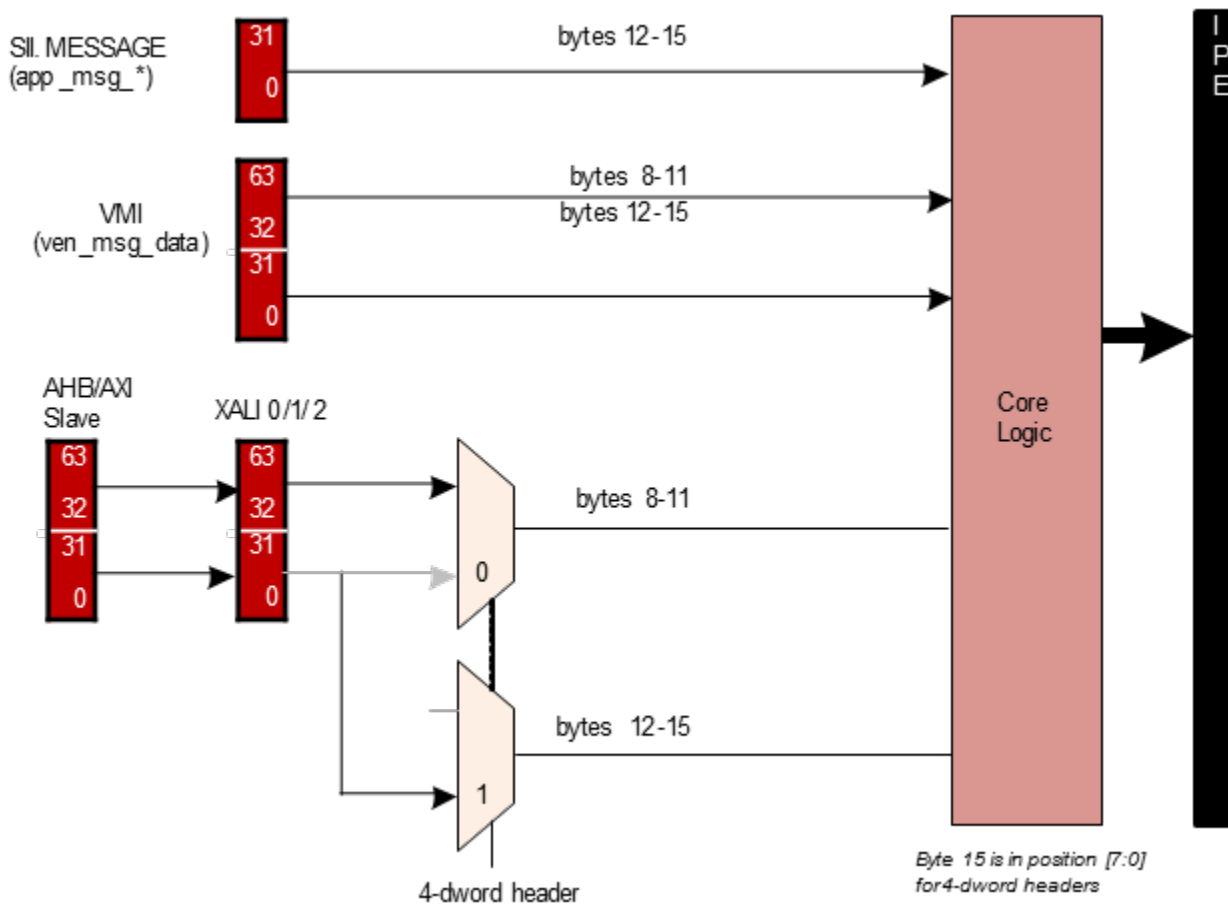

Figure 3-28 Transmitted 3rd and 4th DWORD Message Header Byte Mapping at Interfaces (with AXI Bridge)

PCI Express Controller (PCIe)

Note: In 32-bit address AXI configurations; the controller transmits all '0's instead of `slv_awmisc_info_hdr_34dw[63:32]`

Caution: You must ensure that messages generated by your application do not trigger decomposition as described in "AHB Decomposition Rules" or "AXI Decomposition Rules" .

11.3.3.7.2 Message Reception

The PCI Express controller can receive the following types of messages. The index in the first column refers to the circled numbers in the following diagrams.

Table 3-50Types of Received Messages

Index	Message Source (Type)	EP Mode	RC Mode
1	Power Management (Msg).	For more details, see "Power Management"	For more details, see "Power Management"
1a	Slot Power Limit (MsgD)	Set_Slot_Power_Limit Support message	n/a

Table continues on the next page...

2	Error Signalling from Downstream Component (Msg).		n/a	COR_ERR / ERR_NONFATAL / ERR_FATAL
3	Vendor Defined (Msg/MsgD).	For more details, see "Routing of Received Messages"		
4	Locked Transaction (Msg).		Unlock message	n/a
5	Legacy PCI Interrupts from Downstream Devices (Msg).		n/a	sys_int*
6	LTR Request and Clear (Msg).		n/a	For more details, see "Latency Tolerance Reporting (LTR) Message Reception (RC Mode)"
7	Optimized Buffer Flush Fill (OBFF) (Msg).	OBFF messages received on the radm_msg_cpu_active/radm_msg_idl e/ radm_msg_obff outputs. For more details, see "OBFF Message Reception [EP Mode]"		n/a
8	ATS Invalidate Request (Msg).	For more details, see "ATS, PASID and PRS"		n/a
9	ATS Request (Msg). ATS Invalidation Completion (Msg).		n/a	For more details, see "ATS, PASID and PRS"
10	DRS/FRS (Msg)		n/a	For more details, see "FRS Queue (RC Mode)"
11	PTM	PTM Response (Msg/MsgD)		PTM Request (Msg)
		For more details, see "Precision Time Measurement (PTM)"		

Figure 3-29 Message Reception: EP Mode

PCI Express Controller (PCIe)

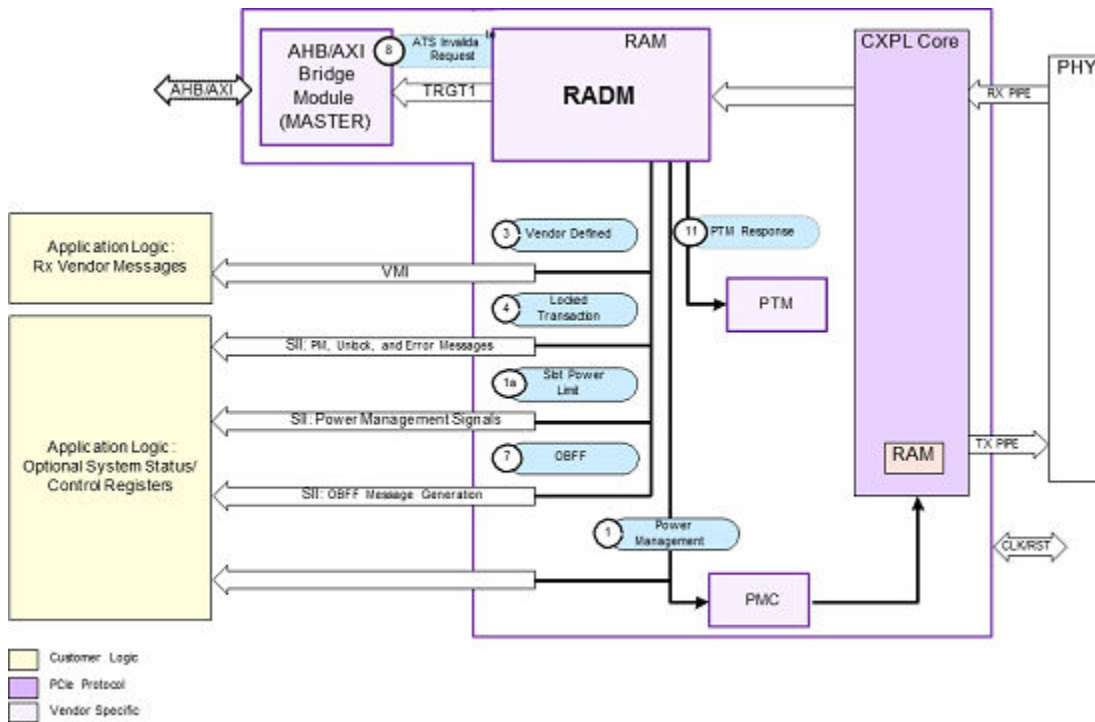

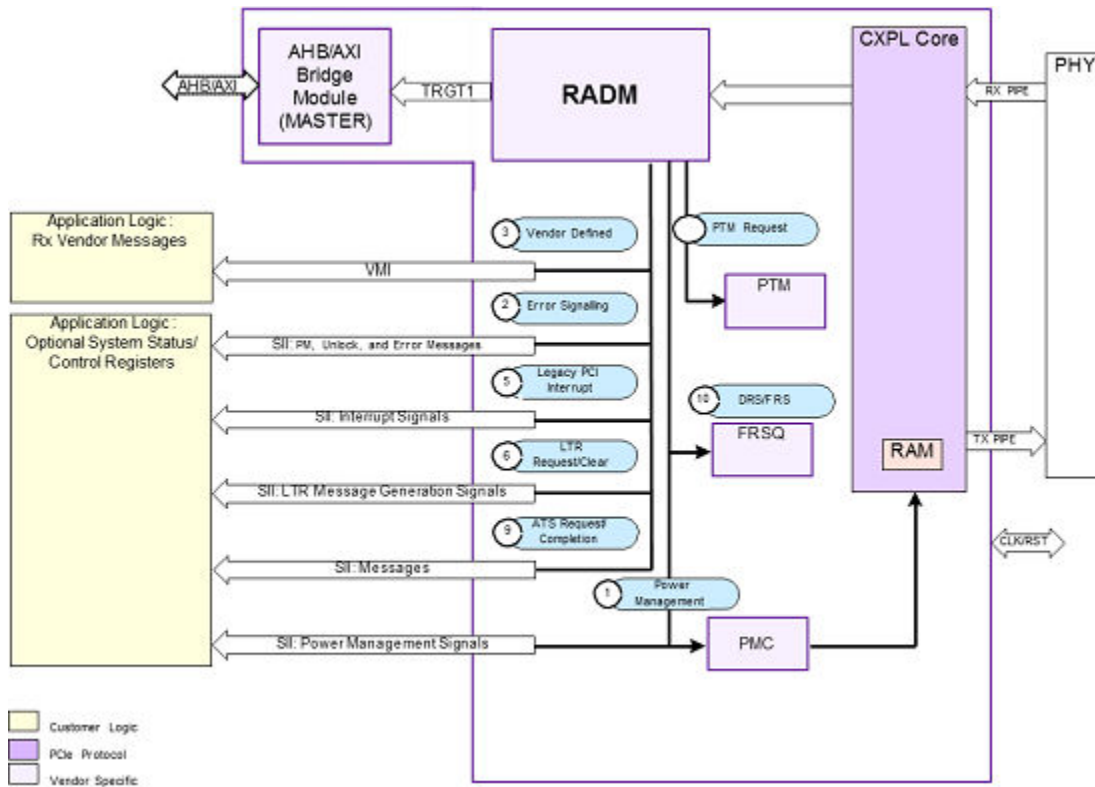

Figure 3-30 Message Reception: RC Mode

11.3.3.7.2.1 Message Reception I/O Interfaces

The RADM filter provides a message interface that is grouped as part of the System Information Interface (SII) to handle the message TLPs received from the upstream component. The RADM filter processes the message and decodes the header before sending it to your application logic on the SII. Some of the message reception signals are also used in "Interrupts" and "Reliability, Availability, and Serviceability (RAS)".

11.3.3.7.2.1.1 Routing of Received Messages

All error-free MSG requests are decoded internally, signaled on the SII interface, and then dropped (not forwarded to your application on TRGT1 (or AXI bridge Master when present)). When a MSG request is filtered with UR/CA/CRS status, the TLP is always dropped.

Summary of Message Delivery

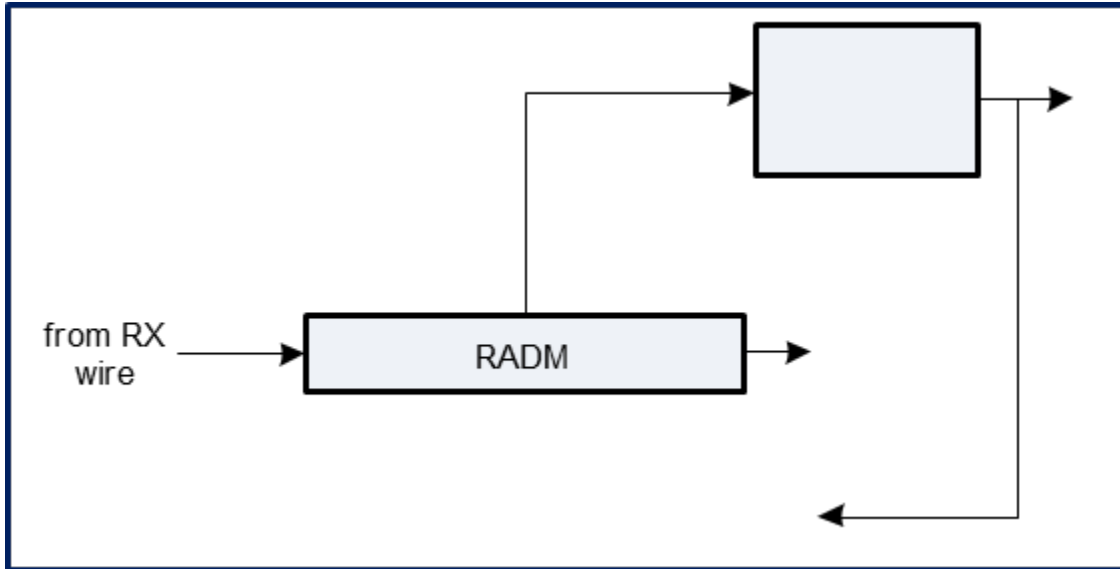

- By default received messages (Msg/MsgD) are delivered (without the payload for MsgD) on the SII interface and are not delivered on the TRGT1 (or AXI bridge master) interface.
- The SII message reception interface provides the requester ID and message type (from the first and second TLP DWORDs) and the contents of the third and fourth TLP DWORDs.
- If you also want the message delivered on the TRGT1 (or AXI bridge Master) interface, then you must clear the corresponding filter mask bit. For AHB, do not unmask dropping of Msgc,d. The AHB protocol does not support transfers with no data (payload).
 - a. Except PTM and DRS/FRS.
 - b. The exception to this is an ATS Invalidation Request (in EP mode) which is too big and is delivered on the TRGT1 interface regardless of filter mask settings
 - c. EP Mode: Msg is message without payload. That is all messages except VDM with payload, set_slot_power_limit, and ATS Invalidate request.
 - d. RC Mode: Msg is message without payload. That is all messages except VDM with payload.

11.3.3.7.2.2 Latency Tolerance Reporting (LTR) Message Reception (RC Mode)

You can enable LTR message reception by setting CX_LTR_M_ENABLE. When the controller receives an LTR message, it pulses the radm_msg_ltr output. You can access the LTR message information on the radm_msg_payload output, which is part of the SII

message interface. The actual values in the LTR message received by this downstream port are captured in the port logic LTR Latency Register (LTR_LATENCY_REG). They are also reflected on the app_ltr_latency[31:0]output.

Figure 3-31 LTR Registers

When you configure the controller with a 256-bit datapath, and when two LTR messages are received in the same clock cycle (back-to-back), the earlier message is discarded.

- It is preferable to use the SII interface to receive LTR messages. The bridge master cannot support reception of LTR messages.
- A full set of limitations for the AXI bridge is available at "AXI Bridge Limitations" and "AHB Bridge Limitations" .

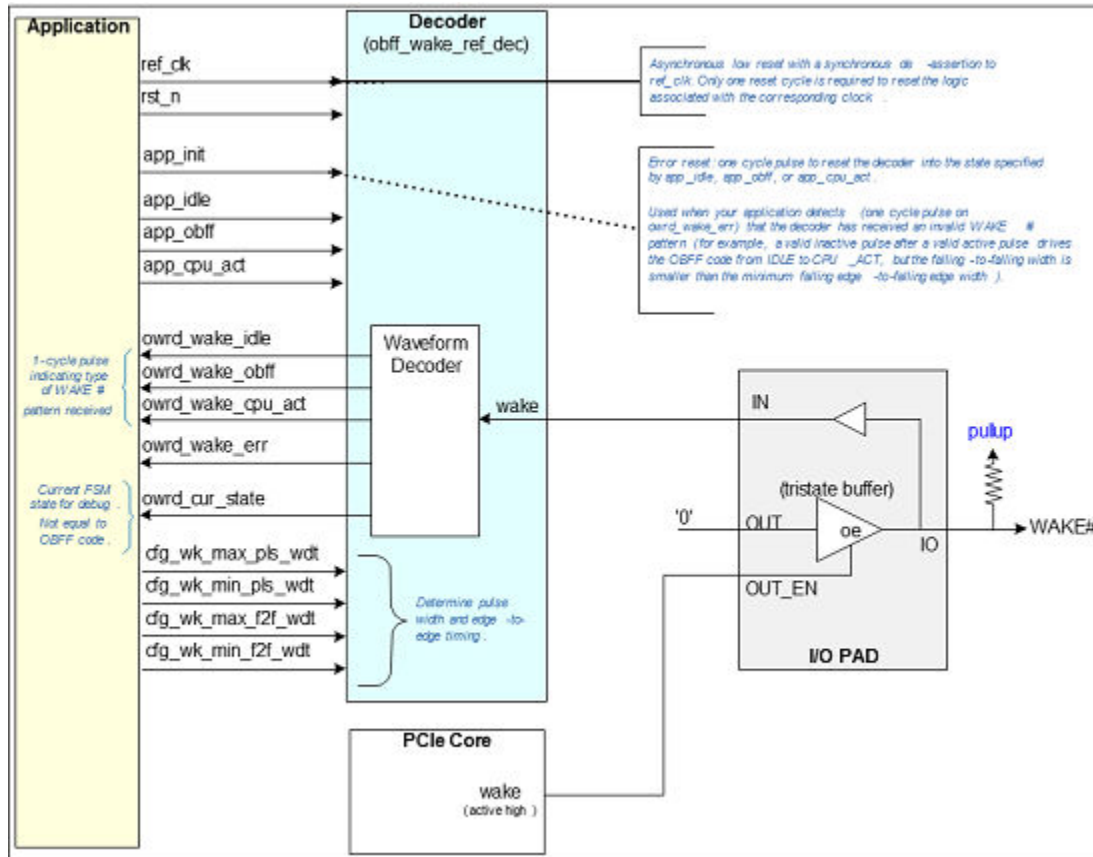

OBFF Message Reception [EP Mode]

You can enable OBFF message reception by setting CX_OBFF_SUPPORT. When you configure the controller with a 256-bit datapath, and when two OBFF messages are received in the same clock cycle (back-to-back), the earlier message is discarded. When you have not enabled OBFF in the Device Control 2 register, or when the Traffic Class is non-zero; then the controller generates an UR completion when it receives an OBFF message. When the upstream port receives an OBFF message, it pulses one of the radm_msg_obff, radm_msg_cpu_active, or radm_msg_idle outputs. Your application logic must use these outputs to control the traffic it generates. For more details, see *PCI Express Base Specification, Revision 4.0, Version 0.7*.

- It is preferable to use the SII interface to receive OBFF messages. The bridge master cannot support reception of OBFF messages.

■ A full set of limitations for the AHB/AXI bridge is available at "AXI Bridge Limitations" and "AHB Bridge Limitations" .

Figure 3-32 Decoder Example Design (USP)

Note: You must fully verify the integration of the example encoder/decoder in your testbench.

Table 3-51 OBFF WAKE# AC Specification (Table 2.6.2 of PCIe Specification)

a. Period of the clock this is running to detect wakeup events.

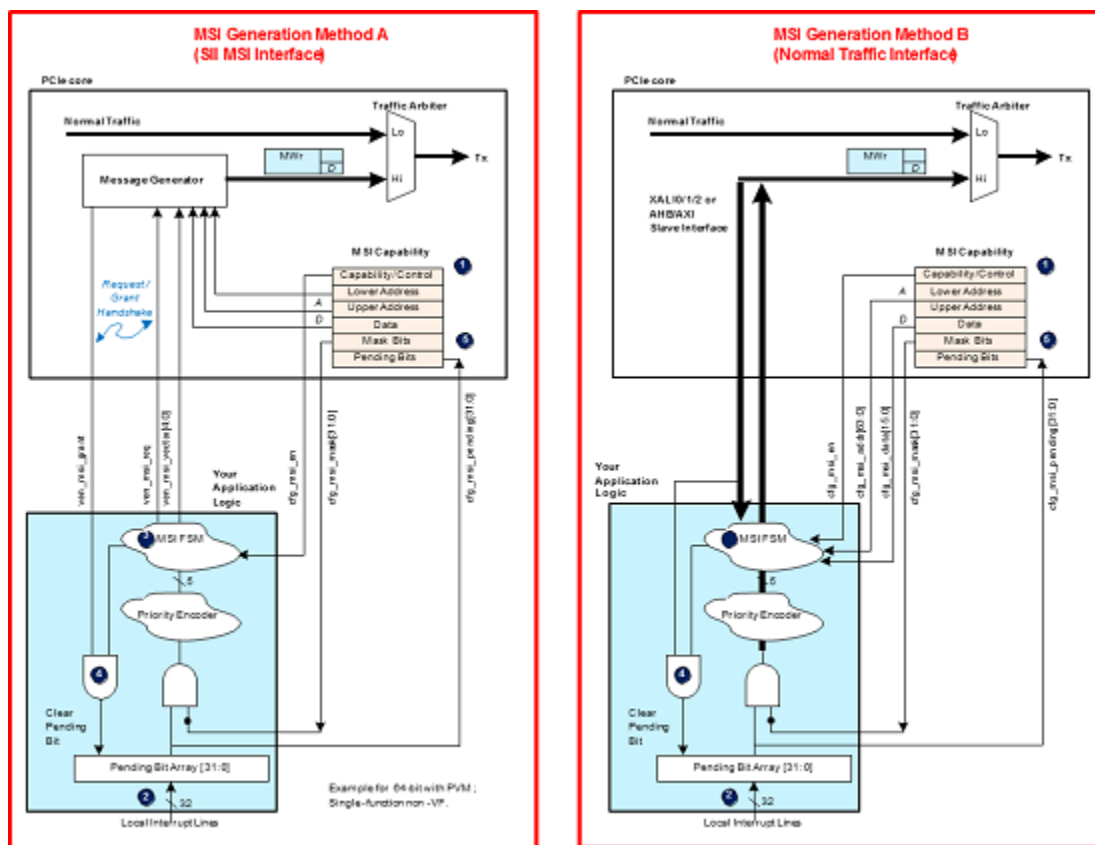

11.3.3.8 Interrupts

The following section describes the processing of interrupts in the controller. You should be familiar with the different types of interrupts as specified in Sections 6.1.1, "Rationale for PCI Express Interrupt Model", 6.1.4, "Message Signaled Interrupt (MSI/MSI-X) Support", 6.1.2, "PCI Compatible INTx Emulation", and 6.1.3, "INTx Emulation Software Model" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

11.3.3.8.1 Interrupt Generation (USP)

An USP creates MSI's using MWr requests. Your application logic issues MSI requests through the MSI interface; the controller then generates the corresponding memory write. Alternatively, your application logic can create the MSI MWr and supply it on a XALI01/2/ Tx interface (or AXI slave interface).

Figure 3-33 Example MSI Application Logic (MSI_CAP_ENABLE =1)

An MSI-X interrupt is identical to an MSI, except that it: supports more than 32 vectors (2048) through the use of multiple address and data pairs that are written by software to an MSI-X Table. Your application logic issues MSI requests through the MSI interface; the controller then generates the corresponding memory write. Alternatively, your application logic can create the MSI MWr and supply it on a XALI01/2/ Tx interface (or AXI slave interface).

Figure 3-34 Example MSI-X Application Logic Using SII MSI Interface (MSIX_CAP_ENABLE =1)

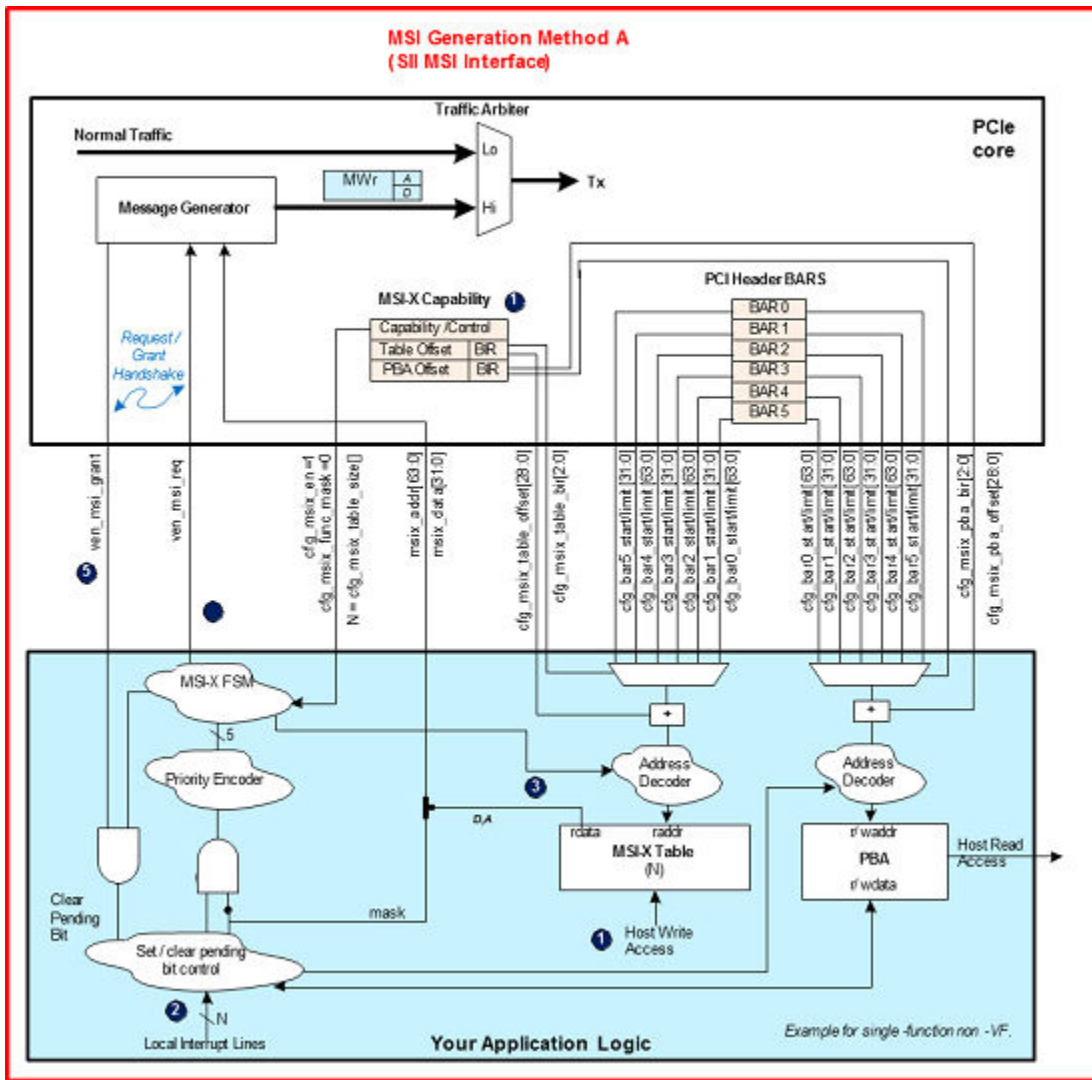

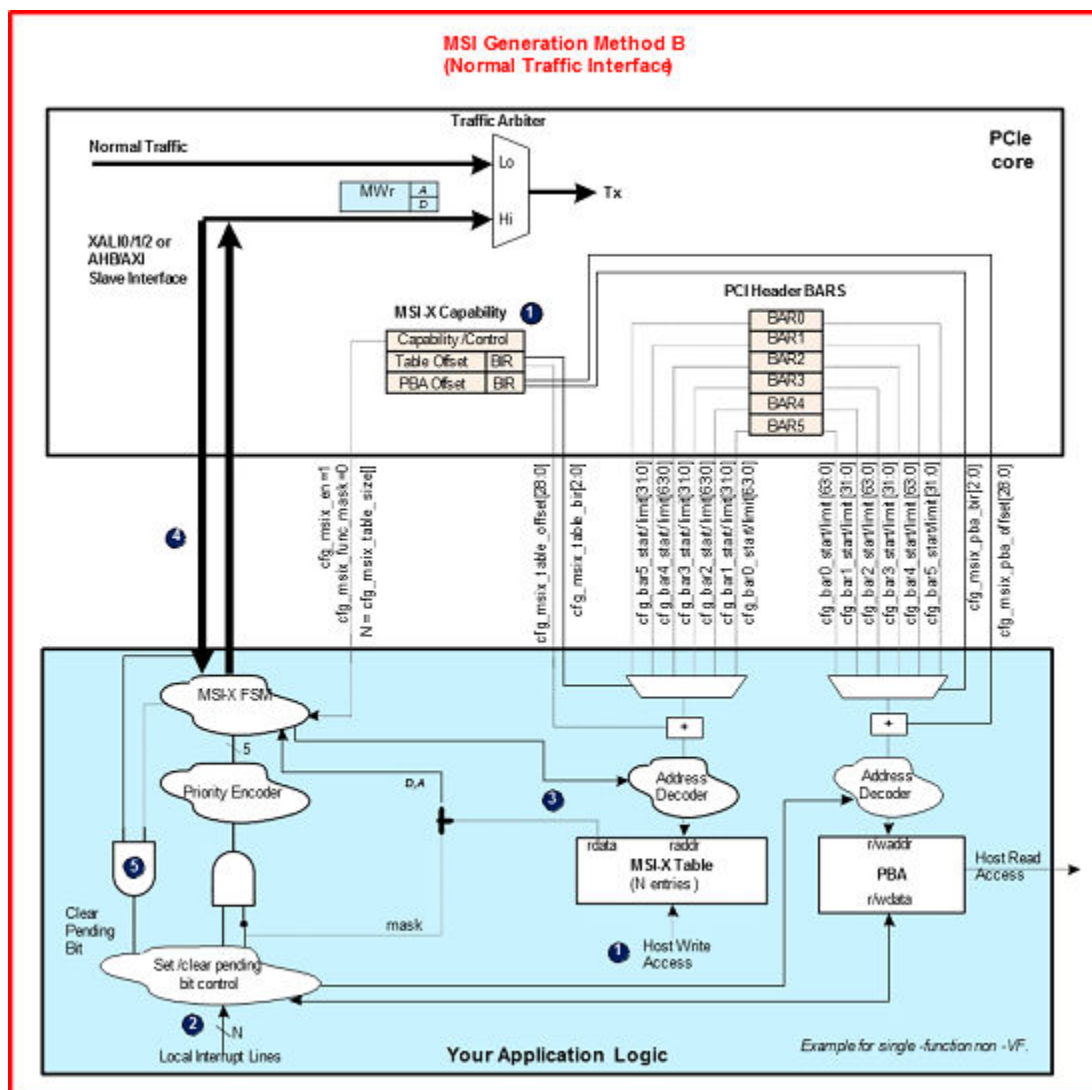

Figure 3-35 Example MSI-X Application Logic Using Normal Tx Interfaces

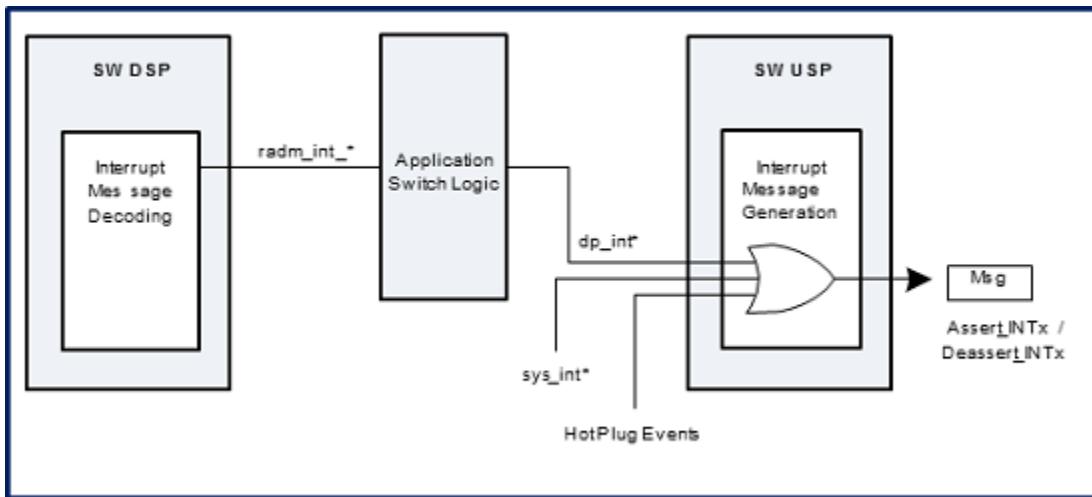

Note: MSI/MSI-X requests created at the MSI interface are given higher Tx priority than traffic at the XALI0/1/2 transmit interfaces (or AXI slave interface).

To preserve ordering, you should supply MSI/MSI-X MWr requests at the XALI0/1/2 transmit interfaces (or AXI slave interface).

11.3.3.8.1.1 PCI Legacy Interrupts (USP)

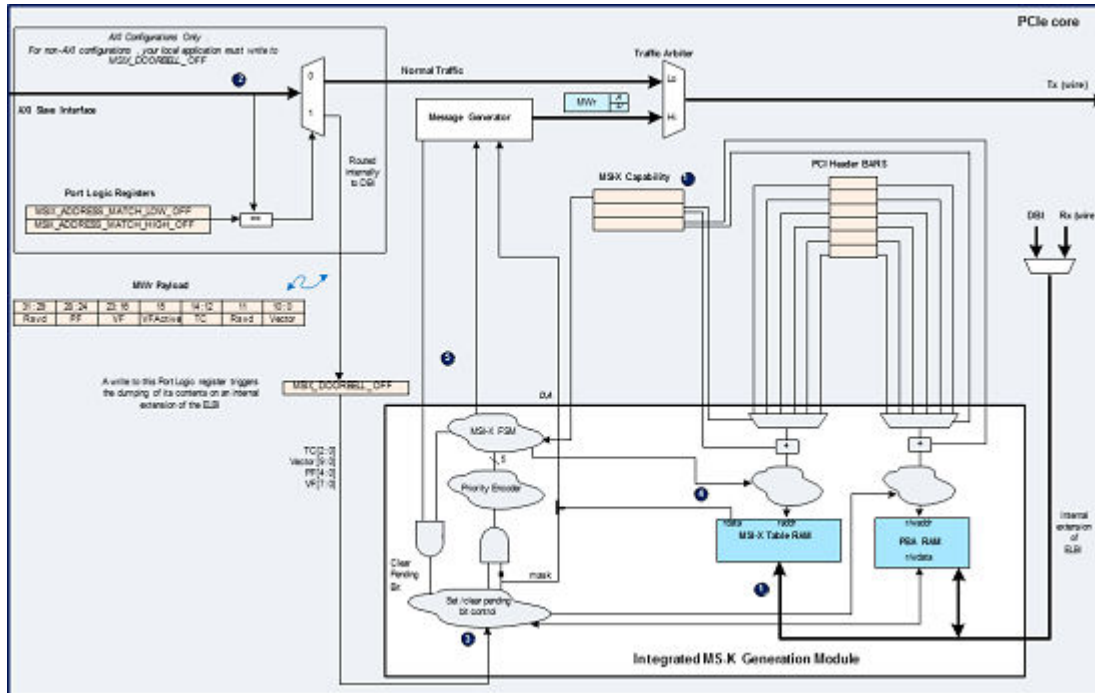

Your USP application asserts the level-sensitive `sys_int` input to notify the controller that it should send an interrupt message. The controller generates two message TLPs, `Assert_INTx` and `Deassert_INTx`, in response to the assertion and the de-assertion of this input. Your application needs to de-assert the virtual interrupt inputs when the link has been placed in a low power state. The controller does not automatically send a `Deassert_INTx` interrupt message when the power state changes.

11.3.3.8.1.2 iMSIX-TX: Integrated MSIX Transmit (USP)

When you enable this feature (MSIX_TABLE_EN=1), the controller implements the logic and RAM required to generate MSI-X requests. When your local application updates MSIX_DOORBELL_OFF, the controller extracts the vector and TC information from the payload and creates the MSI-X request.

Figure 3-36 iMSIX-TX: MSIX Transmit (MSIX_TABLE =1)

11.3.3.8.1.2.1 Operational Features (AXI)

■ Automatic triggering of MSI-X generation when your application issues a MWr at the AXI slave interface with an address equal to MSIX_ADDRESS_MATCH_LOW_OFF and MSIX_ADDRESS_MATCH_HIGH_OFF.

□ MWr must be DWORD-aligned and must contain MSI-X vector, TC, and function number.

■ When your local application issues an MWr on the AXI slave interface to a specific address (MSIX_ADDRESS_MATCH_LOW_OFF), the controller extracts the vector and TC information from the MWr payload and creates the MSI-X request.

■ AXI bridge guarantees ordering coherency by forwarding the MSI-X request after the preceding MWr has been transmitted.

■ Processes one MSI-X request at a time and halts slave access if a second MSI-X request is submitted before first one is complete.

11.3.3.8.1.2.2 Operational Features (Non-AXI)

■ Automatic triggering of MSI-X generation when your local application writes to the MSIX_DOORBELL_OFF register.

11.3.3.8.1.2.3 Operational Features (General)

■ Automatically snoops for cleared vector masks and sends MSI-X for pending vectors.

■ Supports SR-IOV virtual functions.

■ Debug mode allowing direct access to RAMs. Activated using the dbg_table and dbg_pba input pins or the MSIX_RAM_CTRL_DBG_TABLE and MSIX_RAM_CTRL_DBG_PBA fields in MSIX_RAM_CTRL_OFF.

■ FLR clears the RAM contents related to that function. If you want to complete all pending interrupts, you must clear the function and vector masks before asserting FLR.

■ MEM_FUNCn_BARK_TARGET_MAP must be 0 where k=BIR, to ensure all Rx MWr requests to BARK are directed to the ELBI on TRGT0.

■ Hazard elimination for races between remote host and local application read/write accesses.

11.3.3.8.1.2.4 *Function Level Masks.*

■ The controller implements a hardware -lock mechanism to prevent unpredictable behavior that might happen when software asserts function-level masks (PCI_MSIX_FUNCTION_MASK field in PCI_MSIX-

_CAP_ID_NEXT_CTRL_REG) when the controller is processing MSI-X requests.

■ It only allows one function mask to be changed at a time. It does this by delaying the acknowledgment to the write request until the controller has stopped sending MSI-X requests for a function.

■ When a function mask is cleared, the MSIX table processes the PBA for that function.

■ The hardware-lock mechanism only applies to functions that have MSI-X enabled.

11.3.3.8.1.2.5 *RAM*

■ This feature uses two single-port RAMS that are approximately sized as follows:

□Table RAM: Width= 128+3; Depth= (CX_NFUNC+CX_NVFUNC) * (MSIX_TABLE_SIZE+1)

□PBA RAM: Width= 64; Depth= (CX_NFUNC+CX_NVFUNC) * ((MSIX_TABLE_SIZE+1)/64]+a1)

For exact sizes, see the RAM Requirements section in the Architecture chapter of the Databook.

■ Core initializes RAM contents to known values after reset.

■ Core automatically asserts the msix_table_ls/msix_pba_ls outputs when it is not accessing the RAMs. Your external logic can use these signals to control any low-power modes that your RAMs support. You can disable this mode by setting the MSIX_RAM_CTRL_BYPASS field in MSIX_RAM_C-TRL_OFF.

■ You can directly control the RAM low-power mode outputs (cfg_msix_table_ds, cfg_msix-

_table_sd, cfg_msix_pba_ds, and cfg_msix_tpba_sd) by setting the MSIX_RAM_C-TRL_TABLE_DS, MSIX_RAM_CTRL_TABLE_SD, MSIX_RAM_CTRL_PBA_DS, and

MSIX_RAM_CTRL_PBA_SD fields in MSIX_RAM_CTRL_OFF. Your external logic can use these signals to control any low-power modes that your RAMs support.

1. if (([MSIX_TABLE_SIZE+1]%64)==1 then a=1; else a=0

11.3.3.8.1.2.6 Operational Limitations (General)

- PBA BIR must be identical¹ for VFs and PFs.
- Table Offset must be identical¹ for VFs and PFs.
- PBA Offset must be identical¹ for VFs and PFs.
- Table Offset must be aligned to 8 KB boundary. Recommended by PCI specification.
- PBA Offset must be aligned to 4KB boundary. Recommended by PCI specification.
- MSIX_TABLE_SIZE (used to size Table RAM) must be identical for all PFs.
- Not available in AHB bridge.

Operational Limitations (ELBI)

■ ELBI width must be 32-bit; this feature communicates with the rest of the controller using an internal extension of the ELBI bus. ■ All accesses by your host or local application to the RAMs must be 32-bits wide.

■ The ELBI address range available for application registers is the full ELBI interface address range minus the space in bytes claimed by the MSI-X tables, which is:

$$(CX_NFUNC + CX_NVFUNC) * (MSIX_TABLE_SIZE + 1) * 16$$

+

$$(CX_NFUNC + CX_NVFUNC) * ((MSIX_TABLE_SIZE / 64) + 1) * 8$$

The exact addresses claimed depend on the programming of the MSI-X table and PBA offsets in the MSI-X capability registers.

2. One value for all VFs and PFs in the controller. PFs cannot have different values.

11.3.3.8.2 Interrupt Reception (DSP)

11.3.3.8.2.1 Overview

PCI Legacy Interrupts (DSP)

The controller decodes received Assert_INTx/Deassert_INTx messages and pulses the radm_inti_asserted and radm_inti_deasserted outputs where i=a,b,c,d.

11.3.3.8.2.2 PCI Express Hot-Plug Logic Interrupt and Wakeup (DSP)

When MSI or MSI-X is enabled, the controller asserts the `hp_msi` output upon detection of any of these HP events:

- Power Fault Detected
- MRL Sensor Changed
- Presence Detect Changed
- Command Completed
- Attention Button Pressed
- Electromechanical Interlock Status Changed
- Data Link Layer State Changed

When INTx interrupt mode is enabled, the controller asserts the `hp_int` output upon detection of any of the hot-plug events. When PME mode is enabled, the controller asserts the `hp_pme` output upon detection of any of the hot-plug events. The controller does not check if the PM state is D1, D2, or D3hot. Your application must check the value on `pm_dstate` to make sure the device is in D1, D2, or D3hot upon receipt of a `hp_pme` notification.

11.3.3.8.2.3 iMSI-RX: Integrated MSI Receive [AXI Bridge] (DSP)

The bridge provides an integrated MSI reception module to detect and terminate inbound MSI requests. It is enabled by setting `CX_MSI_CTRL_ENABLE = 1`. Rather than propagating MSI MWr TLPs onto the AXI bus through the master interface; the MSI packets are captured and terminated in the AXI bridge and an interrupt is signaled locally through the `msi_ctrl_int` output.

The iMSI-RX is programmed with an address (`MSI_CTRL_ADDR_OFF` and `MSI_CTRL_UPPER_ADDR_OFF`) that is used as the system MSI address. When an inbound (received) MWr request is passed to the AXI bridge and matches this address, as well as the conditions specified for an MSI memory write request, then an MSI interrupt is detected. When this memory write request is about to be driven onto the AXI bridge master interface it is dropped and never appears on the AXI bus.

The iMSI-RX decodes the MSI MWr data payload to determine which endpoint device (EP) sent the MSI and which interrupt vector the MSI corresponds to. When a valid interrupt has been decoded, the `msi_ctrl_int` output is asserted. This output remains asserted when any MSI interrupt is pending. It is only de-asserted when there is no MSI interrupt pending.

11.3.3.8.2.3.1 Features

- Provides support for up to eight EPs. Each supported EP has a set of interrupt enable, mask, and status registers (MSI_CTRL_INT_*).
- Guarantees correct AXI ordering with respect to other inbound posted writes by generating the MSI interrupt only after your application AXI slave acknowledges responses of previous posted TLPs.
- A maximum of 32 interrupts are supported per EP.
- Optional 32-bit register driven general purpose outputs (msi_ctrl_io[31:0]). For more details, see the MSI_GPIO_IO_OFF register.

11.3.3.8.2.3.2 MSI Request Detection Criteria

An MSI interrupt request is detected when the controller receives a MW_r TLP that satisfies these conditions:

- Header attributes bits are zero. No snoop (NS) and relaxed ordering (RO) must be zero.
- Length field is 0x01 to indicate a payload of one DWORD.
- First byte enable (FBE) is 4bxx11 (enabling the first two bytes of the payload.)
- Last byte enable (LBE) is 4b0000.
- TLP address corresponds to systems chosen MSI address as programmed in the MSI_CTRL_ADDR_OFF and MSI_CTRL_UPPER_ADDR_OFF port logic registers. This register is not the MSI Lower 32 Bits Address Register which is part of the PCIe MSI capability register.

In addition to these criteria the MW_r must also pass the receive filtering rules as outlined in “Receive Filtering” .

11.3.3.8.2.3.3 Programming and Usage Model

- The host CPU configures the MSI capabilities of all endpoints through the local DBI bus (or through CFG requests from the remote link partner).
- Program the MSI Data Register (MSI_CAP_OFF_08H_REG or MSI_CAP_OFF_0CH_REG in the MSI capability) as follows to allow the iMSI-RX to decode the interrupt source.

Table 3-52

MSI Data Register (MSI_CAP_OFF_08H_REG or MSI_CAP_OFF_0CH_REG) Programming

15:8	7:5	4:0
Not Used	<p>EP Number</p> <p>Allows each EP to be identified within the system, For example, EP#5 is programmed with 3b101</p>	<p>Interrupt Vector Number</p> <ul style="list-style-type: none"> Identifies the interrupt source within each EP Programmed to 5b00000. Set by MSI generation logic to identify each interrupt source in real time Supports up to 32 Vectors

■ Program the MSI Capability Lower 32 Bits Address Register (MSI_CAP_OFF_04H_REG) of every EP with one common MSI address.

■ The host CPU configures the iMSI-RX through the local DBI bus (or through CFG requests from the remote link partner).

□ Program the iMSI-RX’s MSI_CTRL_ADDR_OFF and MSI_CTRL_UPPER_ADDR_OFF registers with the same value as in MSI_CAP_OFF_04H_REG.

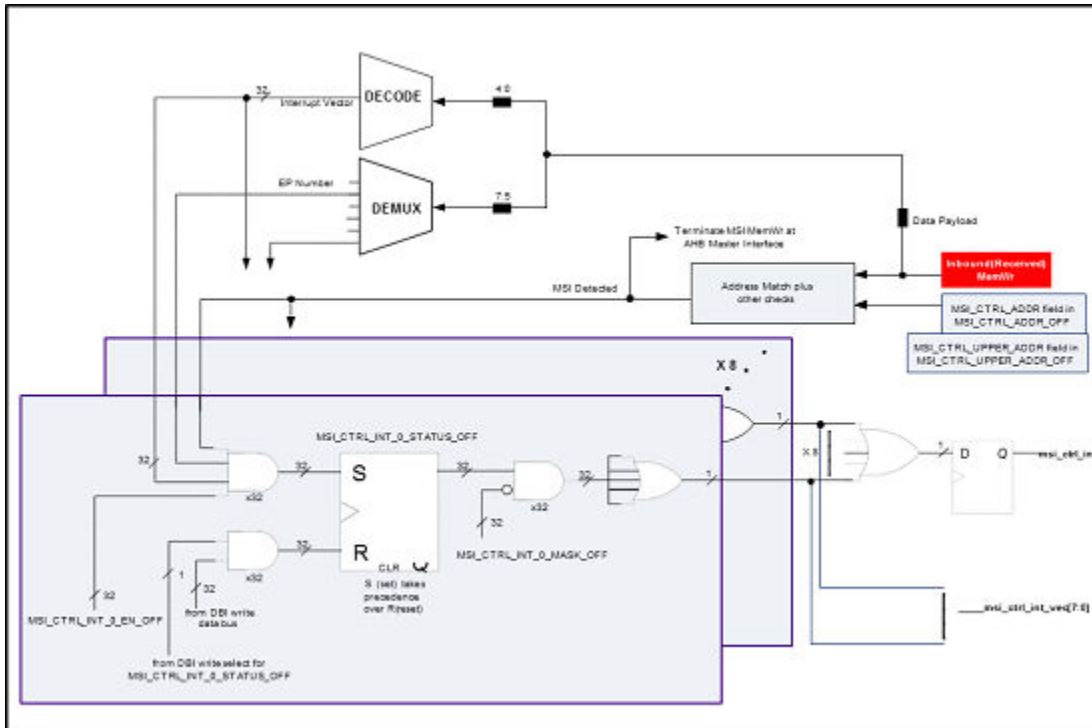

□ Read the MSI capability of each EP to determine the number of vectors enabled in each EP and uses this information to program the iMSI-RX’s interrupt enable register (MSI_CTRL_INT_0_EN_OFF). This register allows up to 32 MSI interrupt vectors to be enabled within the iMSI-RX for a given EP. It is the responsibility of the host CPU to read the contents of the Multiple Message Enable field in an EPs MSI capability structure and program that EPs Interrupt Enable register in the iMSI-RX appropriately. For example when the Multiple Message Enable is 3b100 for endpoint #0 (which corresponds to 16 enabled interrupt vectors), the host CPU should program MSI_CTRL_INT_0_EN_OFF with 0x0000FFFF.

Note: When you include the iMSI-RX in your controller (by setting CX_MSI_CTRL_ENABLE =1), it is active and terminates all received MSI MemWr unless you deactivate it. The iMSI-RX is deactivated twhheenigahlltoMf SI_CTRL_INT_0_EN_OFF ... MSI_CTRL_INT_7_EN_OFF registers have a value of 0x0. The iMSI-RX is also deactivated when it is not in RC mode (device_type !=0x4)

11.3.3.8.2.3.4 Processing of Detected Interrupts

The MSI controller decodes the MSI MWr data payload to determine which EP sent the MSI and to which interrupt vector it corresponds.

Figure 3-37 Architectural Representation: iMSI-RX Interrupt Detection Process

■ When the decoded interrupt vector is enabled and not masked, then the controller sets the corresponding bit in the iMSI-RX Interrupt#0 Status Register (MSI_CTRL_INT_0_STATUS_OFF) and asserts the top-level controller output `msi_ctrl_int`. This signal remains asserted until the host CPU clears the status bit by writing a 1 to the status bit. Writing a 0 has no effect.

■ When any status bit remains set, then `msi_ctrl_int` remains asserted. The interrupt status register provides a status bit for up to 32 interrupt vectors per endpoint. When the decoded interrupt vector is enabled but is masked, then the controller sets the corresponding bit in interrupt status register but it does not assert the top-level controller output `msi_ctrl_int`.

■ When an MSI interrupt vector is received from an endpoint but that vector has not been enabled in the corresponding iMSI-RX Interrupt#0 Enable Register (MSI_CTRL_INT_0_EN_OFF), then the controller does not set any bit in the interrupt status register and it does not assert `msi_ctrl_int`.

■ In addition, when no interrupts have been enabled in any of the eight interrupt enable registers, then all MSI detection logic is disabled and valid MSI MWr request TLPs are not terminated in the bridge but are passed by the AXI master interface to the AXI bus.

■ The iMSI-RX Interrupt#0 Mask Register (MSI_CTRL_INT_0_MASK_OFF) allows the host to mask a given MSI interrupt vector. When a MSI interrupt vector is received for a masked interrupt vector, then the controller sets the corresponding bit in the interrupt status register but it does not assert `msi_ctr_intl` because the interrupt vector is masked.

■ Note: This masking is local to the iMSI-RX and is not part of Per Vector Masking (PVM) in any of the downstream endpoints. The contents of the interrupt mask and interrupt status registers are used to drive the `msi_ctrl_int` output.

■ When any status bit is set and the interrupt vector is not masked, then the controller asserts `msi_c-trl_int`. As long as any interrupt status bit is set and not masked, `msi_ctrl_int` remains asserted.

11.3.3.8.2.3.5 Alternative Data Register Programming

The programming of the MSI Data Register (MSI_CAP_OFF_08H_REG or MSI_CAP_OFF_0CH_REG) as described in Table 3-52 assumes that each endpoint enables 32 vectors. When one or more endpoints only support 16 or less interrupt vectors, then it is possible to share a single set of interrupt enable, interrupt mask, and interrupt status registers among those endpoints.

For example, assume that endpoint #1 enables 16 interrupt vectors and endpoint #2 also enables 16 interrupt vectors. When the MSI data register for endpoint #1 is programmed to 0x20 and the MSI data register for endpoint#2 is programmed to 0x30, as in Table 3-53, then the status for each endpoint is in interrupt status register#1. Endpoint#1s vectors are in the lower 16 bits and endpoint#2s vectors are in the upper 16 bits. Manipulating the MSI data register format in this manner allows the interrupt controller to support more than eight endpoints using the eight interrupt status registers provided.

Table 3-53 Alternative Data Register Programming

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Endpoint #2									0	0	1	1	0	0	0	0	0

11.3.3.9 Flow Control

The flow control mechanism is divided into two phases: initialization and update. The controller automatically performs both of these phases with minimal support required from your application. By default the RADM is responsible for returning flow control credits when it reads data out of the receive queues.

The controller provides optional I/O signals to enable your application to handle flow control returns in an application-specific manner. For error scenarios in bypass queue mode your application can decide whether to return credits or not based on state of the Bypass/RTRGT1 Interface signals described in Table 3-54.

Table 3-54 Bypass/RTRGT1 Interface Signals to Consider for Credit Return (AXI Bridge not Present)

Bypass/RTRGT1 Interface Signal	State	Credit return policy
radm_bypass_tlp_abort radm_trgt1_tlp_abort	Asserted	Credit needs to be returned
radm_bypass_dllp_abort radm_trgt1_dllp_abort	Asserted	Credit need not be returned
radm_bypass_ecrc_err radm_trgt1_ecrc_err	Asserted	Credit need not be returned. But, it is strongly recommended to return the credit if the TLP is not ambiguous.

11.3.3.9.1 Calculation of Initial Credits and Receive Buffer Sizes

The default buffer sizes and credits for each TLP type are automatically calculated from the number of lanes, the controller datapath width, the maximum PCIe payload (CX_MAX_MTU), flow control update latencies, internal delays, and the PHY latency.

You can determine the transmit posted, non-posted, and completion credits that are advertised by the receiver at the other end of the link by reading the following port logic registers:

- Transmit Posted FC Credit Status (TX_P_FC_CREDIT_STATUS)
- Transmit Non-Posted FC Credit Status (TX_NP_FC_CREDIT_STATUS)
- Transmit Completion FC Credit Status (TX_CPL_FC_CREDIT_STATUS)

Note: You can override the default flow control update latency timer value using the FC Latency Timer Override Value field (TIMER_MOD_FLOW_CONTROL) in the Queue Status register

(Q_STATUS).

Scaled Flow Control

The controller supports Scaled Flow Control (DL_FEATURE_EN =1 followed by FC_SCALE_EN =1) as described in *PCI Express Base Specification, Revision 4.0, Version 0.7* with the following features and limitations:

- This feature when enabled applies individually to all P, NP or CPLs.
- This feature when enabled applies to all VCs.
- The allocated initial credits will scale down to 127 header credits and 2047 data credits, if the link partner does not support scaling.
- At larger scaling factors, it is not possible to return single credits.
- When scaling, the minimum number of header and data credits must be calculated as follows:
 - Minimum Number of Header Credits = $32 * \text{Scaling Factor}$, and
 - Minimum Number of Data Credits = $512 * \text{Scaling Factor}$.
- When manually enabling Flow Control Scaling on a new configuration by editing the configuration file (without going through the coreConsultant flow):
 - If you are modifying the Header and Data credits, the scaling factors must be specified.
 - If the Header and Data credits have default values, there is no need to add the scaling factors.
- Due to a potential deadlock scenario, if an MRIOV_INIT is received during Data Link (DL) Feature setup, the link immediately exits DL Feature, and starts transmitting INITFCs.

11.3.3.10 ATS, PASID and PRS

This section discusses the following optional features of the controller as per PCI Express Address Translation Services 1.1 Specification, January 26 2009:

11.3.3.10.1 Address Translation Services (ATS)

The controller implements ATS (CX_ATS_ENABLE) with the following features and limitations.

- To send an ATS TLP, you must supply it on an application transmit client interface (XALI0/1/2) taking note of the _ats/_nw inputs, or on the AXI bridge slave interface as per Figure 3-44.

You can also send an Invalidation Completion using the VMI1.

- The controller does not pass Rx ATS Invalidate Requests and ATS Invalidate Completions to the SII interface because they are too big. All ATS Invalidate Requests and ATS Invalidate/Completions pass through to TRGT1 (or AXI bridge Master) regardless of the filtering rule settings.

- The controller routes all Rx ATS TLPs to the TRGT12 receive interface (note the ats/_nw outputs), or to the AXI bridge master interface (note the mstr_a*misc_info_ats/mstr_a*misc_info_nw outputs).

The controller also routes all Rx ATS TLPs. (except ATS Invalidate Requests ATS Invalidate Completions) to the SII interface.

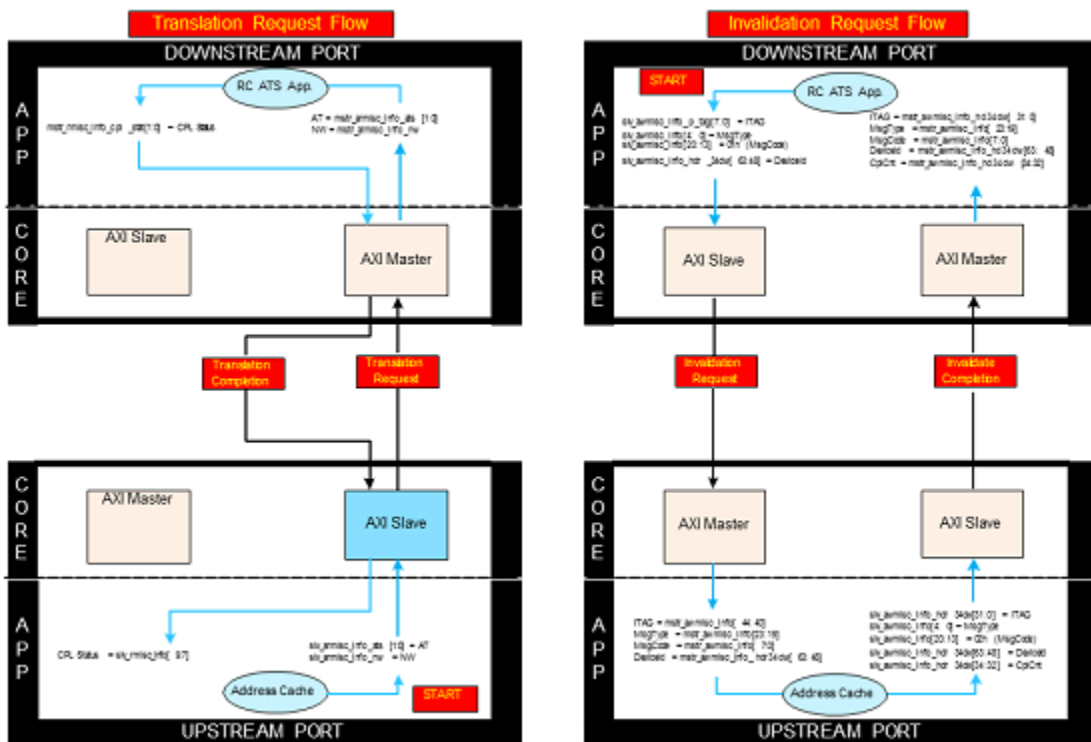

- When the AXI bridge is enabled:

- Requests for multiple translations are not supported.

- Translation requests (AT =01) are supported for a single address only (length =two DWORDs).

- The controller does not implement the ATS cache.

Figure 3-44 AXI ATS Sideband Signal Usage

2. There is no need for an NW bit on BYP because the non-posted request RX queue cannot be put into bypass mode.

1. ven_msg_type[4:0]=0x12; ven_msg_code[7:0]=0x02; ven_msg_data[63:0]={ITAG Vector, CC, Device ID}

11.3.3.10.2 Process Address Space ID (PASID)

The controller includes the PASID capability structure (in EP mode) when you set CX_PASID_ENABLE.

■ The PASID TLP prefix is additionally permitted on Translation and Invalidation Requests when ATS is enabled. The controller does not implement the ATS cache, so your application must process the PASID prefix on radm_*_tlp_prfx according to the ATS specification.

■ SRIOV is supported.

■ The controller does not implement the IDO ordering rules based on PASIDs.

1. If the global pass-messages field (CX_FLT_MASK_MSG_DROP) in FILTER_MASK_2_OFF is "1 (pass)", then the setting on CX_FLT_MASK_PRS_DROP is ignored and all PRS messages are passed.

11.3.3.10.3 Page Request Services (PRS)

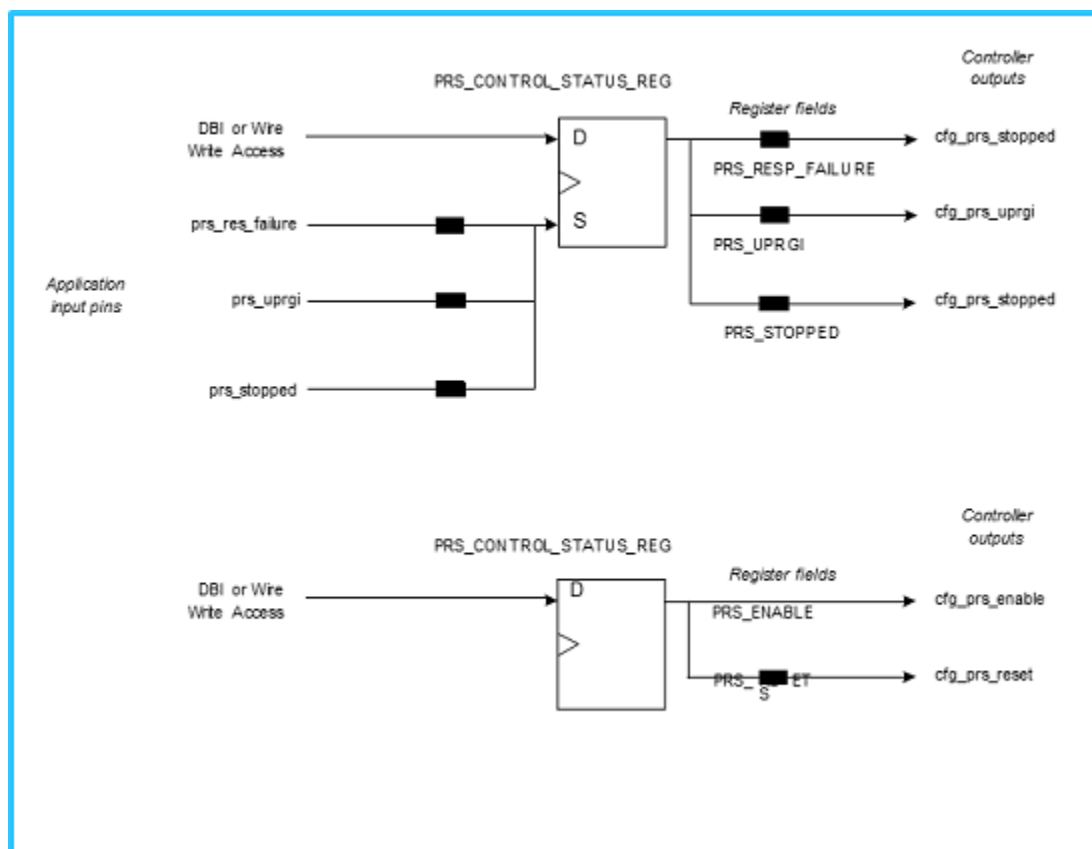

The controller supports PCI-SIG PRS when you set CX_PRS_ENABLE =1. The PRS capability structure is included in the controller so that your EP application can use the memory page request mechanism. Your RC application can receive PRS messages.

■ It supports memory requests with and without translated addresses (ATS).

■ The controller does not process the PASID, Execute Requested, or Privileged Mode Requested fields of the PASID TLP prefix. Therefore, your application must determine if the rules are met for these fields. Consequently, the PCIe controller does not process the PASID TLP Prefix to determine if PASIDs are permitted on Address Translation or Invalidation Requests, or on untranslated memory requests. If required, your application must check if the PASID Width value is valid.

■ A PASID TLP prefix is an End-End TLP prefix that an endpoint can prepend to requests that it generates.

Figure 3-45 PRS Control & Status Register-to-Pin Connections

You can clear the `CX_FLT_MASK_PRS_DROP` bit in the `MASK_RADM_2` field of `FILTER_MASK_2_OFF` to

instruct the controller to pass PRS messages to the application on the Rx interfaces; otherwise they are silently dropped.

11.3.3.11 Peer-to-Peer Support (P2P)

In certain multi-port PCI Express applications such as a PCIe switch or multi-port root complex, it is useful to allow TLPs to flow from one endpoint port to another, instead of strictly flowing up and down the PCIe hierarchy. The PCI Express specification describes this capability in terms of routing peer-to-peer (P2P) transactions between ports. Though identified by the PCIe specification, the mechanism and support of this feature is considered to be outside the scope of the base specification. The DM (RC mode) provides support for this mechanism. To enable P2P support in RC mode, you must set the `CX_P2P_ENABLE` configuration parameter. Enabling P2P support modifies the operation of the controller in the following ways:

- The controller preserves the original requester or completer IDs for P2P transmit traffic while automatically adding the appropriate ID for locally generated traffic.

- Only received completions corresponding to requests originated by the device are subject to the normal receive completion LUT processing. Completions of P2P requests do not reference the LUT.
- The controller preserves the original requester or completer IDs for P2P transmit traffic while automatically adding the appropriate ID for locally generated traffic.
- All TLP header fields are preserved in both transmit and receive directions. Therefore the controller provides all reserved fields at receive interfaces and expects your application to drive them at the client interfaces.
- The controller optionally appends ECRC fields to locally generated TLPs, passing P2P traffic along without modification. The following limitations apply with respect to the P2P feature:
 - Receive queue architecture must be segmented-buffer.
 - No ECRC stripping.
 - The controller does not split transmit packets. Your application must handle this condition when the peer-to-peer packet exceeds the max payload limitation.

Attention: You cannot enable the `CX_P2P_ENABLE` parameter when you configure the controller with the AXI. This means that the previously mentioned features for supporting P2P are not available in the controller. However, you can still support P2P operation by implementing similar features in your application logic. Assuming (for example) that you have two RC ports connected together by your AXI application logic. Then P2P transactions appear to terminate and originate from your application even though the device generating the originating requests and the target completer were EPs on different PCIe hierarchical trees.

Full details of I/O signals and timing requirements for the P2P are described in “Peer-to-Peer Support (P2P)”

11.3.3.12 Gen 2/3/4 Speed Modes

11.3.3.12.1 Gen2 5.0 GT/s Operation

The controller supports all of the non-optional Gen2 5.0 GT/s features defined in the *PCI Express Base Specification, Revision 4.0, Version 0.7*. The interface between the controller and the PHY is compliant with *PIPE Specification for PCI Express, Version 4.3*. The controller supports two different mechanisms of achieving the Gen2 rate: dynamic frequency and dynamic width.

■ For dynamic frequency configurations, the number of active symbols on the PIPE is constant and the frequency of the controller doubles each time as the controller transitions from Gen1 -> Gen2 rate.

■ When supporting dynamic width, the clock frequency of the controller remains constant and the number of active symbols on the PIPE doubles each time as the controller transitions from Gen1 -> Gen2 rate.

11.3.3.12.1.1 Speed Changing

When you set the default of the Directed Speed Change field of the Link Width and Speed Change Control register (GEN2_CTRL_OFF . DIRECT_SPEED_CHANGE) using the DEFAULT_GEN2_SPEED_CHANGE configuration parameter to 1, then the speed change is initiated automatically after link up, and the controller clears the contents of GEN2_CTRL_OFF . DIRECT_SPEED_CHANGE. If you want to prevent this automatic speed change, then write a lower speed value to the Target Link Speed field of the Link Control 2 register (LINK_CONTROL2_LINK_STATUS2_REG . PCIE_CAP_TARGET_LINK_SPEED) through the DBI before link up.

To manually initiate the speed change then:

■ Write to LINK_CONTROL2_LINK_STATUS2_REG . PCIE_CAP_TARGET_LINK_SPEED in the local device

■ Deassert GEN2_CTRL_OFF . DIRECT_SPEED_CHANGE in the local device

■ Assert GEN2_CTRL_OFF . DIRECT_SPEED_CHANGE in the local device

The controller uses the mac_phy_rate output to negotiate the link data rate. It changes the rate signal and waits for a pulse on the phy_mac_phystatus signal to confirm that the PHY has accepted the requested rate. For core_clk considerations when changing speed, see “Gen2, Gen3, or Gen4 Speed Changing Considerations (CX_FREQ_STEP_EN =1)”

Note: As per the PCI Express Base Specification, Revision 4.0, Version 0.7, the controller does not implement the optional Compliance Receive bit for Gen1 configurations.

11.3.3.12.2 Gen3 8.0 GT/s Operation

The controller supports all of the non-optional Gen3 8.0 GT/s features defined in the *PCI Express Base Specification, Revision 4.0, Version 0.7*. The interface between the controller and the PHY is compliant with *PIPE Specification for PCI Express, Version 4.3*. The controller supports two different mechanisms of achieving the Gen3 rate: dynamic frequency and dynamic width.

■ For dynamic frequency configurations, the number of active symbols on the PIPE is constant and the frequency of the controller doubles each time as the controller transitions from Gen1 -> Gen2 -> Gen3 rates.

■ When supporting dynamic width, the clock frequency of the controller remains constant and the number of active symbols on the PIPE doubles each time as the controller transitions from Gen1 -> Gen2 -> Gen3 rates.

11.3.3.12.2.1 Gen3 Speed Changing

See "Speed Changing"

11.3.3.12.2.2 Gen3 8.0 GT/s Transmitter Equalization

The controller performs link equalization during link training to improve signal quality by adjusting the transmitter and receiver equalization parameters for each lane on each side of the link. There are three modes for the mapping of presets to coefficients, selectable at configuration time using the CX_GEN3_EQ_PSET_COEF_MAP_MODE parameter:

■ Dynamic PHY: The coefficients are dynamically mapped in the PHY. This is the default mode.

■ Dynamic MAC: The coefficients are dynamically mapped in the MAC.

■ Programmable Table: The coefficients are programmed in a table by your application.

There are two feedback modes for determining the optimal equalization settings, programmable using the Gen3 EQ Control Register (GEN3_EQ_CONTROL_OFF).

■ Figure of merit (FOM)

■ Direction change with optional convergence support

11.3.3.12.3 Gen4 16.0 GT/s Operation

The controller supports the Gen4 16.0 GT/s feature defined in the *PCI Express Base Specification, Revision 4.0, Version 0.7 with limitations*. The interface between the controller and the PHY is compliant with *PIPE Specification for PCI Express, Version 4.3*. The controller supports two different mechanisms of achieving the Gen4 rate: dynamic frequency and dynamic width.

■ For dynamic frequency configurations, the number of active symbols on the PIPE is constant and the frequency of the controller doubles each time as the controller transitions from Gen1 -> Gen2 -> Gen3

-> Gen4 rates.

■ When supporting dynamic width, the clock frequency of the controller remains constant and the number of active symbols on the PIPE doubles each time as the controller transitions from Gen1 -> Gen2 -> Gen3 rates -> Gen4.

11.3.3.12.3.1 Gen4 Speed Changing

See "Speed Changing"

11.3.3.12.3.2 Gen4 16.0 GT/s Transmitter Equalization

The controller performs link equalization during link training to improve signal quality by adjusting the transmitter and receiver equalization parameters for each lane on each side of the link. There are three modes for the mapping of presets to coefficients, selectable at configuration time using the `CX_GEN3_EQ_PSET_COEF_MAP_MODE` parameter:

■ **Dynamic PHY:** The coefficients are dynamically mapped in the PHY. This is the default mode.

■ **Dynamic MAC:** The coefficients are dynamically mapped in the MAC.

■ **Programmable Table:** The coefficients are programmed in a table by your application.

There are two feedback modes for determining the optimal equalization settings, programmable using the Gen3 EQ Control Register (`GEN3_EQ_CONTROL_OFF`).

■ **Figure of merit (FOM)**

■ **Direction change with optional convergence support**

11.3.3.13 Power Management

This section discusses the power management (PM) features of the controller. For a proper understanding of PCIe power management, you should read *Power Management of the PCI Express Base Specification, Revision 4.0, Version 0.7*.

11.3.3.13.1 Overview

The controller supports two categories of PM operations to control the device state (D-state) and link state.

11.3.3.13.1.1 Software PCI Compatible PM (PCI-PM)

- D-state PM of Function. The host software can direct the function to enter any of the D1, D2, or D3 low-power states. It does this by writing to the Power Management Control and Status Register (PMCSR) in the PCI-PM capability structure.
- D-state PM of Link. Link states are not visible to PCI-PM legacy compatible software, and are derived from the power management D-states of the components connected to that link. The action of changing the D-state in the PMCSR indirectly causes a change in the link power state. The L1 state is entered whenever all functions of a USP on a link are programmed to a non-D0 state. The entry into L2 and L3 states is initiated by the DSP.
- Clock PM (L1 with REFCLK removal/PLL Off). This is an optional feature that enables components on a link to further reduce idle power consumption while the link is in L1, by turning off the PLL.

11.3.3.13.1.2 Native PCIe PM Mechanisms

- Active State PM (ASPM). When the USP is in L0 and detects idleness on the link for a specific amount of time, it automatically transitions the link to the L0s or L1 (optional) power state.
- L1 Substates. This is an optional PCIe feature that enables components on a link to further reduce idle power consumption while the link is in L1, including almost complete removal of power for the high speed PHY circuits.

11.3.3.13.1.3 Relationship Between D-state, Link State, and PHY State

The link state and D-state determine what power and clock supplies are on or off. For implementation details of low-power clocking logic, see "Clock Requirements"

Table 3-64 Power/Clock Supply Status in Low-Power States of Interest (DSP or Single Function non-ARI USP)

D-State	Permissible Quiescent Link States	Link State Change	Active Power Supplies	Active Clock Supplies ^a	pipe_clk core_clk	PHY State
---------	-----------------------------------	-------------------	-----------------------	------------------------------------	----------------------	-----------

Table continues on the next page...

		Trigger (see Table 3-65)				
D0uninitialized	L0	n/a	V b main Vaux	REFCLK AUXCLK	ON	P0, P0S
D0active	L0	ASPM				
	L0S					
	L1			ONc	P1	
D1, D2, D3hot	L1	PCI-PM				
D3co d Id	L2	PCI-PM	Vaux	AUXCLK	OFF	P2/OFF
	L3e		None	None		

a. REFCLK is the platform reference clock for the PHY TX PLL. AUXCLK is the platform low-power clock. For more details, see “Clock Requirements”

b. Optionally removable in L2 and L1.2

c. You can remove REFCLK (and pipe_clk/core_clk). For more details, see “Removing the Reference Clock”

d. Transitioned from D3hot to D3cold by removal of Vmain. D3cold is entered by the controller in response to PME_Turn_Off MSG

e. A function can be transitioned from L2 to L3 by the removal of Vaux.

Note: D0 is divided into two distinct substates, the uninitialized substate and the active substate. When a component comes out of conventional reset or FLR, it defaults to the D0uninitialized state. A function enters the D0active state whenever any of the functions Memory Space Enable, I/O Space Enable, or Bus Master Enable bits have been enabled by system software.

Table 3-65 Link-State-Change Trigger Capabilities For Each Port Type

Port Type	Can Trigger L0/L0s Entry	Can Trigger L1 Entry	Can Trigger L2/L3 Entry
USP	Yes	Yes, on any of these triggers: <ul style="list-style-type: none"> • Software programs non-D0 state (PCI-PM) • USPs idle timer expires (ASPM) • Application requests the USP to enter L1b 	No
DSP	No	Noc	Yesd

a. You can prevent/delay the controller from entering L1-ASPM (not L1-PCI-PM) by asserting app_xfer_pending.

- b. USP application asserts the app_req_entr_11 input. A DSP controller ignores this input.
- c. DSP can indirectly initiate L1 by writing non-D0 value to PMCSR of the USP link partner. A non-D0 write to the USP PMCSR always triggers a transition to L1.
- d.L2/L3 entry is initiated after the RC PM software transitions a device into a D3 state and subsequently instructs the DSP to transmit PME_Turn_Off message TLP to initiate the removal of power and clocks.

Table 3-66 indicates the different levels of power savings (obtained by switching off circuits outside the controller) that can be expected from executing L1 in different ways. Higher exit latencies are associated with higher power savings. Power saving and latency are PHY implementation specific, and may be determined by consulting your PHY documentation.

Table 3-66 L1 Execution Modes and Permissible Power States of PHY Circuits

L1 Execution Mode	Permissible Power States for PHY Circuits		
	PLL/REFCLK	RX Electrical Idle Detector	TX Common Mode
L1 without Clock PM	ON	ON	ON
L1 with Clock PM	OFF	ON	ON
L1.1	OFF	OFF	ON
L1.2	OFF	OFF	OFF

11.3.3.13.1.4 Device State (D-state) Power Management of a Function (USP)

The host software can direct the downstream device function to enter any of the low-power states:

- D1 (light sleep)
- D2 (deep sleep)
- D3hot (full of; reference clock optionally removed; Vmain normally available)
- D3cold (full of; reference clock removed; Vmain removed; Vaux optionally available)

It does this by writing to the PMCSR in the PCI-PM capability structure. This action also indirectly causes the downstream component (USP) to change the link power state. The controller negotiates with the link partner using PM TLPs and DLLPs before entering the corresponding low-power link state. The controller exits the device low-power state (and returns to D0) when it detects a CFG access to a device function, or when it detects a PME such as an event on the outband_pwrup_cmd1 input signal. For a function in device power states D1, D2, and D3hot, the controller only accepts CFG and MSG requests

TLPs for that function. All other incoming request types for that function are treated as unsupported requests (UR). For more details see Section 5.3.3, “Power Management Event Mechanisms” of the PCI Express Base Specification, Revision 4.0, Version 0.7.

11.3.3.13.1.5 Active State Power Management (ASPM)

You must enable ASPM through the ASPM Control field in the Link Control register. When the USP is in L0 and detects idleness on the link for a specific amount of time (determined by the L0s Entrance Latency field² in the "Ack Frequency and L0-L1 ASPM Control Register" `ACK_F_ASPM_CTRL_OFF`), it automatically transitions the link to the L0s power state. Each link direction (TX and RX) is processed separately. The controller exits L0s when there is traffic waiting to be sent.

When the USP is in L0 or L0s and it detects idleness on the link (both directions) for a specific amount of time (determined by the L1 Entrance Latency field in `ACK_F_ASPM_CTRL_OFF`), it automatically transitions the link to the L1 power state. The link partners must negotiate entry into the L1 link power state using PM TLPs and DLLPs. The L1 state achieves greater power savings but the exit latency from this state is higher than from L0s. You can also instruct an USP controller (only) to enter L1 by asserting the `app_req_entr_l1` input. The USP exits L1 when there is traffic waiting to be sent or when a PME (such as an event on the `app_req_exit_l1` input) is received.

If the ASPM exit latencies from L0s or L1 are too high for the overall PCIe system data latency requirements, then the host software can disable ASPM using the ASPM Control Field of the Link Control register. The controller reports the exit latencies using the Link Capability registers. You set these by writing to these registers or by setting the `DEFAULT_L0S_EXIT_LATENCY` and `DEFAULT_L1_EXIT_LATENCY` parameters.

11.3.3.13.2 L1 Substates

This section discusses the L1 link substates.

The L1 substates are applicable in both the ASPM and PCI-PM L1 link states. L1 substates management utilizes a per-link sideband signal called `CLKREQ#`. The controller supports this feature (with the additional I/O as shown in "Removing the Reference Clock") when you set `CX_L1_SUBSTATES_ENABLE = 1`.

11.3.3.13.2.1 Assumptions and Limitations

■ The `CLKREQ#` signal is not directly controlled by the controller. You must implement external logic to do so; see “Removing the Reference Clock” for examples.

■ During L1 substates it is assumed that `core_clk` is turned off and that `aux_clk` is active. It is required that your application switches `aux_clk` to a low frequency free running clock on entry into L1.

■ The controller uses `aux_clk` for counting time during L1 substates. You must program the frequency of this clock into the `L1_SUBSTATES_OFF` register with a value in the range 1...1000MHz to count real time. Frequencies lower than 1 MHz are possible but with a loss of accuracy in the time counted.

■ It is assumed that the `phy_mac_rxelecidle` input from the PHY remains stable at 1 during L1 substates when:

- Electrical idle detection is disabled and
- Electrical idle detection is being re-enabled and until fully functional again.

11.3.3.13.2.2 PIPE 4.3 Operation

The controller supports two interface options for L1 substates.

■ PIPE 4.2 + Sideband signals (`CX_PIPE43_SUPPORT=0`)

The controller uses the sideband signals `mac_phy_rxelecidle_disable`, `mac_phy_txcommonmode_disable`, and `phy_mac_pclkack_n`.

■ PIPE 4.3 (`CX_PIPE43_SUPPORT=1`)

The controller and PHY use the `mac_phy_powerdown[3:0]` output to indicate the PHY power state.

You can specify the power-down encodings using the `CX_PIPE43_P1CPM_ENCODING`, `CX_PIPE43_P1_1_ENCODING`, and `CX_PIPE43_P1_2_ENCODING` parameters.

You can specify P1.CPM entry sequence using the `CX_PIPE43_P0_P1CPM` parameter.

The sideband signals `mac_phy_rxelecidle_disable`, `mac_phy_txcommonmode_disable`, and `phy_mac_pclkack_n` do not exist on the top of the controller.

Figure 3-46 PIPE 4.3 L1 SS Operation (`CX_PIPE43_ASYNC_HS_BYPASS=0` / `CX_PIPE43_P0_P1CPM=0`)

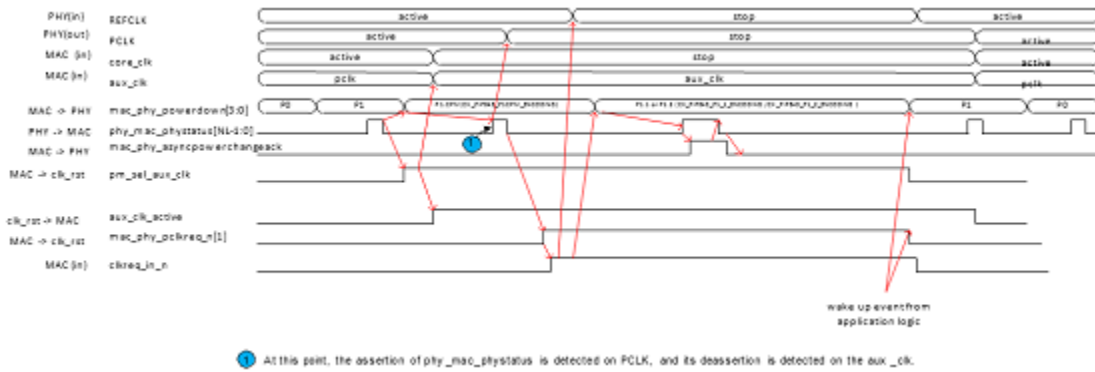

Figure 3-47 PIPE 4.3 L1 SS Operation (CX_PIPE43_ASYNC_HS_BYPASS=0 / CX_PIPE43_P0_P1CPM=1)

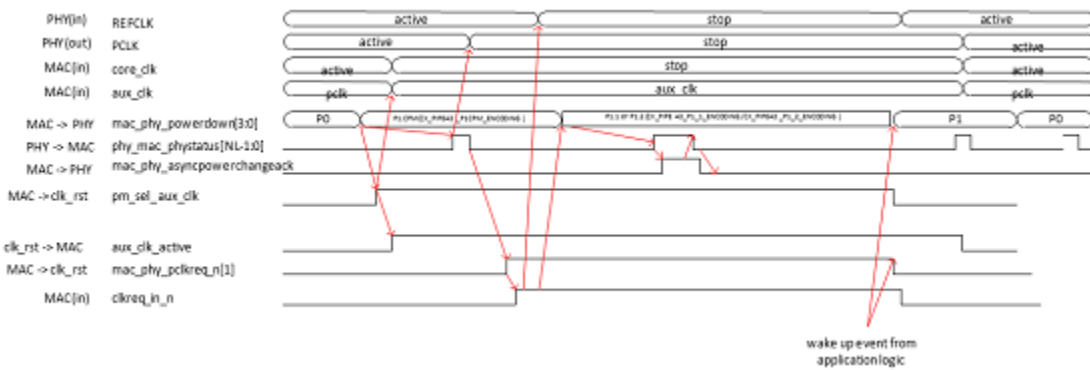

Figure 3-48 PIPE 4.3 L1 SS Operation (CX_PIPE43_ASYNC_HS_BYPASS=1 / CX_PIPE43_P0_P1CPM=1)

11.3.3.13.2.3 L1.1 and L1.2 Entry and Exit Conditions

This section discusses the L1 link state.

11.3.3.13.2.3.1 Overview

After the link has entered L1 through the normal L1 negotiation, the USP can initiate the sequence for entering the target L1 substate (L1.1 or L1.2) by tri-stating its CLKREQ# output buffer. The entry sequence can only proceed if the DSP is also tri-stating its CLKREQ# output buffer, resulting in the bidirectional CLKREQ# signal being pulled up to 1. Otherwise CLKREQ# will remain asserted at 0 and the link state will stay in L1. The exit sequence can be initiated by either ports by asserting CLKREQ# to 0. For each port there are two cases to consider, the first where the exit is initiated locally, the second where the exit is initiated remotely. The following sections provide details on the signaling that occurs between the PCIe controller as the controller, the PHY and the CLKREQ# output buffer for entering and exiting L1 substates. L1 substates management utilizes a per-link sideband signal called CLKREQ#. After all of the entry conditions for a L1 substate are met, the controller asserts the `mac_phy_rxelecidle_disable` output. When the target L1 substate is L1.2, it also asserts the `mac_phy_txcommonmode_disable` output.

11.3.3.13.2.3.2 PIPE 4.2 L1 Substates Entry

1. Controller deasserts `mac_phy_pclkreq_n[1]`
2. PHY deasserts `phy_mac_pclkack_n` when ready for REFCLK removal, PCLK is off
3. CLKREQ# output buffer tri-stated
4. Controller waits for `clkreq_in_n` to de-assert
5. Controller asserts `mac_phy_rxelecidle_disable` (and `mac_phy_txcommonmode_disable` if the target L1 substate is L1.2)
6. PHY disables receiver Electrical Idle detection, `phy_max_rxelecidle` is maintained stable to 1, if

`mac_phy_txcommonmode_disable` =1 the PHY also disables transmitter Common Mode.

Note: If PHY does not deassert `phy_mac_pclkack_n` within 3 μ s in step 2, controller asserts

`mac_phy_pclkreq_n` again.

11.3.3.13.2.3.3 PIPE 4.2 L1 Substates Exit (Locally Initiated)

1. Any of the normal L1 exit conditions in "L1-PM/L1-ASPM Exit" are met
2. Controller asserts `mac_phy_pclkreq_n[1]`

3. Controller deasserts `mac_phy_rxelecidle_disable` (and `mac_phy_txcommonmode_disable` if asserted)
4. PHY re-enables receiver Electrical Idle detection, if disabled the PHY also re-enables transmitter Common Mode
5. `CLKREQ#` output buffer is asserted
6. PHY asserts `phy_mac_pclkack_n` when PCLK is on
7. Controller transitions the PHY to P0 in the usual way

11.3.3.13.2.3.4 PIPE 4.2 L1 Substates Exit (Remotely Initiated)

1. The remote link partner asserts `CLKREQ#`
2. Controller input `clkreq_in_n` asserts
3. Controller asserts `mac_phy_pclkreq_n[1]`
4. Controller deasserts `mac_phy_rxelecidle_disable` (and `mac_phy_txcommonmode_disable` if asserted)
5. PHY re-enables receiver Electrical Idle detection, if disabled the PHY also re-enables transmitter Common Mode
6. PHY asserts `phy_mac_pclkack_n` when PCLK is on
7. Controller transitions the PHY to P0 in the usual way

11.3.3.13.2.3.5 PIPE 4.3 L1 Substates Entry

1. MAC transitions the PHY to P1
2. PHY asserts `phy_mac_phystatus` for P1 entry
3. Controller transitions the PHY to P1.CPM and asserts `pm_sel_aux_clk` to turn off `core_clk`
4. PHY asserts `phy_mac_phystatus` for P1.CPM entry and `CLK_RST` asserts `aux_clk_active`
5. Controller deasserts `mac_phy_pclkreq_n[1]`
6. `CLKREQ#` output buffer tri-stated
7. Controller waits for `clkreq_in_n` to de-assert
8. Controller transitions the PHY to P1.1 (or P1.2)
9. PHY asserts `phy_mac_phystatus` for P1.1 (or P1.2)

10. Controller asserts mac_phy_asyncpowerchangeack
11. PHY deasserts phy_mac_phystatus
12. Controller deasserts mac_phy_asyncpowerchangeack

Note: When CX_PIPE43_P0_P1CPM = 1, steps 1 -2 are bypassed and when CX_PIPE43_ASYNC_HS_BYPASS = 1, steps 9 - 12 are bypassed.

11.3.3.13.2.3.6 PIPE 4.3 L1 Substates Exit (Locally Initiated)

1. Any of the normal L1 exit conditions in "L1-PM/L1-ASPM Exit" are met
2. Controller input clkreq_in_n asserts
3. Controller transitions the PHY to P1 and deasserts pm_sel_aux_clk to turn on core_clk
4. CLKREQ# output buffer is asserted
5. PHY asserts phy_mac_phystatus for P1 entry and CLK_RST deasserts aux_clk_active
6. Controller transitions the PHY to P0 in the usual way

11.3.3.13.2.3.7 PIPE 4.3 L1 Substates Exit (Remotely Initiated)

1. The remote link partner asserts CLKREQ#
2. Controller input clkreq_in_n asserts
3. Controller asserts mac_phy_pclkreq_n[1]
4. Controller transitions the PHY to P1 and deasserts pm_sel_aux_clk to turn on core_clk
5. PHY asserts phy_mac_phystatus for P1 entry and DWC_pcie_clkrst.v deasserts aux_clk_active
6. Controller transitions the PHY to P0 in the usual way

11.3.3.13.2.3.8 L1 Substates Software Control

When the controller enters L1, the target L1 substate depends on several programming bits:

- PM Control/Status Register
- USP: The current D-state
- DSP: The DLLP type that was used by USP to request L1

■ L1 Substates Control 1 Register

ASPM PM L1.1 Enabled

ASPM PM L1.2 Enabled

PCI PM L1.1 Enabled

PCI PM L1.2 Enabled

After the USP controller enters L1, it uses the D-state of the device to determine if L1 was entered in ASPM mode or PCI-PM mode. After the DSP controller enters L1, it uses the USPs DLLP L1 request type to determine if L1 was entered in ASPM mode or PCI-PM mode. The next tables shows the target L1 substate as a function of the relevant programming bits.

Table 3-67 Target L1 Substate As A Function Of Software Controls (USP)

D-State ^a	ASPM PM L1.1 Enabled	ASPM PM L1.2 Enabled	Reported LTR >= L1.2 Threshold	PCI PM L1.1 Enabled	PCI PM L1.2 Enabled	Target L1 Substate
!D0	-	-	-	0	0	L1
!D0	-	-	-	1	0	L1.1
!D0	-	-	-	-	1	L1.2
D0	0	0	-	-	-	L1
D0	1	0	-	-	-	L1.1
D0	0	1	0	-	-	L1
D0	1	1	0	-	-	L1.1
D0	-	1	1	-	-	L1.2

a. In all functions of a multifunction device

Table 3-68 Target L1 Substate As A Function Of Software Controls (DSP)

DLLP Received	ASPM PM L1.1 Enabled	ASPM PM L1.2 Enabled	Reported LTR >= L1.2 Threshold	PCI PM L1.1 Enabled	PCI PM L1.2 Enabled	Target L1 Substate
PM_Enter_L1	-	-	-	0	0	L1
	-	-	-	1	0	L1.1
	-	-	-	-	1	L1.2
PM_Active_ State_Reque st_L1	0	0	-	-	-	L1
	1	0	-	-	-	L1.1
	0	1	0	-	-	L1
	1	1	0	-	-	L1.1
	-	1	1	1	-	-

The Reported LTR is the maximum of the snoop/nosnoop latency values embedded in LTR messages transmitted by the upstream ports or received by the downstream port. The controller stores these values in the port logic LTR Latency Register (LTR_LATENCY_OFF). When the requirement bit in the message is 0, the latency value is considered infinite (that is, the check with the threshold always pass). For more details on LTR, see “Latency Tolerance Reporting (LTR) Message Reception (RC Mode)” and “Latency Tolerance Reporting (LTR) Message Generation [EP Mode]” .

Figure 3-49 Role of LTR in L1 Substates

11.3.3.13.2.3.9 L1 Exit Latency (PIPE 4.2)

This section provides a breakdown of the L1 exit latency when CX_L1_SUBSTATES is enabled for L1 substates or L1 Clock PM in a PIPE 4.2 system.

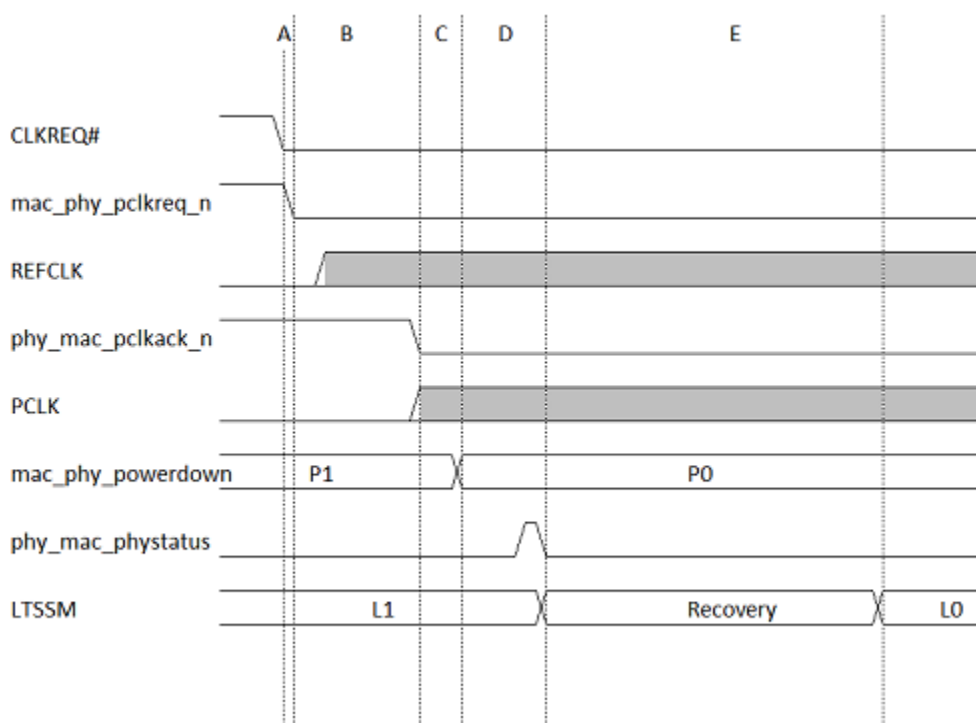

Table 3-69 L1 PIPE 4.2 Substates and L1 Clock PM Exit Latency Component Values

	A	B	C	D	E

11.3.3.13.2.4 L0s Entry and Exit Conditions

This section discusses the L1 link state.

11.3.3.13.2.4.1 Overview

L0s is a low-power state enabled by ASPM. ASPM controls entry into L0s for the transmitter. The remote device controls entry into L0s for the receiver.

11.3.3.13.2.4.2 L0s Entry

All of these condition must be met in the USP:

- ASPM L0s is enabled through the ASPM Control field in the Link Control register.

■ L0s entry conditions as defined in Section 5.4.1.1.1, “Entry into the L0s State” of the PCI Express Base Specification, Revision 4.0, Version 0.7, exist for a duration of time (determined by the LOS_EN- TRANCE_LATENCY field in ACK_F_ASPM_CTRL_OFF).

■ No higher stage of power-down requested.

11.3.3.13.2.4.3 L0s Exit

Any of these condition can be met in the USP:

■ A DLLP or TLP is pending to be sent.

■ L1 entry conditions as defined in Section 5.4.1.2.1, “Entry into the L1 State” of the PCI Express Base Specification, Revision 4.0, Version 0.7 are satisfied.

■ PCIe link partner requests to enter into link recovery.

11.3.3.13.2.4.4 Multifunction and ARI Capable Devices (Endpoint)

Table 3-71 indicates the variation in conditions for ASPM L0s entry for ARI capable and multifunction devices. For more details, see Chapter 5.4.1, "Active State Power Management (ASPM)" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

Table 3-71 Dependency of Endpoint ASPM Link State Transitions Upon CX_NFUNC and CX_ARI_ENABLE

CX_NFUNC	CX_ARI_ENABLE	ASPM Control and D-State Prerequisite Conditions
1	0	Function is in D0 and policy is determined by ASPM control settings
>1	0	Functions not in D0 are ignored. At least one function is in D0 and policy is determined by ASPM control settings according to the algorithm outlined in Chapter 5.4.1, Active State Power Management (ASPM) of the PCI Express Base 3.1 Specification, revision 1.0.
1	1	D-state ignored. Function is in any D-state and policy is determined by ASPM control settings.
>1	1	D-state ignored. Functions are in any D-state and policy is determined by PF0 # control settings.

11.3.3.13.2.5 L1 Operation (Non-substates)

11.3.3.13.2.5.1 L1 (ASPM/PM) Entry and Exit Conditions

This section discusses the L1 link state. L1 is a low-power state enabled either by ASPM (L1-ASPM) or by the software changing the D-state (L1-PM). The L1 state is a bi-directional link low-power state and both link partners must negotiate to go to this state.

11.3.3.13.2.5.1.1 L1-ASPM Overview

The L1-ASPM entry negotiation handshake uses PM_Active_State_Request_L1 DLLPs, PM_Request_Ack DLLPs, and PM_Active_State_Nak MSG TLPs. There are three scenarios that cause the controller to enter L1 under ASPM conditions.

11.3.3.13.2.5.1.2 L1-ASPM Entry (Scenario 1): L1 Idle Timeout In L0s

All of these condition must be met in the USP:

- ASPM L1 and L0s are enabled through the ASPM Control field in the Link Control register.

- The ENTER_ASPM field of ACK_F_ASPM_CTRL_OFF is set to '0' and the link state is L0s for both link partners,

or

the ENTER_ASPM field of ACK_F_ASPM_CTRL_OFF is set to '1'.

- L1 entry conditions as defined in Section 5.4.1.2.1, "Entry into the L1 State" of the PCI Express Base Specification, Revision 4.0, Version 0.7, exist for a duration of time (determined by the L1_EN- TRANCE_LATENCY field in ACK_F_ASPM_CTRL_OFF).

- No higher stage of power-down requested.

- Your USP application is not asserting the app_xfer_pending input.

- There are no in-progress transactions¹ in the controller such as:

- Rx queue P/NP Request TLPs

- Rx queue CPL TLPs

- Outstanding/expected wire completions

- Outstanding/expected application (at the AXI master interface when present) completions

- There are no pending requests at the AXI slave interface, that is, `slv_a*valid` must be 0.
- There are no pending DMA transfers.

1. Created by your application, or remote link partner, or the embedded DMA. DBI requests do not prevent L1 entry because the CDM registers (including DMA) are clocked off `aux_clk_g`.

11.3.3.13.2.5.1.3 L1-ASPM Entry (Scenario 2): L1 Idle Timeout In L0

All of these condition must be met in the USP:

- ASPM L1 is enabled and L0s is not enabled through the ASPM Control field in the Link Control register.
- Link state is L0.
- L1 entry conditions as defined in Section 5.4.1.2.1, "Entry into the L1 State" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*, exist for a duration of time (determined by the `L1_EN- TRANCE_LATENCY` field in `ACK_F_ASPM_CTRL_OFF`).
- No higher stage of power down-requested.
- Your USP application is not asserting the `app_xfer_pending` input.
- There are no in-progress transactions in the controller such as:
 - Rx queue P/NP Request TLPs
 - Rx queue CPL TLPs
 - Outstanding/expected wire completions
 - Outstanding/expected application (at the AXI master interface when present) completions
- There are no pending requests at the AXI slave interface, that is, `slv_a*valid` must be 0.
- There are no pending DMA transfers.

11.3.3.13.2.5.1.4 L1-ASPM Entry (Scenario 3): Application Controlled (USP only)

All of these condition must be met in the USP:

- ASPM L1 is enabled through the ASPM Control field in the Link Control register.
- Your application logic pulses the `app_req_entr_l1` input.

- Your USP application is not asserting the app_xfer_pending input.
- There are no in-progress transactions¹ in the controller such as:
 - Rx queue P/NP Request TLPs
 - Rx queue CPL TLPs
 - Outstanding/expected wire completions
 - Outstanding/expected application (at the AXI master interface when present) completions
- There are no pending requests at the AXI slave interface, that is, slv_a*valid must be 0.
- There are no pending DMA transfers.

1. Created by your application or remote link partner, or the embedded DMA. DBI requests do not prevent L1 entry because the CDM registers (including DMA) are clocked off aux_clk_g.

11.3.3.13.2.5.1.5 L1-ASPM Additional Information (USP)

Table 3-72 indicates the variation in conditions for ASPM L1 entry for ARI capable and multifunction devices. For more details, see Chapter 5.4.1, "Active State Power Management (ASPM)" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

Table 3-72 Dependency of Endpoint ASPM Link State Transitions Upon CX_NFUNC and CX_ARI_ENABLE

CX_NFUNC	CX_ARI_ENABLE	ASPM Control and D-State Prerequisite Conditions
1	0	Function is in D0 and policy is determined by ASPM control settings
>1	0	Functions not in D0 are ignored. At least one function is in D0 and policy is determined by ASPM control settings according to the algorithm outlined in Chapter 5.4.1, "Active State Power Management (ASPM)" of the <i>PCI Express Base Specification, Revision 4.0, Version 0.7</i> .
1	1	D-state ignored. Function is in any D-state and policy is determined by ASPM control settings.
>1	1	D-state ignored. Functions are in any D-state and policy is determined by PF0 # control settings.

11.3.3.13.2.5.1.6 L1-PM Entry

The power management state of a link is determined by the D-state of the USP. When you change the device state of the USP to D1, D2, or D3hot by writing to the PMCSR, the controller must initiate a link state transition to L1. The USP of a non-ARI multi-function device must not initiate a link state transition to L1 until all of its functions have been programmed to a non-D0 D-state. L1 state is a bi-directional link low-power state. Both link partners must negotiate to go this state. The L1-PM negotiation handshake uses the following DLLPs:

- PM_Enter_L1

- PM_Request_Ack

All of these condition must be met:

- L1 entry conditions are satisfied as defined in Section 5.3.2.1, "Entry into the L1 State" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

Note: An USP application asserting the app_xfer_pending input does not prevent L1-PM entry, but will cause immediate exit from L1-PM.

Table 3-73 indicates the variation in conditions for L1 entry for ARI capable and multifunction devices. For more details, see Chapter 5.3.2, "PM Software Control of the Link Power Management State" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

Table 3-73 Dependency of Endpoint PCI-PM Transition L1 Upon CX_NFUNC and CX_ARI_ENABLE

CX_NFUNC	CX_ARI_ENABLE	D-State Prerequisite Conditions
1	0	Function not in D0
>1	0	All functions not in D0
1	1	Function not in D0
>1	1	At least one function not in D0 and all other functions not in D0active

11.3.3.13.2.5.1.7 L1-PM/L1-ASPM Exit

Any of these condition are met:

- A DLLP or TLP is pending to be sent.

- Your application asserts the app_req_exit_l1 input.

- Your application asserts the `app_xfer_pending` input.
- Your application asserts the `apps_pm_xmt_pme` input.

When the USP is programmed¹ with capability to support PME; it sends a PME message to the RC which calls the PM software to transition the USP to the D0 state. Therefore, you should only use `apps_pm_xmt_pme` for L1-PM exit.

- Link partner is requesting exit from L1.
- PM software (RC) requests a higher stage of power-down by writing to the PMCSR in the USP.
- Your application is requesting to send traffic by asserting `client0_tlp_hv` (non-AXI) or `slv_a*valid` (AXI2).
- Your application enables a DMA read or write channel, or DMA controller is requesting data.
- Your application (DSP) initiates link disable, or link retrain (by setting `PCIE_CAP_LINK_DISABLE` or `PCIE_CAP_RETRAIN_LINK` field in `LINK_CONTROL_LINK_STATUS_REG` to 1).
- Your application (DSP) initiates hot reset by either:
 - setting `RESET_ASSERT` field in `PORT_LINK_CTRL_OFF` to 1, or
 - setting `SBR` field in `BRIDGE_CTRL_INT_PIN_INT_LINE_REG` to 1, or
 - toggling `app_init_rst`
- Your application requests a speed change (by setting `DIRECT_SPEED_CHANGE` field in `GEN2_C-TRL_OFF` to 1).
- Your application requests link width change (by setting `DIRECT_LINK_WIDTH_CHANGE` field in `MULTI_LANE_CONTROL_OFF` is set to 1).
- Your application (USP) requests transmission of VDM, MSI/MSIX3, or LTR message.
- Your application (DSP) requests transmission of Unlock message.

1. `PME_ENABLE` bit is set in `CON_STATUS_REG`, and the `PME_SUPPORT` bit is set in `CAP_ID_NXT_PTR_REG` for the corresponding D-state for which the function is currently in.

2. Requests from the AHB slave interface do not trigger L1 exit.

3. This exit mechanism does not apply to legacy interrupts. Before requesting the transmission of a legacy interrupt the application should use an existing L1 exit mechanism.

Note: L1 Exit

- MSIX accesses cannot be performed when the controller is in L1. To perform MSIX access, the controller must be woken up from L1.
- The CDM space is accessible in L1, but some CDM register bits will not produce the desired results.
- Writing to CDM register bits which trigger LTSSM state transitions in L1 will not have the desired effect, because the LTSSM clock is not running in L1.

Caution: DMA Doorbell L1

- Any DMA register can be accessed in L1 because the DMA registers are clocked on `aux_- clk_g`.
- Writing to other DMA registers does not trigger L1 exit.
- During L1 exit, there is a latency in restoring the `core_clk`. A second read or write Doorbell is not acknowledged until `core_clk` is restored.

11.3.3.13.2.5.2 L1 Clock PM (L1 with REFCLK removal/PLL Off) Overview

This feature allows you to shut down the PLL and the reference clock during standard (non-substates) L1. Table 3-74 lists the inputs and outputs that are considered for L1 Clock PM.

Table 3-74 Inputs and Outputs to Consider for L1 Clock PM

CX_L1_SUBSTATES_EN	CX_PIPE43_SUPPORT	I/O Signals
0	0	clk_req_n phy_clk_req_n
	1	clk_req_n mac_phy_powerdown[3:0] =CX_PIPE43_P1CPM_ENCODING phy_mac_phystatus
1	0	mac_phy_pclkreq_n[0] phy_mac_pclkack_n
	1	mac_phy_pclkreq_n[0] mac_phy_powerdown[3:0] =CX_PIPE43_P1CPM_ENCODING phy_mac_phystatus

For PIPE 4.3 (CX_PIPE43_SUPPORT=1),

PCI Express Controller (PCIe)

■ The controller and PHY use `mac_phy_powerdown[3:0]` to indicate the PHY power state.

■ You can specify the power-down encodings using the `CX_PIPE43_P1CPM_ENCODING` parameter.

■ You can specify P1.CPM entry sequence using the `CX_PIPE43_P0_P1CPM` parameter.

For an USP, host software uses the Enable Clock Power Management bit in the Link Control register to enable this feature. For a DSP, this register bit is hard coded to '0' and cannot be used to control this behavior. Your application can use the `app_clk_pm_en` input to dynamically control whether to execute L1 with or without Clock PM. The `CLKREQ#` signal is not directly controlled by the controller. You must implement external logic to do so; see “Removing the Reference Clock” for examples.

Figure 3-52 PIPE 4.3 L1 CPM Operation (`CX_PIPE43_P0_P1CPM=0`)

Figure 3-53 PIPE 4.3 L1 CPM Operation (`CX_PIPE43_P0_P1CPM=1`)

11.3.3.13.2.5.3 L1 Clock PM (L1 with REFCLK removal/PLL Off); Entry and Exit Conditions

To enable the controller (upstream port only) to execute L1 with Clock PM:

■ The Support Clock Power Management bit in the Link Capabilities register must be set. The default value of this register is controlled by the `DEFAULT_CLK_PM_CAP` parameter. For downstream ports it is hardcoded to 0, for upstream ports it can be accessed through the DBI.

■ The Enable Clock Power Management bit in the Link Control register must be set.

■ You must set the `app_clk_pm_en` input to 1. The controller only samples `app_clk_pm_en` when L1 is entered.

L1 with Clock PM and L1 substates work orthogonal to each other. L1 with Clock PM uses the `mac_phy_pclkreq_n[0]` signaling, and L1 substates uses the `mac_phy_pclkreq_n[1]` signaling. However, L1 substates takes precedence over Clock PM within the cores PM state machine. This means that when the entry conditions for any L1 substate are satisfied (as per “L1 Substates Software Control”), then the controller's LTSSM executes the corresponding L1 substate protocol.

For details on L1 exit latency, see “L1-PM/L1-ASPM Exit”.

11.3.3.13.2.6 L2 and L3 Power Down Entry and Exit Conditions (USP)

This section discusses the L2 and L3 link states.

11.3.3.13.2.6.1 Overview

L2/L3 entry is initiated¹ after the RC calls power management software to initiate the removal of power and clocks. USPs of devices in D0, D1, D2, and D3hot must respond to the receipt of a `PME_Turn_Off MSG TLP` by transmitting a `PME_TO_Ack MSG TLP`. The device must then request a link transition to `L2/L3_Ready`. `L2/L3_Ready` is a bi-directional link power down state. If your application is not ready to be shut-down, it must keep the `app_ready_entr_l23` input de-asserted. This causes the controller to delay sending the `PM_Enter_L23 DLLP` and thereby stalling the negotiation handshake that uses the following DLLPs:

■ `PM_Enter_L23`

■ `PM_Request_Ack`

When your application is eventually ready for transitioning to D3cold, that is, loss of main power and reference clock, `L2/L3_Ready` is entered and the downstream device begins preparation for the power and clock removal. After main power has been removed, the link transitions to L2 if `Vaux` is provided, or it transitions to L3 if no `Vaux` is provided.

Note: 1. In preparation for removing the main power source, your RC application asserts the `apps_pm_xmt_turnoff` input which causes the RC to broadcast the `PME_Turn_Off MSG TLP` to all USPs.

11.3.3.13.2.6.2 L2/L3 Entry

All of these condition must be met:

- `PME_Turn_Off/PME_TO_Ack` handshake has been completed.
- Your USP application is ready to be turned off; `app_ready_entr_l23 = 1`.
- After sending the `PME_TO_Ack`, the USP initiates the L2/L3 Ready transition protocol by sending the `PM_Enter_L23 DLLP`. The RC responds with the `PM_Request_Ack`.

11.3.3.13.2.6.3 L2/L3 Exit

Any of these condition can be met:

Any of these condition can be met:

- When the USP is programmed¹ with capability to support PME, your application can assert the `apps_pm_xmt_pme` input to request the controller to wakeup. The USP then sends a `PM_PME MSG TLP` to the RC which calls the PM software to transition the USP out of the D3 state.
- Device is programmed with capability to support PME and your application requests the controller to wakeup by triggering a native hot-plug event.
- Link partner is requesting exit from L2/L3.

The controller supports beacon signaling by asserting the wake output when a PCIe device initiates a wake-up event.

Note: 1. `PME_ENABLE` bit is set in `CON_STATUS_REG`, and the `PME_SUPPORT` bit is set in `CAP_ID_NXT_PTR_REG` for the corresponding D-state for which the function is currently in.

11.3.3.13.2.7 Dynamic Power Allocation (DPA)

The DPA capability enables software to actively manage and optimize function power usage when in the D0 state. DPA is not applicable to power states D1-D3. The controller supports this feature when the parameter `CX_DPA_ENABLE` is set.

11.3.3.13.2.7.1 Feature and Limitations

- Each function implements a DPA capability.
- The controller implements a maximum of 32 substates per function. Substate #0 has the highest power. Your application sets each function's substate number through the DBI. Your application also sets the capability registers to the required values through the DBI.
- For details on how your application interacts with the controller, see the description of the `dpa_sub-state_update` I/O signal.

11.3.3.13.2.8 Outbound TLP Blocking In USP (When AHX/AXI Bridge Not Used)

According to the PCI Express specification, a function must not transmit any request TLPs when it is in a D1, D2, or D3 low-power state. A function can still send completion TLPs regardless of the D-state. The controller sets `pm_xtlh_block_tlp=1` when all of the cores functions are in a low-power state.

Single Function Device:

- When a transmit interface (XALI0, XALI1, or XALI2) is only used for request TLPs, then you should set the corresponding `CX_CLIENT0/1/2_BLOCK_NEW_TLP` configuration parameter to 1. Then the controller automatically blocks all outbound TLPs (regardless of TLP type) on that transmit interface, when the controller is in a D1, D2, or D3 power state.
- When a transmit interface (XALI0, XALI1, or XALI2)1 is only used for completion TLPs, then you should set the corresponding `CX_CLIENT0/1/2_BLOCK_NEW_TLP` configuration parameter to 0. Then the controller allows all outbound completion TLPs on that transmit interface, when the controller is in a D1, D2, or D3 power state.
- When a transmit interface (XALI0, XALI1, or XALI2)1 is used for request and completion TLPs, then you should set the corresponding `CX_CLIENT0/1/2_BLOCK_NEW_TLP` configuration parameter to 0, and design your application to prevent all new request TLPs from appearing on the corresponding transmit interface when `pm_xtlh_block_tlp=1`. Your application can continue to generate completion TLPs.

11.3.3.13.2.8.1 Multifunction Device:

- The controller ignores CX_CLIENT0/1/2_BLOCK_NEW_TLP and sets pm_xtlh_block_tlp=0 until all functions are in low-power. Therefore, you must use pm_dstate to identify those functions that are in a low-power state, and block them from generating request TLPs until pm_xtlh_block_tlp=1.
- When a transmit interface (XALI0, XALI1, or XALI2) is only used for request TLPs, then you should set the corresponding CX_CLIENT0/1/2_BLOCK_NEW_TLP configuration parameter to 1.
- When a transmit interface (XALI0, XALI1, or XALI2)1 is only used for completion TLPs, then you should set the corresponding CX_CLIENT0/1/2_BLOCK_NEW_TLP configuration parameter to 0.
- When a transmit interface (XALI0, XALI1, or XALI2)1 is used for request and completion TLPs, then you should set the corresponding CX_CLIENT0/1/2_BLOCK_NEW_TLP configuration parameter to 0.

11.3.3.13.2.9 Advanced Power Management and Power Domain Gating

This section discusses advanced power management and power gating.

This feature allows you to implement power domain gating in your SoC design. It provides all the necessary clock, reset, and power gating controls.

Table 3-75 Advanced Power Management Features and Assumptions

Description	Supported
C-PCIe Features

You can also inspect the VTB test cases at <workspace/doc/vtb/testenv/index.html> for programming examples. For more details on VTB, see the Integrating the Core and VIP using VTB section in the Integration chapter of the User Guide.

11.3.3.13.2.9.1 PCIe System-Initiated L2 Power Gating

When the controller MAC is in L2 (after being programmed to D3), the system might decide to power-down the primary supply of VMAIN by asserting `perst_n`. Therefore, the assertion of `perst_n` is an indication that the system power controller is going to switch off VMAIN.

■ `CX_L2_PG_EN = 1`

■ `CX_L12_PG_EN = 0`

■ `CX_L1_SUBSTATES_ENABLE=0` || (`CX_L1_SUBSTATES_ENABLE = 1` && `app_l1_pwr_off_en = 0`)

■ `CX_L1_RETENTION = 0`

Table 3-76 L2 Configuration

Link State	Power Supply	
	AUX	MAIN
L0/L1	ON	ON
L2	ON	OFF
L3	OFF	OFF

■ The controller ignores CX_CLIENT0/1/2_BLOCK_NEW_TLP and sets pm_xtlh_block_tlp=0 until all functions are in low-power. Therefore, you must use pm_dstate to identify those functions that are in a low-power state, and block them from generating request TLPs until pm_xtlh_block_tlp=1.

■ CX_L12_PG_EN =0

■ When a transmit interface (XALI0, XALI1, or XALI2) is only used for request TLPs, then you should set the corresponding CX_CLIENT0/1/2_BLOCK_NEW_TLP configuration parameter to 1.

■ CX_L1_SUBSTATES_ENABLE=0 || (CX_L1_SUBSTATES_ENABLE =1 && app_l1_pwr_off_en =0)

■ The Support Clock Power Management bit in the Link Capabilities register must be set. The default value of this register is controlled by the DEFAULT_CLK_PM_CAP parameter. For downstream ports it is hardcoded to 0, for upstream ports it can be accessed through the DBI.

■ PME_Turn_Off/PME_TO_Ack handshake has been completed.

2. In preparation for removing the main power source, your RC application asserts the apps_pm_xmt_turnoff input which causes the RC to broadcast the PME_Turn_Off MSG TLP to all USPs.

11.3.3.13.2.9.2 PCIe L2 Power Gating + Autonomous L1.2 Power Gating (No Retention Registers)

There is a power switch in the UPF to allow the cores power management circuitry to automatically switch off the primary power supply to selected parts of the design. There are certain parts¹ of the design which will require retaining state when power is removed. The state retention task is achieved by creating always on supply islands for modules requiring power in L1 sub-states. There are seven L1ON power islands (representing different parts of the RTL hierarchy) defined in the UPF. You can merge these into one power domain (PD_L1ON).

11.3.3.13.2.9.6 UPF Files

A set of configuration-specific UPF files which are supported by VTB simulations and synthesis are created by the coreConsultant tool in workspace/upf. The main UPF file defines:

- Power domains
- Isolation rules
- Level shifter rules
- Retention cell technology cell name. You must edit the UPF and replace this with the actual name of the retention registers in your technology vendor's library.
- Power supplies
- Power states
- Power state table

11.3.3.14 Alternative Routing-ID Interpretation (ARI)

ARI allows an endpoint to support more than eight physical functions (PFs). ARI is enabled by the `CX_ARI_ENABLE` parameter. It is an optional feature for non-IOV endpoints, and it is a mandatory feature for SR-IOV endpoints. Routing IDs, requester IDs, and completer IDs are 16-bit identifiers traditionally composed of three fields: an 8-bit bus number, a 5-bit device number, and a 3-bit function number. With ARI, the 16-bit field is interpreted as two fields instead of three: an 8-bit bus number and an 8-bit function number, the device number field is eliminated, because it is always zero. This new interpretation enables an ARI device to support up to 256 functions instead of 8 functions.

11.3.3.14.1 Features and Limitations

- PCIe controller supports a maximum total of 32 PFs (`CX_NFUNC`)
- The PF routing IDs are sequential and not sparse.
- When a device supports ARI (even if ARI is not enabled in the system), then the following are determined solely by settings in PF0:
 - Max Payload Size
 - Clock Power Management
 - ASPM Control

- Common Clock Configuration
- AXI bridge operation supported.
- Optional AXI DBI slave requires 33-bit address.
- Shared AXI slave interface for DBI access not supported.

11.3.3.15 Single Root I/O Virtualization (SR-IOV)

This section describes the SR-IOV features implemented. SR-IOV is only supported in EP mode.

11.3.3.15.1 Overview

The PCI Express controller implements revision 1.1 of the SR-IOV specification, which defines extensions to enable multiple system images running on a single root to share PCI Express hardware resources. The parameter for enabling SR-IOV is `CX_SRIOV_ENABLE`.

General Features and Limitations

■ Every VF supports:

- Error Handling
- MSI-X Capability
- PCI Express Capability
- ARI Capability
- AER Capability (optional)
- MSI Capability (optional)
- PM Capability (optional)

■ PCIe controller supports:

- Maximum total of 32 PFs (`CX_NFUNC`)
- Minimum total of 2 internal VFs (`CX_NVFUNC = SUM {CX_MAX_VF_n}`)
- Maximum totals of 256 internal VFs (`CX_NVFUNC = SUM {CX_MAX_VF_n}`)
- External VFs through Extensible IOV Interface (`CX_EXTENSIBLE_VFUNC=1`) when you need more than 256 VFs. In this release, you cannot have both internal and external VFs.

- Programmable Allocation of VFs over PFs (this is not VF migration, which the controller does not support).
- Supports two sets of VF Stride and First VF Offset registers per PF one each for ARI and non-ARI hierarchies. Selection is performed by host software through the ARI Capable Hierarchy bit of the Control register in the PF0 SR-IOV capability structure
- VF Stride must be a power of two (that is, 1, 2, 4, 8, 16,)
- VF Offset can be any number ≥ 1
- “Target Completion Lookup Table (No AXI Bridge)” is supported.
- When the number of PFs is greater than eight, the routing ID TLP header field format is ARI
- Supports TLP processing hints (for more details, see “TPH support for SR-IOV”).
- The controller processes a CFG request that targets a non-zero device number, as an unsupported request
- The DMA module supports SR-IOV
- The AXI bridge module supports SR-IOV

11.3.3.15.2 AXI Operational Considerations

When you are using the AXI bridge, the following considerations should be noted:

- Optional AXI DBI slave requires a 33-bit address
- Shared AXI slave interface for DBI access not supported.
- Your application slave does not have to provide any PF or VF info on the AXI master response sideband inputs, as this information is stored and automatically filled in by the internal target completion LUT. See also “Function Number Translation Bypass Feature”.
- The AXI slave interface does not provide any PF or VF info on the AXI slave response sideband outputs. In the case of AXI, it is assumed that your AXI bus fabric is able to route transactions back to the source using the AXI ID.

11.3.3.15.3 Gate Count Costs

- Each additional VF results in about 2K extra gates
- Each additional PF results in about 20K extra gates
- When MSI and AER are enabled for VFs, there are an extra few thousand gates for each extra VF

- You should disable `DYNAMIC_VF_ENABLE` when you are using static VF allocation. This saves gates and eases timing closure.
- You should enable `CX_VF_STRIDE_ALWAYS_ONE` when you know that you will never use a stride value greater than 1. This saves gates and eases timing closure.

11.3.3.15.4 SRIOV and ARI Capable Hierarchy Bit

Routing IDs, requester IDs, and completer IDs are 16-bit identifiers traditionally composed of three fields: an 8-bit bus number, a 5-bit device number, and a 3-bit function number. With ARI, the 16-bit field is interpreted as two fields instead of three: an 8-bit bus number and an 8-bit function number the device number field is eliminated - as it is always zero. This new interpretation enables an ARI device to support up to 256 functions instead of 8 functions.

The host software sets the ARI Capable Hierarchy bit in the PF0 SR-IOV capability to inform the EP that the PCIe hierarchy supports ARI. When the hierarchy supports ARI, the EP is permitted to locate VFs in function numbers 8 to 255 (which corresponds to setting the device number bits to a non-zero value). When the hierarchy does not support ARI, the device is required to locate VFs in such a way that the device number bits are all zero. The PCIe controller supports these different requirements by providing two different sets of VF Stride and First VF Offset, one to be used when the ARI Capable Hierarchy bit is set, the other when the ARI Capable Hierarchy bit is not set. The default provided by the controller for both sets of values should suit most applications. It is possible to reprogram these values by accessing the VF Stride and First VF Offset registers using the DBI. When you reprogram the values, care must be taken to ensure that the new values are supported by the controller.

The determination of the VF routing ID depends on the VF Stride and First VF Offset settings now advertised by the device. In the general case, these are per-PF settings (that is, different PFs can have different settings). The VF Stride and First VF Offset values might also depend on how the system configures NumVFs. All VFs (within a single PF) have routing IDs that are automatically calculated by the controller, by adding the VF Stride to the previous VF routing ID. The first VF routing ID is calculated by adding the First VF Offset to the PF routing ID.

You must correctly program the values of VF Stride, First VF Offset, InitialVFs, and TotalVFs registers for non-ARI hierarchies, such that the controller generates routing IDs with a device number equal to 0. The generation of routing IDs from PF and VF numbers is not dependent on the ARI Capable Hierarchy bit.

When you configure the controller for SR-IOV and set the ARI Capable Hierarchy bit of the Control register

in the PF0 SR-IOV Capability Structure to zero, it stills generates routing IDs based on VF Offset and VF Stride. If you do not program these values correctly, then the controller generates routing IDs with non-zero device numbers.

Figure 3-68 Interpretation of Device Number By Non-ARI Hierarchy

When the ARI Capable Hierarchy bit of the Control register in the PF0 SR-IOV Capability Structure is zero, indicating a non-ARI hierarchy, then the controller processes a CFG request targeting a non-zero device number as an unsupported request (UR).

11.3.3.15.5 Programmable Virtual Function Allocation

When you are configuring the controller in coreConsultant, you can determine the number of VFs you want to allocate to each PF by setting the `CX_MAX_VF_N` parameter for each PF. This is called static VF allocation and it assumed that your firmware does not intend to change this allocation. However, programmable VF allocation allows you to change the allocation of VFs to PFs at reset by writing to the InitialVFs register in each PF to override the default value of `CX_MAX_VF_N` with a different value. This is not VF migration, which the controller does not support. At reset, the constants `CX_MAX_VF_n`, $n=0..31$ initialize the InitialVFs register in the SR-IOV capability of each PF. Your firmware reprograms the InitialVFs field in the SR-IOV capabilities of each PF. You must disable all VFs before remapping.

Your host software can allocate all VFs to any particular PF or distribute the VFs across a different subset of PFs. Figure 3-69 is an example in which the VF-to-PF allocation is changed three times.

1. The number of VFs assigned to PF0 and PFNFUNC-1 is increased at the expense of PF1.
2. All VFs are equally distributed across PF0 and PF1, with no VFs allocated to other PF.s
3. All VFs are assigned to PFNFUNC-1.

Figure 3-69 Example of Programmable VF Allocation

The RTL code (workspace/src/cdm/cdm_vf_map.v) supports three modes of VF allocation:

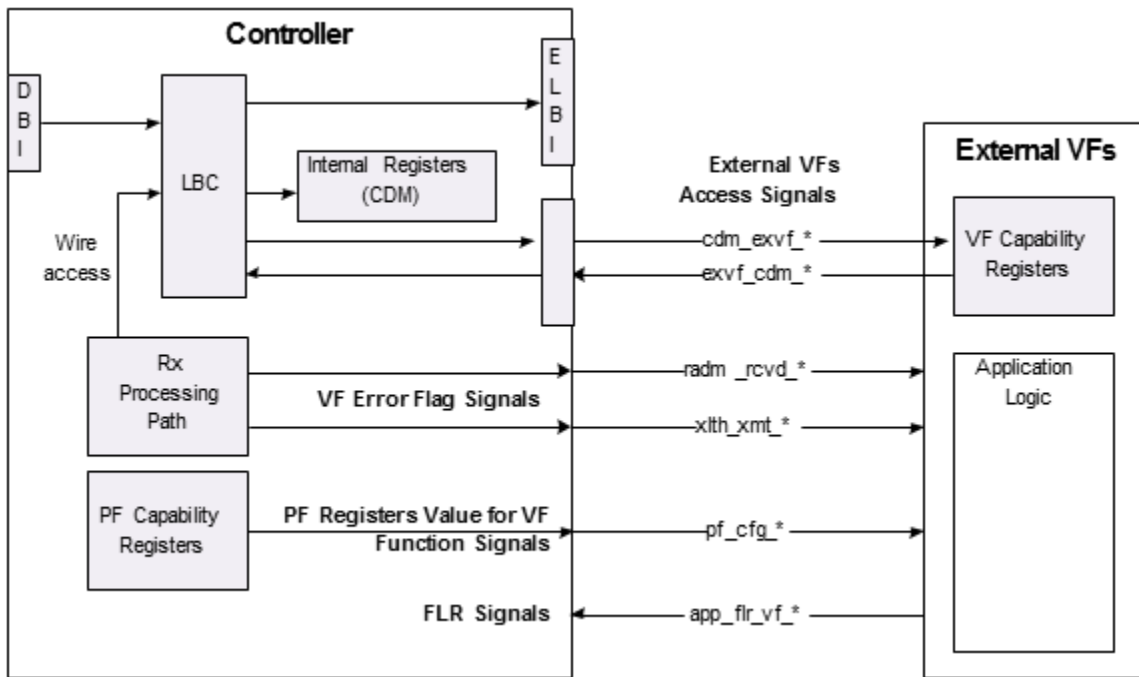

- Static (DYNAMIC_VF_ENABLE =0)
- Programmable (DYNAMIC_VF_ENABLE =1)
- Dynamic: The code has inputs that you must manually export to allow your external mappings to be used instead of the ones calculated from the InitialVFs field of the PFs. You can use this feature to design and attach your own code to directly control the mapping between VF and PF indexes, and explicitly assign a PF number to each VF index.

Note: You should disable DYNAMIC_VF_ENABLE when you are using static VF allocation. This saves gates and eases timing closure.

11.3.3.15.6 Extensible IOV Feature

When you need more than 256 VFs, you can implement external VF registers in your application logic and interface to them through the Extensible IOV (CX_EXTENSIBLE_VFUNC=1) interfaces shown in Figure 3-70.

Figure 3-70 Extensible IOV Interface Signals

■ Your application logic must implement the external VF registers at the address defined by `EXT_VF_*_PTR` in `workspace/src/include/port_cfg.vh`.

■ The bus protocol for accessing your external registers is identical to that of the “External Local Bus Interface (ELBI)”.

■ In this release, you cannot have both internal and external VFs.

■ During FLR, your application must notify the core (using the `app_flr_vf_*` inputs) when it is resetting the external VF’s. For more details, see “Extensible VF Considerations”.

■ When the VF register has the same value as the corresponding register in the parent PF, you can instruct the controller (using the `exvf_cdm_convert_pfddata` input) to compose the read data of the selected VF register by copying the contents from the corresponding register of the parent PF.

■ The MSIX Table (`MSIX_TABLE_EN`) feature is not supported, and you must implement the MSI-X table externally for all PFs and VFs. You can send MSI-X requests using the application interface (AXI bridge slave or XALI0/1/2) or the MSI interface. For more details, see “Interrupt Generation (USP)”.

■ The MSI interface does not support sending MSI’s for external VFs because the controller does not have the external VF’s MSI address/data information. You can send MSI requests using the application interface (AXI bridge slave or XALI0/1/2). ■ There is no support for external FRS (Function Readiness Status) or PM (Power Management) capabilities. Your application can send FRS messages from the application interface (AXI bridge slave or XALI0/1/2).

- Shared “AER Multiple Header Logging” is not supported for external VFs.
- The controller normally schedules any error messages required for the VFs. With external VFs, your application logic must create and schedule send all error messages by using the application interface (AXI bridge slave or XALI0/1/2).

11.3.3.16 Function Level Reset (FLR)

FLR is a mechanism to allow specific functions to be reset without affecting other functions, or the link as a whole. FLR applies to both physical functions (PFs) and virtual functions (VFs). FLR is an optional feature for non-SR-IOV endpoints but mandatory for SR-IOV endpoints. You can enable FLR by setting the CX_FLR_ENABLE parameter.

11.3.3.16.1 DMA Support

FLR does not directly affect the DMA transfer, so you must manually stop the DMA transfer before initiating an FLR. For more details, see "Stopping the DMA Transfer (Software Stop)".

11.3.3.16.2 AXI Bridge Support

FLR does not directly affect the AXI bridge, so your application must ensure that all outstanding host requests to the function have completed before initiating an FLR. For more details, see "Initialization".

11.3.3.16.3 Operational Notes

- During FLR of a function, the controller concurrently:
 - Delivers from the Rx queues to your application, all requests and completions for the function that arrived from the wire before FLR started. Therefore your application logic should not halt the receive interface during FLR. Your application logic can silently drop them or complete them with UR status (non-posted requests only) before the software re-enables the function.
 - Discards¹ all new requests² received for a FLR function using Unsupported Request (UR) for posted and non-posted requests, and Unexpected Completion (UC) for completions. Therefore, the software driver should put the function into a quiescent state (by clearing the BME or other- wise) before initiating an FLR so that the function does not issue requests in close proximity to the FLR event. Otherwise, any completions from these requests will be dropped later on. On a related topic, the function should not issue requests during FLR. Otherwise, completions from these requests (received by the

controller after the function has exited FLR) are treated as unexpected and dropped (with TLP abort signal `radm_*_tlp_abort=1`) by the controller, because the Rx Completion LUT3 does not accept entries for a function that is in FLR.

□ Clears all entries in the completion LUT for that function when the controller detects `app_flr_p-f_done` set to 1. This process is completed in $4 * CX_MAX_TAG * \text{clock_periods}$. This causes the Transaction Pending bit in the Device Status register for that function to be cleared.

■ While a function is required to complete the FLR operation within 100 ms, the subsequent function-specific initialization sequence by your application logic might require additional time. When additional time is required, your application logic for that function must return a configuration request retry status (CRS) completion status when a configuration request is received after the time limit above. After the function responds to a configuration request with a completion other than CRS, it is not permitted to return CRS until it is reset again. ■ Any outstanding INTx interrupt asserted by the function must be de-asserted by sending the corresponding `Deassert_INTx` Message prior to starting the FLR.

■ When you initiate FLR for a function of a multifunction device, the controller does not transmit a `Deassert_INTx` Message if a different function continues to assert a matching INTx.

■ Your reset generation logic should not assert `non_sticky_rst_n` when resetting VF or PF during a FLR. 1. After the update of flow control credits, the discarded completions are treated as unexpected CPL errors. 2. For Rx non-posted requests, the controller also transmits a completion with UR status. 3. Tracks outstanding wire CPLs for transmitted non-posted requests.

■ When the controller resets a PF, it also resets all of the corresponding VFs of that PF.

11.3.3.16.4 Stale Completions

An FLR causes the function to lose track of its outstanding non-posted requests. Any corresponding completions that arrive after the controller has completed the FLR or that were present in the receive queue¹ at the time your software initiated FLR are referred to as being stale.

During FLR, the controller delivers from the receive queues to your application, all requests and completions for the function that arrived before FLR started. Therefore your application logic should not halt the receive interface during FLR. Your application logic can silently drop them or complete them with UR status (non-posted requests only) before the software re-enables the function.

The following scenario can cause data corruption:

- There are outstanding non-posted requests from a function.
- The software issues an FLR for that function.
- FLR for the function completes.
- There are stale completions in the receive buffer or on the wire.
- The software re-enables the function for operation without processing the stale completions.
- Stale completions arrive and cause data corruption by being mistaken by the function as belonging to requests issued after the FLR.

There is a software algorithm for avoiding such data corruption from stale completions in the implementation note in Chapter 6.6.2, “Function-Level Reset (FLR)” of the PCI Express Base Specification, Revision 4.0, Version 0.7.

11.3.3.16.5 Tag Reuse

When generating requests for functions that are not in FLR, your application logic might be able to re-use the tags from the function in FLR. Your application can decide as follows:

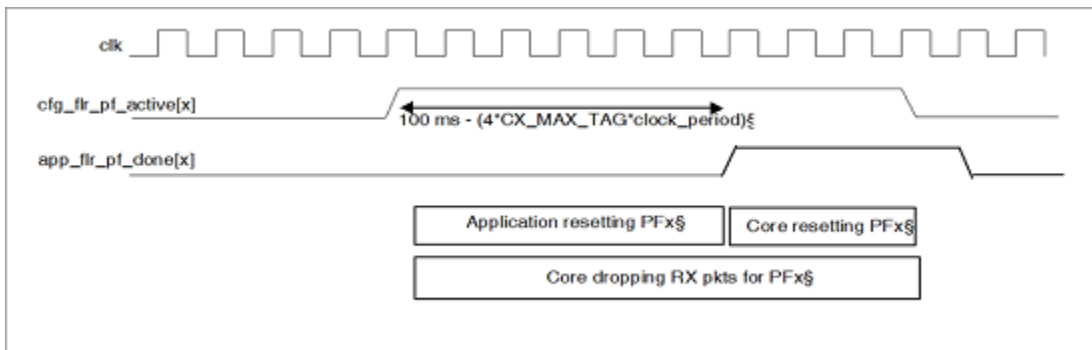

- If the Transaction Pending bit was 0 when the software initiated FLR for that function, then there are no stale completions in the queue and your application can reuse the tags immediately. However, it needs to differentiate between stale completion and new completions from the re-used tag by sampling the requester ID (`radm_cpl_reqid`) to ignore the stale completion.
- If the Transaction Pending bit was 1 when the software initiated FLR for that function, then there are stale completions in the queue and your application cannot reuse tags immediately. Your application must wait until the controller clears all entries in the completion LUT for the function in FLR. It can watch for the Transaction Pending bit being cleared for the function, or the tag being released on the `radm_cpl_timeout2` bus.

11.3.3.16.6 FLR Signal Interface Timing

The *PCI Express Base Specification, Revision 4.0, Version 0.7* requires the entire reset process to be completed within 100ms. The controller requires $(4 * CX_MAX_TAG * clock_period)$ to reset the function. Figure 3-71 shows the timing flow for FLR of physical function x (PFx). The process is the same for a virtual function (VF) except that `cfg_flr_vf_active` and `app_flr_vf_done` are used instead of `cfg_flr_pf_active` and `app_flr_pf_done`.

1. The host software writes to the Initiate FLR bit of PFX using a CfgWr request. It cannot use a local DBI write. The controller asserts the `cfg_flr_pf_active[x]` output signal in response.
2. Your application terminates TLP transmission from PFX's application logic. During this time, your receive application logic should not halt the receive interface for TLPs directed to PFX.
3. When your application has stopped/reset the PFX application logic, it asserts `app_flr_pf_done[x]`.
4. When the controller detects 1 on `app_flr_pf_done[x]`, it initiates FLR of PFX.
5. When the reset is complete, the controller de-asserts `cfg_flr_pf_active[x]`.

Figure 3-71 FLR Timing Flow

11.3.3.16.7 Extensible VF Considerations

When you implement external VF registers using the "Extensible IOV Feature", your application must notify the core (using the `app_flr_vf_set` input) when it has completed writing '1' to the external FLR register.

Figure 3-72 FLR Timing for Extensible VF Feature.

11.3.3.17 Completion Timeout Ranges

Timeout ranges are supported as defined in the *PCI Express Base Specification, Revision 4.0, Version 0.7*. The controller supports all ranges. The Device Control 2 Register has a default equal to the default in the specification: 0000b Default range: 50 us to 50 ms. When the default is used, then the timeout is in Range B: 0101b: 16 ms to 55 ms. This range was chosen for the default because the *PCI Express Base Specification, Revision 4.0, Version 0.7* states, "It is strongly recommended that the completion Timeout mechanism not expire in less than 10 ms". Table 3-81 illustrates the specification values versus the PCI Express controller values for the ranges.

Attention: As the PCIe specification states, This mechanism is intended to be activated only when there is no reasonable expectation that the completion is returned, and should never occur under normal operating conditions.

Table 3-81 Comparison of PCIe Specification and PCIe Core Completion Timeout Ranges (CX_CPL_TO_RANGES_ENABLE = 1)

Range	Encoding	Spec Minimum	Spec Maximum	PCIe controller Minimum	PCIe controller Maximum
Default	0000b	50 us	50 ms	28 ms	44 ms (M-PCIe: 45)
A	0001b	50 us	100 us	65 us	99 ms (M-PCIe: 100)
A	0010b	1 ms	10 ms	4.1 ms	6.2 ms (M-PCIe: 6.4)
B	0101b	16 ms	55 ms	28 ms	44 ms (M-PCIe: 45)
B	0110b	65 ms	210 ms	86 ms	131 ms (M-PCIe: 133)
C	1001b	260 ms	900 ms	260 ms	390 ms (M-PCIe: 398)
C	1010b	1s	3.5 s	1.8 s	2.8 s (M-PCIe: 2.8)
D	1101b	4s	13 s	5.4 s	8.2 s (M-PCIe: 8.4)
D	1110b	17s	64 s	38 s	58 s (M-PCIe: 59)

11.3.3.18 Crosslink

Crosslink allows a downstream port to be connected to another downstream port or an upstream port to be connected to another upstream port. When a crosslink capable port negotiates a crosslink connection, the port changes its behavior accordingly (see

description of device_type input in "SII : Global Core Control". For this reason crosslink is supported in the DM controller because this product already contains the functionality for both upstream and downstream support.

Crosslink provides more than simply the ability to connect two like ports together. For instance, a DM operating in EP mode that negotiates a crosslink connection switches to RC mode and follows all of the *PCI Express Base Specification, Revision 4.0, Version 0.7* rules for an RC.

Part of the crosslink functionality requires a random timeout to be used. Your application is required to provide this non-zero value on the app_crosslink_time[7:0] input. Your application must update this value randomly every time the controller pulses the smlh_crosslink_time_request signal. The controller samples the app_crosslink_time[7:0] inputs 4 us later for a CX_FREQ=1 configuration, 8 us later for a CX_FREQ=2 configuration, and 16 us later for a CX_FREQ=3 configuration, after it pulses the smlh_crosslink_time_request signal.

The crosslink feature is enabled by the CX_CROSSLINK_ENABLE configuration parameter.

Note: To be compliant with the PCI Express Specification and to make sure crosslink functions properly when two instances of the same device are connected together, the random timeout must be unique to each device.

11.3.3.19 TLP Processing Hints

TLP Processing Hints (TPH) allows your application to provide or process hints on a per transaction basis to optimize the processing of transactions targeting memory space. Posted and non-posted requests targeting memory space can use the PH and 2-byte ST fields in the header. For more information, see the PCI Express ECN TLP Processing Hints document.

You can enable TPH globally for all physical functions (PF) by setting the CX_TPH_ENABLE parameter.

11.3.3.19.1 Assumptions

■ When your application is generating requests, it must retrieve the steering tag (ST) from the software programmable ST table. The ST table can be located in the TPH capability structure or combined with the two most significant bytes of the Vector Control register of each MSI-X Table entry in the MSI-X capability structure. When

using the interrupt vector mode of operation, and when steering tags are located in the TPH capability structure, then your application must decode the MSI/MSI-X interrupt vector number and select the correct value from the ST table.

■ The application is responsible for passing only valid values to the controller when TPH is enabled or disabled. The controller does not perform any signal checks or corrections.

11.3.3.19.2 Limitations

■ The “MSI-X Interface” and “Message Signaled Interrupt (MSI) Interface” do not support TPH. The controller internally forces the TPH fields to zero.

■ The controller does not support the Extended TPH feature.

■ When TPH is enabled, the device is enabled as both a requester and a completer. No control is given to support these features individually.

■ In the Interrupt Vector Mode of operation:

□ If `TPH_ST_TABLE_SIZE_# < MSIX_TABLE_SIZE_#` then your application is permitted to do any of the following:

■ Not use TPH for certain transactions

■ Use TPH with a Steering Tag of 0

■ Use TPH with an implementation defined mechanism used to select a ST value from the ST Table.

□ If the `TPH_ST_TABLE_SIZE_#` is larger than the enabled range of interrupt vector numbers, then ST Table Entries corresponding to out-of-range interrupt vector numbers are ignored by the function.

■ There is no TPH support in the “Internal Address Translation Unit (iATU)”. The iATU is not aware of TPH field. Therefore type translation is not possible. However, address translation based on address or BAR matching is possible, and all TPH TLP fields are preserved during translation.

■ There is no TPH support in the LBC for the ELBI. The controller does not forward the TPH bits from the TLP to the ELBI. TPH support for SR-IOV

To enable TPH globally for all virtual functions (when you have SR-IOV enabled), you must set `VF_TPH_ENABLE`.

Figure 3-73 VF TPH Requester Capability Register Programming

11.3.3.20 Atomic Operations (AtomicOps)

You can enable support for AtomicOps by setting the `CX_ATOMIC_ENABLE` parameter. AtomicOps defines three new PCIe request TLPs:

- Fetch and Add (FetchAdd)
- Unconditional Swap (Swap)
- Compare and Swap (CAS)

FetchAdd and Swap supports 32-bit and 64-bit operand sizes. CAS supports 32-bit, 64-bit, and 128-bit operand sizes. For more information, see the PCI Express ECN Atomic Operations PCI-SIG document. When you enable AtomicOps, the controller receives and forwards AtomicOp TLPs to your application, and generates AtomicOp TLPs in response to requests from your application on the XALI client interfaces. Your application must generate the required completion for any AtomicOps that are passed to it. The PCI Express controller does not generate completions for AtomicOps.

Four bit fields in the Device Capabilities 2 Register allow your software to discover the complete capabilities for PCIe functions, and the AtomicOp routing capabilities of routing elements. Two bit fields in the Device Control 2 Register allow your software to program a function, enabling it to:

- Initiate AtomicOp requests or

- Block the egress port of a routing element (SW) to avoid forwarding an AtomicOp request to a component that should not receive it.

11.3.3.20.1 Limitations

- When you enable 128-bit Atomic CAS instructions (through the CX_ATOMIC_128_CAS_EN configuration parameter), you must configure the controller (through the RADM_NP_DCRD_VCn configuration parameter) to advertise more than one non-posted data credit on at least one VC.

- The controller rejects AtomicOps that target the ELBI, and returns a completion with CA status.

- The AXI bridge module does not support AtomicOps.

- The DMA module does not support AtomicOps.

- AtomicOp TLP type cannot be nullified on TX.

11.3.3.20.2 Internal Address Translation Unit (iATU) Support

The "Internal Address Translation Unit (iATU)" supports AtomicOps. Outbound address translation is provided through address matching. By correctly programming the type field, a matched address can be translated into an AtomicOp. The setting of the format field is automatically handled within the controller.

For inbound address matching, you can program the iATU to also match other fields, including the type field. The iATU also supports fuzzy match mode to allow a group of requests to be matched to a partial type field. When fuzzy mode is set (bit 27 of the iATU Control 2 Register, and the type[4:2] field (iATU Control 1 Register) is set to 3'b011, all AtomicOp requests are matched.

11.3.3.20.3 Atomic Routing - Egress Blocked Support

When AtomicOp Egress Blocking is enabled through the Device Control 2 Register in an egress port (A in Figure 3-74), and an AtomicOp request is scheduled to or go out that port, then that port must:

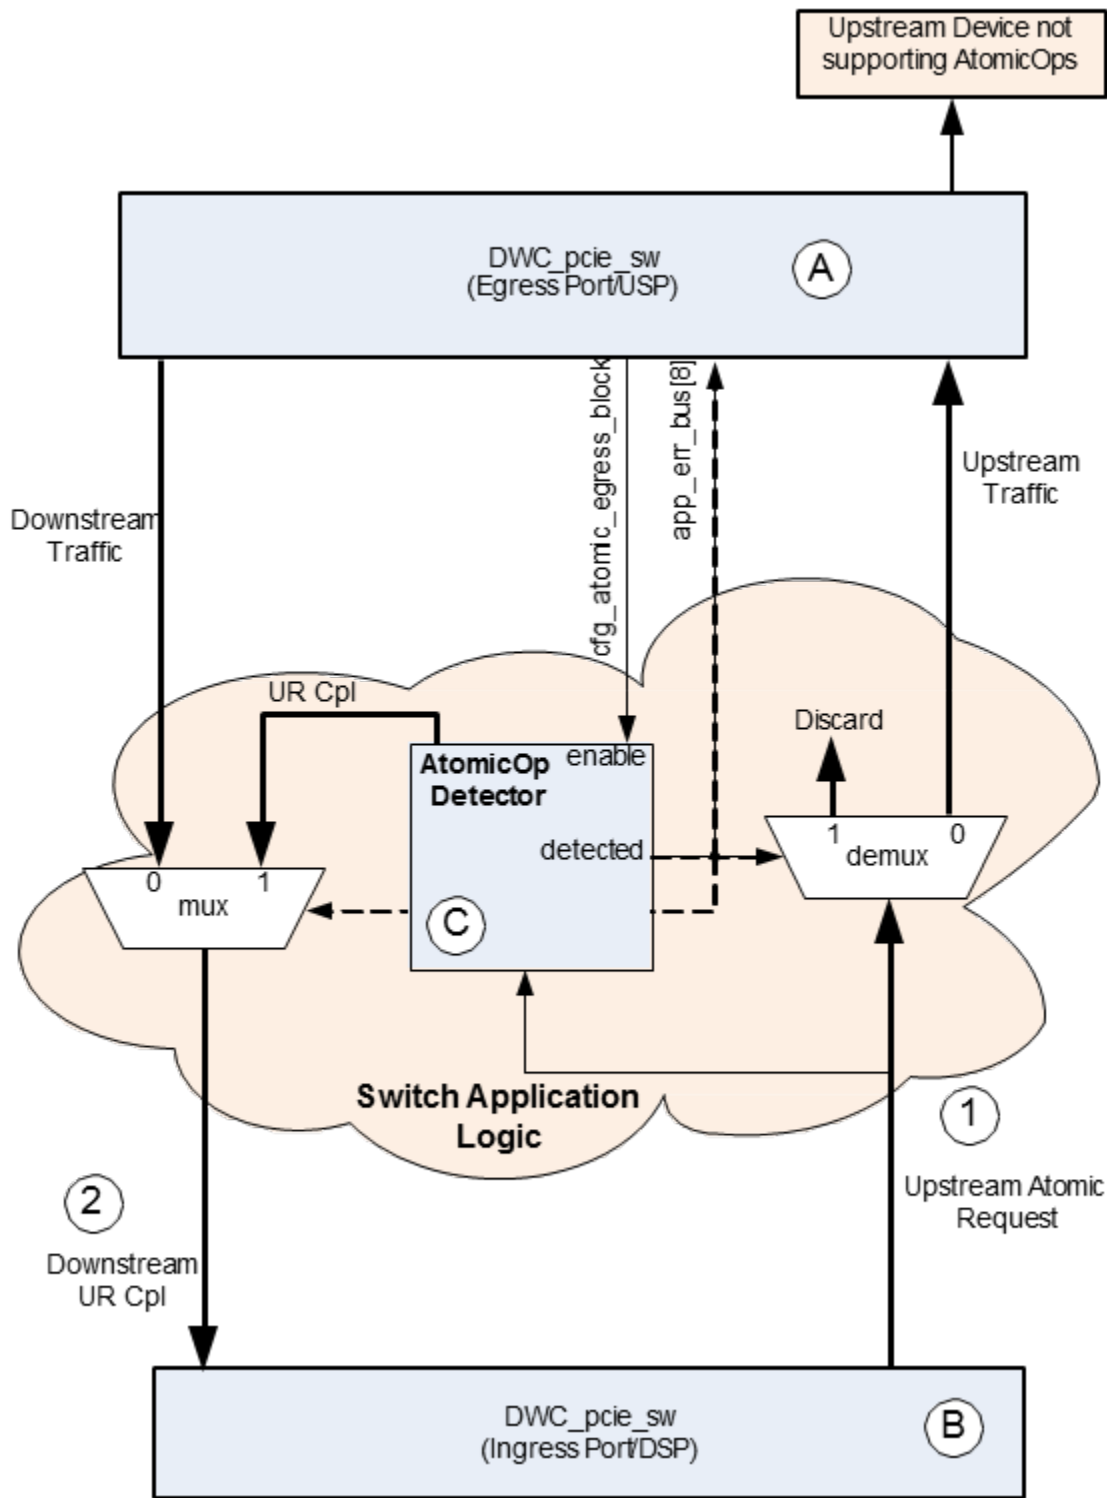

- Handle the request as an AtomicOp Egress Blocked error by setting the appropriate bit in the Uncorrectable Error Status Register.

- Return a completion with a completion status of UR. A possible way to do this (using a switch as an example) is:

- Set As AtomicOp Egress Blocking bit in the Device Control 2 Register.

- Design an AtomicOp Detector (C in Figure 3-74) in your application logic that:
 - a. Detects an AtomicOp forwarded by the ingress/downstream port (B in Figure 3-74).
 - b. Discards (blocks) that AtomicOp.
 - c. Generates downstream completion with status of UR1, for the blocked AtomicOp.
 - d. Sets the AtomicOp Egress Blocked error status bit in the egress port using the `app_err_bus[8]`.

Figure 3-74 Example Of AtomicOp Egress Blocking Using Switch

11.3.3.21 TLP Prefix

The TLP prefix mechanism extends the TLP by adding DWORDs in front of the TLP header to carry additional information. The controller supports this feature when you set the parameter `CX_NPRFX >0`. The controller forwards TLP prefixes unaltered. It validates each prefix by checking its format field before forwarding it. Each validated prefix has its type field read to determine if it is Local or End-End. Only

End-End prefixes are included in the ECRC (if enabled). The controller analyzes the extracted prefixes to ensure that the TLP prefix rules are met.

11.3.3.21.1 Features and Limitations

- The controller supports a maximum of seven prefixes, including a maximum of four End-End prefixes.
- There is no prefix support for messages which are handled over the SII (such as LTR messages) or over the VMI (vendor-defined messages).

11.3.3.21.2 End-End TLP Prefix Blocking (RC mode only)

When enabled, your application must report blocking errors on the SII. It must set the End-End TLP Prefix Blocking bit field in the Device Control 2 Register (`DEVICE_CONTROL2_DEVICE_STATUS2_REG`) in ports that support End-End TLP Prefixes but that do not support forwarding of End-End TLP Prefixes.

11.3.3.22 Separate Refclk Independent SSC (SRIS)

You can enable support for the Separate Refclk with Independent Spread Spectrum Clocking (SRIS) feature as defined by the PCI-SIG ECN, by setting `CX_SRIS_SUPPORT =1`. This also populates the `app_sris_mode` input pin. When `CX_SRIS_SUPPORT =1` and `app_sris_mode = 1`, then L0s is not supported and must not be advertised in the ASPM Support Capability Registers.

Table 3-82 SKP Ordered Set Intervals in SRIS and non-SRIS Modes

<code>CX_SRIS_SUPPORT</code>	<code>app_sris_mode</code>	SKP Ordered Set Intervals (8b/10b Encoding)	SKP Ordered Set Intervals (128b/130b Encoding)
0	n/a	Normal (between 1180 and 1538 Symbol times)	Normal (between 370 to 375 Blocks)
1	0	Normal	Normal
1	1	Short (less than 154 Symbol times)	short (less than 38 Blocks)

Note: The controller does not implement the Lower and Upper “SKP OS Generation Supported Speeds Vector” fields in the Link Capabilities 2 register because the controller architecture does benefit from a lower SKP frequency.

11.3.3.23 Readiness Notifications

The controller supports the optional Readiness Notification features as outlined in Table 3-83. These features provide multiple mechanisms for a device or function to notify the host software that it is configuration-ready. A configuration-ready function will always respond to a valid configuration request with a completion indicating successful completion status, and not CRS. For more details, see Readiness Notification in the PCI-SIG specification.

Table 3-83 Core Operations

Parameter Name	Description
CX_RN_IMM_EN	<p>Enable Immediate Readiness.</p> <p>When you set the Immediate Readiness bit in the PCI header Status Register, the function is configuration-ready. Software is exempt from all requirements to delay configuration accesses following any type of reset or exit from low-power states.</p>
CX_RN_RTR_EN	<p>Enable Readiness Time Reporting (RTR).</p> <p>RTR provides an optional mechanism for describing the time required for a device or function to become configuration-ready. Software is permitted to issue requests to the device or function (following any type of reset or exit from low-power states) after waiting for the time advertised in this capability and need not wait for the (longer) times required elsewhere.</p>
CX_RN_FRS_SUPPORTED	<p>Enable Function Readiness Status (FRS).</p> <p>FRS provides an optional mechanism for messaging the host software when a function has become configuration-ready. The controller autonomously sends a Vendor-Defined Message (VDM) with no payload when any of these events occur:</p> <ul style="list-style-type: none"> • Function Level Reset (FLR) • Completion of D3hot to D0 transition • Enabling or disabling of a VF • DRS message received (by downstream port) <p>Note</p> 

Table continues on the next page...

	<ol style="list-style-type: none"> 1. Your application can delay/prevent FRS message generation by setting <code>app_p- f_frs_ready=0</code>; (or <code>app_vf_frs_ready</code> for VFs) 2. When multiple FRS events occur in close proximity: <ul style="list-style-type: none"> • Sometimes the controller may transmit a single FRS. • The reason field in the transmitted message may contain a code from any of the events. 3. Software is permitted to issue requests to the function (following any of these events) after receiving an FRS message from this function and need not wait for the (longer) times required elsewhere in the specification for these events. 4. The DSP controller asserts the <code>cfg_up_drs_to_frs</code> output and sends an FRS message with the reason code set to "DRS Message Received" when: <ul style="list-style-type: none"> • It receives a DRS message, and • <code>PCIE_CAP_DRS_SIGNALING_CONTROL</code> in <p><code>LINK_CONTROL_LINK_STA- TUS_REG</code> is 2b10</p>
<p><code>CX_RN_DRS_SUPPORTED</code></p>	<p>Enable Device Readiness Status (DRS).</p> <p>DRS provides an optional mechanism for messaging the host software when a device has become configuration-ready.</p> <p>The controller autonomously sends a Vendor-Defined Message (VDM) with no payload when any of these events occur:</p> <ul style="list-style-type: none"> • Exit from Cold, Warm, or Hot Reset • Exit from Loopback or Disabled • Exit from L2/L3_Ready • Port transitions from DL_Down DL_Up status <p>Note</p>  <ol style="list-style-type: none"> 1. Your application can delay/prevent DRS message generation by setting <p><code>app_req_retry_en=1</code> or <code>app_drs_ready=0</code>.</p> <ol style="list-style-type: none"> 1. Software is permitted to issue requests to the function (following any of these events) after receiving an DRS message from this function and need not wait for the (longer) times required elsewhere in the specification for these events. 2. The DSP controller asserts the <code>cfg_drs_msi</code> output when all of the following are true: <ul style="list-style-type: none"> • It receives a DRS message • <code>PCIE_CAP_DRS_SIGNALING_CONTROL</code> in

LINK_CONTROL_LINK_STA- TUS_REG is 2b01

- MSI or MSI-X is enabled

11.3.3.23.1 FRS Queue (RC Mode)

When `CX_RN_FRS_SUPPORTED = 1`, the controller implements an FRS queue (FRSQ) to collect FRS messages received by the root port or generated by the root port (in response to received DRS messages). The oldest FRS message is visible in the FRS message queue register (`FRS_MESSAGE_QUEUE_OFF`) of the FRSQ capability which can be read through the DBI. Writing to this register clears the oldest FRS message from the queue. The controller asserts the `frsq_msi` output when:

- It receives an FRS message or the FRSQ overflows
- `FRS_INTERRUPT_ENABLE` field in `FRSQ_CONTROL_FRSQ_STATUS_OFF = 1`
- You have enabled MSI or MSI-X.

You can configure the queue depth using the `CX_RN_FRS_QUEUE_MAX_DEPTH` parameter.

11.3.3.24 Precision Time Measurement (PTM)

The controller supports the optional PTM feature (`CX_PTM_ENABLE=1`) as defined in Section 6.22, Precision Time Measurement (PTM) Mechanism of the *PCI Express Base Specification, Revision 4.0, Version 0.7*. This enables the coordination of timing information across multiple devices with independent local time-bases. The PTM synchronization is initiated from a downstream requester (USP) to an upstream responder (DSP). The controller handles the entire timestamp update process without software intervention. Each current ($t\#n$) and previous timestamp ($t\#n-1$) value as well as other context information (clock) can be read from the VSEC registers (`PTM_REQ_*_OFF/PTM_RES_*_OFF`) by software.

11.3.3.24.1 Transmit and Receive Latencies

A key operational goal of PTM is to stamp the time at which a message was transmitted from the physical boundary of the PCIe device. The Tx latency is the time that it takes a message to travel from the boundary of the controller to the boundary of the PCIe device. It is added to the time at which the message left the controller. The Rx latency is the time that it takes a message to travel from the boundary of the PCIe device to the boundary of

the controller. It is subtracted from the time at which the message reaches the controller. The Latency registers may be written to at any time with a more accurate value if required.

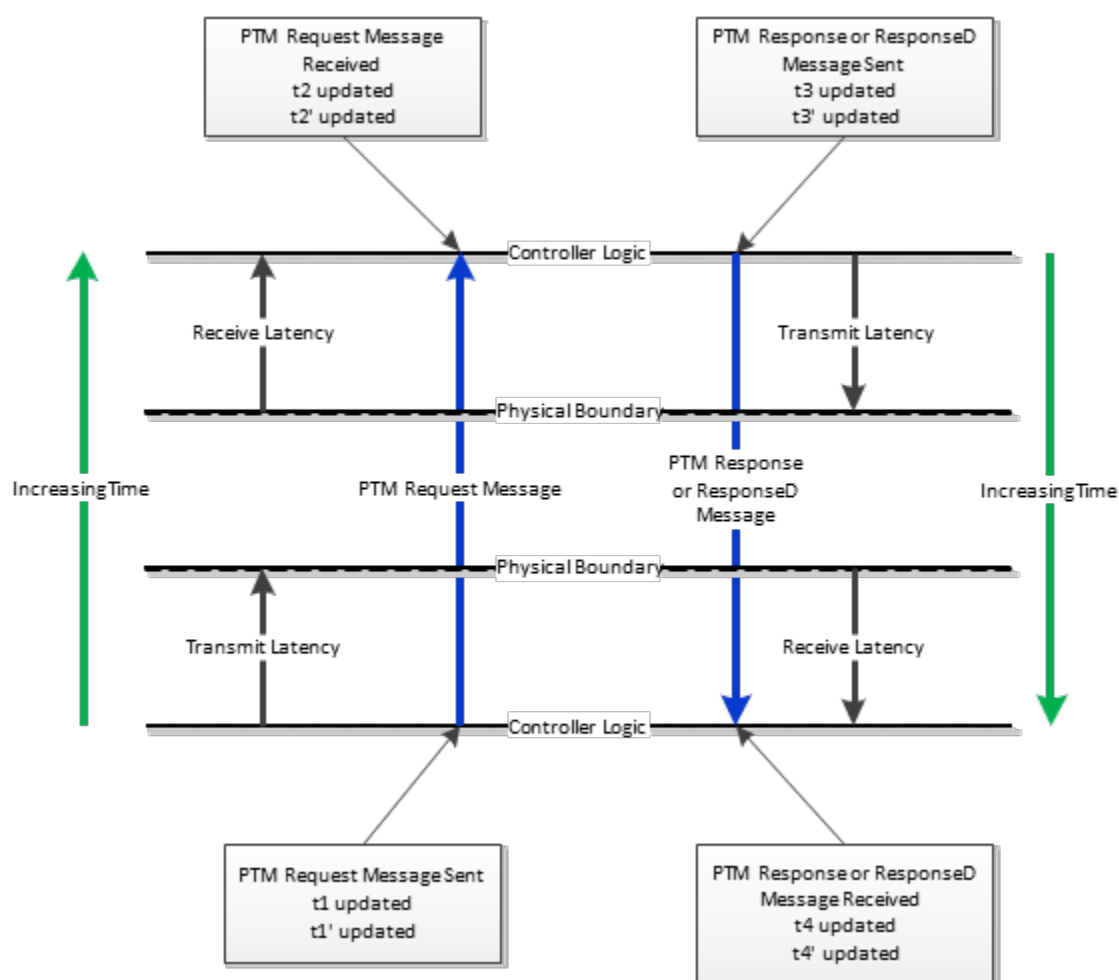

For example:

■ $t_1, t_3 = \text{Local PTM Clock time when message leaves controller} + \text{PTM_REQ_TX_LATEN} - \text{CY_OFF.PTM_REQ_TX_LATENCY}$

■ $t_2, t_4 = \text{Local PTM Clock time when message received by controller} - \text{PTM_REQ_RX_LATEN} - \text{CY_OFF.PTM_REQ_RX_LATENCY}$

Note: Unrealistic values of the Rx and Tx latency timers will result in an unpredictable behavior of the controller.

Figure 3-75 Tx and Rx Latencies

11.3.3.24.2 PTM Timers

The controller implements 1us (used by PTM Root) and 100us timers as per the requirements of the *PCI Express Base Specification, Revision 4.0, Version 0.7*. The controller also implements a 10 ms timer which is used for automatic update of PTM context by the Requester.

11.3.3.24.3 Requester USP Features

- Integrated hardware for scheduling of requests to start PTM dialogs

Figure 3-76 PTM Requester (EP)

- Requester automatically updates PTM request context (starting dialogs) when enabled using any or all of:

- Automatic trigger every 10ms (can be enabled through top-level pin or through a register)
- Manual trigger through top-level pin
- Manual trigger through a register write

- Local PTM Timer

- Runs on core_clk, counts time in ns, and its minimum granularity is defined by the core_clk frequency
- Auto-updated on PTM context refresh
- Can also be updated by software

- ❑ Can be read by software
- ❑ Available through top-level port
- Context automatically invalidated when core_clk stops (for example, in L1 substates)
- Context information stored in PTM Requester VSEC (PTM_REQ_*_OFF); one instance shared across all functions)
- ❑ Provides access to timestamps of most recent context refresh
- ❑ Provides notification when context is valid
- ❑ Programmable Tx and Rx latency values
- Latency compensated.

11.3.3.24.4 Responder (DSP) Features

- Integrated hardware for scheduling of PTM responses to dialog requests when context is valid
- Timestamp generation when PTM Messages are detected

Figure 3-77 PTM Responder (RC)

- Local PTM Timer
- Auto-updated on PTM context refresh
- Can also be updated by software
- Can be read by software
- Available through top-level port
- Context automatically invalidated when core_clk stops (for example, in L1 substates)
- Context information stored in PTM Responder VSEC (PTM_RES_*_OFF)
- Provides access to timestamps of most recent context refresh
- Provides notification when context is valid
- Programmable Tx and Rx latency values
- Latency compensated.
- Root Support
- PTM root behaves like responder with a permanently valid context
- PTM messages must not contain TLP prefixes

11.3.4 Register Configuration Space

This chapter provides information on the following registers for an unconfigured controller:

11.3.4.1 Accessing Configuration Registers

Your local CPU can access the configuration space through the DBI. For an USP, your remote host software accesses the configuration registers over the wire using PCIe CFG requests. There are three types of registers in the controller as shown in Table 6-1

Table 6-1 Types of Registers in PCIe Core

Register Type	Description	Access/Addressing Method
Simple	Single register accessed directly by its address. Most of the registers are of this type.	Direct addressing method. You just supply the address.

Table continues on the next page...

Shadow	Another register exists at the same address as a Simple register. For example the BAR Mask registers have the same address as the BAR registers.	Normally can only be accessed through the DBI where you select between the two registers using the dbi_cs2 input (or the CS2 address bit if you are using an AHB/AXI DBI slave). This is called DBI2, CS2, dbi_cs2, DBI_CS2, or Dbi2 access; all of these terms mean the same thing.
Viewport	Multiple (n) registers existing at the same address as a Simple register. For example Gen3 Coefficient Preset registers.	Indirect addressing method where you first write to a special index register to select which of the n registers at the address you want to access. You then proceed to write to the register address.

There are three views for most registers in the controller (see Table 6-2), depending on how you access a register.

Table 6-2 Types of Views in PCIe Core

View Type	Description	Typical Access Attributes (e.g. R/W, read-only)
Wire (USP only)	Remote access by link partner over the PCIe link.	As per PCI-SIG specification.
Dbi	Local (back-door) access to Simple registers by your application logic through the DBI interface with dbi_cs=1 and dbi_cs2 (or CS2) =0.	<ul style="list-style-type: none"> • Normally as per PCI-SIG specification. • Some read-only registers are permanently R/W. • Some read-only registers can be made temporarily R/W when you write 1 to the DBI_RO_WR_EN bit of the MISC_CONTROL_1_OFF register.
Dbi2	Local (back-door) access to Shadow, iATU, and DMA registers by your application logic through the DBI interface with dbi_cs=1 and dbi_cs2 (or CS2) =1.	<ul style="list-style-type: none"> • Normally R/W • One exception is the BAR mask registers which are W (write-only).

There are some exceptions to these general descriptions, but they are documented for the relevant registers in the Registers chapter

11.3.4.2 Rebuilding Capability Linked Lists

When your configuration software requires any set of standard PCI capability registers to be removed, it can overwrite the next capability pointers through the DBI and rebuild the linked list structure.

11.3.4.3 PCIe Registers (EP Port Mode)

This section describes the implementation of the PCI Express configuration space in the controller in EP mode.

11.3.4.3.1 Register Space Layout and Maps

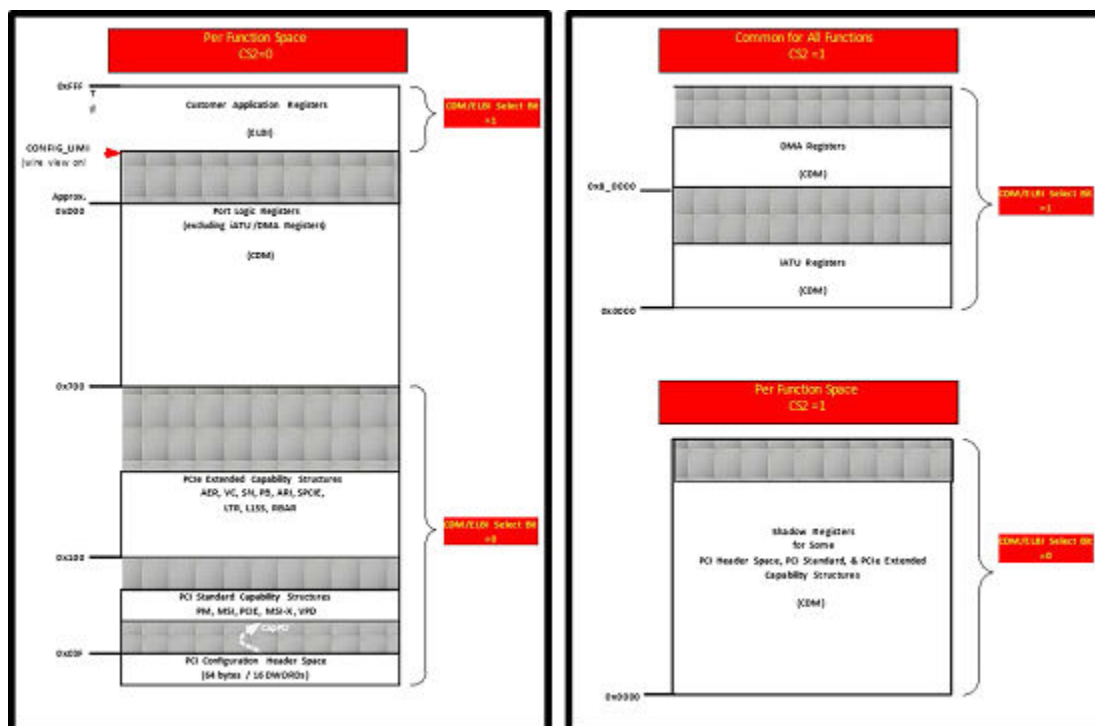

The controller has 4096 bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. For each function the PCI Express configuration space is divided into 256 bytes of PCI configuration space and 3840 bytes of PCI Express extended configuration space. The port logic registers are implementation specific registers.

Capability configuration registers are in structures (groups) identified by a capability ID. Groups are linked together as in PCI. Register locations within a group are specified, but the starting location of each group must be found by traversing the linked list. There are two linked lists of register groups: PCI compatible capability registers and PCI Express extended capability registers. PCI compatible capability register groups begin at the configuration address stored in the capability pointer register at 0x34. PCI Express extended capability register groups begin at address 0x100.

NOTE

Even though there is a unique standard capabilities linked lists provided per function, specific capabilities cannot be included/excluded on a per-function basis. For example, MSI-X capability is included/excluded for all functions (PF) at the same time through the coreConsultant GUI. To modify the linked list for a specific function and remove unwanted capability structures, see “Rebuilding Capability Linked Lists”. Even though there is a unique extended capabilities linked list provided per function, specific capabilities cannot be included/excluded on a per function basis (in particular for LTR and VC, this is a non-fatal violation of a strict reading of the PCIe specification). This is also true for the SR-IOV capability structure when a DM controller is in RC mode. Each function can have a different setup of a capability structure after it is included, although some features/settings are common across all functions. All VFs have the same linked list of capabilities.

Figure 6-2 Cores Configuration Space Layout (EP Mode)

Attention: For releases previous to 4.80a, the iATU and DMA registers were programmed through an indirect addressing scheme using an index register (iATU_VIEWPORT_OFF/ DMA_VIEWPORT_OFF), to reduce the address footprint in the PCI Express extended configuration space. For details, see the previous Databook.

11.3.4.3.1.1 PF PCI Standard Capability Structures Register Maps

The capability pointer register in the PCI-compatible header register points to the next item in the linked list of capabilities, which by default is the PCI Power Management capability.

Note: Even though there is a unique standard capabilities linked lists provided per function, specific capabilities cannot be included/excluded on a per-function basis. For example, MSI-X capability is included/excluded for all functions (PF) at the same time through the coreConsultant GUI. To modify the linked list for a specific function and remove unwanted capability structures, see "Rebuilding Capability Linked Lists".

Even though there is a unique extended capabilities linked list provided per function, specific capabilities cannot be included/excluded on a per function basis (in particular for LTR and VC, this is a non-fatal violation of a strict reading of the PCIe specification). This is also true for the SR-IOV capability structure when a DM controller is in RC mode.

Each function can have a different setup of a capability structure after it is included, although some features/settings are common across all functions.

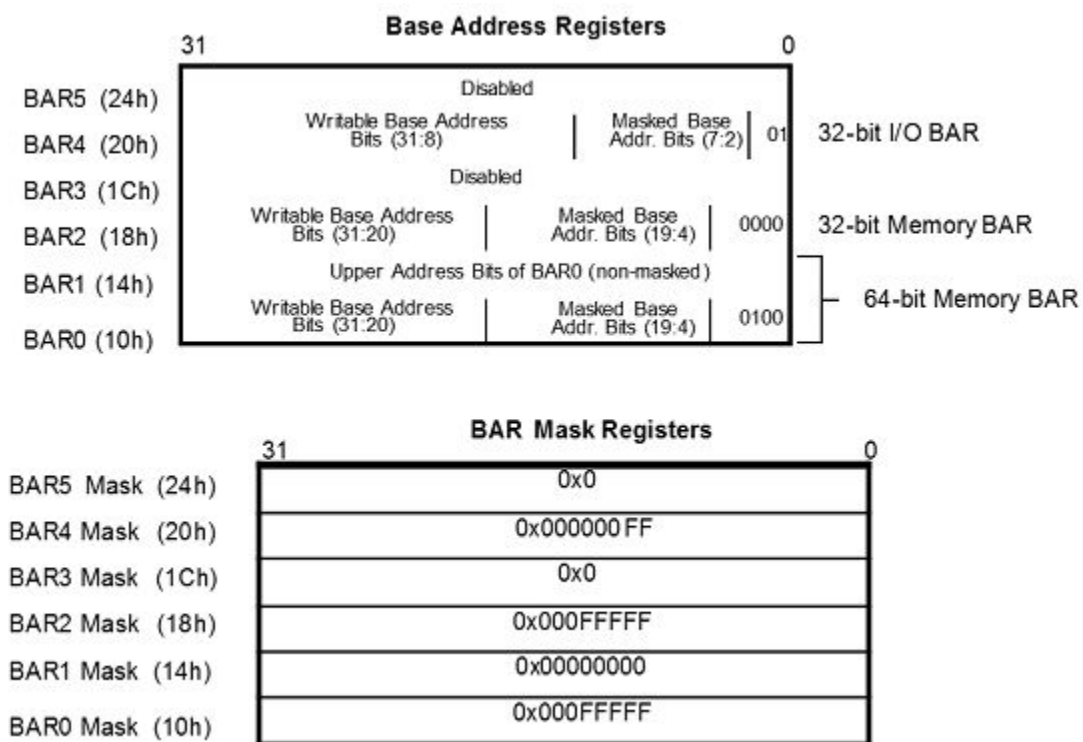

All VFs have the same linked list of capabilities.

Attention: For releases previous to 4.80a, the iATU and DMA registers were programmed through an indirect addressing scheme using an index register (iATU_VIEWPORT_OFF/ DMA_VIEWPORT_OFF), to reduce the address footprint in the PCI Express extended configuration space. For details, see the previous Databook.

■ BAR pairs cannot overlap to form a 64-bit BAR. For example, you cannot combine BARs 1 and 2 to form a 64-bit BAR.

□ BAR0 can be configured as a memory BAR or an I/O BAR.

Figure 6-5 Example Base Address Register Configuration

11.3.4.3.2 BAR Details

11.3.4.3.2.1 Base Address Registers (Offset: 0x100x24)

The controller provides three pairs of 32-bit BARs for each implemented function. Each pair (BARs 0 and 1, BARs 2 and 3, BARs 4 and 5) can be configured as follows:

■ One 64-bit BAR: For example, BARs 0 and 1 are combined to form a single 64-bit BAR.

- Two 32-bit BARs: For example, BARs 0 and 1 are two independent 32-bit BARs.
- One 32-bit BAR: For example, BAR0 is a 32-bit BAR and BAR1 is either disabled or removed from the controller altogether to reduce gate count.

Using `MEM_FUNCN_BARn_TARGET_MAP`, you can configure each BAR to have its matched requests routed to:

- 1: TRGT1 (or AHB/AXI master interface)
- 0: TRGT0 (to access internal port logic registers or your external application registers on the ELBI)

Note: When a TLP is to be routed by its address, the address range in the BAR decides whether the TLP is rejected or accepted. When the address is in the range configured in the BAR, the endpoint accepts the TLP and passes it to the application.

The following sections describe how to set up the BAR types and sizes by programming values into the base address registers.

11.3.4.3.2 BAR Sizing

The BAR masks are used for indicating the amount of address space that each BAR requests from host software. The BAR masks determine which bits in each BAR are non-writable by host software, which determines the size of the address space claimed by each BAR. The BAR mask values indicate the range of low-order bits not to use for address matching. The BAR mask value also indicates the range of low-order bits in the BAR that cannot be written from the host. Your application can write to all BAR bits to allow setting of memory, I/O, and other standard BAR options. There are three schemes that each BAR can use for setting the amount of address space that it requests.

- `BARn_SIZING_SCHEME_N = Fixed Mask (0)`

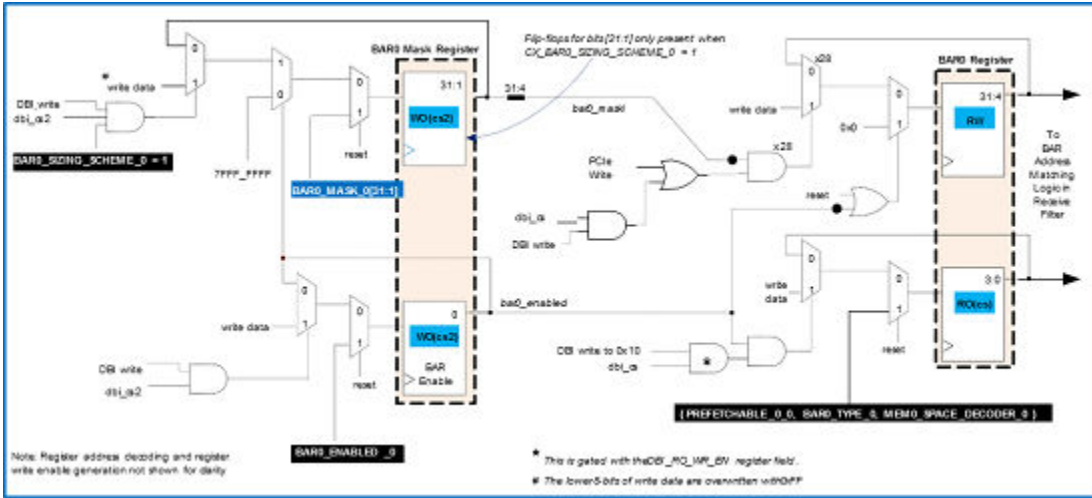

You hardwire the mask using the `BARn_MASK_N` parameter. You cannot change the mask at runtime.

- `BARn_SIZING_SCHEME_N = Programmable Mask (1)`

Mask registers (flip-flops) are instantiated in the controller. You set the default of the mask using the `BARn_MASK_N` parameter. You can change the mask at runtime through the local DBI, at the same address as the corresponding BAR register, by asserting `dbi_cs2` (or the `CS2` address bit when the AHB/AXI bridge is used). The BAR mask registers are only writable through the DBI, and not read-able. They are not visible from the PCIe wire by the remote link partner. When the BAR mask value for a BAR is less than that required for the BAR type, the controller automatically uses the minimum value for the BAR type.

Figure 6-3 Fixed and Programmable Mask Example for 32-bit Memory BAR0 (CX_BAR0_SIZING_SCHEME_N

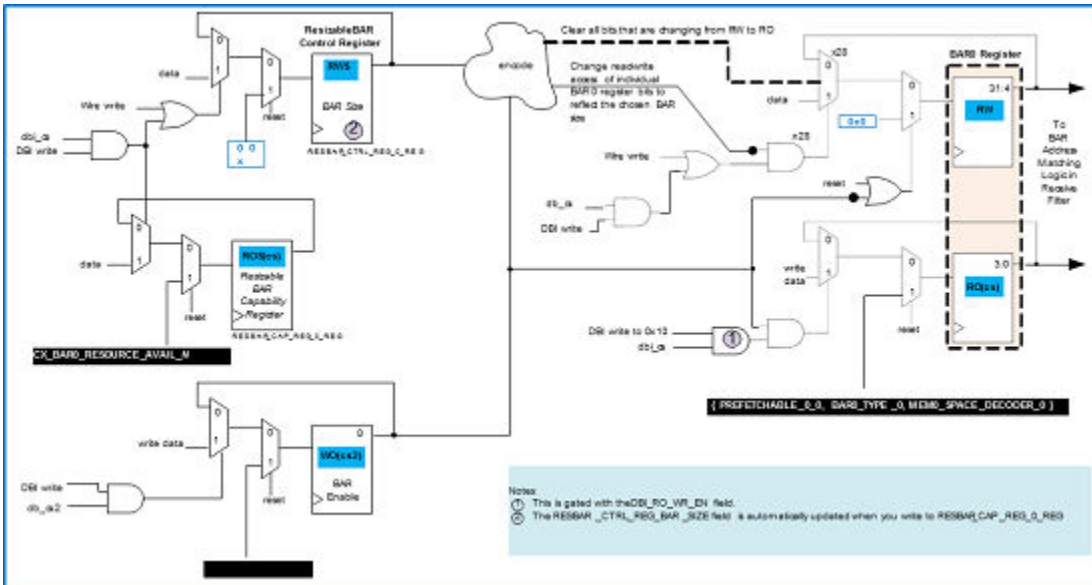

!=2)

■ BARn_SIZING_SCHEME_N =Resizable BAR (2)

When you enable the PCI-SIG resizable BAR feature, the host software reads the Supported Resource Sizes field of the Resizable BAR Capability register.

Figure 6-4 Resizable BAR Example for 32-bit Memory BAR0 (CX_BAR0_SIZING_SCHEME_N =2)

After it selects a BAR size, it writes this value to the BAR Size field of Resizable BAR Control register. From this field, the controller automatically derives the R/W mask for the BAR register. The host software can now start the normal BAR query process. You can change the BAR size at runtime, because the “Supported Resource Sizes” register field is writable through the local DBI (only).

11.3.4.3.2.3 Disabling a BAR

To disable a BAR (in any of the three schemes), your application can write 0 to the LSB of the BAR mask register. The BAR mask register is at the same address as the BAR register, and you can access it through the DBI (only) by asserting `dbi_cs2` (or the CS2 address bit when the AHB/AXI bridge is used). However, when you want to access the LSB (BAR Enable bit), then you must assert `dbi_cs` instead of `dbi_cs2`.

11.3.4.3.2.4 General Rules for BAR Setup (Fixed Mask or Programmable Mask Schemes Only)

At runtime, software can overwrite the BAR contents to reconfigure the BARs (unless the affected BAR is removed during hardware configuration). Software must observe the rules listed below when writing to the BARs. The rules for BAR configuration are the same for all three pairs. Using BARs 0 and 1 as the example pair, the rules for BAR configuration are:

- Any pair (for example BARs 0 and 1) can be configured as one 64-bit BAR, two 32-bit BARs, or one 32-bit BAR.
- BAR pairs cannot overlap to form a 64-bit BAR. For example, you cannot combine BARs 1 and 2 to form a 64-bit BAR.
- Any 32-bit BAR that is not needed can be removed during controller hardware configuration to reduce gate count.
- An I/O BAR must be a 32-bit BAR and cannot be prefetchable.
- When the device is configured as a PCI Express endpoint (not a Legacy endpoint), then any memory that is configured as prefetchable must be assigned to a 64-bit memory BAR.
- When BAR0 is configured as a 64-bit BAR:
 - BAR1 is the upper 32 bits of the combined 64-bit BAR formed by BAR0 and BAR1. Therefore, BAR1 must be disabled and cannot be configured independently.
 - BAR0 must be a memory BAR and can be either prefetchable or non-prefetchable.

The contents of the BAR0 mask register determine the number of writable bits in the 64-bit BAR, subject to the restrictions described in “BAR Mask Registers”. The BAR1 mask register contains the upper 32 bits of the BAR0 mask value.

BAR0 can be disabled by writing 0 to bit [0] of the BAR0 mask register.

■ When BAR0 is configured as a 32-bit BAR:

You can configure BAR1 as an independent 32-bit BAR or remove BAR1 from the controller hardware configuration. BAR0 can be configured as a memory BAR or an I/O BAR.

The contents of the BAR0 mask register determine the number of writable bits in the 32-bit BAR0, subject to the restrictions described in “BAR Mask Registers”.

BAR0 can be disabled by writing 0 to bit [0] of the BAR0 mask register.

■ When BAR0 is configured as a 32-bit BAR, BAR1 is available as an independent 32-bit BAR according to the following rules: BAR1 can be configured as a memory BAR or an I/O BAR.

The contents of the BAR1 mask register determine the number of writable bits in the 32-bit BAR1, subject to the restrictions described in “BAR Mask Registers”.

BAR1 can be disabled by writing 0 to bit [0] of the BAR1 mask register.

When BAR1 is not required in your design, you can remove BAR1 from the hardware configuration by setting both BAR1_ENABLED_N and BAR1_MASK_TYPE_N to 0.

The same rules apply for pairs 2/3 and 4/5.

11.3.4.3.2.5 Memory BAR Sizes

BAR bits [11:0] are always masked for a memory BAR. The controller requires each memory BAR to claim at least 4 KB. The *PCI Express Base Specification, Revision 4.0, Version 0.7* states that the minimum memory address range requested by a BAR is 128 bytes. In the *PCI Local Bus Specification, rev 3.0*, it is recommended that devices that need less than 4 KB of address space should still consume 4 KB of address space in order to minimize the number of bits in the address decoder. A memory BAR size of 256 bytes can be achieved by using a DBI CS2 write to BAR mask.

11.3.4.3.2.6 IO BAR Sizes

BAR bits [7:0] are always masked for an I/O BAR. The controller requires each I/O BAR to claim at least 256 bytes. The PCI Local Bus Specification, rev 3.0 allows I/O BARs to consume between 4 bytes and 256 bytes of address space. The controller only permits I/O BARs to consume 256 bytes of address space. This restriction is used in order to minimize the number of bits in the address decoder.

11.3.4.3.2.7 BAR Mask Registers

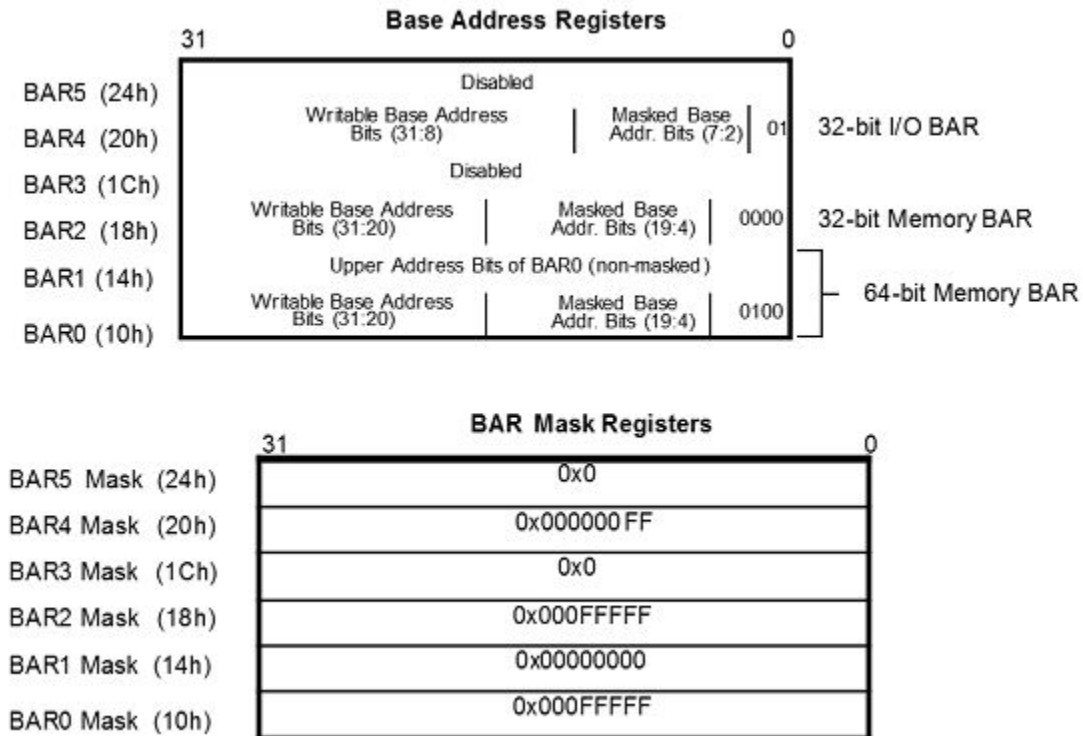

Your local CPU can change the mask at runtime using the DBI. The mask register is at the same address as the BAR register. The mask is a shadow register that is invisible to the PCIe wire but visible to your local CPU through the DBI. Furthermore, it is only visible for a write and not for a read. You cannot read the mask register but you can write to it. It is accessed by asserting `dbi_cs2` and `dbi_cs`. If you only assert `dbi_cs` then you will access the BAR which is the primary register at that location. Use `CS2` instead of `dbi_cs2` when you are using the AHB/AXI bridge.

11.3.4.3.2.8 Example BAR Setup

Figure 6-5 shows an example configuration of the six BARs and their corresponding BAR mask registers. The example configuration includes:

- One 64-bit memory BAR (non-prefetchable)
- One 32-bit memory BAR (non-prefetchable)
- One 32-bit I/O BAR

Figure -5 Example Base Address Register Configuration

11.3.4.3.2.9 Expansion ROM BAR Mask Register (Offset: 0x30; same as the Expansion ROM BAR, but requires dbi_cs2 for write access)

Your local CPU can change the mask at runtime using the DBI. The mask register is at the same address as the BAR register. The mask is a shadow register that is invisible to the PCIe wire but visible to your local CPU through the DBI. Furthermore, it is only visible for a write and not for a read. You cannot read the mask register but you can write to it. It is accessed by asserting dbi_cs2 and dbi_cs. If you only assert dbi_cs then you will access the BAR which is the primary register at that location. Use CS2 instead of dbi_cs2 when you are using the AHB/AXI bridge

11.3.4.4 PCIe Registers (RC Port Mode)

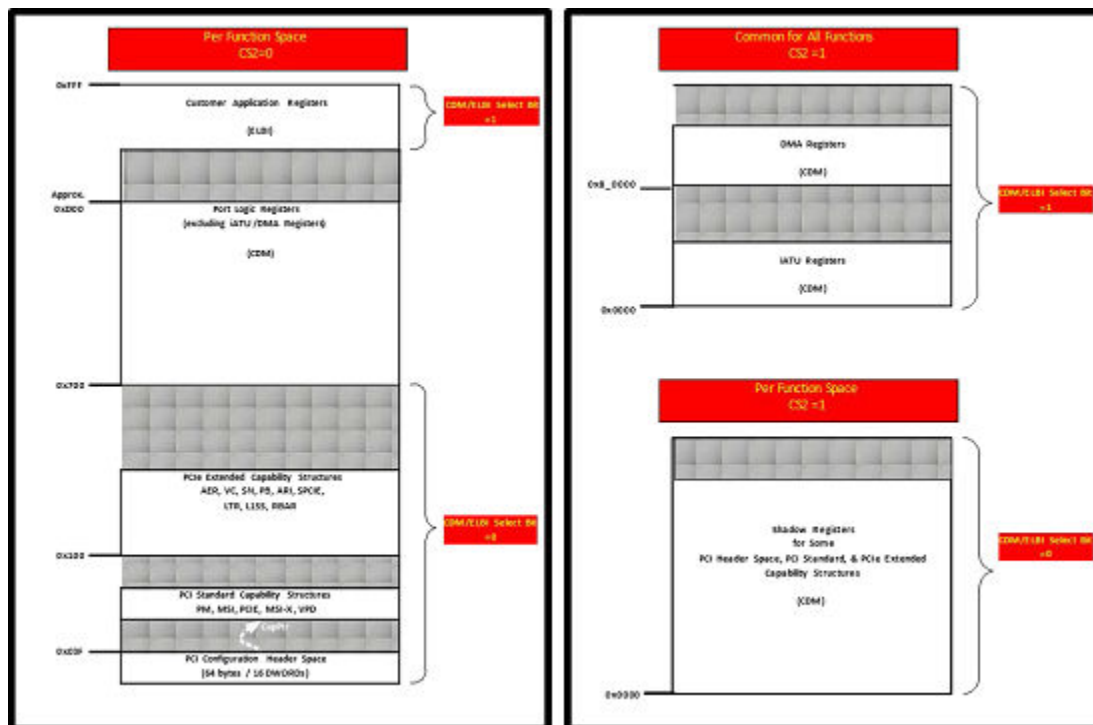

This section describes the controller implementation of the PCI Express configuration space when in RC mode.

11.3.4.4.1 Register Space Layout and Maps

The controller has 4096 bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. The PCI Express configuration space is divided into 256 bytes of PCI

configuration space and 3840 bytes of PCI Express extended configuration space. The port logic registers have specific pre-defined usages, and can optionally be removed from the controller hardware configuration.

Figure 6-6 Core Configuration Space Layout: (RC Mode)

Capability configuration registers are in structures (groups) identified by a capability ID. Groups are linked together as in PCI. Register locations within a group are specified, but the starting location of each group must be found by traversing the linked list. There are two linked lists of register groups: PCI compatible base registers and PCI Express extended capability registers. PCI compatible capability register groups begin at the configuration address stored in capability pointer register at 0x34. PCI Express extended capability register groups begin at address 0x100.

11.3.4.4.2 BAR Details

11.3.4.4.2.1 Base Address Registers (Offset: 0x100x14)

Two BARs are present but are not expected to be used. You should disable them (see "Disabling a BAR") or else they will be unnecessarily assigned memory during device enumeration. If you do use a BAR, then you should program it to capture TLPs that are targeted to your local non-application memory space residing on TRGT11, and not for

the application on TRGT12. The BAR range must be outside of the three Base/Limit regions. The controller provides one pair of 32-bit BARs (BAR0 and BAR1). The BARs can be configured as follows:

- One 64-bit BAR: BAR0 and BAR1 are combined to form a single 64-bit BAR.
- Two 32-bit BARs: BAR0 and BAR1 are two independent 32-bit BARs.
- One 32-bit BAR: BAR0 is a 32-bit BAR and BAR1 is either disabled or removed from controller altogether to reduce gate count.

Note: If you have configured (`MEM_FUNCN_BARn_TARGET_MAP = 0`) any BAR to have its incoming routed to TRGT0 in EP mode, then you must disable that BAR (through a DBI write) when operating the controller in RC mode. See “Disabling a BAR”.

The following sections describe how to set up the BAR types and sizes by programming values into the base address registers.

11.3.4.4.2 BAR Sizing

The BAR masks are used for indicating the amount of address space that each BAR requests from host software. The BAR masks determine which bits in each BAR are non-writable by host software, which determines the size of the address space claimed by each BAR. The BAR mask values indicate the range of low-order bits not to use for address matching. The BAR mask value also indicates the range of low-order bits in the BAR that cannot be written from the host. Your application can write to all BAR bits to allow setting of memory, I/O, and other standard BAR options. There are three schemes that each BAR can use for setting the amount of address space that it requests.

- `BARn_SIZING_SCHEME_0 = Fixed Mask (0)`

You hardwire the mask using the `BARn_MASK_0` parameter. You cannot change it at runtime.

- `BARn_SIZING_SCHEME_0 = Programmable Mask (1)`

Mask registers are instantiated in the controller. You set the default using `BARn_MASK_0`. You can change it at runtime through the DBI, at the same address as the corresponding BAR register, by asserting `dbi_cs2` (or the CS2 address bit when the AHB/AXI bridge is used). The BAR mask registers are only writable through the DBI, and not readable. They are not visible from the PCIe wire by the remote partner. When the BAR mask value for a BAR is less than that required for the BAR type, the controller automatically uses the minimum value for the BAR type.

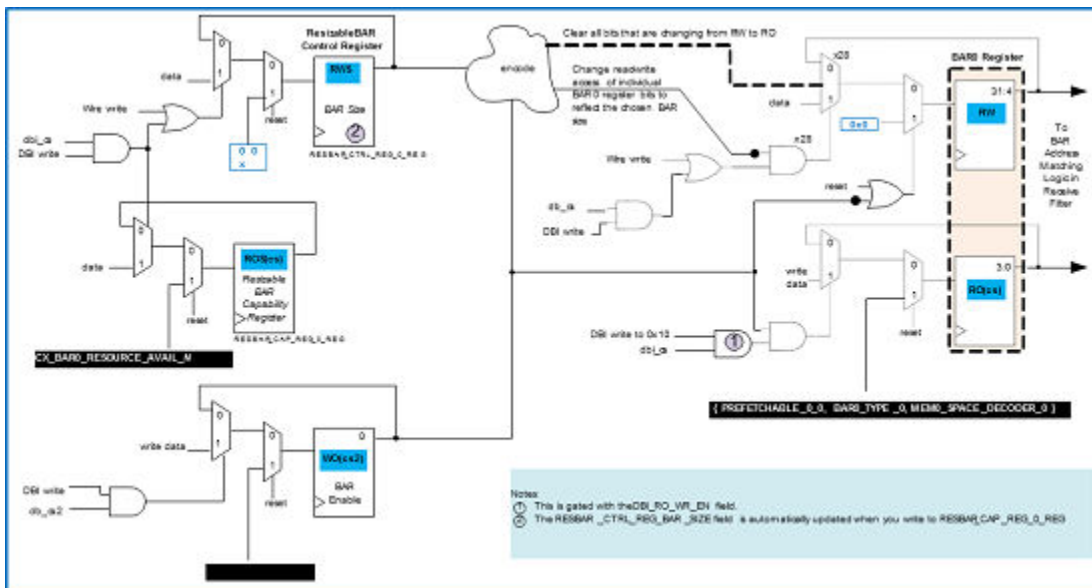

Figure 6-7 Fixed and Programmable Mask Example for 32-bit Memory BAR0 (CX_BAR0_SIZING_SCHEME_0 !=2)

■ BARn_SIZING_SCHEME_0 = Resizable BAR (2)

When you enable the PCI-SIG resizable BAR feature, the host software reads the Supported Resource Sizes field of the Resizable BAR Capability register.

Figure 6-8 Resizable BAR Example for 32-bit Memory BAR0 (CX_BAR0_SIZING_SCHEME_0 =2)

After it selects a BAR size, it writes this value to the BAR Size field of Resizable BAR Control register. From this field, the controller automatically derives the R/W mask for the BAR register. The host software can now start the normal BAR query process. You can change the BAR size at runtime, because the “Supported Resource Sizes” register field is writable through the local DBI (only).

11.3.4.4.2.3 Disabling a BAR

To disable a BAR (in any of the three schemes), your application can write 0 to the LSB of the BAR mask register. The BAR mask register is at the same address as the BAR register, and you can access it through the DBI (only) by asserting `dbi_cs2` (or the CS2 address bit when the AHB/AXI bridge is used). However, when you want to access the LSB (BAR Enable bit), then you must assert `dbi_cs` instead of `dbi_cs2`.

11.3.4.4.2.4 General Rules for BAR Setup (Fixed Mask or Programmable Mask Schemes Only)

At runtime, application software can overwrite the BAR contents to reconfigure the BARs (unless the affected BAR is removed during hardware configuration). Application software must observe the following rules when writing to the BARs:

- BAR0 and BAR1 can be configured as one 64-bit BAR, two 32-bit BARs, or one 32-bit BAR.

- Any 32-bit BAR that is not needed can be removed during controller hardware configuration to reduce gate count.

- An I/O BAR must be a 32-bit BAR and cannot be prefetchable.

- When BAR0 is configured as a 64-bit BAR:

- BAR1 is the upper 32 bits of the combined 64-bit BAR formed by BAR0 and BAR1. Therefore, BAR1 must be disabled and cannot be configured independently.

- BAR0 must be a memory BAR and can be either prefetchable or non-prefetchable.

- The contents of the BAR0 mask register determine the number of writable bits in the 64-bit BAR, subject to the restrictions described in “BAR Mask Registers”. The BAR1 mask register contains the upper 32 bits of the BAR0 mask value.

- BAR0 can be disabled by writing 0 to bit [0] of the BAR0 mask register.

- When BAR0 is configured as a 32-bit BAR:

- You can configure BAR1 as an independent 32-bit BAR or remove BAR1 from the controller hardware configuration.

- BAR0 can be configured as a memory BAR or an I/O BAR.

- The contents of the BAR0 mask register determine the number of writable bits in the 32-bit BAR0, subject to the restrictions described in “BAR Mask Registers”.

- ❑ BAR0 can be disabled by writing 0 to bit [0] of the BAR0 mask register.
- When BAR0 is configured as a 32-bit BAR, BAR1 is available as an independent 32-bit BAR according to the following rules:
 - ❑ BAR1 can be configured as a memory BAR or an I/O BAR.
 - ❑ The contents of the BAR1 mask register determine the number of writable bits in the 32-bit BAR1, subject to the restrictions described in “BAR Mask Registers”.
 - ❑ BAR1 can be disabled by writing 0 to bit [0] of the BAR1 mask register.
 - ❑ When BAR1 is not required in your design, you can remove BAR1 from the hardware configuration by setting both BAR1_ENABLED_0 and BAR1_MASK_TYPE_0 to 0.
 - ❑ The contents of the BAR1 mask register determine the number of writable bits in the 32-bit BAR1, subject to the restrictions described in "BAR Mask Registers".

11.3.4.4.2.5 Memory BAR Sizes

BAR bits [11:0] are always masked for a memory BAR. The PCI Express Base Specification, Revision 4.0, Version

0.7 states that the minimum memory address range requested by a BAR is 128 bytes. In the PCI Local Bus Specification, it is recommended that devices that need less than 4 KB of address space should still consume 4 KB of address space in order to minimize the number of bits in the address decoder. The controller requires each memory BAR to claim at least 4 KB as it does not perform end address checking.

11.3.4.4.2.6 IO BAR Sizes

BAR bits [7:0] are always masked for an I/O BAR. The controller requires each I/O BAR to claim at least 256 bytes. The PCI Local Bus Specification allows I/O BARs to consume between 4 bytes and 256 bytes of address space. The controller only permits I/O BARs to consume 256 bytes of address space. This restriction is used in order to minimize the number of bits in the address decoder.

11.3.4.4.2.7 BAR Mask Registers

You can change the mask at runtime through the local DBI. The mask register is at the same address as the BAR register. The mask is a shadow register that is invisible to the PCIe wire but visible to the local processor over the DBI. Furthermore, it is only visible for a write not for a read. So you cannot read the mask register but you can write to it.

The shadow register is accessed by asserting dbi_cs2 and dbi_cs. If you assert dbi_cs (only) then you access the BAR which is the primary register at that location. Use CS2 instead of dbi_cs2 when you are using the AHB/AXI bridge.

11.3.4.4.2.8 Example BAR Setup

Figure 6-9 shows an example configuration of the BARs and their corresponding BAR mask registers. The example configuration includes one 64-bit memory BAR (non-prefetchable).

Figure 6-9 Example Base Address Register Configuration

11.3.4.4.2.9 Expansion ROM BAR Mask Register (Offset: 0x38; same as the Expansion ROM BAR, but requires dbi_cs2/CS2 for write access)

Your local CPU can change the mask at runtime using the DBI. The mask register is at the same address as the BAR register. The mask is a shadow register that is invisible to the PCIe wire but visible to the local processor over the DBI. Furthermore, it is only visible for a write not for a read. So you cannot read the mask register but you can write to it. The shadow register is accessed by asserting CS2 and CS. If you assert CS (only) then you access the BAR which is the primary register at that location. Use CS2 instead of dbi_cs2 when you are using the AHB/AXI bridge.

11.3.4.5 Port Logic Registers

The port logic (PL) registers are used for configuration of specific controller implementation features, status reporting and testing. The port logic registers reside in your application register section of the configuration space starting at address 0x700.

Non-CFG Wire Access to PL Registers (EP Port Only)

The PL registers (which by default are accessed by CFG requests) can also be accessed by MEM requests.

11.3.4.5.1 Indirect Addressing of Configuration Registers

You access the Gen3 Coefficient Preset registers through a non-standard indirect addressing scheme.

11.3.4.5.2 iATU and DMA Configuration Registers

The iATU and DMA configuration registers are fully accessible from the DBI without any restrictions. These registers can be accessed using a configuration of CS2, and CDM/ELBI selection signals as described in "Data Bus Interface (DBI)".

Non-CFG Wire Access to iATU and DMA Registers (EP Port Only)

The iATU and DMA registers can also be accessed by MEM requests.

11.3.5 DMA Controller

This section describes the optional embedded multichannel DMA controller. You enable the DMA controller by setting the `CC_DMA_ENABLE` configuration parameter.

11.3.5.1 DMA Overview

The RC system CPU, or the EP application CPU, can offload the transferring of large blocks of data to the embedded DMA controller¹, leaving the CPU free to perform other tasks. You can configure the DMA to have one to eight read channels and one to eight write channels. It can simultaneously perform the following types of memory transactions (as shown in Figure 10-1):

■ DMA write

Transfer (copy) of a block of data from local (application) memory to remote (link partner) memory.

■ DMA read

Transfer (copy) of a block of data from remote (link partner) memory to local (application) memory.

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU. The DMA is highly configurable and you can program it using the local DBI or over the PCIe wire2.

In linked list mode, the DMA fetches the transfer control information (called channel context) for each transfer (block), from a list of DMA elements that you have constructed in local memory.

The DMA supports “Native Core Operation (No AXI Bridge)”. You can also use the DMA with the AXI/AHB bridge, in which case the DMA is located between the native PCIe controller and the AXI bridge module.

1. For brevity, the term DMA is used instead of embedded DMA controller, throughout the remainder of this chapter.
2. RC can program the EP DMA using CfgWr or MWr (when ENABLE_MEM_MAP_PL_REG=1), but the EP cannot program the RC DMA over the wire.

11.3.5.1.1 Feature List

The DMA module supports the following features:

Table 10-1 DMA Module Features

DMA Module Feature	Supported
Number of Read Channels	1-8
Number of Write Channels	1-8
AXI Support	Y
Native Core Support (no AXI)	Y
Linked List Mode	Y
Scatter Gather Support (by using Linked Lists)	Y
Full Duplex Read/Write Channel Operation	Y
Separate Tag Pool For DMA Traffic	Y
SAR/DAR Address Alignment	BYTE
Transfer Size	1 byte - 4 GB
AXI Address Bus Width	32, 64
AXI Databus Width	32, 64, 128, 256
Independent Internal, Master and Slave Databus Widths	Y
Independent Core and AXI Clocks	Y
Multifunction Support	Y
DMA	Y

Table continues on the next page...

ARI	Y
SR-IOV	Y
Latency Tolerance Reporting (LTR) Support	Y
OBFF Support	Y
Address Translation Services (ATS) Support	Y
Atomic Ops Support	-
TLP Processing Hints (TPH) Support	Y
TLP Prefix Support (Including PASID)	-
Programmable Interrupt Generation	Y
Reordering Of DMA Read Transfer Completions	Y
ID Based Ordering (IDO) Signaling Supporta	Y
Datapath and RAM Protection For Limitations, see "RAS Data Protection (DP)".	Y
RAM Read Enable for Low-power Optimization	Y
Automatic Flushing/Reset of Bridge (AXI Configurations) When Link Goes Down	Y
Automatic Flushing of Slave (AXI Configurations) When Link is Not Up	Y

a. DMA identifies and decodes IDO bit from the TLP bit stream and passes on the information to the Application through native client interfaces or AXI Bridge. But, IDO bit of the TLP Header cannot be explicitly set by the DMA.

11.3.5.2 DMA Architecture

This section describes the architecture of the DMA.

11.3.5.2.1 Architecture Overview

A DMA write and read channel operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link. When you configure the DMA with multiple read channels, then it uses a weighted round robin (WRR) arbitration scheme to select the next read channel to be serviced. The same applies when you have multiple write channels.

Figure 10-1 System Level View of DMA

11.3.5.2.1.1 DMA Read Transfer

The DMA injects multiple MRd requests of size less than or equal to the minimum of {Max_Read_Request_Size, Max_Payload_Size1} into the outbound request path, directed toward the remote link partner. The DMA converts the read responses into write requests, that it then transmits to the local application. When the DMA data transfer is complete, the CPU is notified. For more details, see "Interrupts and Error Handling". For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory.

11.3.5.2.1.2 DMA Write Transfer

The DMA injects multiple MRd requests of size less than or equal to `Max_Payload_Size` into the inbound request path, directed toward the local application. The DMA converts the read responses into MWr TLPs, that it then transmits to the remote link partner. When the DMA data transfer is complete, the CPU is notified. For more details, see "Interrupts and Error Handling". For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory.

11.3.5.2.1.3 RAM Requirements

This section covers RAM requirements for the controller.

11.3.5.2.1.4 Registers and Context Memory

You program each DMA transfer (channel) using the registers described in "DMA Software Register Map". The registers that are specific to each channel are called the channel context registers. As the transfer progresses, the DMA updates these registers². You program the channel context information and other DMA control registers directly with the local CPU through the DBI or remotely over the PCIe link. Some of the registers are implemented in a high-speed wide interface context RAM. If you implement your RAMs external to the PCIe controller, you must connect this RAM through the external RAM interfaces.

11.3.5.2.2 Interrupts and Error Handling

The registers referenced in Figure 10-2, and Figure 10-3 that are related to error and interrupt handling are described in "DMA Software Register Map".

11.3.5.2.2.1 Interrupt Handling

The DMA generates two interrupts per channel:

- **Done:** The DMA successfully completes the transfer.
- **Abort:** The DMA fails to complete the transfer, or an error occurs during the transfer.

The interrupts are signaled to the software on your CPU, using one or both of the following mechanisms:

- Locally through the `edma_int[CC_NUM_DMA_RD_CHAN+CC_NUM_DMA_WR_CHAN-1:0]` bus.

■ Remotely using a posted memory write (IMWr), which can be interpreted as an MSI or MSIX when directed toward the RC.

□ There are two programmable IMWr addresses per channel, one each for the done and abort interrupts. For MSI, you must program all IMWRr address registers with the same MSI address, as PCIe only supports a single MSI address per function.

a. DMA identifies and decodes IDO bit from the TLP bit stream and passes on the information to the Application through native client interfaces or AXI Bridge. But, IDO bit of the TLP Header cannot be explicitly set by the DMA.

□ A single IMWr data register is used for both types of interrupts, so you must read DMA_READ_INT_STATUS_OFF (or DMA_WRITE_INT_STATUS_OFF) to identify the interrupt type.

Note: The IMWr address and data do not come from the MSI PCIe capability registers but from the "DMA Software Register Map".

For an upstream port, your software must program these registers with the same information that it is using to program the MSI/MSI-X capability for the function that is associated by your software with that channel in a multifunction setup.

You only need to setup these registers at initialization, and not for every DMA transfer.

■ The relaxed ordering (RO) bit is automatically set to zero in the TLP header of all IMWr's so that subsequent MWr TLPs do not arrive at the remote device before the IMWr.

For more information on interrupt handling, see the descriptions of the DMA interrupt registers and "Programming Examples". The interrupt handling mechanism is different for linked list (LL) mode (than non LL mode), and there are also some differences between the read and write channels.

11.3.5.2.2 Non Linked List Mode

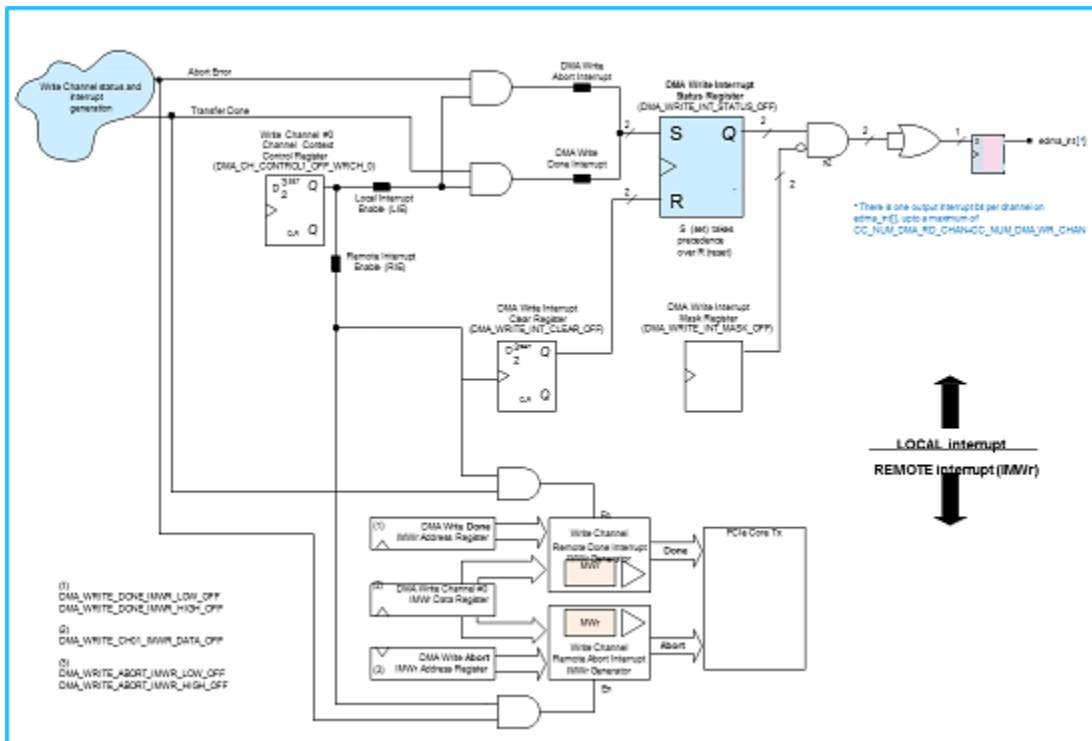

You enable the local and remote interrupts through the local and remote interrupt enable (LIE and RIE) bits:

DMA_CH_CONTROL1_OFF_WRCH_0.lie and
DMA_CH_CONTROL1_OFF_WRCH_0.rie.

In the write channel, there is only one error condition that results in an abort interrupt. For more details, see "Linked List Mode". You mask, clear, and read the status of each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 10-2.

In the read channel, there are five error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 10-3. However, you can read the status of each of the five abort errors (that contribute to the abort interrupt) through DMA_READ_ERR_STATUS_LOW_OFF and DMA_READ_ERR_STATUS_HIGH_OFF.

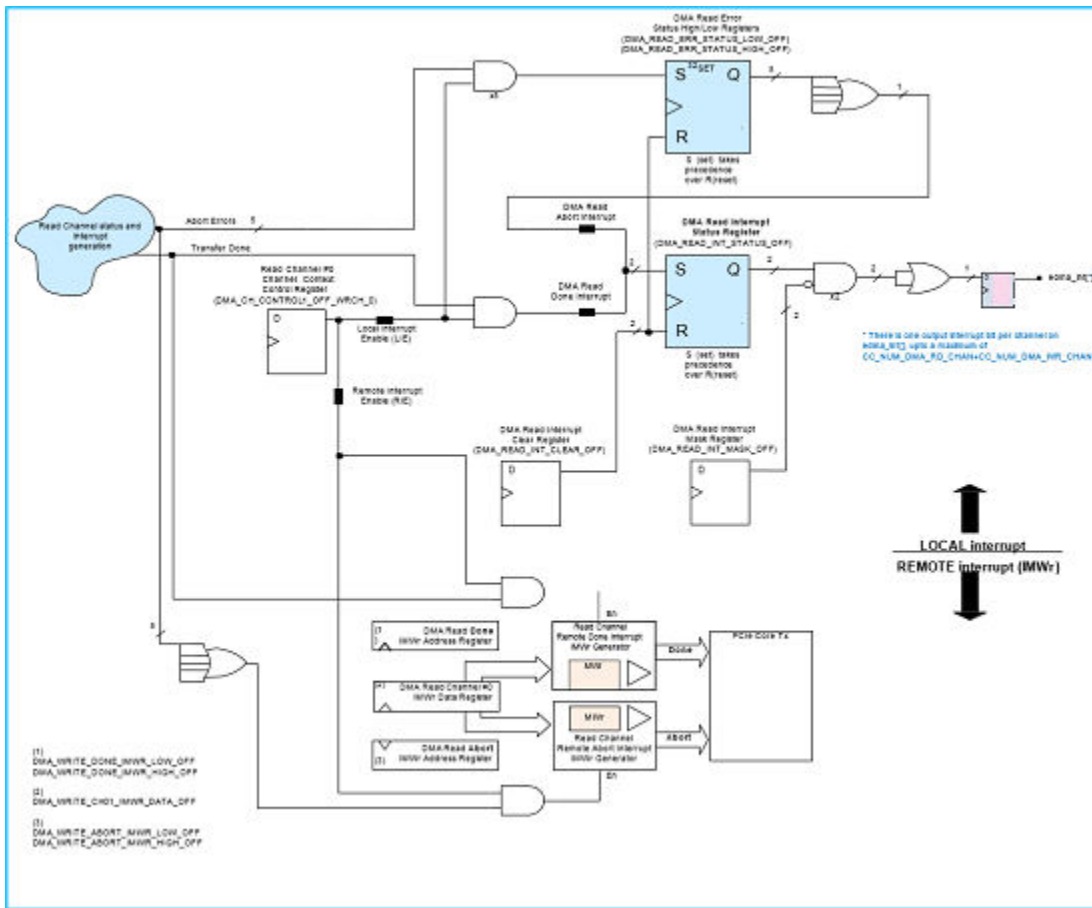

Figure 10-2 Write Interrupt Generation - Non Linked List Mode - Shown For Write Channel #0

If you want a remote interrupt and not a local interrupt then:

- Set LIE and RIE
- Mask the local interrupt using the mask register - This will allow you to poll the status register to distinguish a DONE from an ABORT

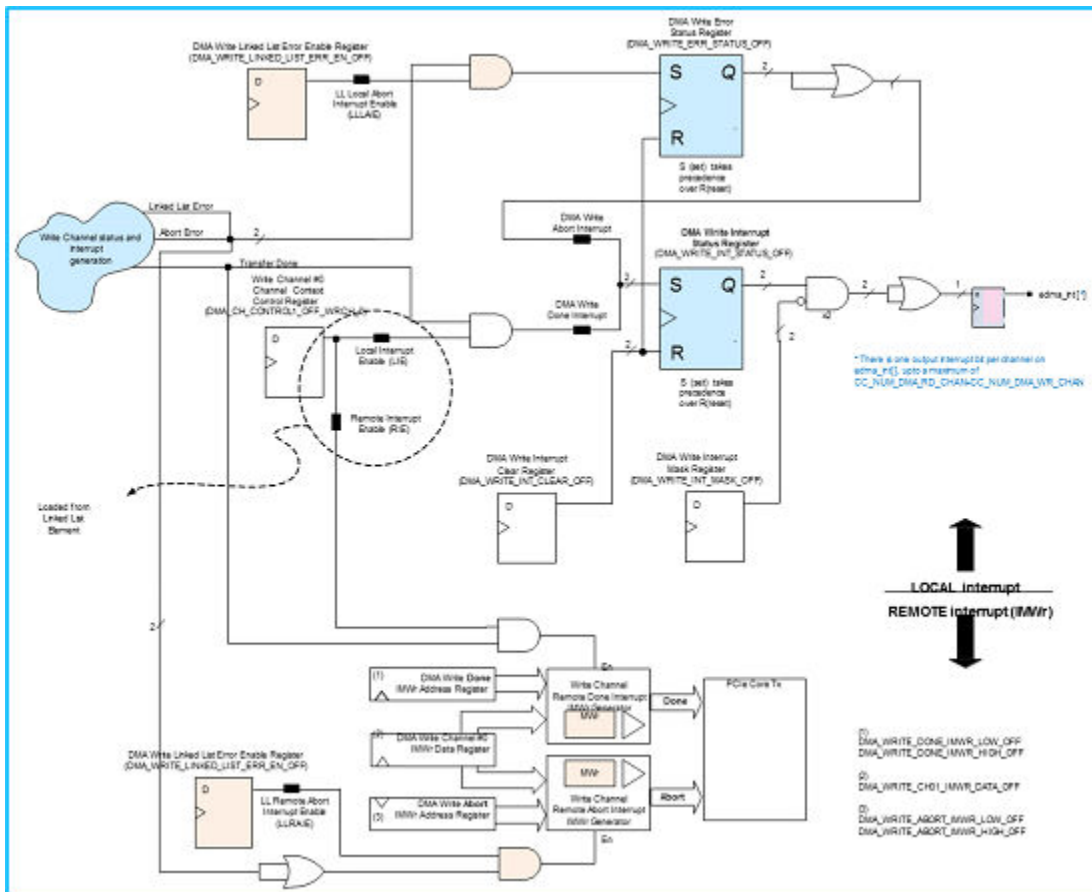

Figure 10-3 Read Interrupt Generation - Non Linked List Mode - Shown For Read Channel #0

11.3.5.2.2.3 Linked List Mode

The LIE and RIE bits in the LL element enable the channel done interrupts (local and remote). The LLLAIE and LLRAIE bits of the DMA_WRITE_LINKED_LIST_ERR_EN_OFF/DMA_READ_LINKED_LIST_ERR_EN_OFF registers enable the channel abort interrupts (local and remote). In the write channel, there are two error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 10-4. You can read the status of each of the two abort errors (that contribute to the abort interrupt) through the DMA_WRITE_ERR_STATUS_OFF register.

Figure 10-4 Write Interrupt Generation - Linked List Mode - Shown For Write Channel #0

In the read channel, there are six error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in Figure 10-5. You can read the status of each of the six abort errors (that contribute to the abort interrupt) through the DMA_READ_ERR_STATUS_LOW_OFF and DMA_READ_ERR_STATUS_HIGH_OFF registers.

Figure 10-5 Read Interrupt Generation - Linked List Mode - Shown For Read Channel #0

For more information on done interrupts in linked list mode, see "Using Interrupts for Linked List Producer-Consumer Synchronization".

Note: In non-linked list mode, LIE acts as a global switch. However when in linked list mode, LIE is just local to the current linked list element and the global switch is LLLAIE.

Attention: If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

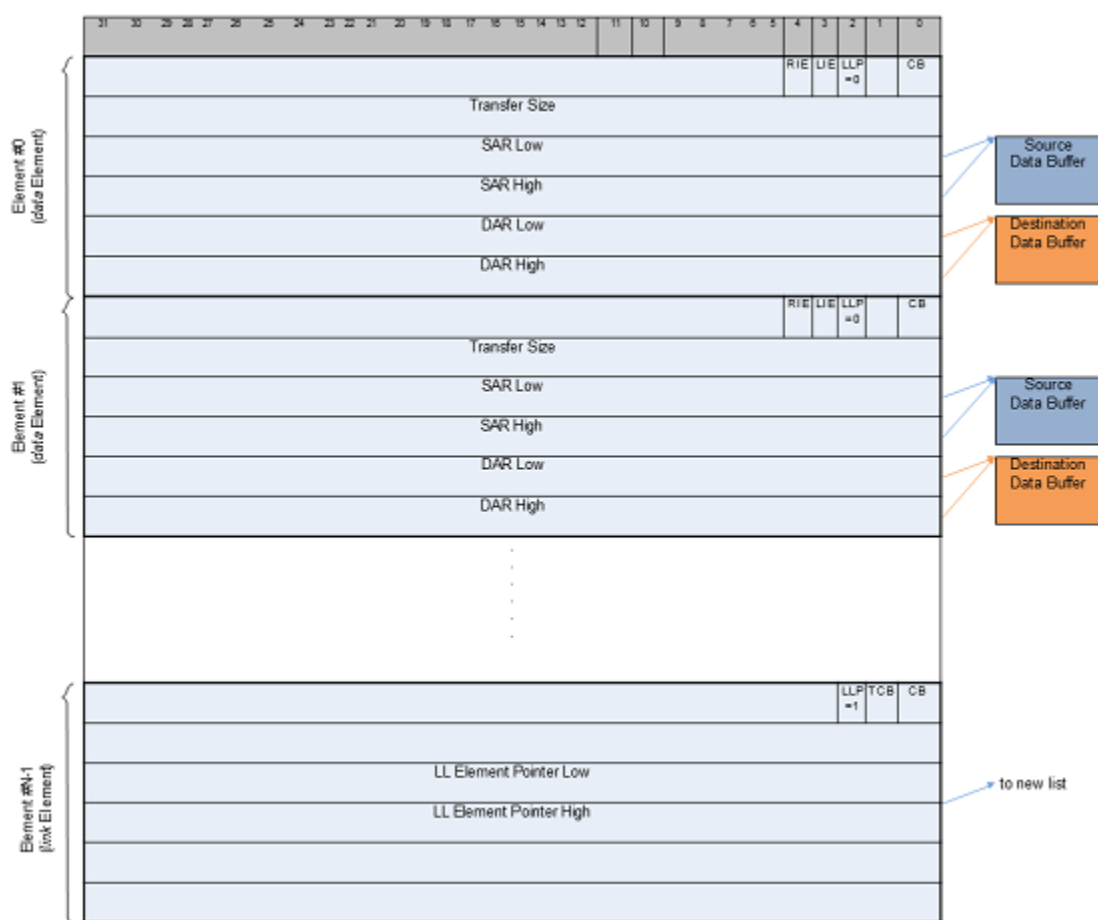

1. This limit is set by the DMA read buffer segment size. For more details, see "Read Buffer" on page 1116.

11.3.5.2.3 Linked List Mode

The DMA provides a linked list (LL) mode to efficiently move data from source to destination with minimal intervention from the local CPU. This mode provides an alternative to programming the DMA multiple times to transfer multiple blocks of data. The programming information (address, size, and so on) for each block of memory is pre-

programmed by your software into a LL element (also known as a descriptor) in local memory. Each element (called a data element) in the LL structure (called a transfer list) can transfer up to 4 GB of data. You enable LL operation for a channel, by setting the LLE field of the DMA_CH_CONTROL1_OFF_WRCH1_0 register to 1. You can enable LL mode independently for each channel. When you enable LL for more than one channel, then you must have a separate LL structure in local memory for each channel. Your application must produce the LL element structure in local memory as shown in Figure 10-6. Normally, all of the elements are contiguous (one after the other) in memory, and each element has six DWORDs containing the information about the block of data to be transferred. You program the channel context registers (DMA_LL_LOW_REG_WRCH_0 and DMA_LL_HIGH_OFF_WRCH_0) with the location of where you have placed the LL element structure in local memory.

Figure 10-6 Linked List Element/Descriptor Structure in Local Memory with N Elements

When you start the DMA transfer (by writing to the DMA Write Doorbell Register DMA_WRITE_DOORBELL_OFF or DMA Read Doorbell Register DMA_READ_DOORBELL_OFF), the DMA reads (consumes) each element from local memory, and loads the information (SAR, DAR, size, and so on) from that element into the channel context registers in the DMA. These channel context registers determine the

operation of the channel that the DMA controller is currently servicing. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory. Normally, all of the elements are contiguous (one after the other) in memory, with the starting address defined in the channel context DMA Linked List Pointer Low Register `DMA_LL_P_LOW_REG_WRCH_0`. When you want to jump in local memory to another element list (or recycle the consumed elements), then you set the LLP bit in the element (for example, link element #N-1 in Figure 10-6), specify the location of the next element structure using the LL Element Pointer DWORDs (as indicated in Figure 10-6), and, set TCB to 1 (for recycling) or to 0 (to jump to another list).

1. Replace WRCH with RDCH for a read channel.

11.3.5.2.3.1 Relationship Between Element DWORDs and Channel Context Registers

Notice the similarity between a data element and the DMA Channel Context registers for each channel. Each element has six DWORDs as in Figure 10-6. There are eight channel context registers (DWORDs) for a channel. The DMA loads the six element DWORDs into the following channel context:

- CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- DMA Transfer Size
- DMA SAR Low and DMA SAR High
- DMA DAR Low and DMA DAR High

The definitions of the element DWORD bit fields are the same as the DMA Channel Context registers described in the "DMA Software Register Map", with the exception of the LIE and RIE bits. The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits (in the channel context registers) enable the done and abort interrupts.

When the LLP field of the first DWORD in the element is set to 1, the element is a link element. The DMA only loads the following information into the channel context registers:

- CB, TCB, and LLP bits of the first DWORD. The LIE and RIE bits are not defined in a link element.
- LL Element Pointer (3rd and 4th DWORDs) into the DMA Linked List Pointer registers (`DMA_LL_P_LOW_REG_WRCH_0` and `DMA_LL_P_HIGH_REG_WRCH_0`).

More detailed information about LL operation is available in "Linked List Operation".

Linked List Operation

■ When you enable linked list operation (`DMA_CH_CONTROL1_OFF_WRCH_0.lle = 1b1`), then the DMA overwrites the following DMA channel context registers with the following information from linked list data elements:

- The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- DMA Transfer Size
- DMA SAR Low & High
- DMA DAR Low & High

■ The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs.

■ The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits enable the done and abort interrupts. For more information, see "Interrupts and Error Handling".

11.3.5.2.4 Native Core Operation (No AXI Bridge)

When you configure the native PCIe controller (that is, with no AXI bridge) with the DMA, then special consideration must be given to the proper use of the Tx and Rx interfaces.

To Avoid Deadlock: ■ Use XALI0 to return PCIe and DMA write channel completions to the controller.

■ Use XALI1 for supplying non-posted requests to the controller.

■ Use XALI2 for supplying posted requests to the controller.

■ Your application must return all DMA write channel completions in the same order as they were requested and must not split completions into multiple smaller responses.

To Avoid Data Corruption: ■ You must implement a non-posted tracker in your application logic as described in “TRGT1 Packet Grant and Halt”

■ As described in “PCIe TAGs”, the DMA uses a fixed number of the PCIe tags in the transmit direction. Therefore your application should not use those tags when generating outbound non-posted requests. a. DMA write channel completions are completions (to MRd requests generated by the DMA write channel) that your application has supplied on the XALI0 interface and that the DMA write channel converts to posted

writes for transmission to the remote link partner. b.The ordering requirement is within a single channel number. If your application prioritizes completions for linked list descriptors over completions, data, then that will improve DMA performance.

When you enable the DMA (CC_DMA_ENABLE =1), the “Target Completion Lookup Table (No AXI Bridge)” is included. The maximum number of outstanding DMA write channel MRd requests (to the local application) is fixed at CX_REMOTE_MAX_TAG +1, and the maximum number of outstanding DMA read channel MWr transactions (to the local application) is fixed at 256. You must correctly drive the signals in Table 10-3.

Table 10-3 Additional I/O Added For Native Core DMA

Name	I/O	Function
d_trgt1_req_dma[2:0]	O	Specifies the source of the request on the TRGT1 Interface.
d_trgt1_req_dma_channel[2:0]	O	DMA channel number.
d_trgt1_wreq_cmplt_dma	I	Your application must pulse this signal every time a DMA read transfer MWr is successfully written to local memory. Note: If you do not pulse this signal, the DMA becomes stuck.
d_trgt1_wreq_cmplt_dma_channel[2:0]	I	You must set this input to the DMA channel number.
d_trgt1_wreq_err_dma	I	Specifies if an error occurred in your application during a DMA read transfer MWr to local memory
radm_trgt1_dma_grant	O	Indicates that a particular DMA transaction has been granted to output. This grant signal is a pulse.
trgt1_radm_dma_pkt_halt	I	Halts the transfer of non-posted packets from DMA.

11.3.5.2.5 SR-IOV Support

When you configure the controller with SR-IOV enabled (CX_SRIOV_ENABLE =1), then you can effectively associate each channel (read and write) with a virtual function (VF) by setting the Virtual Function Enable and Virtual Function Number fields of the DMA Channel Control 2 Register (DMA_CH_CONTROL2_REG_WRCH_0 or DMA_CH_CONTROL2_OFF_RDCH_0). The PCIe controller uses this information to form the requester ID for requests and the completer ID for completions.

11.3.5.3 Using the DMA

This section describes how to use the DMA.

You can configure the DMA to have from one to eight read channels and one to eight write channels. It can simultaneously perform the following types of memory transactions:

■ **DMA write**

Transfer (copy) of a block of data from local memory to remote memory.

■ **DMA read**

Transfer (copy) of a block of data from remote memory to local memory.

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU. The DMA is highly configurable and you can program it using the local DBI or over the PCIe wire.

The channels are named read channel 7..0 and write channel 7..0. Each channel is programmed using a number of registers. For more details, see “DMA Software Register Map”.

11.3.5.3.1 Source and Destination Address Registers (SAR, DAR)

The DMA channel context SAR and DAR registers (DMA_SAR_LOW_OFF_WRCH_01 / DMA_SAR_HIGH_OFF_WRCH_0 / DMA_DAR_LOW_OFF_WRCH_0 / DMA_DAR_HIGH_OFF_WRCH_0) provide support for remote-to-local, and local-to-remote PCIe address mapping. You program the start of the local and remote data buffers using these registers, and the DMA increments the SAR and DAR as the DMA transfer progresses. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 10-7.

Figure 10-7 Write Transfer: SAR and DAR for Write Channel 0

For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory, as shown in Figure 10-8.

Figure 10-8 Read Transfer: SAR and DAR for Read Channel 0

The presence of the DMA controller does not affect:

- Normal filtering rules for inbound TLPs (for example, BAR checking in an Endpoint, as described in “Internal Address Translation Unit (iATU)”)
- The operation of any internal or external address translation, as described in “Receive Filtering”

When you do not want the iATU to translate outbound requests that are generated by the internal DMA module, then you must implement one of the following approaches:

- Ensure that the combination of DMA channel programming and iATU control register programming, causes no translation of DMA traffic to be done in the iATU.
- Activate the DMA bypass mode to allow request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. You can activate DMA bypass mode by setting the DMA Bypass field of the iATU Control 2 Register (IATU_REGION_CTRL_OFF_2_OUTBOUND_0).

11.3.5.3.2 DMA Transfer Size Register

You program the DMA transfer size using the DMA Transfer Size Register (DMA_TRANSFER_SIZE_OFF_WRCH_0). The DMA decrements the value in this register as the DMA transfer progresses. You can read this register at any time to determine the number of bytes remaining to be transferred. When all bytes are successfully transferred, the result is zero. The DMA transfer size can be of any value from one byte, up to a maximum of 4 GB.

11.3.5.3.3 Starting The DMA Transfer

After you program the DMA controller registers (including writing to the DMA Read Engine Enable or DMA Write Engine Enable register), you start a DMA transfer by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF). You can program and start both a read and a write transfer at the same time. The DMA supports full duplex operation, processing read and write transfers at the same time and in parallel with normal (non-DMA) traffic. You can program and start any number of channels in the DMA controller sequentially or simultaneously.

- As described in "PCIe TAGs", the DMA uses a fixed number of the PCIe tags in the transmit direction. Therefore your application should not use those tags when generating outbound non-posted requests.

■ **Sequentially:** configure and start a channel, and then configure and start another channel

a. DMA write channel completions are completions (to MRd requests generated by the DMA write channel) that your application has supplied on the XALI0 interface and that the DMA write channel converts to posted writes for transmission to the remote link partner.

■ **Simultaneously:** configure multiple channels, and then start multiple channels

Caution: You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).

11.3.5.3.4 Detecting the End of The DMA Transfer

If a DMA transfer proceeds without any errors, it stops automatically when finished.

11.3.5.3.4.1 Detecting End of Transfer without Errors

The normal end of a DMA transfer is detected by any of the following methods:

- Done local interrupt (pin) asserted.
- Done remote interrupt (IMWr) received.
- Channel status field of the Channel Control 1 register is Stopped, and the DMA Transfer Size register is 0x0.
- Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF).

11.3.5.3.4.2 Detecting End of Transfer with Errors

The abnormal end of a DMA transfer is detected by any of the following methods:

The abnormal end of a DMA transfer is detected by any of the following methods:

- Abort local interrupt (pin) asserted.
- Abort remote interrupt (IMWr) received.

■ Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF).

■ Channel Status field of the Channel Control 1 register is Halted. When the DMA controller detects an error, it forces the DMA to stop issuing requests for the channel. It also sets the channel status field of the Channel Control 1 register to Halted, generates an abort interrupt (if enabled), and sends an abort IMWr (if enabled). The DMA Transfer Size register indicates the remaining number bytes to be transferred, except when there is an AXI write error during a DMA read transfer. For more details, see Table 10-13.

■ Channel Status field of the Channel Control 1 register is Stopped, and the DMA Transfer Size register is not 0x0. You have prematurely stopped this channel as described in “Stopping the DMA Transfer (Software Stop)”.

11.3.5.3.5 Stopping the DMA Transfer (Software Stop)

You can manually abort (stop) the DMA transfer by writing the channel number to the Doorbell Number field and writing 1 to the Stop field in DMA_WRITE_DOORBELL_OFF. This causes the DMA to:

■ Place the channel in a Stopped state.

The channel Status field in DMA_CH_CONTROL1_OFF_WRCH_0 is Stopped and the value in DMA_TRANSFER_SIZE_OFF_WRCH_0 will not be 0x0.

■ Wait for all outstanding pending transactions.

■ Assert the abort interrupt (if it is enabled) in DMA_WRITE_INT_STATUS_OFF.

You might do this as part of error handling which is described in “Error Handling Assistance by Remote Software”, which is only necessary during software development if you incorrectly program the DMA write channel DAR. You might also do this as part of a function level reset (FLR). FLR does not directly affect the DMA transfer so you must manually stop the DMA transfer before initiating an FLR.

Use This Feature With Caution in Linked List Mode

You should not use the STOP feature in operational mode. It is only a debug feature and has associated hazards.

■ Before setting the Stop bit, you must read the channel status field (CS) of the DMA Channel Control 1 register to ensure that the corresponding channel is Running (transferring data). To eliminate the possibility of a race condition between these two actions (read and write), you should confirm the presence of the abort bit in the DMA

Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF) and check the status of any fatal error if some other event has occurred.

■ After a Stop event, you cannot seamlessly resume the transfer again because the DMA will not carry on exactly from the point that it was stopped at. Therefore you must setup and start the complete channel context again, including the

- linked list pointer
- linked list structure in memory
- related PCS and CCS values

11.3.5.3.6 TLP Generator Header Control

You must program bits [31:12] of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_REG_WRCH_0/DMA_CH_CONTROL1_OFF_RDCH_0), so that the DMA TLP generator correctly sets the TC, RO, NS, AT, and FN TLP header fields for any TLPs that it generates. When SRIOV is enabled, then you must also program DMA_CH_CONTROL2_OFF_WRCH_0/DMA_CH_CONTROL2_OFF_RDCH_0.

11.3.5.3.7 DMA Software Register Map

This section discusses the grouping and access methods of the DMA registers. For specific details of individual DMA registers, see "Register Configuration Space". The following registers are present when the DMA is enabled.

■ DMA Global Registers : these registers control the global settings

Table 10-4 DMA Global Registers

Name	Description
0x8_0000 +0x000	DMA Arbitration Scheme for TRGT1 Interface
+0x008	Number of DMA Channels
+0x00C	DMA Write Engine Enable
+0x010	DMA Write Doorbell
+0x018	DMA Write Engine Channel Arbitration Weight Low
+0x01C	DMA Write Engine Channel Arbitration Weight High
+0x02C	DMA Read Engine Enable
+0x030	DMA Read Doorbell
+0x034	DMA Global Read Control
+0x038	DMA Read Engine Channel Arbitration Weight Low
+0x03C	DMA Read Engine Channel Arbitration Weight High

■ **DMA Interrupt Registers:** these registers control the generation of local interrupts and remote IMWr. The IMWr addresses and data are stored in RAM.

Table 10-5 DMA Interrupt Registers

Byte Offset	Description
0x8_0000 +0x4C	DMA Write Interrupt Status
+0x50	Not used (RsvdP).
+0x54	DMA Write Interrupt Mask
+0x58	DMA Write Interrupt Clear
+0x5C	DMA Write Error Status
+0x60	DMA Write Done IMWr Address Low
+0x64	DMA Write Done IMWr Address High
+0x68	DMA Write Abort IMWr Address Low
+0x6C	DMA Write Abort IMWr Address High
+0x70	DMA Write Channels 1 and 0 IMWr Data
+0x84	DMA Write Channels 3 and 2 IMWr Data
+0x88	DMA Write Channels 5 and 4 IMWr Data
+0x8C	DMA Write Channels 7 and 6 IMWr Data
+0x90	DMA Write Linked List Error Enable
up to +0x9C	Not used (RsvdP).
+0xA0	DMA Read Interrupt Status
+0xA4	Not used (RsvdP).
+0xA8	DMA Read Interrupt Mask
+0xAC	DMA Read Interrupt Clear
+0xB0	Not used (RsvdP).
+0xB4	DMA Read Error Status Low
+0xB8	DMA Read Error Status High
up to +0xC0	Not used (RsvdP).
+0xC4	DMA Read Linked List Error Enable
+0xC8	Not used (RsvdP).
+0xCC	DMA Read Done IMWr Address Low
+0xD0	DMA Read Done IMWr Address High
+0xD4	DMA Read Abort IMWr Address Low
+0xD8	DMA Read Abort IMWr Address High
+0xDC	DMA Read Channels 1 and 0 IMWr Data
+0xE0	DMA Read Channels 3 and 2 IMWr Data
+0xE4	DMA Read Channels 5 and 4 IMWr Data
+0xE8	DMA Read Channels 7 and 6 IMWr Data

■ **DMA Channel Context Registers:** these registers (which are stored in RAM) are for the control and status information that is specific to each channel. There is a set of registers for each channel. The number of channels in the DMA is configurable in each direction (write and read) from 1 to 8 using the CC_NUM_DMA_WR_CHAN and CC_NUM_DMA_RD_CHAN configuration parameters.

Table 10-6 DMA Channel Context Registers for Each Channel

Byte Offset	Description
DMA Channel Context	
0x8_0000 + 0x200*i + 0x100*(WRIRD)b	DMA Channel Control 1 Register
+0x004*i + 0x200*i + 0x100 *(WRIRD)	DMA Channel Control 2 Register
+0x008*i + 0x200*i + 0x100 *(WRIRD)	DMA Transfer Size
+0x00C*i + 0x200*i + 0x100 *(WRIRD)	DMA SAR Low
+0x010*i + 0x200*i + 0x100 *(WRIRD)	DMA SAR High
+0x014*i + 0x200*i + 0x100 *(WRIRD)	DMA DAR Low
+0x018*i + 0x200*i + 0x100 *(WRIRD)	DMA DAR High
+0x01C*i + 0x200*i + 0x100 *(WRIRD)	DMA Linked List Pointer Low
+0x020*i + 0x200*i + 0x100 *(WRIRD)	DMA Linked List Pointer High

a. i is the number of channels

b. WR=0 | RD=1

11.3.5.3.7.1 Implementation of Channel Context Registers

■ The channel context registers are stored in RAM whose contents are automatically initialized after power-on.

■ You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).

Linked List Operation

When you enable linked list operation (Linked List Enable field of DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to 1b1), the DMA overwrites the following DMA channel context registers with the following information from linked list data elements:

■ The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.

■ DMA Transfer Size

- DMA SAR Low
- DMA SAR High
- DMA DAR Low
- DMA DAR High

Note: ■ The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs. For more details, see Relationship Between Element DWORDs and Channel Context Registers.

■ The LIE and RIE bits in a LL element, only enable the Done interrupt. In non-LL mode, the RIE and LIE bits enable the Done and Abort interrupts. For more information, see Interrupts and Error Handling.

11.3.5.3.8 Programming Examples

This section provides a programming and operation flow for each of the following scenarios.

Note: The order in which the registers in the following examples are programmed is not important, except for the Doorbell register, which initiates the DMA transfer. Therefore, to start both a "1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)" and a "1 MB Read Transfer On Read Channel #0 Initiated by Local CPU (Non LL mode)", just execute the commands in Table 10-7 and then execute the commands in Table 10-8. If, as mentioned in "Starting The DMA Transfer", you want both channels to start at (approximately) the same time, then do not execute the last command (at 0x280) in Table 10-7 until after you have executed all the commands in Table 10-8.

Attention: You must enable the DMA before you start a DMA channel. Therefore you must write '1' to DMA Read Engine Enable or DMA Write Engine Enable register before you write '1' to the DMA Read Doorbell or DMA Write Doorbell register.

Note: You can also inspect the VTB test cases at <workspace/doc/vtb/testenv/index.html> for more programming examples. For more details on VTB, see the Integrating the Core and VIP using VTB section in the Integration chapter of the User Guide.

11.3.5.3.8.1 1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)

In this example, the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 10-9. Table 10-7 provides the programming details for this example transfer.

Figure 10-9 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Table 10-7 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Address (0x8_0000+)	Name	Value
0x00C	DMA Write Engine Enable You must not write 0 to this register. Even temporarily writing 0 to this register resets the DMA logic. For more details, see DMA Write Engine Enable Register (DMA_WRITE_ENGINE_EN_OFF).	0x1

11.3.5.3.8.5 Linked List Mode Programming Example (Write Channel #0)

This write channel example corresponds to Figure 10-21, with the following features:

- Recycled linked list (LL) of nine data elements and one link element.
- Transfer is initiated by local CPU.
- Each data element corresponds to a 1 MB (0x0010_0000) write transfer.
- The SARs for each element are separated by 2 MB (0x0020_0000). The DAR for each element are separated by 16 MB (0x0100_0000). The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 10-13.
- The LL transfer list is located at address 0x0000_0200 in local memory.
- No remote interrupt is generated so the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus.
- There is a Watermark interrupt at element #5, and an Empty interrupt at element #8. Both of these interrupts are done interrupts (as opposed to abort interrupts).

You should familiarize yourself with the Linked List Flow for Producer and Consumer as shown in Figure 10-20. These are the main steps for this process in this example:

Step 1: Create TL in local memory

■ Create the 10 elements as per Table 10-11.

□ For elements 0, 1, 2, 3, 4, 6, 7: RIE, LIE, LLP, CB =0,0,0,1

□ For element 5: RIE, LIE, LLP, CB =0,1,0,1 □ For element 8: RIE, LIE, LLP, CB =0,1,0,1 □ For element 9: LLP, TCB, CB =1,1,0

■ For more details, see “PCS-CCS-CB-TCB Producer-Consumer Synchronization” and “Linked List Mode” on page 1084.

Step 2: Program and Start DMA

■ Configure and start the DMA registers as per Table 10-12. Step 4: Wait for done interrupt and recycle TL

■ For more details, see “Using Interrupts for Linked List Producer-Consumer Synchronization”

■ When recycling elements, consider “Element Recycling”

Attention: If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

11.3.5.4 Advanced DMA Information and Operation

This section discusses advanced features and operation of the DMA.

11.3.5.4.1 Overview

The DMA write and read channels operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link.

The DMA can simultaneously perform the following types of memory transactions:

- DMA write: transfer (copy) of a block of data from local memory to remote memory
- DMA read: transfer (copy) of a block of data from remote memory to local memory

After you have programmed and started a DMA transfer (see "Using the DMA"), the DMA transfers the data as described in "**DMA Write Transfer**" and "**DMA Read Transfer**"

PCI Express Controller (PCIe)

When the PCIe controller is configured to use the AXI bridge, then the DMA is located between the native PCIe controller and the AXI bridge module as shown in Figure 10-14. It must share, with your normal non-DMA traffic, access to the AXI bridge, and PCIe controller and link. This sharing process is described in "**DMA Write Transfer**" and "**DMA Read Transfer**". The internal TRGT1, RBYP, and XALI0/1 interfaces have been renamed to iTRGT1, iRBYP, and iXALI0/1.

Figure 10-14 Location of the DMA Controller when the PCIe includes the AXI Bridge

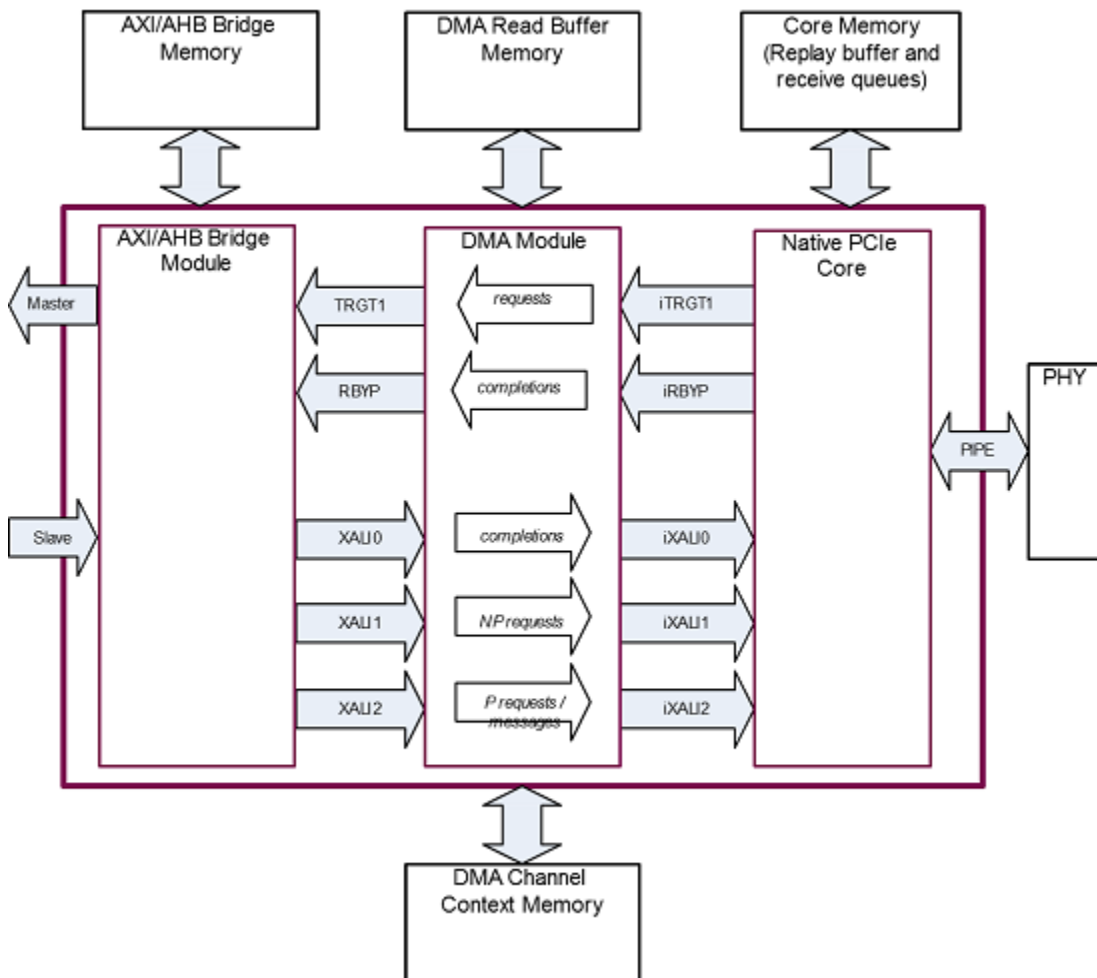

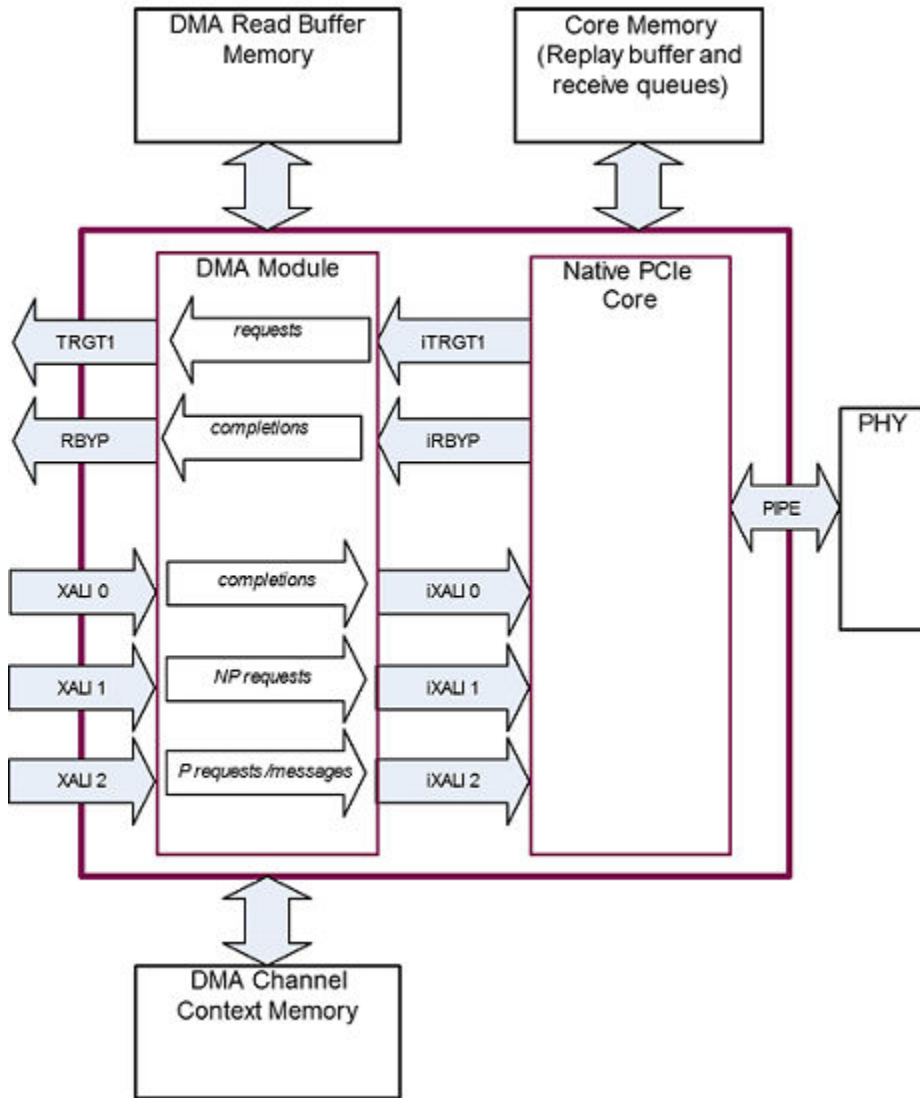

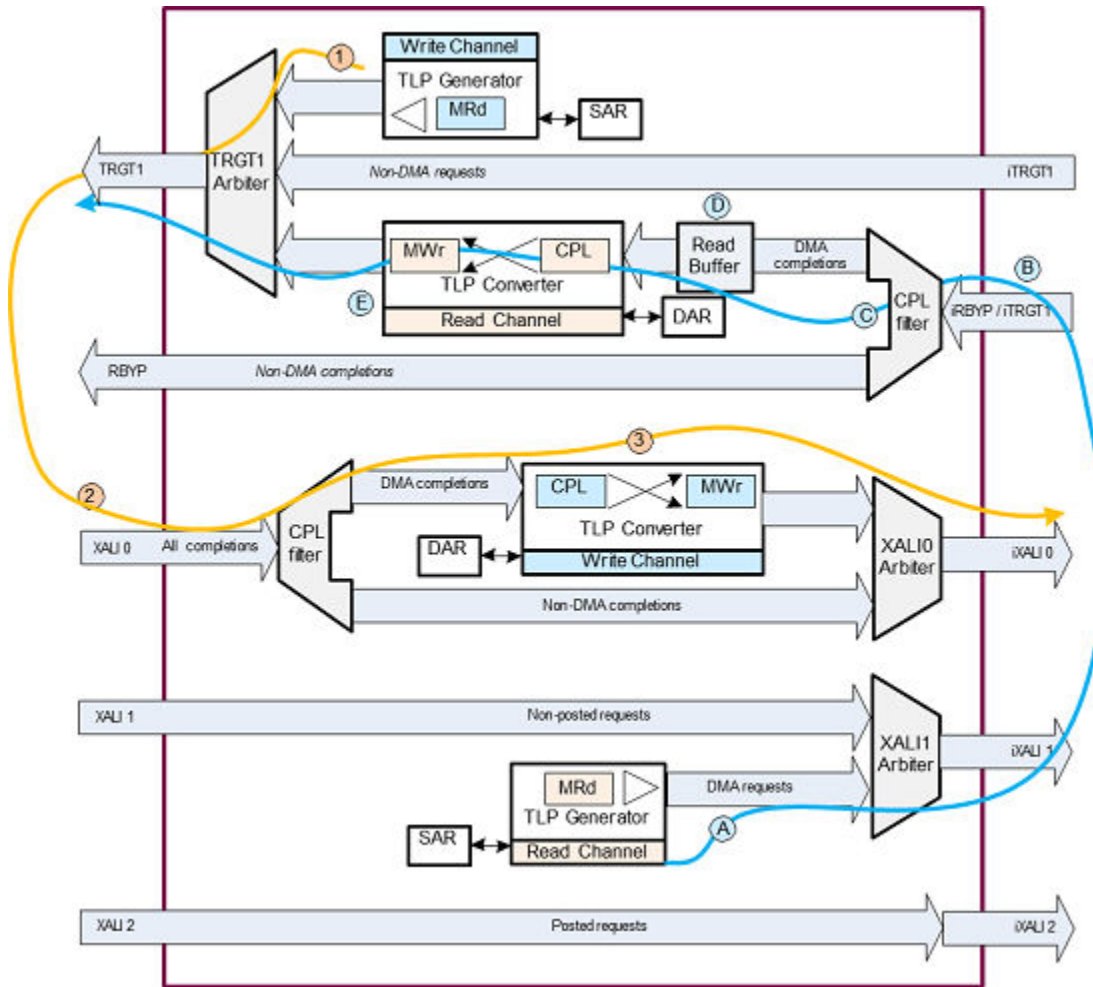

Figure 10-15 Location of the DMA Controller when the PCIe does not include the AXI Bridge

11.3.5.4.2 Internal Architecture

Figure 10-16 Operation of DMA Read (blue) and Write (orange) Channels

11.3.5.4.2.1 DMA Write Transfer

The DMA injects multiple MRd requests of size less than or equal to Max_Payload_Size into the inbound request path. The TLP addresses are derived from the "Source and Destination Address Registers (SAR, DAR)". When the DMA data transfer is complete, the CPU is notified. For more details, see "Interrupts and Error Handling". Referring to the orange paths in Figure 10-16:

1. The DMA generates and sends READ requests to your local application. Because the TRGT_CPL_LUT is always enabled, it uses one of the shared DMA/non-DMA TRGT_CPL_LUT IDs instead of a PCIe TAG.
2. Your application returns data on the XALI0 interface (or AXI bridge master) in response to these requests. Data must be returned in strict order within a single channel.

The DMA converts the CPL TLPs to WRITE requests and sends these to the PCIe native controller for transmission to the remote link partner.

11.3.5.4.2 DMA Read Transfer

The DMA injects multiple MRd requests of size less than or equal to the minimum of {Max_Read_Request_Size, Max_Payload_Size} into the outbound request path. The TLP addresses are derived from the "Source and Destination Address Registers (SAR, DAR)". When the DMA data transfer is complete, the CPU is notified. For more details, see "Interrupts and Error Handling". Referring to the blue paths Figure 10-16:

1. The DMA generates and sends READ requests to the remote link partner. It uses a DMA tag.
2. The link partner returns data in response to these requests on the iRBYP or iTRGT1 interface.
3. The DMA module filters this data from non-DMA traffic on iRBYP/iTRGT1 and sends it to the Read Buffer. The DMA module identifies DMA traffic by looking for PCIe completion TLPs that have a DMA tag.
4. The Read Buffer reorders completions that have been returned out-of-order. This is to ensure that the DMA writes data to the application in address-order.
5. The DMA converts the completion TLPs to WRITE requests and sends these to your application on TRGT1 (or AXI bridge master).

In Figure 10-16, the XALI1 arbitration priority is Read Channel MSI (highest), Write Channel MSI, Non-DMA requests, Read Channel MRd. The TRGT1 arbitration priority is programmable (using the

DMA_CTRL_DATA_ARB_PRIOR_OFF register) and defaults to Non-DMA requests (highest), Write Channel MRd (DMA data requests and LL element/descriptor access), Read Channel MRd (LL element/descriptor access), Read Channel MWr.

11.3.5.4.3 DMA Ordering

The DMA assumes that all DMA read channel data must be written to the local application memory in strict address order. For a DMA read transfer, each original outgoing request has a unique PCIe tag. The remote link partner or intermediate switch does not have to preserve the order of CPLs corresponding to such individual requests. When the DMA receives the CPLs out of order, it reorders that data in the "Read Buffer" as described in "**DMA Read Transfer**". DMA write transfer data is sourced from the local application memory and sent to the remote memory in address order.

11.3.5.4.3.1 AHB Ordering

There are no ordering issues on the AHB interconnect, because there is only one outstanding write channel read request (MRd) issued by the AHB bridge master at any one time.

11.3.5.4.3.2 AXI Ordering (DMA)

IDs '0' -> (CC_MAX_MSTR_TAGS_AXI - 1) are used for non-DMA and DMA non-posted requests (including write channel linked list element access). The write channel uses a unique AXI ID (per channel) for all DMA non-posted requests sent to the AXI master. You can observe the DMA master sideband signals *misc_info_dma to distinguish a DMA non-posted request from a non-DMA non-posted request with same ID. ID 0 is always used for non-DMA and DMA posted requests. Therefore the order of MWr's to local memory is preserved through the AXI fabric.

11.3.5.4.3.3 AXI Master CPL-P Ordering Impact On Performance

The AXI ordering manager ensures that the rule "CPL must not pass a previously-issued P" is obeyed for each virtual channel (VC). It does this by halting the unloading of completions from the native controller's receive queues by the AXI bridge when there are outstanding posted transactions on the AXI master interface. In a system with a single VC, this means that strongly ordered non-DMA completions at the head of the completion queue can block weakly ordered non-DMA completions and impact performance.

DMA outbound read completions are weakly ordered and should be mapped to a different VC (in a multi-VC system), enabling the controller to send the completions to the DMA read buffer when strong and weakly ordered read completions are interleaved on the wire. In a single-VC system, the DMA can still share the VC without impact from these enforced ordering rules if the RO bit (relaxed ordering) is set on DMA read engine transactions.

11.3.5.4.3.4 Native Core Write Channel Deadlock Avoidance

Special consideration must be given to the proper use of the three client interfaces and you must implement a non-posted tracker in your application logic as described in "TRGT1 Packet Grant and Halt" . For more details, see "Native Core Operation (No AXI Bridge)".

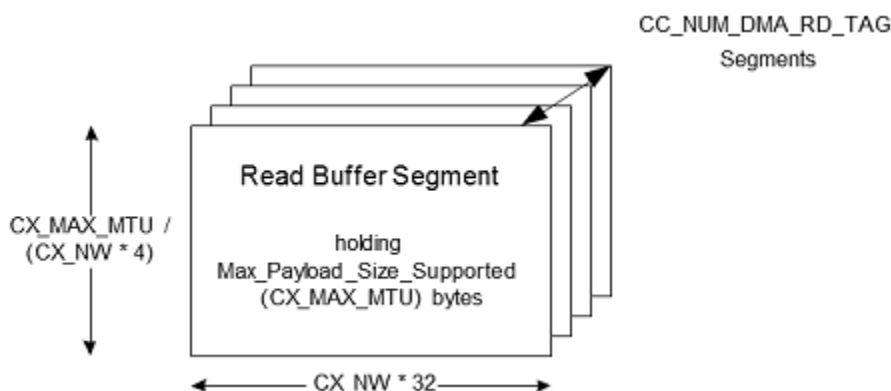

11.3.5.4.4 Read Buffer

The DMA read buffer fulfills two functions:

- Reordering of CPLs that are returned out-of-order as described in "Example Transfer".
- Buffering between the DMA and the AXI bridge master (or application if bridge not used). This is needed for buffering CPLs when your application applies back pressure (stalling/halting), as the controller advertises infinite CPL credits.

The DMA read buffer size is automatically configured at build time and is logically arranged as a segmented-buffer, as shown in Figure 10-17. It has `CC_NUM_DMA_RD_TAG` segments. The configuration parameter `CC_NUM_DMA_RD_TAG` is discussed in detail in "PCIe TAGs". The size of each segment is `CX_MAX_MTU1`. This is the value of the `Max_Payload_Size_Supported` field of the Device Capability register in the PCIe Express Capability Structure. At enumeration time, the RC can program the `Max_Payload_Size` field in the Device Control register in the PCIe Express Capability Structure with any value less than or equal to this.

Figure 10-17 DMA Read Buffer

The DMA read buffer size is as follows:

- **Width:** Same as the controller datapath width = $CX_NW * 32$
- **Depth:** $CC_DMA_SEG_BUF_DEPTH = CC_NUM_DMA_RD_TAG * CX_MAX_MTU / (CX_NW * 4) + 22$

The default segment size is 256 bytes, and the default number of DMA tags is 16. Therefore the default read buffer size is $16 * 256 = 4$ KB. When you implement your RAMs external to the PCIe controller, you must connect this RAM through the external RAM interface.

1. The only other value that could have been picked during the design was 4 KB, which is the maximum amount of data a MRd request can ever request in a PCIe system.

2. This extra two entries only apply for cores with 64-bit and 128-bit datapaths.

11.3.5.4.5 PCIe TAGs

The combined number of PCIe tags assigned to the DMA read channel and your application (or AXI bridge) is always equal to CX_MAX_TAG+1 . You set the $CC_NUM_DMA_RD_TAG$ configuration parameter to specify how many of the CX_MAX_TAG+1 PCIe tags are reserved for DMA MRd request TLP generation. The remaining tags are assigned to non-DMA transfers generated by your application on XALI0/1/2 (or the AXI bridge slave). Figure 10-18 shows the division of PCIe tags between the DMA controller and the rest of the PCIe controller. It also shows the value range of each pool of tags.

Figure 10-18 PCIe Tag Allocation For DMA/Non-DMA MRd Traffic Using $CC_NUM_DMA_RD_TAG$

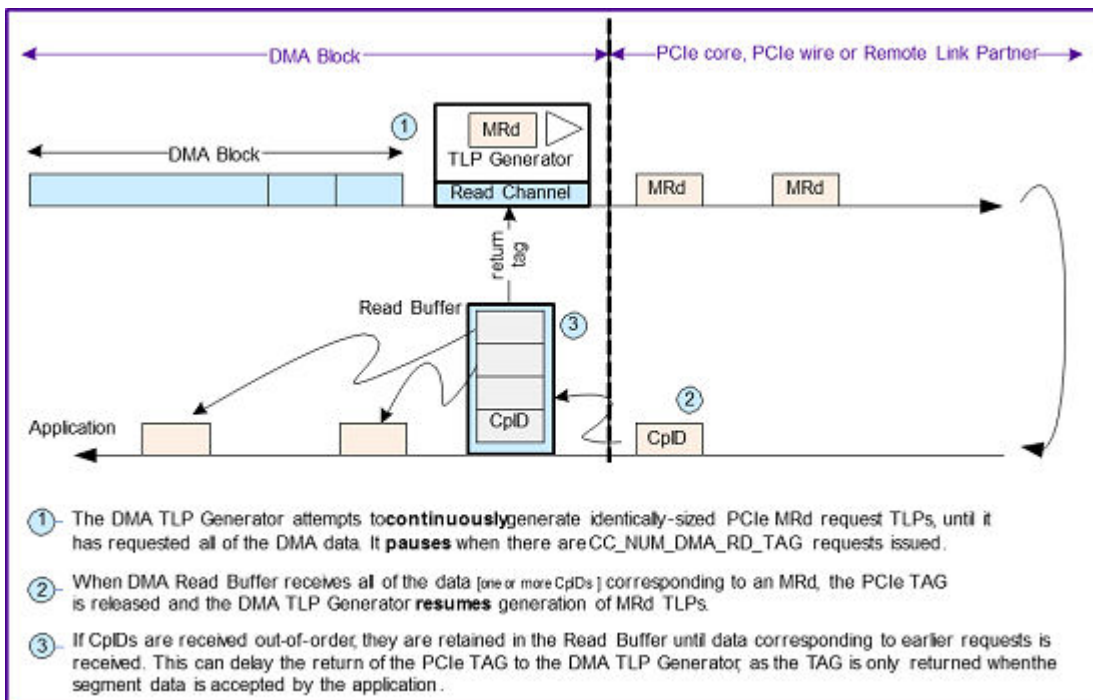

11.3.5.4.5.1 Example Transfer

The DMA never has more than `CC_NUM_DMA_RD_TAG` simultaneous MRd requests outstanding on the PCIe link. To demonstrate this, consider a DMA read transfer as follows. Figure 10-19 shows a scenario where there are four DMA tags (`CC_NUM_DMA_RD_TAG=4`), and the remote link partner is returning out-of-order CPLs. An example of out-of-order CPL delivery would see the CPL (or CPLs) for the first MRd request arriving after the CPL for the second MRd request.

- There are two MRd requests in transit on the PCIe link.
- There is one out-of-order CplD in the DMA read buffer.
- There is one CplD in transit on the PCIe link.

Figure 10-19 DMA Read Transfer Decomposition into Multiple MRd Requests with `CC_NUM_DMA_RD_TAG = 4`

The DMA segments the transfer into a number (up to a maximum of `CC_NUM_DMA_RD_TAG`) of MRd requests. The size of each request is limited to the minimum of {`Max_Read_Request_Size`, `Max_Payload_Size`}.

- When a CplD TLP for an MRd request returns from the PCIe Wire out-of-order:
 - The CplD is stored in the DMA read buffer.
 - The tag is not released back to the DMA tag pool, and the DMA cannot generate another MRd request with this tag number. □ When the CplD from all of the previous MRd requests have been received, the DMA completes the next steps:

- The CplD is converted to an MWr and forwarded to your application (or AXI bridge master for writing to the AXI bus).
- The tag is released back to the DMA tag pool.
- The DMA generates another MRd request with this tag number.
- When a CplD TLP for an MRd request returns from the PCIe Wire in-order:
 - The CplD is converted to an MWr and forwarded to your application (or the AXI bridge master for writing to the AXI bus).
 - The TAG is released back to the DMA tag pool.
 - The DMA generates another MRd request with this tag number.

11.3.5.4.6 Error Handling

The DMA supports full AXI and PCIe error handling in conjunction with the PCIe controller. Table 10-13, and Table 10-14 list the possible sources of an error for DMA read and write transfers. In general,

Table 10-13 Possible Sources of an Error during a DMA Read Transfer

Source	Type	Description
Application Write Error Detected	Fatal	<p>The DMA read channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while writing posted data to it. This error is fatal.</p> <ul style="list-style-type: none"> • You must restart the transfer from the beginning because the channel context is corrupted. • The MWr is not rolled back. • The AXI bridge master does not report this error to software through error logging or MSG. <p>Note: During linked list mode, the Application Write Error only corrupts the current element in the linked list. This is because the DMA does not fetch the next element from local memory until it has completely finished transferring the current block of data (as defined by the current linked list element). Finished implies that your application has successfully acknowledged (without ERROR) all of the MWr requests.</p>

Table continues on the next page...

Unsupported Request (UR)	Non-fatal	The DMA read channel has received a PCIe UR CPL status from the remote device in response to the MRd request.
Completer Abort (CA)	Non-fatal	The DMA read channel has received a PCIe CA CPL status from the remote device in response to the MRd request.
CPL Time Out	Non-fatal	The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received.
Data Poisoning	Fatal	The DMA read channel has detected data poisoning in the CPL from the remote device in response to the MRd request. The DMA read channel will drop the completion and then be halted. The CX_FLT_MASK_UR_POIS filter rule does not affect this behavior.
Linked List Element Fetch Error Detected	Fatal	The DMA read channel has received an error response from the AXI bus (or TRGT1 interface when the AXI bridge is not used) while reading a linked list element from local memory.

Table 10-14 Possible Sources of an Error during a DMA Write Transfer

Source	Type	Description
Application Read Error Detected	Fatal	<p>The DMA write channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while reading data from it.</p> <ul style="list-style-type: none"> The response TLP is discarded by the DMA and is not converted to an outbound MWr TLP. The UR or CA CPL status TLP generated by the bridge is discarded by the DMA. The AXI bridge master does not report this error to software through error logging or MSG.
Linked List Element Fetch Error Detected	Fatal	The DMA write channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while reading a linked list element from local memory.

		<ul style="list-style-type: none"> • The UR or CA CPL status TLP generated by the bridge is discarded by the DMA. • The AXI bridge master1 does not report this (or for non-DMA traffic) error to software through error logging or MSG.
--	--	--

When the DMA detects an error, it performs the following actions (for the channel with the error):

- Stops issuing new requests to the remote link partner.
- Stops issuing new requests to your application.
- All data in the “Read Buffer”, that was received before the error was detected, is valid and is sent to your application. In the case of a non-fatal error, this is reflected in the DMA Transfer Size Register `DMA_TRANSFER_SIZE_OFF_WRCH_0`.
- All data in the read buffer (for that channel), that was received after the error was detected, is discarded.
- Places the DMA channel in a halted state (channel status field of the DMA Channel Control 1 Register is halted).
- Waits for all outstanding requests and CPLs to complete.
- Generates the abort interrupt or IMWr, if enabled, as outlined in “Interrupt Handling”.

For a DMA read transfer, you can read the DMA Read Error Status High Register (`DMA_READ_ERR_STATUS_HIGH_OFF`) and DMA Read Error Status Low Register (`DMA_READ_ERR_STATUS_LOW_OFF`) to identify the source of the error. For a DMA write transfer (in linked list mode only), you can read the DMA Write Error Status Register (`DMA_WRITE_ERR_STATUS_OFF`) to identify the source of the error. After your software has finished error and interrupt routine handling for Non-Fatal errors, you can request the DMA to continue processing (for the channel with the error) by:

- 1.Reprogramming the SAR based on the number of bytes remaining in the DMA Transfer Size register
- 2.Writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (`DMA_WRITE_DOORBELL_OFF`) or DMA Read Doorbell Register (`DMA_READ_DOORBELL_REG`).

Caution: You cannot continue after a Fatal Error is detected, as the channel context is corrupted. Any actions that were in progress are not rolled back. To exit from this condition, you need to Soft Reset the complete DMA controller, as described in DMA Write Engine Enable Register (`DMA_WRITE_ENGINE_EN_OFF`) and DMA Read Engine Enable Register (`DMA_READ_ENGINE_EN_OFF`).

When an error occurs in linked list mode, the next LL element is not fetched from local memory. DMA Linked List Pointer Low Register (DMA_LL_P_LW_OFF_WRCH_0) is not incremented by the DMA, but remains pointing to the element that caused the error.

11.3.5.4.6.1 Error Handling Assistance by Remote Software

During a DMA write transfer, the DMA is not aware of MWr errors that are detected in the remote device, because an MWr is a posted request and has no corresponding completion TLP. In these cases, your remote CPU must manually abort the DMA transfer by writing the channel number to the Doorbell Number field, and 1 to the Stop field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF). This causes the DMA to:

- Place the channel in a Stopped state. The channel Status field of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) is Stopped and the DMA Transfer Size register is not 0x0.
- Wait for all outstanding pending transactions.
- Assert the abort interrupt if it is enabled

For more details, see “Stopping the DMA Transfer (Software Stop)”. Alternatively, your remote CPU can return an error Msg to the local CPU. The local CPU can then stop the channel by setting the Stop field. You can re-start the transfer by rolling back the SAR based on the number of bytes remaining in the DMA Transfer Size Register (DMA_TRANSFER_SIZE_OFF_WRCH_0) subject to the restrictions outlined in “Stopping the DMA Transfer (Software Stop)”.

Note: This procedure is only necessary during software development; when you incorrectly program the DMA write channel DAR. An MWr error is fatal and you must resolve it by fixing your software. In normal operation MWr errors are not expected to occur.

11.3.5.4.7 DMA Debug

To assist you in debugging your hardware, use the following outputs to identify DMA traffic (transfer requests, and linked list element MRds) and non-DMA traffic.

Table 10-15 DMA Debug Outputs

Signal Name	Where Used
mstr_req_misc_info_dma	AHB master
armisc_info_dma	AXI master

Table continues on the next page...

PCI Express Controller (PCIe)

awmisc_info_dma	AXI master
d_trgt1_req_dma	Native controller (no AXI bridge)
d_trgt1_req_dma_channel[2:0]	Native controller (no AXI bridge)

11.3.5.4.7.1 Soft Reset

To assist you in debugging your software, use the DMA write engine enable field of the DMA Write Engine Enable Register (DMA_WRITE_ENGINE_EN_OFF) to reset the DMA write logic. This might be necessary during software development, if you incorrectly program and hang the DMA. Similarly, use the DMA read engine enable field of the DMA Read Engine Enable Register (DMA_READ_ENGINE_EN_OFF) to reset the DMA read logic. This soft reset does not clear the DMA configuration registers.

11.3.5.4.7.2 Stop Bit

To assist you in debugging your software, use the Stop bit of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF), or of the DMA Read Doorbell Register (DMA_READ_DOORBELL_REG), to prematurely stop a DMA transfer. For more information, see "Stopping the DMA Transfer (Software Stop)".

11.3.5.4.7.3 Test Interrupt

You can write to the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF), or the DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF), to emulate interrupt generation, during software or hardware testing. A write to these registers triggers an interrupt, but the DMA does not set the done or abort bits in these registers. This test interrupt is unaffected by the mask bits. To clear this interrupt, you must write to either of the DMA Write Interrupt Clear or the DMA Read Interrupt Clear registers.

11.3.5.4.8 Linked List Operation

This section describes the detailed operation of the DMA in linked list (LL) mode. It also discusses how the software should produce LL elements¹, and how the DMA and software maintain synchronization.

11.3.5.4.8.1 LL Operation Overview

You should first read "Linked List Mode" for an overview of LL mode. In this section, a normal LL operation called recycling² is described in detail. The process is described for a write channel, but it is possible to have duplicate processes running in parallel for other write or read channels. In this process interrupts are used to trigger the producer (software) to recycle elements. Typically a Watermark interrupt (positioned near the middle of the transfer list (TL)) and an Empty interrupt (in the last data element) are used by setting LIE in these two elements to '1'.

The steps in this process are:

1. Software creates a LL element structure called a TL in local memory consisting of N-1 data elements and one link element.

■ The link elements "LL Element Pointer Low/High DWORDs" in Figure 10-6) are programmed to point back to the beginning of the first data element.

■ One of the data elements (near the middle of the TL) is programmed to generate a "Watermark" interrupt.

■ The last data element is programmed to generate an "Empty" interrupt.

2. Software programs the DMA with the location of the TL. This is done by writing to the DMA Linked List Pointer Low Register (DMA_LLPOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LLPHI_OFF_WRCH_0).

3. Software starts the DMA process by ringing the write channel Doorbell. This is done by writing to the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF).

The solid purple loop L1 in Figure 10-20 corresponds to steps 1-3.

4. The DMA reads (**consumes**) each data element from local memory, and if the CB and CCS bits match, loads the information (SAR, DAR, size, and so on) from that data element into the channel context registers. These context registers determine the operation of the channel that the DMA is currently servicing. The DMA executes the check for the CB/CCS match after it has evaluated TCB and toggled CCS. The DMA always loads link elements into the channel context.

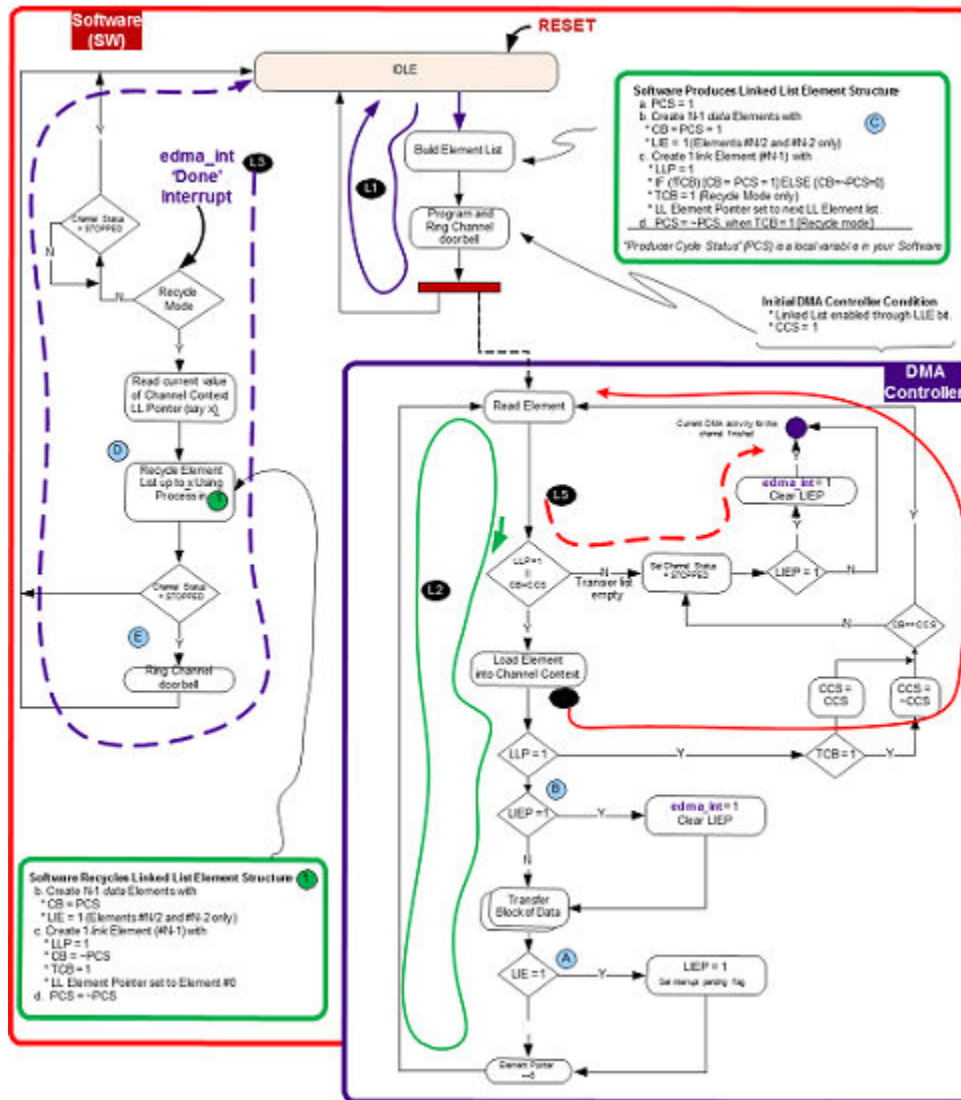

NOTE

If the DMA stops on a link element, then your software must set the DMA Linked List Pointer registers, and restart the DMA process by ringing the doorbell.

1. Also known as descriptors.

2. With recycling, the same LL structure is used over and over again. Another mode of operation would be to jump to a new LL element structure when the current one is consumed.

Figure 10-20 Linked List Flow for Producer and Consumer

5. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory.

The solid green loop L2 in Figure 10-20 corresponds to steps 4-5.

6. The last element in the list (called a link element, and indicated by having its LLP field set to 1) is not used to transfer a block of data.

■ It causes the DMA to effectively repeat the task in step 4.

- Its TCB is typically set to 1. This causes the DMA to toggle its CCS bit, and the software to toggle its PCS bit. The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism to ensure that:

- Software does not recycle elements that have not yet being consumed by the DMA

- DMA correctly recognizes and consumes recycled elements. The solid red loop L4 in Figure 10-20 corresponds to step 6.

7. Upon reception of the interrupt (mentioned in step 1), the software starts to recycle the TL.

- Software reprograms each data element with new DMA transfer information.

- The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism described later in this section.

The dashed purple loop L3 in Figure 10-20 corresponds to step 7.

8. As some point, the software wants to terminate the complete DMA process, by not recycling any more elements. The DMA recognizes this condition when $CB \neq CCS$, and sets the channel status to stopped

The dashed red loop L5 in Figure 10-20 corresponds to step 8.

11.3.5.4.8.2 Using Interrupts for Linked List Producer-Consumer Synchronization

When the DMA is finished with an element, the DMA checks the LIE bit, before reading the next LL element. For more details, see circled step A in Figure 10-20. When the LIE is set, then the DMA does not assert the "done" interrupt immediately, but sets an internal interrupt pending flag (LIEP). It asserts the actual done interrupt after the next data element has been read from system memory. For more details, see circled step B in Figure 10-20. This automatic internal process of delaying the interrupt avoids a race condition between the DMA and software when the LIE bit is set in an element.

Your software should set the "Watermark" interrupt early to schedule the recycling of the consumed elements. Placing the Watermark interrupt too far down in the list, combined with a slow element recycling process in your application; ensures that the DMA returns to the start of the LL before your software has recycled it. The DMA channel STOPS, and you have to restart it by writing to its Doorbell. Typically a "Watermark interrupt" (positioned near the middle of the TL) and an Empty interrupt (in the last data element) are used by setting LIE in these two elements to 1b1. Upon reception of the interrupt, the software starts to recycle the TL.

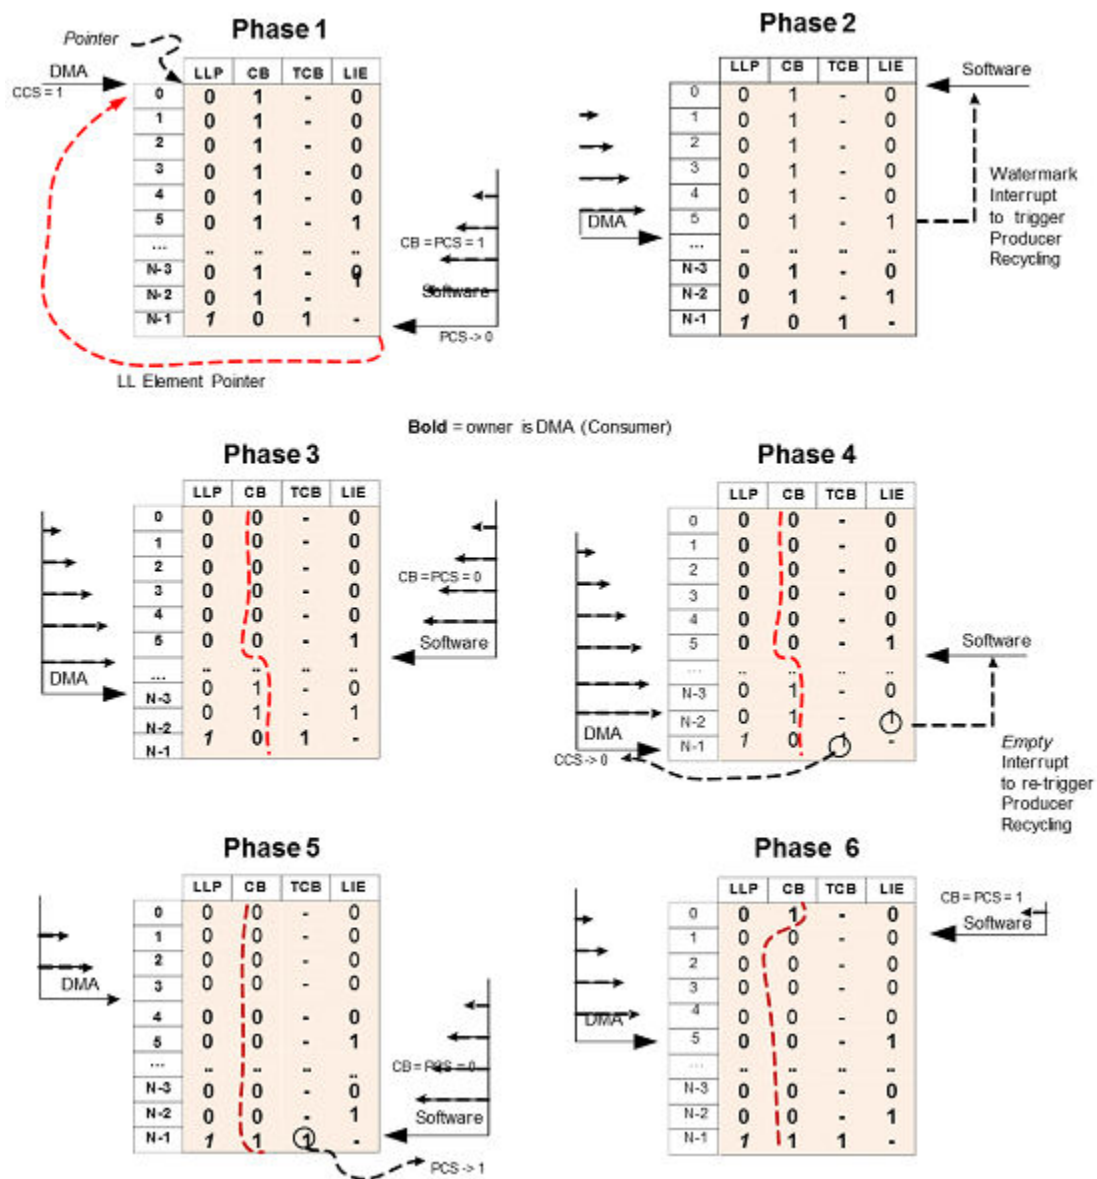

Operational interrupts are always "done" interrupts. For more details, see "Interrupts and Error Handling"

Note: The DMA processes the remote interrupt enable (RIE) bit in the LL element in the same way as the LIE. Therefore, everywhere that LIE and edma_int are mentioned in this section can be interpreted to mean LIE and edma_int, or RIE and IMWr.

11.3.5.4.8.3 PCS-CCS-CB-TCB Producer-Consumer Synchronization

The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism to ensure that software does not recycle elements that have not yet being consumed by the DMA, and that the DMA correctly recognizes and consumes recycled elements. This process, which is shared between the DMA and the software, is illustrated through an example producer-consumer flow in Figure 10-21.

Figure 10-21 Example Producer (Software) - Consumer (DMA) Synchronization Flow

Before looking at the example in detail, it is useful to note that the DMA performs the following two tests as part of this process:

■ Consumer-Owned Element, or Transfer List (TL) Empty Test

The solid red loop L4 in Figure 10-20 corresponds to this test. The Cycle Bit (CB) of DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) (which was loaded from the LL element) is tested against the DMA Consumer Cycle State (CCS) bit of the same register. When $CB = CCS$, the element is owned by the consumer (DMA) and the data transfer is executed. When $CB \neq CCS$, the TL is empty and the DMA sets channel Status (CS) in DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to "Stopped".

■ Toggle Cycle Bit (TCB) Test

The Dashed Red Loop Marked L5 in Figure 10-20 corresponds to this test. When the Toggle Cycle Bit (TCB) of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) (which was loaded from the LL element) is set to 1, the DMA toggles the CCS bit of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to be \sim CB. The producer (software) also performs a similar action on its local variable "Producer Cycle Status" (PCS), as it sets $PCS = \sim PCS$. The TCB field is only valid in the last LL element (the link element). Toggling the PCS and CCS flags in this manner synchronizes the consumer to the producer.

The example in Figure 10-21 has the following six phases:

1. The software builds the transfer list for the write (or read) channel, according to the steps outlined in the circled step C in Figure 10-20. For each element, $CB = PCS = CCS = 1$. The exception to this is the link element where CB is set to the next iteration value because the link element is always loaded into the channel context.
 - The link element points to the start of the TL and its TCB bit is 1. Software toggles its PCS variable.
 - Software writes the location of the TL into the channel context LL Pointer register.
 - Software rings the write channel Doorbell.
2. The DMA starts processing elements. After processing element 5 (and fetching the next element), the DMA asserts a Watermark “done” interrupt to signal the software to start recycling elements.
3. The software is recycling elements. It reads the channel context DMA Linked List Pointer Low Register (DMA_LL_P_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LL_P_HIGH_OFF_WRCH_0), and recycles elements up to this location in the TL. It sets CB for each element to be PCS. The Dashed Purple Loop Marked L3 in Figure 10-20 corresponds to this activity.

The DMA continues processing (consuming) elements as before.
4. The DMA then asserts an Empty “done” interrupt (from the LIE bit in the last data element at the end of TL that was set in the previous phase) to indicate to the software, to start recycling elements again. The DMA reaches the end of the TL, and as the TCB is set to 1, it toggles its CCS bit to 0 (\sim CB). For more details, see circled step D in Figure 10-20.
5. The software reads the channel context DMA Linked List Pointer Low Register (DMA_LL_P_LOW_REG

`_WRCH_0`) and DMA Linked List Pointer High Register (`DMA_LL_P_HIGH_OFF_WRCH_0`), and recycles elements up to this location in the TL. It sets CB for each element to be PCS. As it recycles the link element, it detects that TCB is set to 1. It toggles its internal variable PCS to 0, and the initial TL has been fully recycled.

The DMA starts processing the recycled elements.

6. The DMA continues processing (consuming) elements as before. Software did not have to ring the Doorbell, as the first element was already recycled before the DMA started processing it.

The software might continue recycling from the top of the list, if the DMA had already returned to the top of the list when the software read the channel context DMA Linked List Pointer Low Register (`DMA_LL_P_LOW_OFF_WRCH_0`) and DMA Linked List Pointer High Register (`DMA_LL_P_HIGH_OFF_WRCH_0`), in step 5. If not, it starts recycling again when the DMA processes element 4 and the DMA asserts a Watermark “done” interrupt.

11.3.5.4.8.4 Element Recycling

When your software is recycling elements, it should program the first DWORD (control bits) in Figure 10-6 only after the other DWORDs have been programmed. In addition, it should set the CB bit (to \sim PCS) within this DWORD only after the other bits in this DWORD have been set. This programming sequence avoids the DMA incorrectly fetching an element that software is currently recycling.

When the software is finished recycling it must check the channel context status (CS). When CS is "Stopped", the software must ring the channel Doorbell again. For more details, see circled step E in Figure 10-20. If your element recycling process was fast enough, then the DMA will seamlessly move from processing the last old element to the first new element, without the need for the software to ring the channel Doorbell again. To eliminate the possibility of a race condition between these two actions (read and write), you should first confirm the presence of the "done" interrupt bit in the DMA Write Interrupt Status Register (`DMA_WRITE_INT_STATUS_OFF`) or DMA Read Interrupt Status Register (`DMA_READ_INT_STATUS_OFF`) and also check the DMA Linked List Pointer Low Register (`DMA_LL_P_LOW_REG_WRCH_0`) to confirm that it is pointing to the correct location.

11.3.5.4.8.5 Link Down Recovery

During normal operation when the link goes down, the controller generates a "link reset" request. A

high-to-low transition on `link_req_rst_not` indicates that the PCIe controller is requesting external logic to reset the PCIe controller because the PHY link is down. For more details, see "Hot Reset". To determine the progress of the linked list operation when the link went down, you can read the contents of the channel context DMA Linked List Pointer Low Register (`DMA_LL_P_LOW_OFF_WRCH_0`) and DMA Linked List Pointer High Register (`DMA_LL_P_HIGH_OFF_WRCH_0`).

11.3.5.4.9 Multichannel Arbitration

You can configure the DMA to have one to eight read channels and one to eight write channels using the `CC_NUM_DMA_WR_CHAN` and `CC_NUM_DMA_RD_CHAN` configuration parameters. A DMA write and read channel operate independently in full duplex mode. This maximizes the performance of the DMA read and write data transfers over the PCIe link. When you configure the DMA with multiple read channels, then it uses a weighted round robin (WRR) arbitration scheme to select the next read channel to be serviced. The same applies when you have multiple write channels. The DMA handles the multiple channels in a time-multiplexed way. From a software point of view every channel operates independently, so each one has its own instance of linked list and context. The bandwidth for all channels is shared in time and is controlled by a weighted round-robin arbiter.

You can set the arbitration weight for each channel using the `DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF`, `DMA_WRITE_CHANNEL_ARB_WEIGHT_HIGH_OFF`, `DMA_READ_CHANNEL_ARB_WEIGHT_LOW_REG`, and `DMA_READ_CHANNEL_ARB_WEIGHT_HIGH_OFF` registers. Each register has a 5-bit field (representing a weight from 1 to 32) for up to four channels. You must set the weights before "ringing" the doorbell.

The channel weight specifies the number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached, the WRR arbiter selects the next channel to be processed. For example, consider two DMA write channels (write channel #0 and write channel #1) where you want to assign the bandwidth for write channel #1 to be two times that of write channel #0. Therefore set:

- write channel #0 weight to 32
- write channel #1 weight to 16

Depending on the transfer size and the `max_payload_size`, the DMA will issue 32 MRd requests for write channel #0, followed by 16 MRd requests for write channel #1, followed by 32 MRd requests for write channel #0 and so on, until the current transfer (or element when using LL mode) is finished. Therefore in this example, the weights reserve 33% bandwidth for write channel #1 and 67% bandwidth for write channel #0.

Note: `CX_REMOTE_MAX_TAG+1` constraints the maximum number of outstanding DMA write engine MRd requests to the application, so the sum of weights should not exceed this value. For the DMA read engine, the sum of all weights should not exceed `CC_NUM_DMA_RD_TAG`.

If these limits are exceeded, then the respective DMA engine requester thread is back-pressed, defeating purpose of the round-robin bandwidth sharing mechanism.

When the ratio (`transfer-size / TLP-size`) is smaller than the round-robin arbiter setting (say, `DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF`), the DMA issues less requests than the value in `DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF`. The TLP size is determined by the DMA using each function's `Max_Payload_Size` and `Max_Read_Request_Size` rules. This means that the arbitration value in `DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF` determines the number of TLPs sent and not the absolute data bandwidth.

11.3.5.4.9.1 Request, Response, and Descriptor-Fetch Threading In LL Mode For A Read Channel

For each read channel there are two threads (1) the request thread and (2) the response thread which are running in opposite directions. The DMA processes these threads independently. The request thread does not wait for the individual responses to arrive before issuing the next request. The request thread for the current channel *i* continues to issue requests until one of the following is true:

- The DMA exhausts its pool of available tags and the logic in the “Read Buffer” back-presses the DMA read engine controller.
- The DMA completes its current DMA transfer block for the current channel. It has requested all of the data specified by the currently-loaded LL element.
- The current channel has issued W_i MRd requests, where W_i is the round robin weight associated with that channel.

A channel arbitration event now occurs and the DMA loads the context for the winning channel *j*. When the DMA is loading the new context, the response path for the previous channel *i* will be still utilizing the wire because the response thread lags the request thread. As soon as the DMA has loaded the context (and LL element if in LL mode) for

the current channel j , it starts to issue requests. Therefore, in multichannel operation, when the block for channel i completes and a new LL element is been fetched, the DMA can be issuing requests belonging to other DMA channels. The currently inactive requester thread for channel i needs to synchronize with the response thread (that is, wait for all completions) before fetching its next LL element from local memory.

11.3.6 M-PCIe

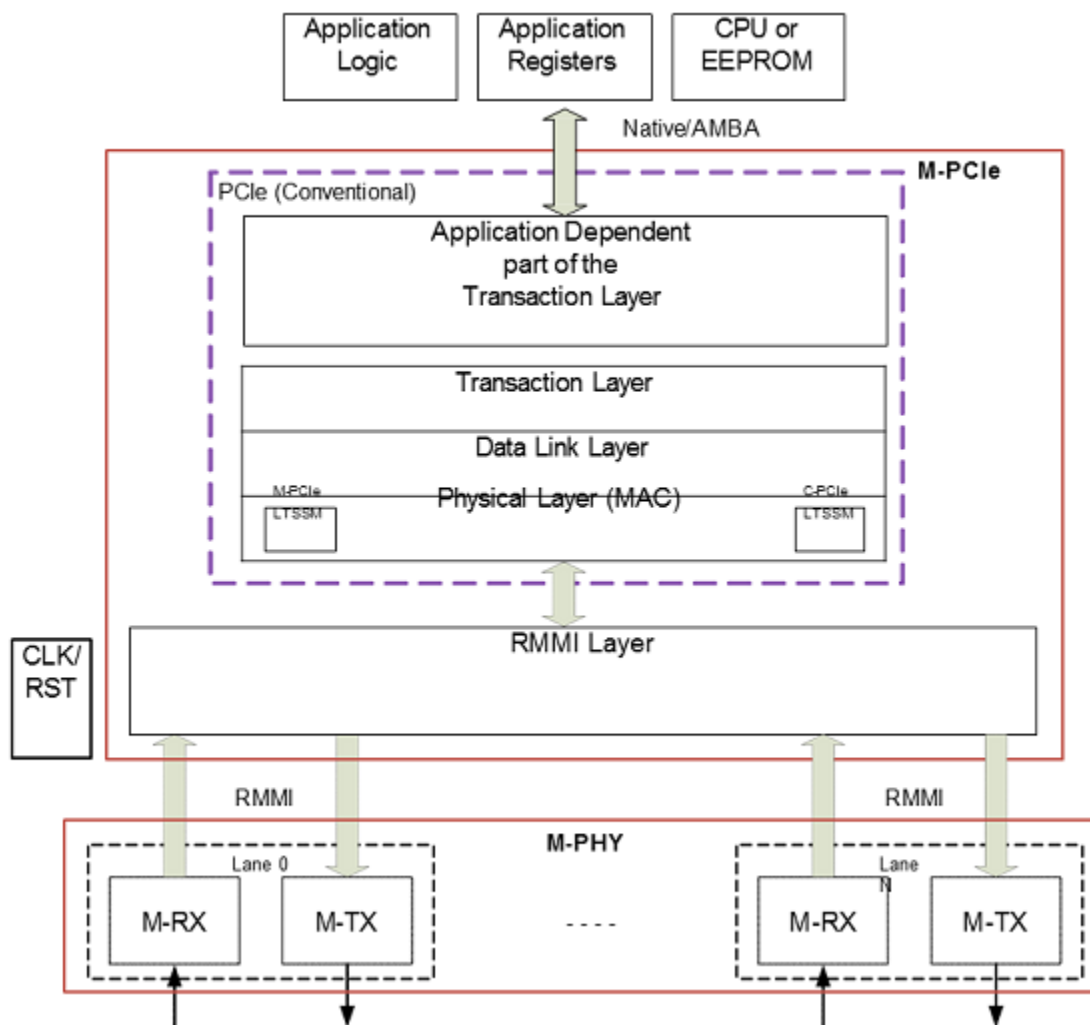

This section describes the optional M-PCIe feature.

11.3.6.1 Feature Description

The new M-PCIe specification enables the PCIe controller to operate over the low-power MIPI M-PHY physical layer technology, extending the benefits of PCIe to mobile devices including thin laptops, tablets and smartphones. The M-PCIe controller is compliant with the M-PCIe ECN1 specification. The interface between the controller and the PHY is compliant with the RMMI (Reference M-PHY MODULE Interface) specified in Annex A of the M-PHY Specification.

A complete M-PCIe port solution includes the controller, an analog PHY macro, and application logic to source and sink data. The physical layer is split across the RMMI such that the MAC functionality (LTSSM, lane-to-lane deskew) is in the controller and the PHY functionality is implemented in the RMMI-compliant PHY. The PHY module resides outside of the controller, interfacing through the standard RMMI. For more details, see Integrating with the PHY in the User Guide.

Figure 11-1 Complete M-PCIe Port Solution

11.3.6.1.2 Limitations

Table 11-2 identifies the temporary limitations when using the M-PCIe module.

Table 11-2 M-PCIe Limitations

Limitation	Note
Limited Analog Loopback Support	<p>Analog loopback requires the M-PHY to autonomously loop and re-transmit the Rx data. However, the RMMI specification does not define the entry mechanism for analog loopback.</p> <ul style="list-style-type: none"> If you are using the M-PHY (which has no input to accept the cores pa_rx_analog_loopback output), the analog loopback path must

Table continues on the next page...

PCI Express Controller (PCIe)

	<p>pass through the controller involving the elastic buffer. The Tx lanes in the controller use the Tx (and not the Rx) clock. The elastic buffer cannot operate indefinitely under this condition. If there is a frequency difference between the Rx and Tx clocks, there will be some data overflow or underflow.</p> <ul style="list-style-type: none"> • If you are using a third party M-PHY, the M-PHY enters analog loop-back mode when the controller asserts <code>pa_rx_analog_loopback</code>. If the M-PHY does not support such an input, you can instruct the M-PCIe controller to do loopback from Rx to Tx through the elastic buffer.
Verilog Testbench (VTB) VIP not Included	M-PCIe configurations currently have no M-PCIe VIP and connect instead to an RTL DUT of the opposite port type.
No Midstream De-assertion of TX_PhyDIRDY	The controller does not support midstream de-assertion of <code>phy_mac_tx_phydirty</code> during burst mode. This is not an M-PCIe or RMMI requirement. However, the <code>tx_symbolclk</code> is derived from the same clock that the M-PHY TX path uses, and there is no reason for the M-PHY to insert wait cycles.
Midstream De-assertion of RX_PhyDORDY	<p>The <code>rx_symbolclk</code> is the recovered clock and there is no elastic buffer in the M-PHY. Therefore, there is no reason for the M-PHY to insert</p> <p>de-assertion of <code>mac_phy_rx_phydordy</code> during burst mode. If your M-PHY de-asserts <code>mac_phy_rx_phydordy</code> during burst mode, there is a risk of underflowing the elastic buffer in the controller.</p>
TLP in 2K+ PPM System with Payload Greater than 2 KB not Supported.	The controller can handle a clock difference of 2K PPM only. When clock compensation greater than 2K PPM is required, the elastic buffer overflows or underflows on receiving a TLP with payload greater than 2 KB.
M-PHY RX Registers Cannot be set when LTSSM Exits L1 or L2.	<p>The controller cannot set M-PHY RX registers when:</p> <ul style="list-style-type: none"> • LTSSM exits L1 in a downstream or upstream port • LTSSM exits L2 in a downstream port.

11.3.6.1.3 Frequency, Speed, and Width Support

To set the M-PCIe frequency, datapath width, and speed modes of the controller, use the following configuration parameters in the coreConsultant GUI:

- Controller Base Frequency (CM_FREQ)
- PHY Base Frequency (CM_PHY_FREQ)
- Controller Gear2 and Gear3 Modes (CM_GEAR2_MODE and CM_GEAR3_MODE)
- PHY Gear2 and Gear3 Modes (CM_PHY_GEAR2_MODE and CM_PHY_GEAR3_MODE)
- Maximum Tx and Rx Link Width (CM_TXNL_GUI and CM_RXNL_GUI)
- $CX_NL = \max \{CM_TXNL_GUI, CM_RXNL_GUI\}$
- $CX_NB = (CM_FREQ == 124.8) ? 1 : (CM_FREQ == 62.4) ? 2 : 4$
- CM_FREQ_STEP_DOWN_EN. This is the enable for the “Frequency Step Module”

11.3.6.1.4 Gear2/Gear3 Modes

For Dynamic Frequency (DF) configurations, the number of active symbols on the RMMI is constant; the frequency of the controller doubles each time as the controller transitions from Gear1 -> Gear2 -> Gear3 rates. For Dynamic Width (DW) configurations, the frequency of the controller is constant; the number of active symbols on the RMMI doubles each time as the controller transitions from Gear1 -> Gear2 -> Gear3 rates. The controller cannot have different Gear2 and Gear3 modes. For example, you cannot configure the controller for Dynamic Width in Gear2 mode, and at the same time configure it for Dynamic Frequency in Gear3 mode. For more details, see Figure 11-3.

Figure 11-3 Gear2/Gear3 Speed Changing Paths

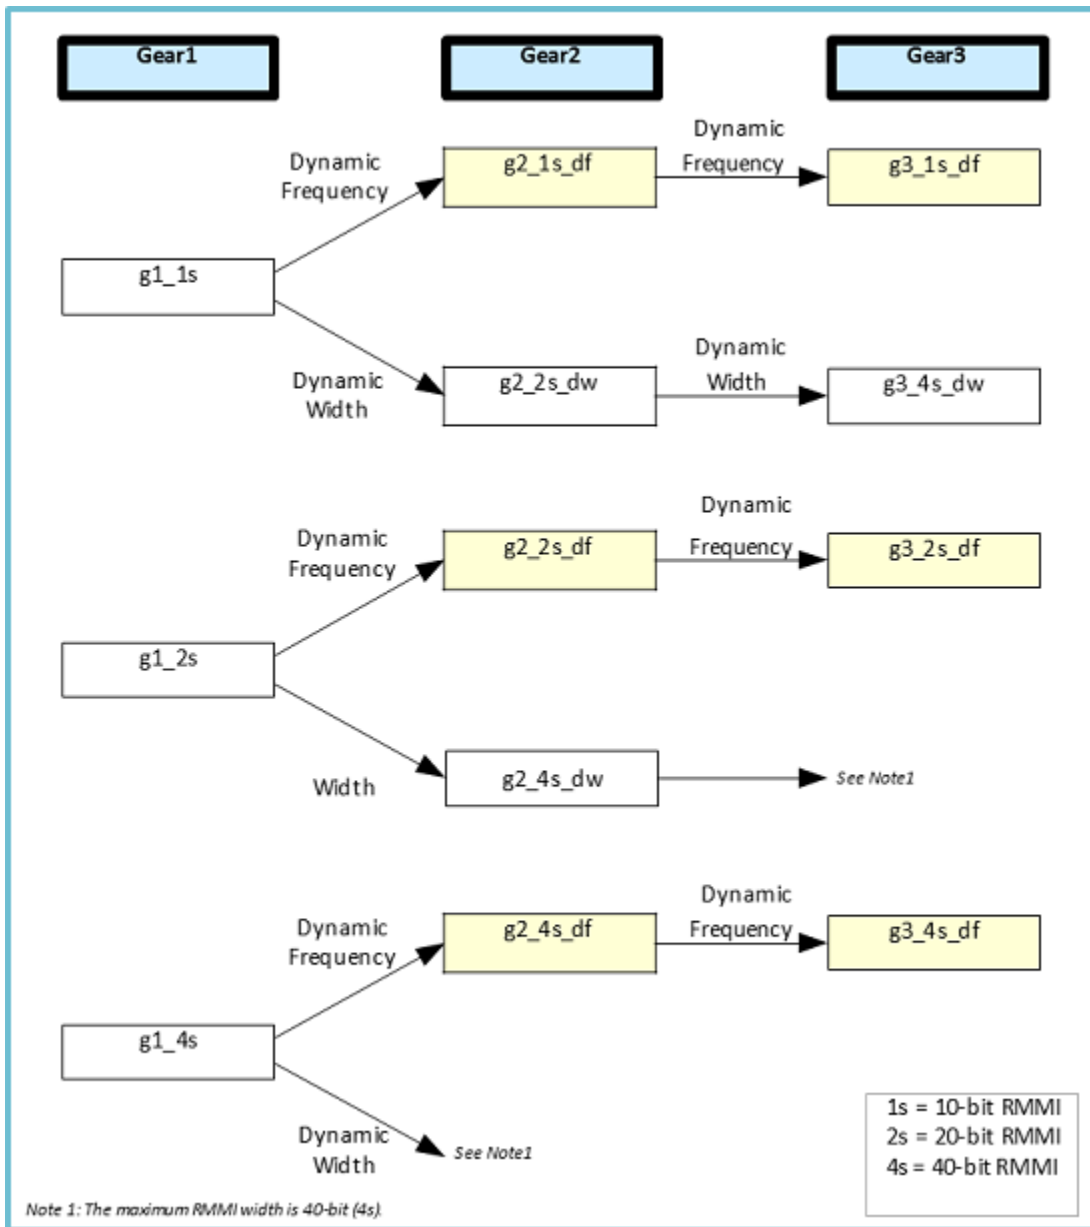

Table 11-3 Supported Controller Configurations in Standard M-PCIe Mode

Gear1 RATE A Frequen cyb (CM_FR EQ)	Gear2 Mode	Gear3 Mode	RMMI Widthc	Maxa Link Width				Maximu m core_clk Frequen cy (x CM_FRE Q)	Gear1 Speed Modee	Gear2 Speed Mode	Gear3 Speed Mode

Table continues on the next page...

31.2			40-bit	x1	x2	x4	x8	x1	g1_4s		
124.8	DW	Disable	20-bit	x2	x4	x8	x16	x1	g1_1s	g2_2s_d w	
62.4	DW		40-bit	x1	x2	x4	x8	x1	g1_2s	g2_4s_d w	
124.8	DF		10-bit	x4	x8	x16	-	x2	g1_1s	g2_1s_df	
62.4	DF		20-bit	x2	x4	x8	x16	x2	g1_2s	g2_2s_df	
31.2	DF		40-bit	x1	x2	x4	x8	x2	g1_4s	g2_4s_df	
124.8	DW	DW	40-bit	x1	x2	x4	x8	x1	g1_1s	g2_2s_d w	g3_4s_d w
124.8	DF	DF	10-bit	x4	x8	x16	-	x4	g1_1s	g2_1s_df	g3_1s_df
62.4	DF	DF	20-bit	x2	x4	x8	x16	x4	g1_2s	g2_2s_df	g3_2s_df
31.2	DF	DF	40-bit	x1	x2	x4	x8	x4	g1_4s	g2_4s_df	g3_4s_df

a. The value in each cell indicates the maximum link width supported. You can configure the controller with a link width up to this value, and coreConsultant automatically calculates the datapath width.

b. Corresponding RATE B frequencies are 145.76, 72.88, and 36.44 MHz.

c. The actual physical RMMI interface I/O width is 10*CM_NB bits per lane. The coreConsultant tool automatically calculates this width from CM_GEAR2_MODE, CM_GEAR3_MODE, and CM_FREQ. In a DW configuration, the number of active bits in the RMMI interface increases as the controller transitions to a higher Gear speed.

d. A 64-bit datapath requires a 32-bit/64-bit license. You cannot create a 32-bit or 64-bit configuration with a 128-bit/256-bit license

e. The ‘g’ value indicates the speed mode. The ‘s’ value indicates the number of 10-bit symbols processed per clock cycle per lane by the controller RMMI I/F, in the indicated speed mode. The ‘dw/df’ value indicates how the speed change to that mode is achieved

11.3.6.1.5 Controller PHY Compatibility

The following tables indicate which combinations of controller configurations from Table 11-3 and PHYs are supported. In Table 11-4, the triplet of values for each row indicates how the controller moves from Gear1 to Gear2 speed mode and from Gear2 to Gear3 speed mode. The triplet of values also identifies the particular controller configuration in Table 11-3. The controller always uses the same mechanism (DF or DW) to go from Gear1 to Gear2 and from Gear2 to Gear3.

11.3.6.1.6 Frequency Step Module

When the controller RMMI lane width (CM_NB) and M-PHY RMMI lane width (CM_PHY_NB) are different, or when the controller and the PHY have different Gear2 speed changing modes, the automatically-derived CM_FREQ_STEP_DOWN_EN parameter is defined, and a RMMI adapter module1 is added between the controller RMMI and the PHY RMMI.

Figure 11-4 Location of freq_step RMMI Adapter Module

This module steps up/down the signals to/from the RMMI interface and adapts (x2,x4, x0.5, x0.25) the controller RMMI width to the PHY RMMI width when the controller clock frequency is slower or faster than the RMMI clock frequency.

11.3.7 Memory Map and register definition

This section includes the PCIe module memory map and detailed descriptions of all registers.

11.3.7.1 register descriptions

11.3.7.1.2 Device ID and Vendor ID Register. (TYPE1_DEV_ID_VEND_ID_REG)

11.3.7.1.2.1 Offset

Register	Offset
TYPE1_DEV_ID_VEND_ID_REG	0h

11.3.7.1.2.2 Diagram

11.3.7.1.2.3 Fields

Field	Function
31-16 DEVICE_ID	Device ID. The Device ID register identifies the particular Function. This identifier is allocated by the vendor. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 VENDOR_ID	Vendor ID. The Vendor ID register identifies the manufacturer of the Function. Valid vendor identifiers are allocated by the PCI-SIG to ensure uniqueness. It is not permitted to populate this register with a value of FFFFh, which is an invalid value for Vendor ID. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.7.1.3 Status and Command Register. (TYPE1_STATUS_COMMAND_REG)

11.3.7.1.3.1 Offset

Register	Offset
TYPE1_STATUS_COM MAND_REG	4h

11.3.7.1.3.2 Diagram

11.3.7.1.3.3 Fields

Field	Function
31 DETECTED_PARITY_ERROR	Detected Parity Error. This bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register. The bit is set when the Poisoned TLP is received by a Function's primary side.
30 SIGNALED_SY S_ERROR	Signaled System Error. This bit is set when a Function sends an ERR_FATAL or ERR_NONFATAL Message, and the SERR# Enable bit in the Command register is 1b.
29 RCVD_MASTE R_ABORT	Received Master Abort. This bit is set when a Requester receives a Completion with Unsupported Request Completion status. The bit is set when the Unsupported Request is received by a Function's primary side.

Table continues on the next page...

Field	Function
28 RCVD_TARGET_ABORT	Received Target Abort. This bit is set when a Requester receives a Completion with Completer Abort Completion status. The bit is set when the Completer Abort is received by a Function's primary side.
27 SIGNALLED_TARGET_ABORT	Signaled Target Abort. This bit is set when a Function completes a Posted or Non-Posted Request as a Completer Abort error. This applies to a Function when the Completer Abort was generated by its primary side.
26-25 DEV_SEL_TIMING	DEVSEL Timing. This field was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires it to 00b.
24 MASTER_DPE	Master Data Parity Error. This bit is set by a Function if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: - Port receives a Poisoned Completion going downstream - Port transmits a Poisoned Request upstream If the Parity Error Response bit is 0b, this bit is never set.
23 FAST_B2B_CAP	Fast Back-to-Back Transactions Capable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
22 RSVDP_22	Reserved for future use.
21 FAST_66MHZ_CAP	66 MHz Capable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
20 CAP_LIST	Capabilities List. Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, the controller hardwires this bit to 1b.
19 INT_STATUS	Interrupt Status. When set, indicates that an INTx emulation interrupt is pending internally in the Function. INTx emulation interrupts forwarded by Functions from the secondary side are not reflected in this bit. Setting the Interrupt Disable bit has no effect on the state of this bit. For Functions that do not generate INTx interrupts, the controller hardwires this bit to 0b.
18-17 RSVDP_17	Reserved for future use.
16 —	Reserved.
15-11 RESERV	Reserved.
10 INT_EN	Interrupt Disable. Controls the ability of a Function to generate INTx emulation interrupts. When set, Functions are prevented from asserting INTx interrupts. Note: - Any INTx emulation interrupts already asserted by the Function must be deasserted when this bit is set. INTx interrupts use virtual wires that must, if asserted, be deasserted using the appropriate Deassert_INTx message(s) when this bit is set. - Only the INTx virtual wire interrupt(s) associated with the Function(s) for which this bit is set are affected. - For Functions that generate INTx interrupts on their own behalf, this bit is required. This bit has no effect on interrupts forwarded from the secondary side. For Functions that do not generate INTx interrupts on their own behalf this bit is optional. If this bit is not implemented, the controller hardwires it to 0b.
9 RSVDP_9	Reserved for future use.
8 SERREN	SERR# Enable. When set, this bit enables reporting upstream of Non-fatal and Fatal errors detected by the Function. Note: The errors are reported if enabled either through this bit or through the PCI Express

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	specific bits in the Device Control register. For more details see the "Error Registers" section of the PCI Express Specification. In addition, this bit controls transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error Messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages.
7 IDSEL	IDSEL Stepping/Wait Cycle Control. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
6 PERREN	Parity Error Response. This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Status register. For more details see the "Error Registers" section of the PCI Express Specification.
5 VGAPS	VGA Palette Snoop. This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
4 MWI_EN	Memory Write and Invalidate. This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. For PCI Express to PCI/PCI-X Bridges, refer to the PCI Express to PCI/PCI-X Bridge Specification for requirements for this register.
3 SCO	Special Cycle Enable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
2 BME	Bus Master Enable. This bit controls forwarding of Memory or I/O requests by a port in the Upstream direction. When this bit is 0b, Memory and I/O Requests received at a Root Port must be handled as Unsupported Requests (UR) For Non-Posted Requests a Completion with UR completion status must be returned. This bit does not affect forwarding of Completions in either the Upstream or Downstream direction. The forwarding of Requests other than Memory or I/O Requests is not controlled by this bit.
1 MSE	Memory Space Enable. This bit controls a Function's response to Memory Space accesses received on its primary side. - When set, the Function is enabled to decode the address and further process Memory Space accesses. - When clear, all received Memory Space accesses are caused to be handled as Unsupported Requests. You cannot write to this register if your configuration has no MEM bars; that is, the internal signal has_mem_bar =0. Note: The access attributes of this field are as follows: - Dbi: !has_mem_bar ? RO : RW
0 IO_EN	IO Space Enable. This bit controls a Function's response to I/O Space accesses received on its primary side. - When set, the Function is enabled to decode the address and further process I/O Space accesses. - When clear, all received I/O accesses are caused to be handled as Unsupported Requests. You cannot write to this register if your configuration has no IO bars; that is, the internal signal has_io_bar =0. Note: The access attributes of this field are as follows: - Dbi: !has_io_bar ? RO : RW

11.3.7.1.4 Class Code and Revision ID Register. (TYPE1_CLASS_CODE_REV_ID_REG)

11.3.7.1.4.1 Offset

Register	Offset
TYPE1_CLASS_CODE_REV_ID_REG	8h

11.3.7.1.4.2 Diagram

11.3.7.1.4.3 Fields

Field	Function
31-24 BASE_CLASS_CODE	Base Class Code. A code that broadly classifies the type of operation the Function performs. Encodings for base class, are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
23-16 SUBCLASS_CODE	Sub-Class Code. Specifies a base class sub-class, which identifies more specifically the operation of the Function. Encodings for sub-class are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-8 PROGRAM_INTERFACE	Programming Interface. This field identifies a specific register level programming interface (if any) so that device independent software can interact with the Function. Encodings for interface are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
7-0 REVISION_ID	Revision ID. The value of this field specifies a Function specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. The Revision ID should be viewed as a vendor defined extension to the Device ID. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.7.1.5 BIST, Header Type, Latency Timer, and Cache Line Size Register. (TYPE1_BIST_HDR_TYPE_LAT_CACHE_LINE_SIZE_REG)

11.3.7.1.5.1 Offset

Register	Offset
TYPE1_BIST_HDR_TYPE_LAT_CACHE_LINE_SIZE_REG	Ch

11.3.7.1.5.2 Diagram

11.3.7.1.5.3 Fields

Field	Function
31-24 BIST	BIST. This register is used for control and status of BIST. Functions that do not support BIST must hardwire the register to 00h. A Function whose BIST is invoked must not prevent normal operation of the PCI Express Link. Bit descriptions: - [31]: BIST Capable. When set, this bit indicates that the Function supports BIST. When Clear, the Function does not support BIST. - [30]: Start BIST. If BIST Capable is set, set this bit to invoke BIST. The Function resets the bit when BIST is complete. Software is permitted to fail the device if this bit is not Clear (BIST is not complete) 2 seconds after it had been set. Writing this bit to 0b has no effect. The controller hardwires this bit to 0b if BIST Capable is clear. - [29:28]: Reserved. - [27:24]: Completion Code. This field encodes the status of the most recent test. A value of 0000b means that the Function has passed its test. Non-zero values mean the Function failed. Function-specific failure codes can be encoded in the non-zero values. This field's value is only meaningful when BIST Capable is set and Start BIST is Clear. This field must be hardwired to 0000b if BIST Capable is clear.
23 MULTI_FUNC	Multi-Function Device. - When set, indicates that the device may contain multiple Functions, but not necessarily. Software is permitted to probe for Functions other than Function 0. - When clear, software must not probe for Functions other than Function 0 unless explicitly indicated by another mechanism, such as an ARI or SR-IOV Capability structure. Except where stated otherwise, it is recommended that this bit be set if there are multiple Functions, and clear if there is only one Function. Note: This register field is sticky.
22-16 HEADER_TYPE	Header Layout. This field identifies the layout of the second part of the predefined header. The controller uses 000 0001b encoding. The encoding 000 0010b is reserved. This encoding was originally described in the PC Card Standard Electrical Specification and is used in previous versions of the programming model. Careful consideration should be given to any attempt to repurpose it.
15-8 LATENCY_MASTER_TIMER	Latency Timer. This register is also referred to as Primary Latency Timer. The Latency Timer was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this register to 00h.
7-0 CACHE_LINE_SIZE	Cache Line Size. The Cache Line Size register is programmed by the system firmware or the operating system to system cache line size. However, legacy conventional PCI software may not always be able to program this register correctly especially in the case of Hot-Plug devices. This read-write register is implemented for legacy compatibility purposes but has no effect on any PCI Express device behavior.

11.3.7.1.6 Secondary Latency Timer, Subordinate Bus Number, Secondary Bus Number, and Primary Bus Number Register. (SEC_LAT_TIMER_SUB_BUS_SEC_BUS_PRI_BUS_REG)

11.3.7.1.6.1 Offset

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.3.7.1.6.3 Fields

Field	Function
31-24 SEC_LAT_TIMER	Secondary Latency Timer. This register does not apply to PCI Express. The controller hardwires it to 00h.
23-16 SUB_BUS	Subordinate Bus Number. The Subordinate Bus Number register is used to record the bus number of the highest numbered PCI bus segment which is behind (or subordinate to) the bridge. Configuration software programs the value in this register. The bridge uses this register in conjunction with the Secondary Bus Number register to determine when to respond to and pass on a Type 1 configuration transaction on the primary interface to the secondary interface.
15-8 SEC_BUS	Secondary Bus Number. The Secondary Bus Number register is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this register. The bridge uses this register to determine when to respond to and convert a Type 1 configuration transaction on the primary interface into a Type 0 transaction on the secondary interface.
7-0 PRIM_BUS	Primary Bus Number. This register is not used by PCI Express Functions. It is implemented for compatibility with legacy software.

11.3.7.1.7 Secondary Status, and I/O Limit and Base Register. (SEC_STAT_IO_LIMIT_IO_BASE_REG)

11.3.7.1.7.1 Offset

Register	Offset
SEC_STAT_IO_LIMIT_IO_BASE_REG	1Ch

11.3.7.1.7.2 Function

Secondary Status, and I/O Limit and Base Register. The I/O Limit and I/O Base registers are optional and define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other. If a bridge does not implement an I/O address range, then both the I/O Limit and I/O Base registers must be implemented as read-only registers that return zero when read. If a bridge supports an I/O address range, then these registers must be initialized by configuration software so default states are not specified.

11.3.7.1.7.3 Diagram

11.3.7.1.7.4 Fields

Field	Function
31 SEC_STAT_DP E	Detected Parity Error. This bit is set by a Function when a Poisoned TLP is received by its secondary side, regardless of the state the Parity Error Response Enable bit in the Bridge Control register.
30 SEC_STAT_RC VD_SYS_ERR	Received System Error. This bit is set when the secondary side of a Function receives an ERR_FATAL or ERR_NONFATAL message.
29 SEC_STAT_RC VD_MSTR_ABR T	Received Master Abort. This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Unsupported Request Completion status.
28 SEC_STAT_RC VD_TRGT_ABR T	Received Target Abort. This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Completer Abort Completion status.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
27 SEC_STAT_SIG_TRGT_ABRT	Signaled Target Abort. This bit is set when the secondary side of the Function (for Requests completed by the Type 1 header Function itself) completes a Posted or Non-Posted request as a Completer Abort error.
26-25 RSVDP_25	Reserved for future use.
24 SEC_STAT_MDPE	Master Data Parity Error. This bit is set by a Function if the Parity Error Response Enable bit in the Bridge Control register is set, and either of the following two conditions occurs: - Port receives a Poisoned Completion coming Upstream - Port transmits a Poisoned Request Downstream If the Parity Error Response Enable bit is clear, this bit is never set.
23 RSVDP_23	Reserved for future use.
22-16 SEC_STAT_RESERV	Reserved.
15-12 IO_LIMIT	I/O Limit Address. These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O limit address (not implemented in the I/O Limit register) are FFFh. The I/O Limit register can be programmed to a smaller value than the I/O Base register, if there are no I/O addresses on the secondary side of the bridge. In this case, the bridge will not forward any I/O transactions from the primary bus to the secondary and will forward all I/O transactions from the secondary bus to the primary bus.
11-9 IO_RESERV1	Reserved.
8 IO_DECODE_BIT8	I/O Addressing Encode (IO Limit Address). This bit encodes the IO addressing capability of the bridge. IO_DECODE_BIT8 indicates the following: - 0h: The bridge supports only 16-bit I/O addressing (for ISA compatibility). For the purpose of address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O limit address (not implemented in I/O Limit register) are zero. Note: The bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be restricted to the first 64 KB of I/O Space (0000 0000h to 0000 FFFFh). - 01h: The bridge supports 32-bit I/O address decoding, and the I/O Limit Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Limit address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge anywhere in the 4-GB I/O Space. Note: The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing. Note: The access attributes of this field are as follows: - Dbi: R
7-4 IO_BASE	I/O Base Address. These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O base address (not implemented in the I/O Base register) are zero.
3-1 IO_RESERV	Reserved.
0 IO_DECODE	I/O Addressing Encode (IO Base Address) This bit encodes the IO addressing capability of the bridge. IO_DECODE indicates the following: - 0h: The bridge supports only 16-bit I/O addressing (for ISA compatibility). For the purpose of address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O base address (not implemented in I/O base register) are zero. Note: The bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be restricted to the first 64 KB of I/O Space (0000 0000h to 0000 FFFFh). - 01h: The bridge supports 32-bit I/O address decoding, and the I/O Base Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Base address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge anywhere in the 4-GB I/O Space. Note: The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.3.7.1.8 Memory Limit and Base Register. (MEM_LIMIT_MEM_BASE_REG)

11.3.7.1.8.1 Offset

Register	Offset
MEM_LIMIT_MEM_BASE_REG	20h

11.3.7.1.8.2 Function

Memory Limit and Base Register. The Memory Limit and Memory Base registers define a memory mapped address range which is used by the bridge to determine when to forward memory transactions from one interface to the other. If there is no prefetchable memory space, and there is no memory-mapped space on the secondary side of the bridge, then the bridge will not forward any memory transactions from the primary bus to the secondary bus and will forward all memory transactions from the secondary bus to the primary bus.

11.3.7.1.8.3 Diagram

11.3.7.1.8.4 Fields

Field	Function
31-20 MEM_LIMIT	Memory Limit Address. These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory limit address (not implemented in the Memory Limit register) are F FFFFh. The Memory Limit register must be programmed to a smaller value than the Memory Base register if there is no memory-mapped address space on the secondary side of the bridge.
19-16 MEM_LIMIT_RE SERV	Reserved.
15-4 MEM_BASE	Memory Base Address. These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory base address (not implemented in the Memory Base register) are zero.
3-0 MEM_BASE_R ESERV	Reserved.

11.3.7.1.9 Prefetchable Memory Limit and Base Register. (PREF_MEM_LIMIT_PREF_MEM_BASE_REG)

11.3.7.1.9.1 Offset

Register	Offset
PREF_MEM_LIMIT_P REF_MEM_BASE_REG	24h

11.3.7.1.9.2 Function

Prefetchable Memory Limit and Base Register. The Prefetchable Memory Limit and Prefetchable Memory Base registers must indicate that 64-bit addresses are supported, as defined in PCI-to-PCI Bridge Architecture Specification. The Prefetchable Memory Limit and Prefetchable Memory Base registers are optional. They define a prefetchable memory address range which is used by the bridge to determine when to forward memory transactions from one interface to the other (see the PCI-to-PCI Bridge Architecture Specification for additional details).

11.3.7.1.9.3 Diagram

11.3.7.1.9.4 Fields

Field	Function
31-20 PREF_MEM_LIMIT	Prefetchable Memory Limit Address. If the Prefetchable Memory Limit register indicates support for 32-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read-only register that returns zero when read. If the Prefetchable Memory Limit registers indicate support for 64-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read/write register which must be initialized by configuration software. If a 64-bit prefetchable memory address range is supported, the Prefetchable Limit Upper 32 Bits register specifies the upper 32 bits, corresponding to Address[63:32], of the 64-bit limit addresses which specify the prefetchable memory address range.
19-17 PREF_RESERV 1	Reserved.
16 PREF_MEM_LIMIT_DECODE	Prefetchable Memory Limit Decode. This bit encodes whether or not the bridge supports 64-bit addresses. The value of PREF_MEM_LIMIT_DECODE indicates the following: - 0b: Indicates that the bridge supports only 32 bit addresses - 1b: Indicates that the bridge supports 64 bit addresses. Prefetchable Limit Upper 32 Bits registers holds the rest of the 64-bit prefetchable limit address.
15-4 PREF_MEM_BASE	Prefetchable Memory Base Address. If the Prefetchable Memory Base register indicates support for 32-bit addressing, then the Prefetchable Base Upper 32 Bits register is implemented as a read-only register that returns zero when read. If the Prefetchable Memory Base register indicates support for 64-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read/write register

Field	Function
31-8 RSVDP_8	Reserved for future use.
7-0 CAP_POINTER	Capabilities Pointer. This register is used to point to a linked list of capabilities implemented by this Function. Since all PCI Express Functions are required to implement the PCI Express Capability structure, this register must point to a valid capability structure and either this structure is the PCI Express Capability structure, or a subsequent list item points to the PCI Express Capability structure. The bottom

Field	Function
	two bits are Reserved and must be set to 00b. Software must mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.7.1.14 Expansion ROM Base Address Register. (TYPE1_EXP_ROM_BASE_REG)

11.3.7.1.14.1 Offset

Register	Offset
TYPE1_EXP_ROM_BASE_REG	38h

11.3.7.1.14.2 Function

Expansion ROM Base Address Register. This register is defined to handle the base address and size information for this expansion ROM. The mask for this ROM BAR exists (if implemented) as a shadow register at this address. The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the second register at this address.

11.3.7.1.14.3 Diagram

11.3.7.1.14.4 Fields

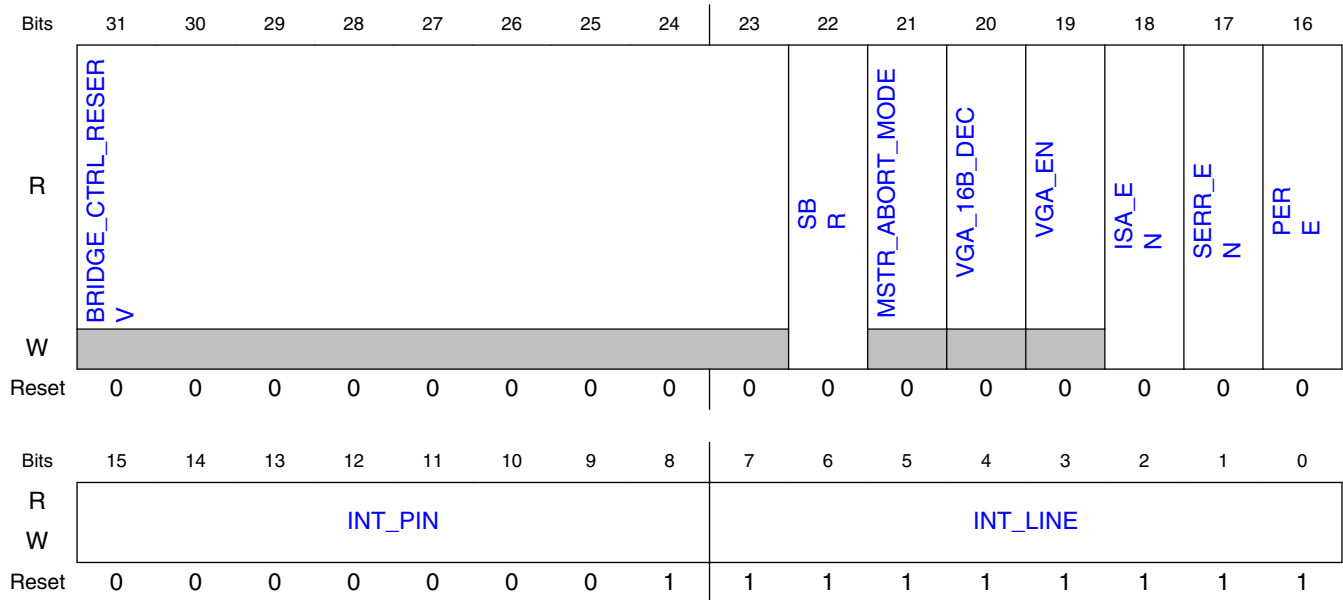

Field	Function
31-11 EXP_ROM_BASE_ADDRESS	Expansion ROM Base Address. Upper 21 bits of the Expansion ROM base address. The number of bits (out of these 21) that a Function actually implements depends on how much address space the Function requires. The mask for this ROM BAR exists (if implemented) as a shadow register at this address. The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the second register at this address. Note: The access attributes of this field are as follows: - Dbi: R/W
10-1 RSVDP_1	Reserved for future use.
0 ROM_BAR_ENABLE	Expansion ROM Enable. This bit controls whether or not the Function accepts accesses to its expansion ROM. When this bit is 0b, the Function's expansion ROM address space is disabled. When the bit is 1b, address decoding is enabled using the parameters in the other part of the Expansion ROM Base Address register. The Memory Space Enable bit in the Command register has precedence over the Expansion ROM Enable bit. A Function must claim accesses to its expansion ROM only if both the Memory Space Enable bit and the Expansion ROM Enable bit are set. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.15 Bridge Control, Interrupt Pin, and Interrupt Line Register. (BRIDGE_CTRL_INT_PIN_INT_LINE_REG)

11.3.7.1.15.1 Offset

Register	Offset
BRIDGE_CTRL_INT_PIN_INT_LINE_REG	3Ch

11.3.7.1.15.2 Diagram

11.3.7.1.15.3 Fields

Field	Function
31-23 BRIDGE_CTRL_RESERV	Reserved.
22 SBR	Secondary Bus Reset. Setting this bit triggers a hot reset on the corresponding PCI Express Port. Software must ensure a minimum reset duration (Trst) as defined in the PCI Local Bus Specification. Software and systems must honor first-access-following-reset timing requirements, unless the Readiness Notifications mechanism is used or if the Immediate Readiness bit in the relevant Function's Status Register register is set. Port configuration registers must not be changed, except as required to update Port status.
21 MSTR_ABORT_MODE	Master Abort Mode. This bit was originally described in the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R/W
20 VGA_16B_DEC	VGA 16 bit decode. This bit only has meaning if VGA Enable bit is set. This bit enables system configuration software to select between 10-bit and 16-bit I/O address decoding for all VGA I/O register accesses that are forwarded from primary to secondary. The following actions are taken based on the value of the VGA_16B_DEC bit: - 0b: Execute 10-bit address decodes on VGA I/O accesses - 1b: Execute 16-bit address decodes on VGA I/O accesses For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R
19 VGA_EN	VGA Enable. Modifies the response by the bridge to VGA compatible addresses. If the VGA Enable bit is set, the bridge will positively decode and forward the following accesses on the primary interface to the secondary interface (and, conversely, block the forwarding of these addresses from the secondary to primary interface): - Memory accesses in the range 000A 0000h to 000B FFFFh - I/O addresses in the first 64 KB of the I/O address space (Address[31:16] are 0000h) where Address[9:0] are in the ranges 3B0h to 3BBh and 3C0h to 3DFh (inclusive of ISA address aliases determined by the setting of VGA 16-bit Decode) If the VGA Enable bit is set, forwarding of these accesses is independent of the I/O address range and memory address ranges defined by the I/O Base and Limit registers, the Memory Base and

Table continues on the next page...

Field	Function
	Limit registers, and the Prefetchable Memory Base and Limit registers of the bridge. (Forwarding of these accesses is also independent of the setting of the ISA Enable bit (in the Bridge Control register) when the VGA Enable bit is set. Forwarding of these accesses is qualified by the I/O Space Enable and Memory Space Enable bits in the Command register.) The following actions are taken based on the value of the VGA_EN bit: - 0b: Do not forward VGA compatible memory and I/O addresses from the primary to the secondary interface (addresses defined above) unless they are enabled for forwarding by the defined I/O and memory address ranges - 1b: Forward VGA compatible memory and I/O addresses (addresses defined above) from the primary interface to the secondary interface (if the I/O Space Enable and Memory Space Enable bits are set) independent of the I/O and memory address ranges and independent of the ISA Enable bit For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R
18 ISA_EN	ISA Enable. Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of I/O address space (0000 0000h to 0000 FFFFh). If this bit is set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1-KB block. In the opposite direction (secondary to primary), I/O transactions will be forwarded if they address the last 768 bytes in each 1-KB block. The following actions are taken based on the value of the ISA_EN bit: - 0b: Forward downstream all I/O addresses in the address range defined by the I/O Base and I/O Limit registers - 1b: Forward upstream ISA I/O addresses in the address range defined by the I/O Base and I/O Limit registers that are in the first 64 KB of PCI I/O address space (top 768 bytes of each 1-KB block).
17 SERR_EN	SERR# Enable. This bit controls forwarding of ERR_COR, ERR_NONFATAL and ERR_FATAL from secondary to primary.
16 PERE	Parity Error Response Enable. This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Secondary Status register.
15-8 INT_PIN	Interrupt PIN. The Interrupt Pin register register that identifies the legacy interrupt Message(s) the Function uses. Valid values are: - 01h, 02h, 03h, and 04h: map to legacy interrupt Messages for INTA, INTB, INTC, and INTD respectively. - 00h: indicates that the Function uses no legacy interrupt Message(s). - 05h through FFh: Reserved. PCI Express defines one legacy interrupt Message for a single Function device and up to four legacy interrupt Messages for a multi-Function device. For a single Function device, only INTA may be used. Any Function on a multi-Function device can use any of the INTx Messages. If a device implements a single legacy interrupt Message, it must be INTA; if it implements two legacy interrupt Messages, they must be INTA and INTB; and so forth. For a multi-Function device, all Functions may use the same INTx Message or each may have its own (up to a maximum of four Functions) or any combination thereof. A single Function can never generate an interrupt request on more than one INTx Message. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 INT_LINE	Interrupt Line. The Interrupt Line register communicates interrupt line routing information. The register must be implemented by any Function that uses an interrupt pin. Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems.

MSI Capability ID, Next Pointer, Capability/Control Registers. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.18.3 Diagram

11.3.7.1.18.4 Fields

Field	Function
31-27 RSVDP_27	Reserved for future use.
26 PCI_MSI_EXT_DATA_EN	Extended Message Data Enable. For a description of this standard PCIe register, see the PCI-SIG ECN for Extended MSI Data, Feb 24, 2016, affecting PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: PCI_MSI_CAP_ID_NEXT_CTRL_REG.PCI_MSI_EXT_DATA_CAP ? RW : RO
25 PCI_MSI_EXT_DATA_CAP	Extended Message Data Capable. For a description of this standard PCIe register, see the PCI-SIG ECN for Extended MSI Data, Feb 24, 2016, affecting PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
24 PCI_PVM_SUPPORT	MSI Per Vector Masking Capable. For a description of this standard PCIe register field, see the PCI Express Specification.
23 PCI_MSI_64_BIT_ADDR_CAP	MSI 64-bit Address Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
22-20 PCI_MSI_MULTIPLE_MSG_EN	MSI Multiple Message Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
19-17	MSI Multiple Message Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

Table continues on the next page...

Field	Function
PCI_MSI_MULTIPLE_MSG_CAP	
16 PCI_MSI_ENABLE	MSI Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
15-8 PCI_MSI_CAP_NEXT_OFFSET	MSI Capability Next Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 PCI_MSI_CAP_ID	MSI Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.19 MSI Message Lower Address Register. (MSI_CAP_OFF_04H_REG)

11.3.7.1.19.1 Offset

Register	Offset
MSI_CAP_OFF_04H_REG	54h

11.3.7.1.19.2 Function

MSI Message Lower Address Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.19.3 Diagram

11.3.7.1.19.4 Fields

Field	Function
31-2 PCI_MSI_CAP_OFF_04H	MSI Message Lower Address Field. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
1-0 RSVDP_0	Reserved for future use.

11.3.7.1.20 For a 32 bit MSI Message, this register contains Data. (MSI_CAP_OFF_08H_REG)

11.3.7.1.20.1 Offset

Register	Offset
MSI_CAP_OFF_08H_REG	58h

11.3.7.1.20.2 Function

For a 32 bit MSI Message, this register contains Data. For 64 bit it contains the Upper Address. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.20.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.3.7.1.20.4 Fields

Field	Function
31-16 PCI_MSI_CAP_OFF_0AH	For a 32 bit MSI Message, this field contains Ext MSI Data. For 64-bit it contains upper 16 bits of the Upper Address. For a description of this standard PCIe register field, see the PCI Express Specification Note: The access attributes of this field are as follows: - Dbi: PCI_MSI_64_BIT_ADDR_CAP `DEFAULT_EXT_MSI_DATA_CAPABLE ? R/W : R
15-0 PCI_MSI_CAP_OFF_08H	For a 32-bit MSI Message, this field contains Data. For 64-bit it contains lower 16 bits of the Upper Address. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: PCI_MSI_64_BIT_ADDR_CAP ? R/W : R

11.3.7.1.21 For a 64 bit MSI Message, this register contains Data. (MSI_CAP_OFF_0CH_REG)

11.3.7.1.21.1 Offset

Register	Offset
MSI_CAP_OFF_0CH_REG	5Ch

11.3.7.1.21.2 Function

For a 64 bit MSI Message, this register contains Data. For 32 bit, it contains Mask Bits if PVM enabled. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.21.3 Diagram

11.3.7.1.21.4 Fields

Field	Function
31-16 PCI_MSI_CAP_OFF_0EH	For a 64-bit MSI Message, this field contains Data. For 32-bit, it contains the upper Mask Bits if PVM is enabled. For a description of this standard PCIe register field, see the PCI Express Specification Note: The access attributes of this field are as follows: - Dbi: (!MSI_64_EN && MSI_PVM_EN_VALUE) ? RW: MSI_64_EN && DEFAULT_EXT_MSI_DATA_CAPABLE ? RW : RO
15-0 PCI_MSI_CAP_OFF_0CH	For a 64-bit MSI Message, this field contains Data. For 32-bit, it contains the lower Mask Bits if PVM is enabled. For a description of this standard PCIe register field, see the PCI Express Specification Note: The access attributes of this field are as follows: - Dbi: PCI_MSI_64_BIT_ADDR_CAP MSI_PVM_EN ? R/W : R

11.3.7.1.22 Used for MSI when Vector Masking Capable. (MSI_CAP_OFF_10H_REG)

11.3.7.1.22.1 Offset

Register	Offset
MSI_CAP_OFF_10H_REG	60h

11.3.7.1.22.2 Function

Used for MSI when Vector Masking Capable. For 32 bit contains Pending Bits. For 64 bit, contains Mask Bits. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.22.3 Diagram

11.3.7.1.22.4 Fields

Field	Function
31-0 PCI_MSI_CAP_OFF_10H	Used for MSI when Vector Masking Capable. For 32-bit contains Pending Bits. For 64-bit, contains Mask Bits. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: PCI_MSI_64_BIT_ADDR_CAP && MSI_PVM_EN ? R/W : R

11.3.7.1.23 Used for MSI 64 bit messaging when Vector Masking Capable. (MSI_CAP_OFF_14H_REG)

11.3.7.1.23.1 Offset

Register	Offset
MSI_CAP_OFF_14H_REG	64h

11.3.7.1.23.2 Function

Used for MSI 64 bit messaging when Vector Masking Capable. Contains Pending Bits. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.23.3 Diagram

11.3.7.1.23.4 Fields

Field	Function
31-0 PCI_MSI_CAP_OFF_14H	Used for MSI 64-bit messaging when Vector Masking Capable. Contains Pending Bits. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.24 PCI Express Capabilities, ID, Next Pointer Register. (PCIE_CAP_ID_PCIE_NEXT_CAP_PTR_PCIE_CAP_REG)

11.3.7.1.24.1 Offset

Register	Offset
PCIE_CAP_ID_PCIE_NEXT_CAP_PTR_PCIE_CAP_REG	70h

11.3.7.1.24.2 Function

PCI Express Capabilities, ID, Next Pointer Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.24.3 Diagram

11.3.7.1.24.4 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30 RSVD	Reserved. For a description of this standard PCIe register field, see the PCI Express Specification.
29-25 PCIE_INT_MSG_NUM	PCIe Interrupt Message Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
24 PCIE_SLOT_IMP	PCIe Slot Implemented Valid. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
23-20 PCIE_DEV_PORT_TYPE	PCIe Device/PortType. For a description of this standard PCIe register field, see the PCI Express Specification.
19-16 PCIE_CAP_RE G	PCIe Capability Version Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 PCIE_CAP_NEXT_PTR	PCIe Next Capability Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 PCIE_CAP_ID	PCIe Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.25 Device Capabilities Register. (DEVICE_CAPABILITIES_REG)

11.3.7.1.25.1 Offset

Register	Offset
DEVICE_CAPABILITIES_REG	74h

11.3.7.1.25.2 Function

Device Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.25.3 Diagram

11.3.7.1.25.4 Fields

Field	Function
31-16	Reserved for future use.

Table continues on the next page...

Field	Function
RSVDP_16	
15 PCIE_CAP_ROLE_BASED_ERROR_REPORT	Role-based Error Reporting Implemented. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
14-6 RSVDP_6	Reserved for future use.
5 PCIE_CAP_EXTENDED_TAG_SUPPORT	Extended Tag Field Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
4-3 PCIE_CAP_PHANTOM_FUNCTION_SUPPORT	Phantom Functions Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
2-0 PCIE_CAP_MAX_PAYLOAD_SIZE	Max Payload Size Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

11.3.7.1.26 Device Control and Status Register. (DEVICE_CONTROL_DEVICE_STATUS)

11.3.7.1.26.1 Offset

Register	Offset
DEVICE_CONTROL_DEVICE_STATUS	78h

11.3.7.1.26.2 Function

Device Control and Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.26.3 Diagram

11.3.7.1.26.4 Fields

Field	Function
31-22 RSVDP_22	Reserved for future use.

Table continues on the next page...

Field	Function
21 PCIE_CAP_TRANS_PENDING	Transactions Pending Status. For a description of this standard PCIe register field, see the PCI Express Specification.
20 PCIE_CAP_AUX_POWER_DETECTED	Aux Power Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification. This bit is derived by sampling the sys_aux_pwr_det input.
19 PCIE_CAP_UNSUPPORTED_REQ_DETECTED	Unsupported Request Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
18 PCIE_CAP_FATAL_ERR_DETECTED	Fatal Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
17 PCIE_CAP_NON_FATAL_ERR_DETECTED	Non-Fatal Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
16 PCIE_CAP_CORRECTABLE_ERR_DETECTED	Correctable Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
15 PCIE_CAP_INITIATE_FLR	Initiate Function Level Reset (for endpoints). For a description of this standard PCIe register field, see the PCI Express Specification.
14-12 PCIE_CAP_MAX_READ_REQ_SIZE	Max Read Request Size. For a description of this standard PCIe register field, see the PCI Express Specification.
11 PCIE_CAP_ENABLE_NO_SNOOP	Enable No Snoop. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R
10 PCIE_CAP_AUX_POWER_PM_ENABLE	Aux Power PM Enable. For a description of this standard PCIe register field, see the PCI Express Specification. This bit is derived by sampling the sys_aux_pwr_det input. Note: This register field is sticky.
9 PCIE_CAP_PHANTOM_FUNC_ENABLE	Phantom Functions Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_PHANTOM_FUNC_SUPPORT field of DEVICE_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_PHANTOM_FUNC_SUPPORT ? RW : RO
8 PCIE_CAP_EXTENDED_TAG_ENABLE	Extended Tag Field Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_EXT_TAG_SUPP field of DEVICE_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_EXT_TAG_SUPP ? RW : RO

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
7-5 PCIE_CAP_MAX_PAYLOAD_SIZE_CS	Max Payload Size. Max_Payload_Size . This field sets maximum TLP payload size for the Function. Permissible values that can be programmed are indicated by the Max_Payload_Size Supported field (PCIE_CAP_MAX_PAYLOAD_SIZE) in the Device Capabilities register (DEVICE_CAPABILITIES_REG).
4 PCIE_CAP_ENABLE_REL_ORDER	Enable Relaxed Ordering. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
3 PCIE_CAP_UNSUPPORTED_REQUEST_REPORTING_ENABLE	Unsupported Request Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
2 PCIE_CAP_FATAL_ERROR_REPORTING_ENABLE	Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 PCIE_CAP_NON_FATAL_ERROR_REPORTING_ENABLE	Non-fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 PCIE_CAP_CORRECTABLE_ERROR_REPORTING_ENABLE	Correctable Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.27 Link Capabilities Register. (LINK_CAPABILITIES_REG)

11.3.7.1.27.1 Offset

Register	Offset
LINK_CAPABILITIES_REG	7Ch

11.3.7.1.27.2 Function

Link Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.27.3 Diagram

11.3.7.1.27.4 Fields

Field	Function
31-24 PCIE_CAP_PORT_NUM	Port Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
23 RSVDP_23	Reserved for future use.
22 PCIE_CAP_AS PM_OPT_COM PLIANCE	ASPM Optionality Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
21 PCIE_CAP_LIN K_BW_NOT_CA P	Link Bandwidth Notification Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
20 PCIE_CAP_DLL _ACTIVE_REP_ CAP	Data Link Layer Link Active Reporting Capable. For a description of this standard PCIe register field, see the PCI Express Specification.
19 PCIE_CAP_SU RPRISE_DOWN _ERR_REP_CA P	Surprise Down Error Reporting Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
18 PCIE_CAP_CL OCK_POWER_ MAN	Clock Power Management. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
17-15 PCIE_CAP_L1 EXIT_LATENCY	L1 Exit Latency. For a description of this standard PCIe register field, see the PCI Express Specification. There are two each of these register fields, this one and a shadow one at the same address. The Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG) determines which one is used by the controller and which one is accessed by a read request. Common Clock operation is supported (possible) in the controller when one or more of the following expressions is true: - CX_NFTS !=CX_COMM_NFTS - DEFAULT_L0S_EXIT_LATENCY !=DEFAULT_COMM_L0S_EXIT_LATENCY - DEFAULT_L1_EXIT_LATENCY !=DEFAULT_COMM_L1_EXIT_LATENCY Common Clock operation is enabled in the controller when you set the Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG). The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the shadow field at this location. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
14-12 PCIE_CAP_L0S _EXIT_LATENC Y	L0s Exit Latency. For a description of this standard PCIe register field, see the PCI Express Specification. There are two each of these register fields, this one and a shadow one at the same address. The Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG) determines which one is used by the controller and which one is accessed by a read request. Common Clock operation is supported (possible) in the controller when one or more of the following expressions is true: - CX_NFTS !=CX_COMM_NFTS - DEFAULT_L0S_EXIT_LATENCY !=DEFAULT_COMM_L0S_EXIT_LATENCY - DEFAULT_L1_EXIT_LATENCY !=DEFAULT_COMM_L1_EXIT_LATENCY Common Clock operation is enabled in the controller when you set the Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG). The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the shadow field at this location. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

Table continues on the next page...

Field	Function
11-10 PCIE_CAP_ACTIVE_STATE_LINK_PM_SUPPORT	Level of ASPM (Active State Power Management) Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
9-4 PCIE_CAP_MAX_LINK_WIDTH	Maximum Link Width. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
3-0 PCIE_CAP_MAX_LINK_SPEED	Maximum Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

11.3.7.1.28 Link Control and Status Register. (LINK_CONTROL_LINK_STATUS_REG)

11.3.7.1.28.1 Offset

Register	Offset
LINK_CONTROL_LINK_STATUS_REG	80h

11.3.7.1.28.2 Function

Link Control and Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.28.3 Diagram

11.3.7.1.28.4 Fields

Field	Function
31	Link Autonomous Bandwidth Status. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG.

Table continues on the next page...

Field	Function
PCIE_CAP_LINK_AUTO_BW_STATUS	
30 PCIE_CAP_LINK_BW_MAN_STATUS	Link Bandwidth Management Status. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG.
29 PCIE_CAP_DLL_ACTIVE	Data Link Layer Active. For a description of this standard PCIe register field, see the PCI Express Specification.
28 PCIE_CAP_SLOT_CLK_CONFIG	Slot Clock Configuration. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
27 PCIE_CAP_LINK_TRAINING	LTSSM is in Configuration or Recovery State. For a description of this standard PCIe register field, see the PCI Express Specification.
26 RSVDP_26	Reserved for future use.
25-20 PCIE_CAP_NEGO_LINK_WIDTH	Negotiated Link Width. For a description of this standard PCIe register field, see the PCI Express Specification.
19-16 PCIE_CAP_LINK_SPEED	Current Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification.
15-14 PCIE_CAP_DRS_SIGNALING_CONTROL	DRS Signaling Control. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES2_REG.DRS_SUPPORTED ? RW : RO
13-12 RSVDP_12	Reserved for future use.
11 PCIE_CAP_LINK_AUTO_BW_INTERRUPT_ENABLE	Link Autonomous Bandwidth Management Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
10 PCIE_CAP_LINK_BW_MAN_INTERRUPT_ENABLE	Link Bandwidth Management Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
9 PCIE_CAP_HW_AUTO_WIDTH_DISABLE	Hardware Autonomous Width Disable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
8	Enable Clock Power Management. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_CLOCK_POWER_MAN field in

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
PCIE_CAP_EN_CLK_POWER_MAN	LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_CLOCK_POWER_MAN ? RWS : ROS Note: This register field is sticky.
7 PCIE_CAP_EXTENDED_SYNC_H	Extended Synch. For a description of this standard PCIe register field, see the PCI Express Specification.
6 PCIE_CAP_COMMON_CLK_CONFIG	Common Clock Configuration. For a description of this standard PCIe register field, see the PCI Express Specification.
5 PCIE_CAP_RETRAIN_LINK	Initiate Link Retrain. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: see description
4 PCIE_CAP_LINK_DISABLE	Initiate Link Disable. For a description of this standard PCIe register field, see the PCI Express Specification. In a DSP that supports crosslink, the controller gates the write value with the CROSS_LINK_EN field in PORT_LINK_CTRL_OFF. Note: The access attributes of this field are as follows: - Dbi: CX_CROSSLINK_ENABLE=1 && PORT_LINK_CTRL_OFF.CROSS_LINK_EN=1 CX_CROSSLINK_ENABLE=0 && dsp=1? RW : RO
3 PCIE_CAP_RCB	Read Completion Boundary (RCB). Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
2 RSVDP_2	Reserved for future use.
1-0 PCIE_CAP_ACTIVE_STATE_LINK_PM_CONTROL	Active State Power Management (ASPM) Control. Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s; otherwise, the result is undefined. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.29 Slot Capabilities Register. (SLOT_CAPABILITIES_REG)

11.3.7.1.29.1 Offset

Register	Offset
SLOT_CAPABILITIES_REG	84h

11.3.7.1.29.2 Function

Slot Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.29.3 Diagram

11.3.7.1.29.4 Fields

Field	Function
31-19 PCIE_CAP_PHY_SLOT_NUM	Physical Slot Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
18 PCIE_CAP_NO_CMD_CPL_SUPPORT	No Command Completed Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
17 PCIE_CAP_ELECTROMECHANICAL_INTERLOCK	Electromechanical Interlock Present. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
16-15 PCIE_CAP_SLOT_POWER_LIMIT_SCALE	Slot Power Limit Scale. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
14-7 PCIE_CAP_SLOT_POWER_LIMIT_VALUE	Slot Power Limit Value. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
6 PCIE_CAP_HOT_PLUG_CAPABLE	Hot Plug Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
5 PCIE_CAP_HOT_PLUG_SURPRISE	Hot Plug Surprise possible. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
4 PCIE_CAP_POWER_INDICATOR	Power Indicator Present. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
3 PCIE_CAP_ATTENTION_INDICATOR	Attention Indicator Present. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
2 PCIE_CAP_MRL_SENSOR	MRL Present. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
1 PCIE_CAP_POWER_CONTROLLER	Power Controller Present. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
0 PCIE_CAP_ATTENTION_INDICATOR_BUTTON	Attention Button Present. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.3.7.1.30 Slot Control and Status Register. (SLOT_CONTROL_SLOT_STATUS)

11.3.7.1.30.1 Offset

Register	Offset
SLOT_CONTROL_SLOT_STATUS	88h

11.3.7.1.30.2 Function

Slot Control and Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.30.3 Diagram

11.3.7.1.30.4 Fields

Field	Function
31-25	Reserved for future use.

Table continues on the next page...

Field	Function
RSVDP_25	
24 PCIE_CAP_DLL _STATE_CHAN GED	Data Link Layer State Changed. For a description of this standard PCIe register field, see the PCI Express Specification.
23 PCIE_CAP_ELE CTROMECH_IN TERLOCK_STA TUS	Electromechanical Interlock Status. For a description of this standard PCIe register field, see the PCI Express Specification.
22 PCIE_CAP_PR ESENCE_DETE CT_STATE	Presence Detect State. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R
21 PCIE_CAP_MR L_SENSOR_ST ATE	MRL Sensor State. For a description of this standard PCIe register field, see the PCI Express Specification.
20 PCIE_CAP_CM D_CPLD	Command Completed. For a description of this standard PCIe register field, see the PCI Express Specification.
19 PCIE_CAP_PR ESENCE_DETE CTED_CHANG ED	Presence Detect Changed. For a description of this standard PCIe register field, see the PCI Express Specification.
18 PCIE_CAP_MR L_SENSOR_CH ANGED	MRL Sensor Changed. For a description of this standard PCIe register field, see the PCI Express Specification.
17 PCIE_CAP_PO WER_FAULT_D ETECTED	Power Fault Detected. For a description of this standard PCIe register field, see the PCI Express Specification.
16 PCIE_CAP_ATT ENTION_BUTT ON_PRESSED	Attention Button Pressed. For a description of this standard PCIe register field, see the PCI Express Specification.
15-13 RSVDP_13	Reserved for future use.
12 PCIE_CAP_DLL _STATE_CHAN GED_EN	Data Link Layer State Changed Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
11	Electromechanical Interlock Control. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
PCIE_CAP_ELEMENT_LOCK_CTRL	
10 PCIE_CAP_POWER_CONTROLLER_CTRL	Power Controller Control. For a description of this standard PCIe register field, see the PCI Express Specification.
9-8 PCIE_CAP_POWER_INDICATOR_CTRL	Power Indicator Control. For a description of this standard PCIe register field, see the PCI Express Specification.
7-6 PCIE_CAP_ATTENTION_INDICATOR_CTRL	Attention Indicator Control. For a description of this standard PCIe register field, see the PCI Express Specification.
5 PCIE_CAP_HOT_PLUG_INTERRUPT_ENABLE	Hot Plug Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
4 PCIE_CAP_COMMAND_CPL_INTERRUPT_ENABLE	Command Completed Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Write value is gated with PCIE_CAP_NO_CMD_CPL_SUPPORT field in SLOT_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: SLOT_CAPABILITIES_REG.PCIE_CAP_NO_CMD_CPL_SUPPORT ? RO : RW
3 PCIE_CAP_PRESENCE_DETECT_CHANGE_ENABLE	Presence Detect Changed Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
2 PCIE_CAP_MRL_SENSOR_CHANGED_ENABLE	MRL Sensor Changed Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 PCIE_CAP_POWER_FAULT_DETECTED_ENABLE	Power Fault Detected Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 PCIE_CAP_ATTENTION_BUTTON_PRESSED_ENABLE	Attention Button Pressed Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.31 Root Control and Capabilities Register. (ROOT_CONTROL_ROOT_CAPABILITIES_REG)

11.3.7.1.31.1 Offset

Register	Offset
ROOT_CONTROL_ROOT_CAPABILITIES_REG	8Ch

11.3.7.1.31.2 Function

Root Control and Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.31.3 Diagram

11.3.7.1.31.4 Fields

Field	Function
31-17 RSVDP_17	Reserved for future use.
16 PCIE_CAP_CR S_SW_VISIBILI TY	CRS Software Visibility Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W (Sticky) else R (Sticky) Note: This register field is sticky.
15-5 RSVDP_5	Reserved for future use.
4 PCIE_CAP_CR S_SW_VISIBILI TY_EN	Configuration Request Retry Status (CRS) Software Visibility Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: ROOT_CONTROL_ROOT_CAPABILITIES_REG.PCIE_CAP_CR_S_SW_VISIBILITY ? RW : RO
3 PCIE_CAP_PM E_INT_EN	PME Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
2 PCIE_CAP_SY S_ERR_ON_FA TAL_ERR_EN	System Error on Fatal Error Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 PCIE_CAP_SY S_ERR_ON_NO N_FATAL_ERR _EN	System Error on Non-fatal Error Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 PCIE_CAP_SY S_ERR_ON_CO RR_ERR_EN	System Error on Correctable Error Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.32 Root Status Register. (ROOT_STATUS_REG)

11.3.7.1.32.1 Offset

Register	Offset
ROOT_STATUS_REG	90h

11.3.7.1.32.2 Function

Root Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.32.3 Diagram

11.3.7.1.32.4 Fields

Field	Function
31-18 RSVDP_18	Reserved for future use.
17 PCIE_CAP_PME_PENDING	PME Pending. For a description of this standard PCIe register field, see the PCI Express Specification.
16 PCIE_CAP_PME_STATUS	PME Status. For a description of this standard PCIe register field, see the PCI Express Specification.
15-0 PCIE_CAP_PME_REQ_ID	PME Requester ID. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.33 Device Capabilities 2 Register. (DEVICE_CAPABILITIES2_REG)

11.3.7.1.33.1 Offset

Register	Offset
DEVICE_CAPABILITIES2_REG	94h

11.3.7.1.33.2 Function

Device Capabilities 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.33.3 Diagram

11.3.7.1.33.4 Fields

Field	Function
31	Reserved.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
—	
30-24 RSVDP_24	Reserved for future use.
23-20 —	Reserved.
19-18 PCIE_CAP_OB FF_SUPPORT	(OBFF) Optimized Buffer Flush/fill Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
17 PCIE_CAP2_10 _BIT_TAG_REQ _SUPPORT	10-Bit Tag Requester Supported. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.
16 PCIE_CAP2_10 _BIT_TAG_CO MP_SUPPORT	10-Bit Tag Completer Supported. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.
15-14 —	Reserved.
13 PCIE_CAP_TP H_CMPLT_SUP PORT_1	TPH Completer Supported Bit 1. For a description of this standard PCIe register field, see the PCI Express Specification.
12 PCIE_CAP_TP H_CMPLT_SUP PORT_0	TPH Completer Supported Bit 0. For a description of this standard PCIe register field, see the PCI Express Specification.
11 PCIE_CAP_LTR _SUPP	LTR Mechanism Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
10 PCIE_CAP_NO _RO_EN_PR2P R_PAR	No Relaxed Ordering Enabled PR-PR Passing. For a description of this standard PCIe register field, see the PCI Express Specification.
9 PCIE_CAP_128 _CAS_CPL_SU PP	128 Bit CAS Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
8 PCIE_CAP_64_ ATOMIC_CPL_ SUPP	64 Bit AtomicOp Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
7 PCIE_CAP_32_ ATOMIC_CPL_ SUPP	32 Bit AtomicOp Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
6 PCIE_CAP_ATOMIC_ROUTING_SUPPORT	Atomic Operation Routing Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
5 PCIE_CAP_ARI_FORWARD_SUPPORT	ARI Forwarding Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
4 PCIE_CAP_COMPLETION_TIMEOUT_DISABLE_SUPPORT	Completion Timeout Disable Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 PCIE_CAP_COMPLETION_TIMEOUT_RANGES	Completion Timeout Ranges Supported. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.34 Device Control 2 and Status 2 Register. (DEVICE_CONTROL2_DEVICE_STATUS2_REG)

11.3.7.1.34.1 Offset

Register	Offset
DEVICE_CONTROL2_DEVICE_STATUS2_REG	98h

11.3.7.1.34.2 Function

Device Control 2 and Status 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.34.3 Diagram

11.3.7.1.34.4 Fields

Field	Function
31-6 —	Reserved.
5 PCIE_CAP_ARI_FORWARD_SUPPORT_CS	ARI Forwarding Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
4 PCIE_CAP_CPL_TIMEOUT_DISABLE	Completion Timeout Disable. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 PCIE_CAP_CPL_TIMEOUT_VALUE	Completion Timeout Value. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.35 Link Capabilities 2 Register. (LINK_CAPABILITIES2_REG)

11.3.7.1.35.1 Offset

Register	Offset
LINK_CAPABILITIES2_REG	9Ch

11.3.7.1.35.2 Function

Link Capabilities 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.35.3 Diagram

11.3.7.1.35.4 Fields

Field	Function
31 —	Reserved.
30-25 RSVDP_25	Reserved for future use.
24-23 —	Reserved.
22-9 RSVDP_9	Reserved for future use.
8 PCIE_CAP_CR OSS_LINK_SU PPOINT	Cross Link Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
7-1 PCIE_CAP_SU PPOINT_LINK_S PEED_VECTOR	Supported Link Speeds Vector. For a description of this standard PCIe register field, see the PCI Express Specification. This field has a default of (PCIE_CAP_MAX_LINK_SPEED == 0100) ? 0001111 : (PCIE_CAP_MAX_LINK_SPEED == 0011) ? 0000111 : (PCIE_CAP_MAX_LINK_SPEED == 0010) ? 0000011 : 0000001 where PCIE_CAP_MAX_LINK_SPEED is a field in the LINK_CAPABILITIES_REG register.
0 RSVDP_0	Reserved for future use.

11.3.7.1.36 Link Control 2 and Status 2 Register. (LINK_CONTROL2_LINK_STATUS2_REG)

11.3.7.1.36.1 Offset

Register	Offset
LINK_CONTROL2_LINK_STATUS2_REG	A0h

11.3.7.1.36.2 Function

Link Control 2 and Status 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.36.3 Diagram

11.3.7.1.36.4 Fields

Field	Function
31 DRS_MESSAGE_RECEIVED	DRS Message Received. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0. Note: The access attributes of this field are as follows: - Dbi: RW1C
30-28	Downstream Component Presence. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
DOWNSTREAM_COMPO_PRESENCE	
27-26 RSVDP_26	Reserved for future use.
25-17 —	Reserved.
16 PCIE_CAP_CURR_DEEMPHASIS	Current De-emphasis Level. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode this register is always 0x0. In C-PCIe mode, its contents are derived by sampling the PIPE
15-12 PCIE_CAP_COMPLIANCE_PRESSET	Sets Compliance Preset/De-emphasis for 5 GT/s and 8 GT/s. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
11 PCIE_CAP_COMPLIANCE_SETTINGS	Sets Compliance Skip Ordered Sets transmission. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
10 PCIE_CAP_ENTER_MODIFIED_COMPLIANCE	Enter Modified Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
9-7 PCIE_CAP_TX_MARGIN	Controls Transmit Margin for Debug or Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
6 PCIE_CAP_SELECT_DEEMPHASIS	Controls Selectable De-emphasis for 5 GT/s. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
5 PCIE_CAP_HW_AUTO_SPEED_DISABLE	Hardware Autonomous Speed Disable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
4 PCIE_CAP_ENTER_COMPLIANCE	Enter Compliance Mode. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
3-0 PCIE_CAP_TARGET_LINK_SPEED	Target Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the contents of this field are derived from other registers. Note: This register field is sticky.

11.3.7.1.37 Advanced Error Reporting Extended Capability Header. (AER_EXT_CAP_HDR_OFF)

11.3.7.1.37.1 Offset

Register	Offset
AER_EXT_CAP_HDR_OFF	100h

11.3.7.1.37.2 Function

Advanced Error Reporting Extended Capability Header. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.37.3 Diagram

11.3.7.1.37.4 Fields

Field	Function
31-20 NEXT_OFFSET	Next Capability Offset. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
19-16 CAP_VERSION	Capability Version. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 CAP_ID	AER Extended Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.7.1.38 Uncorrectable Error Status Register. (UNCORR_ERR_STATU S_OFF)

11.3.7.1.38.1 Offset

Register	Offset
UNCORR_ERR_STATU S_OFF	104h

11.3.7.1.38.2 Function

Uncorrectable Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.38.3 Diagram

11.3.7.1.38.4 Fields

Field	Function
31-26 RSVDP_26	Reserved for future use.
25 TLP_PRFX_BLOCKED_ERR_STATUS	TLP Prefix Blocked Error Status. For a description of this standard PCIe register field, see the PCI Express Specification. Note: Not supported.
24	Reserved.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
—	
23 RSVDP_23	Reserved for future use.
22 INTERNAL_ER R_STATUS	Uncorrectable Internal Error Status. For a description of this standard PCIe register field, see the PCI Express Specification. The controller sets this bit when your application asserts app_err_bus[9]. It does not set this bit when it detects internal uncorrectable internal errors such as parity and ECC failures. You should use the outputs from these errors to drive the app_err_bus[9] input. For more details, see the "Data Integrity (Wire, Datapath, and RAM Protection)" section in the Databook.
21 —	Reserved.
20 UNSUPPORTED_REQ_ERR_STATUS	Unsupported Request Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
19 ECRC_ERR_STATUS	ECRC Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
18 MALF_TLP_ERR_STATUS	Malformed TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
17 REC_OVERFLOW_ERR_STATUS	Receiver Overflow Status. For a description of this standard PCIe register field, see the PCI Express Specification.
16 UNEXP_CMPLT_ERR_STATUS	Unexpected Completion Status. For a description of this standard PCIe register field, see the PCI Express Specification.
15 CMPLT_ABORT_ERR_STATUS	Completer Abort Status. For a description of this standard PCIe register field, see the PCI Express Specification.
14 CMPLT_TIMEOUT_ERR_STATUS	Completion Timeout Status. For a description of this standard PCIe register field, see the PCI Express Specification.
13 FC_PROTOCOL_ERR_STATUS	Flow Control Protocol Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
12 POIS_TLP_ERR_STATUS	Poisoned TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
11-6 RSVDP_6	Reserved for future use.
5	Surprise Down Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
SURPRISE_DOWN_ERR_STATUS	
4 DL_PROTOCOL_ERR_STATUS	Data Link Protocol Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 RSVDP_0	Reserved for future use.

11.3.7.1.39 Uncorrectable Error Mask Register. (UNCORR_ERR_MASK_OFF)

11.3.7.1.39.1 Offset

Register	Offset
UNCORR_ERR_MASK_OFF	108h

11.3.7.1.39.2 Function

Uncorrectable Error Mask Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.39.3 Diagram

11.3.7.1.39.4 Fields

Field	Function
31-26 RSVDP_26	Reserved for future use.
25 TLP_PRFX_BLOCKED_ERR_MASK	TLP Prefix Blocked Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: Not supported. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Table continues on the next page...

Field	Function
24 ATOMIC_EGRESS_BLOCKED_ERR_MASK	AtomicOp Egress Block Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
23 RSVDP_23	Reserved for future use.
22 INTERNAL_ERROR_MASK	Uncorrectable Internal Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
21 —	Reserved.
20 UNSUPPORTED_REQ_ERR_MASK	Unsupported Request Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
19 ECRC_ERROR_MASK	ECRC Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
18 MALF_TLP_ERROR_MASK	Malformed TLP Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
17 REC_OVERFLOW_ERR_MASK	Receiver Overflow Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
16 UNEXP_CMPLT_ERR_MASK	Unexpected Completion Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15 CMPLT_ABORT_ERR_MASK	Completer Abort Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
14 CMPLT_TIMEOUT_ERR_MASK	Completion Timeout Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
13 FC_PROTOCOL_ERR_MASK	Flow Control Protocol Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
12 POIS_TLP_ERR_MASK	Poisoned TLP Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
11-6 RSVDP_6	Reserved for future use.
5	Surprise Down Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi:

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
SURPRISE_DOWN_ERR_MASK	LINK_CAPABILITIES_REG.PCIE_CAP_SURPRISE_DOWN_ERR_REP_CAP ? RW : RO Note: This register field is sticky.
4 DL_PROTOCOL_ERR_MASK	Data Link Protocol Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
3-0 RSVDP_0	Reserved for future use.

11.3.7.1.40 Uncorrectable Error Severity Register. (UNCORR_ERR_SEV_OFFSET)

11.3.7.1.40.1 Offset

Register	Offset
UNCORR_ERR_SEV_OFFSET	10Ch

11.3.7.1.40.2 Function

Uncorrectable Error Severity Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.40.4 Fields

Field	Function
31-26 RSVDP_26	Reserved for future use.
25 TLP_PRFX_BLOCKED_ERR_SEVERITY	TLP Prefix Blocked Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: Not supported. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
24 ATOMIC_EGRESS_BLOCKED_ERROR_SEVERITY	AtomicOp Egress Blocked Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
23 RSVDP_23	Reserved for future use.
22 INTERNAL_ERROR_SEVERITY	Uncorrectable Internal Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
21 —	Reserved.
20 UNSUPPORTED_REQUEST_ERROR_SEVERITY	Unsupported Request Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
19 ECRC_ERROR_SEVERITY	ECRC Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
18 MALFORMED_TLP_ERROR_SEVERITY	Malformed TLP Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
17 RECEIVER_OVERFLOW_ERROR_SEVERITY	Receiver Overflow Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
16 UNEXPECTED_COMPLETION_ERROR_SEVERITY	Unexpected Completion Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15 COMPLETER_ABORT_ERROR_SEVERITY	Completer Abort Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
14 COMPLETION_TIMEOUT_ERROR_SEVERITY	Completion Timeout Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
13 FLOW_CONTROL_PROTOCOL_ERROR_SEVERITY	Flow Control Protocol Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
12 POISONED_TLP_ERROR_SEVERITY	Poisoned TLP Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
11-6 RSVDP_6	Reserved for future use.
5 SURPRISE_DOWN_ERR_SEVERITY	Surprise Down Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_SURPRISE_DOWN_ERR_REP_CAP ? RW : RO Note: This register field is sticky.
4 DL_PROTOCOL_ERR_SEVERITY	Data Link Protocol Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
3-0 RSVDP_0	Reserved for future use.

11.3.7.1.41 Correctable Error Status Register. (CORR_ERR_STATUS_OFF)

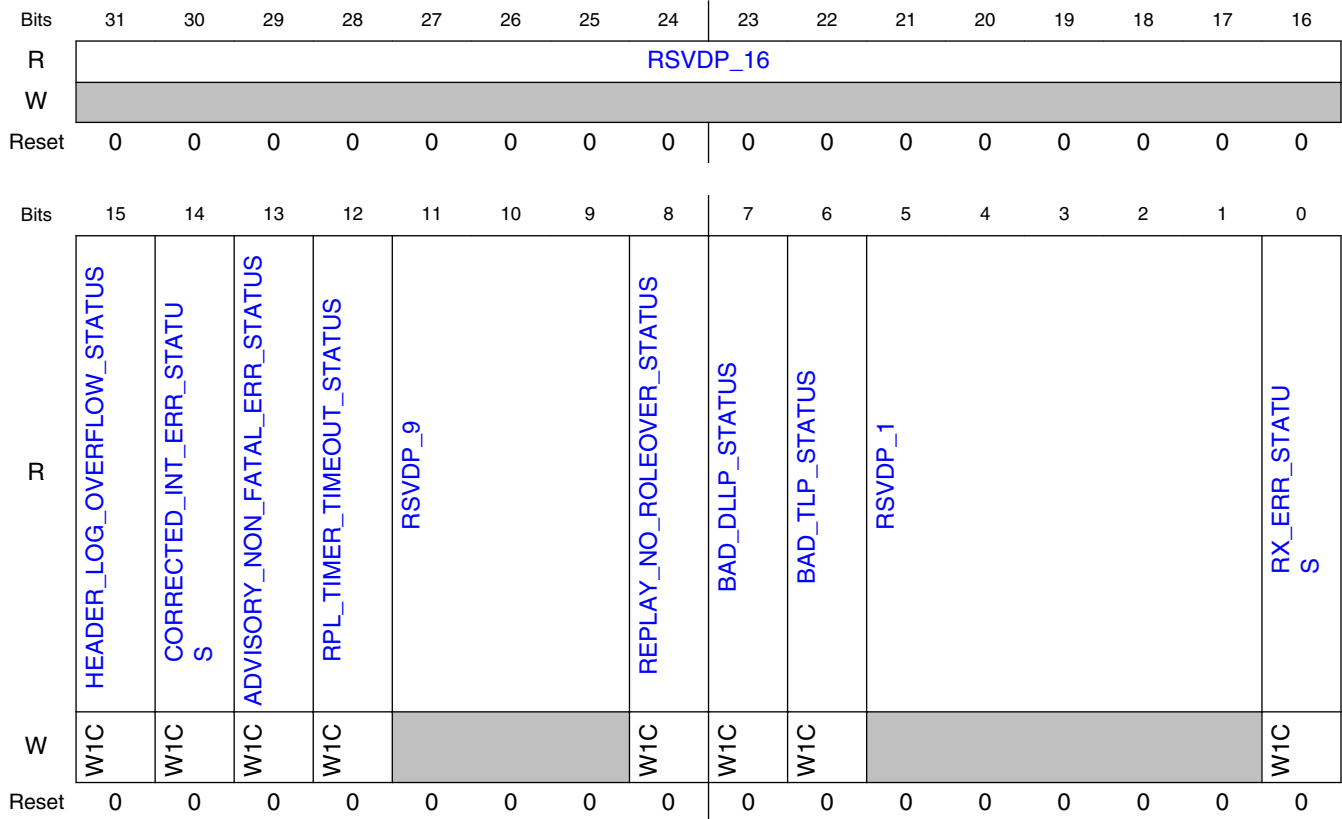

11.3.7.1.41.1 Offset

Register	Offset
CORR_ERR_STATUS_OFF	110h

11.3.7.1.41.2 Function

Correctable Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.41.3 Diagram

11.3.7.1.41.4 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15 HEADER_LOG_OVERFLOW_S TATUS	Header Log Overflow Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.
14 CORRECTED_I NT_ERR_STAT US	Corrected Internal Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.
13 ADVISORY_NO N_FATAL_ERR _STATUS	Advisory Non-Fatal Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
12	Replay Timer Timeout Status. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
RPL_TIMER_TIMEOUT_STATUSES	
11-9 RSVDP_9	Reserved for future use.
8 REPLAY_NO_ROLLOVER_STATUS	REPLAY_NUM Rollover Status. For a description of this standard PCIe register field, see the PCI Express Specification.
7 BAD_DLLP_STATUS	Bad DLLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
6 BAD_TLP_STATUS	Bad TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
5-1 RSVDP_1	Reserved for future use.
0 RX_ERR_STATUS	Receiver Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.42 Correctable Error Mask Register. (CORR_ERR_MASK_OFF)

11.3.7.1.42.1 Offset

Register	Offset
CORR_ERR_MASK_OFF	114h

11.3.7.1.42.2 Function

Correctable Error Mask Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.42.3 Diagram

11.3.7.1.42.4 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15 HEADER_LOG_OVERFLOW_MASK	Header Log Overflow Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
14 CORRECTED_INT_ERR_MASK	Corrected Internal Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
13 ADVISORY_NON_FATAL_ERR_MASK	Advisory Non-Fatal Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
12 RPL_TIMER_TIMEOUT_MASK	Replay Timer Timeout Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
11-9 RSVDP_9	Reserved for future use.

Table continues on the next page...

Field	Function
8 REPLAY_NO_R OLEOVER_MA SK	REPLAY_NUM Rollover Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7 BAD_DLLP_MA SK	Bad DLLP Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
6 BAD_TLP_MAS K	Bad TLP Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
5-1 RSVDP_1	Reserved for future use.
0 RX_ERR_MASK	Receiver Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.43 Advanced Error Capabilities and Control Register. (ADV_ERR_CAP_CTRL_OFF)

11.3.7.1.43.1 Offset

Register	Offset
ADV_ERR_CAP_CTRL_OFF	118h

11.3.7.1.43.2 Function

Advanced Error Capabilities and Control Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.43.3 Diagram

11.3.7.1.43.4 Fields

Field	Function
31-12 RSVDP_12	Reserved for future use.
11 —	Reserved.
10 MULTIPLE_HEADER_EN	Multiple Header Recording Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
9 MULTIPLE_HEADER_CAP	Multiple Header Recording Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
8 ECRC_CHECK_EN	ECRC Check Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7 ECRC_CHECK_CAP	ECRC Check Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
6 ECRC_GEN_EN	ECRC Generation Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
5	ECRC Generation Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
ECRC_GEN_C AP	
4-0 FIRST_ERR_P OINTER	First Error Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.44 Header Log Register 0. (HDR_LOG_0_OFF)

11.3.7.1.44.1 Offset

Register	Offset
HDR_LOG_0_OFF	11Ch

11.3.7.1.44.2 Function

Header Log Register 0. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.44.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

11.3.7.1.44.4 Fields

Field	Function
31-24 FIRST_DWORD _FOURTH_BYT E	Byte 3 of Header log register of First 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
23-16 FIRST_DWORD_THIRD_BYTE	Byte 2 of Header log register of First 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 FIRST_DWORD_SECOND_BYTE	Byte 1 of Header log register of First 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 FIRST_DWORD_FIRST_BYTE	Byte 0 of Header log register of First 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.45 Header Log Register 1. (HDR_LOG_1_OFF)

11.3.7.1.45.1 Offset

Register	Offset
HDR_LOG_1_OFF	120h

11.3.7.1.45.2 Function

Header Log Register 1. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.45.3 Diagram

11.3.7.1.45.4 Fields

Field	Function
31-24 SECOND_DWORD_FOURTH_BYTE	Byte 3 of Header log register of Second 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16 SECOND_DWORD_THIRD_BYTE	Byte 2 of Header log register of Second 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 SECOND_DWORD_SECOND_BYTE	Byte 1 of Header log register of Second 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 SECOND_DWORD_FIRST_BYTE	Byte 0 of Header log register of Second 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.46 Header Log Register 2. (HDR_LOG_2_OFF)

11.3.7.1.46.1 Offset

Register	Offset
HDR_LOG_2_OFF	124h

11.3.7.1.46.2 Function

Header Log Register 2. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.46.3 Diagram

11.3.7.1.46.4 Fields

Field	Function
THIRD_DWORD_FOURTH_BYTE	Byte 3 of Header log register of Third 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
THIRD_DWORD_THIRD_BYTE	Byte 2 of Header log register of Third 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
THIRD_DWORD_SECOND_BYTE	Byte 1 of Header log register of Third 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
THIRD_DWORD_FIRST_BYTE	Byte 0 of Header log register of Third 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.47 Header Log Register 3. (HDR_LOG_3_OFF)

11.3.7.1.47.1 Offset

Register	Offset
HDR_LOG_3_OFF	128h

11.3.7.1.47.2 Function

Header Log Register 3. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.47.3 Diagram

11.3.7.1.47.4 Fields

Field	Function
31-24 FOURTH_DWORD_FOURTH_BYTE	Byte 3 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16 FOURTH_DWORD_THIRD_BYTE	Byte 2 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 FOURTH_DWORD_SECOND_BYTE	Byte 1 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 FOURTH_DWORD_FIRST_BYTE	Byte 0 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.48 Root Error Command Register. (ROOT_ERR_CMD_OFF)

11.3.7.1.48.1 Offset

Register	Offset
ROOT_ERR_CMD_OFF	12Ch

11.3.7.1.48.2 Function

Root Error Command Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.48.3 Diagram

11.3.7.1.48.4 Fields

Field	Function
31-3 RSVDP_3	Reserved for future use.
2 FATAL_ERR_R EPORTING_EN	Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 NON_FATAL_E RR_REPORTIN G_EN	Non-Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 CORR_ERR_R EPORTING_EN	Correctable Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.49 Root Error Status Register. (ROOT_ERR_STATUS_OFF)

11.3.7.1.49.1 Offset

Register	Offset
ROOT_ERR_STATUS_OFF	130h

11.3.7.1.49.2 Function

Root Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.49.3 Diagram

11.3.7.1.49.4 Fields

Field	Function
31-27 ADV_ERR_INT_MSG_NUM	Advanced Error Interrupt Message Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
26-7 RSVDP_7	Reserved for future use.
6 FATAL_ERR_MSG_RX	One or more Fatal Error Messages Received. For a description of this standard PCIe register field, see the PCI Express Specification.
5 NON_FATAL_ERR_MSG_RX	One or more Non-Fatal Error Messages Received. For a description of this standard PCIe register field, see the PCI Express Specification.
4 FIRST_UNCORR_FATAL	First Uncorrectable Error is Fatal. For a description of this standard PCIe register field, see the PCI Express Specification.
3 MUL_ERR_FATAL_NON_FATAL_RX	Multiple Fatal or Non-Fatal Errors Received. For a description of this standard PCIe register field, see the PCI Express Specification.
2 ERR_FATAL_NON_FATAL_RX	Fatal or Non-Fatal Error Received. For a description of this standard PCIe register field, see the PCI Express Specification.
1 MUL_ERR_CORR_RX	Multiple Correctable Errors Received. For a description of this standard PCIe register field, see the PCI Express Specification.
0 ERR_CORR_RX	Correctable Error Received. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.50 Error Source Identification Register. (ERR_SRC_ID_OFF)

11.3.7.1.50.1 Offset

Register	Offset
ERR_SRC_ID_OFF	134h

11.3.7.1.50.2 Function

Error Source Identification Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.50.3 Diagram

Bits	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

11.3.7.1.50.4 Fields

Field	Function
31-16 ERR_FATAL_N ON_FATAL_SO URCE_ID	Source of Fatal/Non-Fatal Error. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-0 ERR_COR_SO URCE_ID	Source of Correctable Error. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.51 TLP Prefix Log Register 1. (TLP_PREFIX_LOG_1_OFF)

11.3.7.1.51.1 Offset

Register	Offset
TLP_PREFIX_LOG_1_ OFF	138h

11.3.7.1.51.2 Function

TLP Prefix Log Register 1. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.51.3 Diagram

11.3.7.1.51.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_1_FOURTH_BYTE	Byte 3 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_1_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_1_SECONDBYTE	Byte 1 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_1_FIRST_BYTE	Byte 0 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.52 TLP Prefix Log Register 2. (TLP_PREFIX_LOG_2_OFF)

11.3.7.1.52.1 Offset

Register	Offset
TLP_PREFIX_LOG_2_OFF	13Ch

11.3.7.1.52.2 Function

TLP Prefix Log Register 2. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.52.3 Diagram

11.3.7.1.52.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_2_FOURTH_BYTE	Byte 3 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_2_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_2_SECONDS_BYTE	Byte 1 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_2_FIRST_BYTE	Byte 0 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.53 TLP Prefix Log Register 3. (TLP_PREFIX_LOG_3_OFF)

11.3.7.1.53.1 Offset

Register	Offset
TLP_PREFIX_LOG_3_OFF	140h

11.3.7.1.53.2 Function

TLP Prefix Log Register 3. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.53.3 Diagram

11.3.7.1.53.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_3_FOURTH_BYTE	Byte 3 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_3_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_3_SECONDBYTE	Byte 1 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_3_FIRST_BYTE	Byte 0 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.54 TLP Prefix Log Register 4. (TLP_PREFIX_LOG_4_OFF)

11.3.7.1.54.1 Offset

Register	Offset
TLP_PREFIX_LOG_4_OFF	144h

11.3.7.1.54.2 Function

TLP Prefix Log Register 4. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.54.3 Diagram

11.3.7.1.54.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_4_FOURTH_BYTE	Byte 3 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_4_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_4_SECOND_BYTE	Byte 1 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_4_FIRST_BYTE	Byte 0 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.7.1.55 L1 Substates Extended Capability Header. (L1SUB_CAP_HEADER_REG)

11.3.7.1.55.1 Offset

Register	Offset
L1SUB_CAP_HEADER_REG	148h

11.3.7.1.55.2 Function

L1 Substates Extended Capability Header. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.55.3 Diagram

11.3.7.1.55.4 Fields

Field	Function
31-20 NEXT_OFFSET	Next Capability Offset. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
19-16 CAP_VERSION	Capability Version. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 EXTENDED_CAP_ID	L1SUB Extended Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.7.1.56 L1 Substates Capability Register. (L1SUB_CAPABILITY_REG)

11.3.7.1.56.1 Offset

Register	Offset
L1SUB_CAPABILITY_REG	14Ch

11.3.7.1.56.2 Function

L1 Substates Capability Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.56.3 Diagram

11.3.7.1.56.4 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-19 PWR_ON_VALUE_SUPPORT	Port T Power On Value. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
18 RSVDP_18	Reserved for future use.
17-16 PWR_ON_SCALE_SUPPORT	Port T Power On Scale. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 COMM_MODE_SUPPORT	Port Common Mode Restore Time. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
7-5	Reserved for future use.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
RSVDP_5	
4 L1_PMSUB_SUPPORT	L1 PM Substates ECN Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
3 L1_1_ASPM_SUPPORT	ASPM L11 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
2 L1_2_ASPM_SUPPORT	ASPM L12 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
1 L1_1_PCIPM_SUPPORT	PCI-PM L11 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
0 L1_2_PCIPM_SUPPORT	PCI-PM L12 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.57 L1 Substates Control 1 Register. (L1SUB_CONTROL1_REG)

11.3.7.1.57.1 Offset

Register	Offset
L1SUB_CONTROL1_REG	150h

11.3.7.1.57.2 Function

L1 Substates Control 1 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.57.3 Diagram

11.3.7.1.57.4 Fields

Field	Function
31-29 L1_2_TH_SCA	LTR L12 Threshold Scale. For a description of this standard PCIe register field, see the PCI Express Specification.
28-26 RSVDP_26	Reserved for future use.
25-16 L1_2_TH_VAL	LTR L12 Threshold Value. For a description of this standard PCIe register field, see the PCI Express Specification.
15-8 T_COMMON_M ODE	Common Mode Restore Time. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
7-4 RSVDP_4	Reserved for future use.
3 L1_1_ASPM_E N	ASPM L11 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
2 L1_2_ASPM_E N	ASPM L12 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 L1_1_PCIPM_E N	PCI-PM L11 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
0 L1_2_PCIPM_EN	PCI-PM L12 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.58 L1 Substates Control 2 Register. (L1SUB_CONTROL2_REG)

11.3.7.1.58.1 Offset

Register	Offset
L1SUB_CONTROL2_REG	154h

11.3.7.1.58.2 Function

L1 Substates Control 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.7.1.58.3 Diagram

11.3.7.1.58.4 Fields

Field	Function
31-8	Reserved for future use.

Table continues on the next page...

Field	Function
RSVDP_8	
7-3 T_POWER_ON_VALUE	T Power On Value. For a description of this standard PCIe register field, see the PCI Express Specification.
2 RSVDP_2	Reserved for future use.
1-0 T_POWER_ON_SCALE	T Power On Scale. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.7.1.59 Ack Latency Timer and Replay Timer Register. (ACK_LATENCY_TIMER_OFF)

11.3.7.1.59.1 Offset

Register	Offset
ACK_LATENCY_TIMER_OFF	700h

11.3.7.1.59.2 Diagram

11.3.7.1.59.3 Fields

Field	Function
31-16 REPLAY_TIME_LIMIT	Replay Timer Limit. The replay timer expires when it reaches this limit. The controller initiates a replay upon reception of a NAK or when the replay timer expires. For more details, see "Transmit Replay". You can modify the effective timer limit with the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-4,

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	3-5, and 3-6 of the PCIe 3.0 specification. If there is a change in the payload size or link speed, the controller will override any value that you have written to this register field, and reset the field back to the specification-defined value. It will not change the value in the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.
15-0 ROUND_TRIP_LATENCY_TIMER_LIMIT	Ack Latency Timer Limit. The Ack latency timer expires when it reaches this limit. For more details, see "Ack Scheduling". You can modify the effective timer limit with the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-7, 3-8, and 3-9 of the PCIe 3.0 specification. The limit must reflect the round trip latency from requester to completer. If there is a change in the payload size or link width, the controller will override any value that you have written to this register field, and reset the field back to the specification-defined value. It will not change the value in the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.

11.3.7.1.60 Vendor Specific DLLP Register. (VENDOR_SPEC_DLLP_OFF)

11.3.7.1.60.1 Offset

Register	Offset
VENDOR_SPEC_DLLP_OFF	704h

11.3.7.1.60.2 Diagram

11.3.7.1.60.3 Fields

Field	Function
31-0 VENDOR_SPEC_DLLP	Vendor Specific DLLP Register. Used to send a specific PCI Express DLLP. Your application writes the 8-bit DLLP Type and 24-bits of Payload data into this register, then sets the field VENDOR_SPECIFIC_DLLP_REQ of PORT_LINK_CTRL_OFF to send the DLLP. - [7:0] = Type - [31:8] = Payload (24 bits) The dllp type is in bits [7:0] while the remainder is the vendor defined payload. Note: This register field is sticky.

11.3.7.1.61 Port Force Link Register. (PORT_FORCE_OFF)

11.3.7.1.61.1 Offset

Register	Offset
PORT_FORCE_OFF	708h

11.3.7.1.61.2 Diagram

11.3.7.1.61.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23 DO_DESKEW_FOR_SRIS	Use the transitions from TS2 to Logical Idle Symbol, SKP OS to Logical Idle Symbol, and FTS Sequence to SKP OS to do deskew for SRIS instead of using received SKP OS if DO_DESKEW_FOR_SRIS is set to 1. Note: This register field is sticky.
22 RSVDP_22	Reserved for future use.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
21-16 LINK_STATE	Forced LTSSM State. The LTSSM state that the controller is forced to when you set the FORCE_EN bit (Force Link). LTSSM state encoding is defined by the lts_state variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
15 FORCE_EN	Force Link. The controller supports a testing and debug capability to allow your software to force the LTSSM state machine into a specific state, and to force the controller to transmit a specific Link Command. Asserting this bit triggers the following actions: - Forces the LTSSM to the state specified by the Forced LTSSM State field. - Forces the controller to transmit the command specified by the Forced Link Command field. This is a self-clearing register field. Reading from this register field always returns a "0".
14-12 RSVDP_12	Reserved for future use.
11-8 FORCED_LTSSM	Forced Link Command. The link command that the controller is forced to transmit when you set FORCE_EN bit (Force Link). Link command encoding is defined by the ltssm_cmd variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
7-0 LINK_NUM	Link Number. Not used for endpoint. Not used for M-PCIe. Note: This register field is sticky.

11.3.7.1.62 Ack Frequency and L0-L1 ASPM Control Register. (ACK_F_AS PM_CTRL_OFF)

11.3.7.1.62.1 Offset

Register	Offset
ACK_F_AS PM_CTRL_ OFF	70Ch

11.3.7.1.62.2 Diagram

11.3.7.1.62.3 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30 ENTER_ASPM	ASPM L1 Entry Control. - 1: Core enters ASPM L1 after a period in which it has been idle. - 0: Core enters ASPM L1 only after idle period during which both receive and transmit are in L0s. Note: This register field is sticky.
29-27 L1_ENTRANCE_LATENCY	L1 Entrance Latency. Value range is: - 000: 1 us - 001: 2 us - 010: 4 us - 011: 8 us - 100: 16 us - 101: 32 us - 110 or 111: 64 us Note: Programming this timer with a value greater than 32us has no effect unless extended sync is used, or all of the credits are infinite. Note: This register field is sticky.
26-24 L0S_ENTRANCE_LATENCY	L0s Entrance Latency. Values correspond to: - 000: 1 us - 001: 2 us - 010: 3 us - 011: 4 us - 100: 5 us - 101: 6 us - 110 or 111: 7 us This field is applicable to STALL while in L0 for M-PCIe. Note: This register field is sticky.
23-16 COMMON_CLK_N_FTS	Common Clock N_FTS. This is the N_FTS when common clock is used. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. This field is only writable (sticky) when all of the following configuration parameter equations are true: - CX_NFTS !=CX_COMM_NFTS - DEFAULT_L0S_EXIT_LATENCY !=DEFAULT_COMM_L0S_EXIT_LATENCY - DEFAULT_L1_EXIT_LATENCY !=DEFAULT_COMM_L1_EXIT_LATENCY The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R
15-8 ACK_N_FTS	N_FTS. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
7-0 ACK_FREQ	Ack Frequency. The controller accumulates the number of pending ACKs specified here (up to 255) before sending an ACK DLLP. - 0: Indicates that this Ack frequency control feature is turned off. The controller schedules a low-priority ACK DLLP for every TLP that it receives. - 1-255: Indicates that the controller will schedule a high-priority ACK after receiving this number of TLPs. It might schedule the ACK before receiving this number of TLPs, but never later. For a typical system, you do not have to modify the default setting. For more details, see "ACK/NAK Scheduling". Note: This register field is sticky.

11.3.7.1.63 Port Link Control Register. (PORT_LINK_CTRL_OFF)

11.3.7.1.63.1 Offset

Register	Offset
PORT_LINK_CTRL_OFF	710h

11.3.7.1.63.2 Diagram

11.3.7.1.63.3 Fields

Field	Function
31-28 RSVDP_28	Reserved for future use.
27 TRANSMIT_LANE_REVERSALE_ENABLE	TRANSMIT_LANE_REVERSALE_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
26	EXTENDED_SYNC is an internally reserved field. Do not use. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
EXTENDED_SYNCH	
25 CORRUPT_LCRC_ENABLE	CORRUPT_LCRC_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
24 BEACON_ENABLE	BEACON_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
23-22 —	Reserved.
21-16 LINK_CAPABLE	Link Mode Enable. Sets the number of lanes in the link that you want to connect to the link partner. When you have unused lanes in your system, then you must change the value in this register to reflect the number of lanes. You must also change the value in the "Predetermined Number of Lanes" field of the "Link Width and Speed Change Control Register". For more information, see "How to Tie Off Unused Lanes". For information on upsizing and downsizing the link width, see "Link Establishment". - 000001: x1 - 000011: x2 - 000111: x4 - 001111: x8 - 011111: x16 - 111111: x32 (not supported) This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.
15-12 RSVDP_12	Reserved for future use.
11-8 LINK_RATE	LINK_RATE is an internally reserved field. Do not use. Note: This register field is sticky.
7 FAST_LINK_MODE	Fast Link Mode. Sets all internal LTSSM millisecond timers to Fast Mode for speeding up simulation. Forces the LTSSM training (link initialization) to use shorter time-outs and to link up faster. The default scaling factor can be changed using the DEFAULT_FAST_LINK_SCALING_FACTOR parameter or through the FAST_LINK_SCALING_FACTOR field in the TIMER_CTRL_MAX_FUNC_NUM_OFF register. Fast Link Mode can also be activated by setting the diag_ctrl_bus[2] pin to '1'. For more details, see the "Fast Link Simulation Mode" section in the "Integrating the Core with the PHY or Application RTL or Verification IP" chapter of the User Guide. For M-PCIe, this field also affects Remain Hibern8 Time, Minimum Activate Time, and RRAP timeout. If this bit is set to '1', tRRAPInitiatorResponse is set to 1.88 ms(60 ms/32). Note: This register field is sticky.
6 LINK_DISABLE	LINK_DISABLE is an internally reserved field. Do not use. Note: This register field is sticky.
5 DLL_LINK_EN	DLL Link Enable. Enables link initialization. When DLL Link Enable =0, the controller does not transmit InitFC DLLPs and does not establish a link. Note: This register field is sticky.
4 RSVDP_4	Reserved for future use.
3 RESET_ASSERT	Reset Assert. Triggers a recovery and forces the LTSSM to the hot reset state (downstream port only). Note: This register field is sticky.
2 LOOPBACK_ENABLE	Loopback Enable. Turns on loopback. For more details, see "Loopback". For M-PCIe, to force the master to enter Digital Loopback mode, you must set this field to "1" during Configuration.start state(initial discovery/configuration). M-PCIe doesn't support loopback mode from L0 state - only from Configuration.start. Note: This register field is sticky.
1 SCRAMBLE_DISABLE	Scramble Disable. Turns off data scrambling. Note: This register field is sticky.

Table continues on the next page...

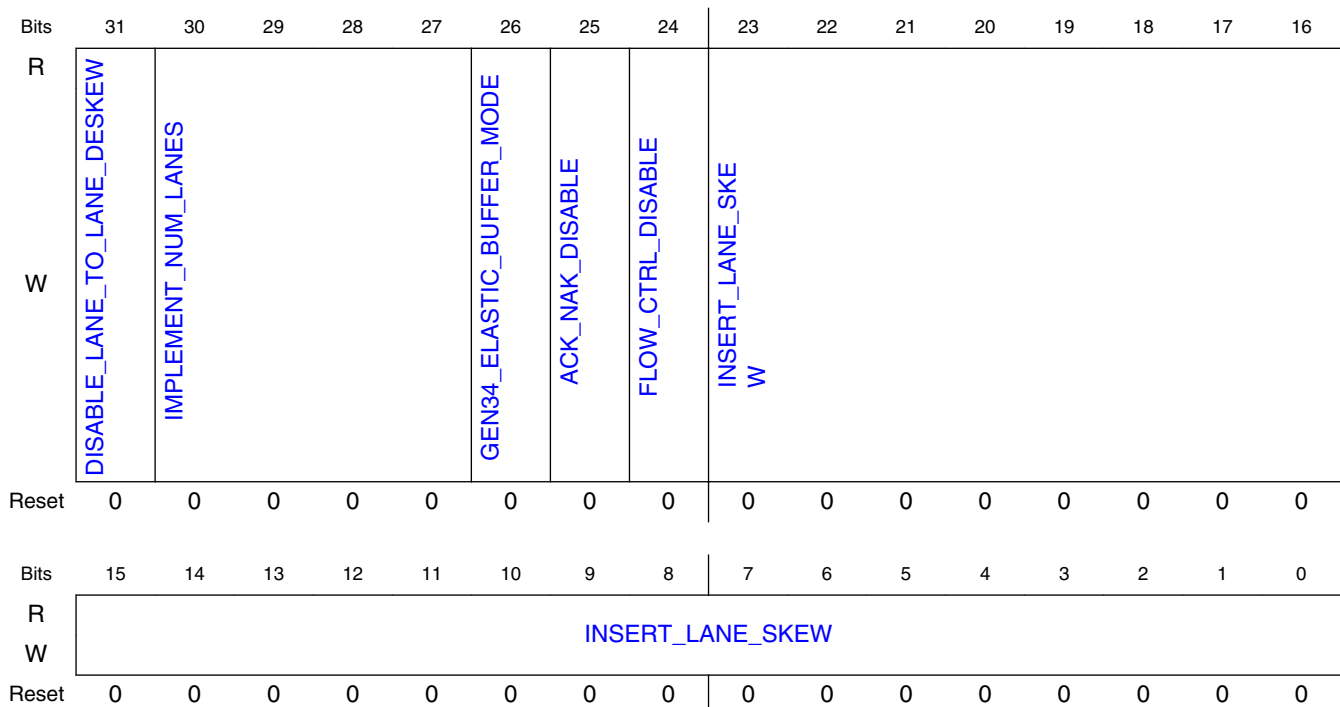

Field	Function
0 VENDOR_SPECIFIC_DLLP_REQUEST	Vendor Specific DLLP Request. When software writes a '1' to this bit, the controller transmits the DLLP contained in the VENDOR_SPEC_DLLP field of VENDOR_SPEC_DLLP_OFF. Reading from this self-clearing register field always returns a '0'.

11.3.7.1.64 Lane Skew Register. (LANE_SKEW_OFF)

11.3.7.1.64.1 Offset

Register	Offset
LANE_SKEW_OFF	714h

11.3.7.1.64.2 Diagram

11.3.7.1.64.3 Fields

Field	Function
31	Disable Lane-to-Lane Deskew. Causes the controller to disable the internal Lane-to-Lane deskew logic. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
DISABLE_LANE_TO_LANE_DESKEW	
30-27 IMPLEMENT_NUM_LANES	Implementation-specific Number of Lanes. Set the implementation-specific number of lanes. Allowed values are: - 4'b0000: 1 lane - 4'b0001: 2 lanes - 4'b0011: 4 lanes - 4'b0111: 8 lanes - 4'b1111: 16 lanes The number of lanes to be used when in Loopback Master. The number of lanes programmed must be equal to or less than the valid number of lanes set in LINK_CAPABLE field. You must configure this field before initiating Loopback by writing in the LOOPBACK_ENABLE field. The controller will transition from Loopback.Entry to Loopback.Active after receiving two consecutive TS1 Ordered Sets with the Loopback bit asserted on the implementation specific number of lanes configured in this field. Note: This register field is sticky.
26 GEN34_ELASTIC_BUFFER_MODE	Selects Elasticity Buffer operating mode in Gen3 or Gen4 rate: 0: Nominal Half Full Buffer mode 1: Nominal Empty Buffer Mode This register bit only affects Gen3 or Gen4 operating rate. For Gen1 or Gen2 operating rate the Elasticity Buffer operating mode is always the Nominal Half Full Buffer mode. Note: This register field is sticky.
25 ACK_NAK_DISABLE	Ack/Nak Disable. Prevents the controller from sending ACK and NAK DLLPs. Note: This register field is sticky.
24 FLOW_CTRL_DISABLE	Flow Control Disable. Prevents the controller from sending FC DLLPs. Note: This register field is sticky.
23-0 INSERT_LANE_SKEW	INSERT_LANE_SKEW is an internally reserved field. Do not use. Note: This register field is sticky.

11.3.7.1.65 Timer Control and Max Function Number Register. (TIMER_CTRL_MAX_FUNC_NUM_OFF)

11.3.7.1.65.1 Offset

Register	Offset
TIMER_CTRL_MAX_FUNC_NUM_OFF	718h

11.3.7.1.65.2 Diagram

11.3.7.1.65.3 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30-29 FAST_LINK_SCALING_FACTOR R	Fast Link Timer Scaling Factor. Sets the scaling factor of LTSSM timer when FAST_LINK_MODE field in PORT_LINK_CTRL_OFF is set to '1'. - 0: Scaling Factor is 1024 (1ms is 1us) - 1: Scaling Factor is 256 (1ms is 4us) - 2: Scaling Factor is 64 (1ms is 16us) - 3: Scaling Factor is 16 (1ms is 64us) Default is set by the hidden configuration parameter DEFAULT_FAST_LINK_SCALING_FACTOR which defaults to '0'. Not used for M-PCIe. Note: This register field is sticky.
28-24 UPDATE_FREQ_TIMER	UPDATE_FREQ_TIMER is an internally reserved field. Do not use. Note: This register field is sticky.
23-19 TIMER_MOD_ACK_NAK	Ack Latency Timer Modifier. Increases the timer value for the Ack latency timer in increments of 64 clock cycles. A value of "0" represents no modification to the timer value. For more details, see the ROUND_TRIP_LATENCY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
18-14 TIMER_MOD_REPLAY_TIMER	Replay Timer Limit Modifier. Increases the time-out value for the replay timer in increments of 64 clock cycles at Gen1 or Gen2 speed, and in increments of 256 clock cycles at Gen3 speed. A value of "0" represents no modification to the timer limit. For more details, see the REPLAY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. At Gen3 speed, the controller automatically changes the value of this field to DEFAULT_GEN3_REPLAY_ADJ. For M-PCIe, this field increases the time-out value for the replay timer in increments of 64 clock cycles at HS-Gear1, HS-Gear2, or HS-Gear3 speed. Note: This register field is sticky.
13-8 RSVDP_8	Reserved for future use.
7-0 MAX_FUNC_NUMBER	Maximum function number that can be used in a request. Configuration requests targeted at function numbers above this value are returned with UR (unsupported request). Note: This register field is sticky.

11.3.7.1.66 Symbol Timer Register and Filter Mask 1 Register. (SYMBOL_TIMER_FILTER_1_OFF)

11.3.7.1.66.1 Offset

Register	Offset
SYMBOL_TIMER_FILTER_1_OFF	71Ch

11.3.7.1.66.2 Function

Symbol Timer Register and Filter Mask 1 Register. The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

11.3.7.1.66.3 Diagram

11.3.7.1.66.4 Fields

Field	Function
31-16 MASK_RADM_1	<p>Filter Mask 1. The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule. [31]: CX_FLT_MASK_RC_CFG_DISCARD - 0: For RADM RC filter to not allow CFG transaction being received - 1: For RADM RC filter to allow CFG transaction being received [30]: CX_FLT_MASK_RC_IO_DISCARD - 0: For RADM RC filter to not allow IO transaction being received - 1: For RADM RC filter to allow IO transaction being received [29]: CX_FLT_MASK_MSG_DROP - 0: Drop MSG TLP (except for Vendor MSG). Send decoded message on the SII. - 1: Do not Drop MSG (except for Vendor MSG). Send message TLPs to your application on TRGT1 and send decoded message on the SII. - The default for this bit is the inverse of FLT_DROP_MSG. That is, if FLT_DROP_MSG =1, then the default of this bit is "0" (drop message TLPs). This bit only controls message TLPs other than Vendor MSGs. Vendor MSGs are controlled by Filter Mask Register 2, bits [1:0]. The controller never passes ATS Invalidate messages to the SII interface regardless of this filter rule setting. The controller passes all ATS Invalidate messages to TRGT1 (or AXI bridge master), as they are too big for the SII. [28]: CX_FLT_MASK_CPL_ECRC_DISCARD - Only used when completion queue is advertised with infinite credits and is in store-and-forward mode. - 0: Discard completions with ECRC errors - 1: Allow completions with ECRC errors to be passed up - Reserved field for SW. [27]: CX_FLT_MASK_ECRC_DISCARD - 0: Discard TLPs with ECRC errors - 1: Allow TLPs with ECRC errors to be passed up [26]: CX_FLT_MASK_CPL_LEN_MATCH - 0: Enforce length match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err - 1: MASK length match for completions [25]: CX_FLT_MASK_CPL_ATTR_MATCH - 0: Enforce attribute match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask attribute match for completions [24]: CX_FLT_MASK_CPL_TC_MATCH - 0: Enforce Traffic Class match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Traffic Class match for completions [23]: CX_FLT_MASK_CPL_FUNC_MATCH - 0: Enforce function match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask function match for completions [22]: CX_FLT_MASK_CPL_REQID_MATCH - 0: Enforce Req. Id match for completions; a violation result in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Req. Id match for completions [21]: CX_FLT_MASK_CPL_TAGERR_MATCH - 0: Enforce Tag Error Rules for</p>

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	<p>completions; a violation result in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Tag Error Rules for completions [20]: CX_FLT_MASK_LOCKED_RD_AS_UR - 0: Treat locked Read TLPs as UR for EP; Supported for RC - 1: Treat locked Read TLPs as Supported for EP; UR for RC [19]: CX_FLT_MASK_CFG_TYPE1_REQ_AS_UR - 0: Treat CFG type1 TLPs as UR for EP; Supported for RC - 1: Treat CFG type1 TLPs as Supported for EP; UR for RC - When CX_SRIOV_ENABLE is set then this bit is set to allow the filter to process Type 1 Config requests if the EP consumes more than one bus number. [18]: CX_FLT_MASK_UR_OUTSIDE_BAR - 0: Treat out-of-bar TLPs as UR - 1: Do not treat out-of-bar TLPs as UR [17]: CX_FLT_MASK_UR_POIS - 0: Treat poisoned request TLPs as UR - 1: Do not treat poisoned request TLPs as UR - The native controller always passes poisoned completions to your application except when you are using the DMA read channel. [16]: CX_FLT_MASK_UR_FUNC_MISMATCH - 0: Treat Function MisMatched TLPs as UR - 1: Do not treat Function MisMatched TLPs as UR Note: This register field is sticky.</p>
15 DISABLE_FC_WD_TIMER	Disable FC Watchdog Timer. Note: This register field is sticky.
14-11 EIDLE_TIMER	EIDLE_TIMER is an internally reserved field. Do not use. Note: This register field is sticky.
10-0 SKP_INT_VAL	<p>SKP Interval Value. The number of symbol times to wait between transmitting SKP ordered sets. Note that the controller actually waits the number of symbol times in this register plus 1 between transmitting SKP ordered sets. Your application must program this register accordingly. For example, if 1536 were programmed into this register (in a 250 MHz controller), then the controller actually transmits SKP ordered sets once every 1537 symbol times. The value programmed to this register is actually clock ticks and not symbol times. In a 125 MHz controller, programming the value programmed to this register should be scaled down by a factor of 2 (because one clock tick = two symbol times in this case). Note: This value is not used at Gen3 speed; the skip interval is hardcoded to 370 blocks. For M-PCIe configurations, if the 2K_PPM_DISABLED field in the M-PCIe Configuration Attribute is changed, then this field is changed automatically as follows. - 2K_PPM_DISABLED=1: 1280 / CX_NB - 2K_PPM_DISABLED=0: 228/CX_NB You need to set this field again if necessary when 2K_PPM_DISABLED is changed. Note: This register field is sticky.</p>

11.3.7.1.67 Filter Mask 2 Register. (FILTER_MASK_2_OFF)

11.3.7.1.67.1 Offset

Register	Offset
FILTER_MASK_2_OFF	720h

11.3.7.1.67.2 Function

Filter Mask 2 Register. This register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

11.3.7.1.67.3 Diagram

11.3.7.1.67.4 Fields

Field	Function
31-0 MASK_RADM_2	Filter Mask 2. This field modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule. [31:8]: Reserved [7]: CX_FLT_MASK_PRS_DROP - 0: Allow PRS message to pass through - 1: Drop PRS Messages silently - This bit is ignored when the CX_FLT_MASK_MSG_DROP bit in the MASK_RADM_1 field of the SYMBOL_TIMER_FILTER_1_OFF register is set to '1'. [6]: CX_FLT_UNMASK_TD - 0: Disable unmask TD bit if CX_STRIP_ECRC_ENABLE - 1: Enable unmask TD bit if CX_STRIP_ECRC_ENABLE [5]: CX_FLT_UNMASK_UR_POIS_TRGT0 - 0: Disable unmask CX_FLT_MASK_UR_POIS with TRGT0 destination - 1: Enable unmask CX_FLT_MASK_UR_POIS with TRGT0 destination [4]: CX_FLT_MASK_LN_VENMSG1_DROP - 0: Allow LN message to pass through - 1: Drop LN Messages silently [3]: CX_FLT_MASK_HANDLE_FLUSH - 0: Disable controller Filter to handle flush request - 1: Enable controller Filter to handle flush request [2]: CX_FLT_MASK_DABORT_4UCPL - 0: Enable DLLP abort for unexpected completion - 1: Do not enable DLLP abort for unexpected completion [1]: CX_FLT_MASK_VENMSG1_DROP - 0: Vendor MSG Type 1 dropped silently - 1: Vendor MSG Type 1 not dropped [0]: CX_FLT_MASK_VENMSG0_DROP - 0: Vendor MSG Type 0 dropped with UR error reporting - 1: Vendor MSG Type 0 not dropped Note: This register field is sticky.

11.3.7.1.68 AMBA Multiple Outbound Decomposed NP SubRequests Control Register. (AMBA_MUL_OB_DECOMP_NP_SUB_REQ_CTRL_OFF)

11.3.7.1.68.1 Offset

Register	Offset
AMBA_MUL_OB_DECO MP_NP_SUB_REQ_CT RL_OFF	724h

11.3.7.1.68.2 Diagram

11.3.7.1.68.3 Fields

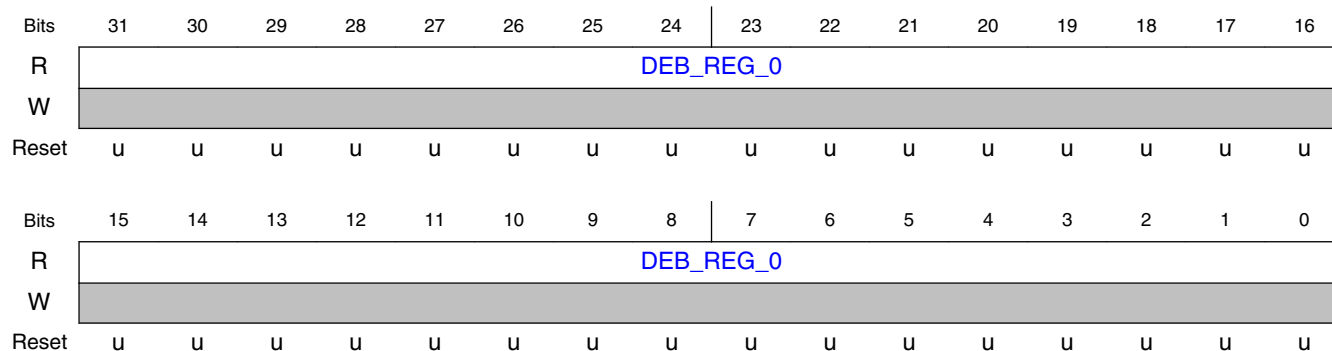

Field	Function
31-1 RSVDP_1	Reserved for future use.
0 OB_RD_SPLIT_BURST_EN	Enable AMBA Multiple Outbound Decomposed NP SubRequests. This bit when set to "0" disables the possibility of having multiple outstanding non-posted requests that were derived from decomposition of an outbound AMBA request. For more details, see "AXI Bridge Ordering" in the AXI chapter of the Databook. You should not clear this register unless your application master is requesting an amount of read data greater than Max_Read_Request_Size, and the remote device (or switch) is reordering completions that have different tags. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

11.3.7.1.69 Debug Register 0 (PL_DEBUG0_OFF)

11.3.7.1.69.1 Offset

Register	Offset
PL_DEBUG0_OFF	728h

Register	Offset
QUEUE_STATUS_OFF	73Ch

11.3.7.1.74.2 Diagram

11.3.7.1.74.3 Fields

Field	Function
31 TIMER_MOD_FLOW_CONTROL_EN	FC Latency Timer Override Enable. When this bit is set, the value from the "FC Latency Timer Override Value" field in this register will override the FC latency timer value that the controller calculates according to the PCIe specification. Note: This register field is sticky.
30-29 RSVDP_29	Reserved for future use.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
28-16 TIMER_MOD_F LOW_CONTROL	FC Latency Timer Override Value. When you set the "FC Latency Timer Override Enable" in this register, the value in this field will override the FC latency timer value that the controller calculates according to the PCIe specification. For more details, see "Flow Control". Note: This register field is sticky.
15 RX_SERIALIZA TION_Q_READ _ERR	Receive Serialization Read Error. Indicates the serialization queue has attempted to read an incorrectly formatted TLP.
14 RX_SERIALIZA TION_Q_WRIT E_ERR	Receive Serialization Queue Write Error. Indicates insufficient buffer space available to write to the serialization queue.
13 RX_SERIALIZA TION_Q_NON_ EMPTY	Receive Serialization Queue Not Empty. Indicates there is data in the serialization queue.
12-4 RSVDP_4	Reserved for future use.
3 RX_QUEUE_O VERFLOW	Receive Credit Queue Overflow. Indicates insufficient buffer space available to write to the P/NP/CPL credit queue.
2 RX_QUEUE_N ON_EMPTY	Receive Credit Queue Not Empty. Indicates there is data in one or more of the receive buffers.
1 TX_RETRY_BU FFER_NE	Transmit Retry Buffer Not Empty. Indicates that there is data in the transmit retry buffer.
0 RX_TLP_FC_C REDIT_NON_R ETURN	Received TLP FC Credits Not Returned. Indicates that the controller has received a TLP but has not yet sent an UpdateFC DLLP indicating that the credits for that TLP have been restored by the receiver at the other end of the link.

RESERVED8	
19-12 VC0_CPL_HEA DER_CREDIT	VC0 Completion Header Credits. The number of initial Completion header credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Dbi: R (sticky) Note: This register field is sticky.
11-0 VC0_CPL_DAT A_CREDIT	VC0 Completion Data Credits. The number of initial Completion data credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Dbi: R (sticky) Note: This register field is sticky.

11.3.7.1.80 Link Width and Speed Change Control Register. (GEN2_CTRL_OFF)

11.3.7.1.80.1 Offset

Register	Offset
GEN2_CTRL_OFF	80Ch

11.3.7.1.80.2 Diagram

11.3.7.1.80.3 Fields

Field	Function
31-22 RSVDP_22	Reserved for future use.
21 GEN1_EI_INFERENCE	Electrical Idle Inference Mode at Gen1 Rate. Programmable mode to determine inferred electrical idle (EI) in Recovery.Speed or Loopback.Active (as slave) state at Gen1 speed by looking for a "1" value on RxElecIdle instead of looking for a "0" on RxValid. If the PHY fails to deassert the RxValid signal in Recovery.Speed or Loopback.Active (because of corrupted EIOS for example), then EI cannot be inferred successfully in the controller by just detecting the condition RxValid=0. - 0: Use RxElecIdle signal to infer Electrical Idle - 1: Use RxValid signal to infer Electrical Idle Note: This register field is sticky.
20 SEL_DEEMPHASIS	Used to set the de-emphasis level for upstream ports. This bit selects the level of de-emphasis the link operates at. - 0: -6 dB - 1: -3.5 dB This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
19 CONFIG_TX_COMP_RX	Config Tx Compliance Receive Bit. When set to 1, signals LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to "1"). This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
18 CONFIG_PHY_TX_CHANGE	Config PHY Tx Swing. Controls the PHY transmitter voltage swing level. The controller drives the mac_phy_txswing output from this register bit field. - 0: Full Swing - 1: Low Swing This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
17 DIRECT_SPEED_CHANGE	Directed Speed Change. Writing "1" to this field instructs the LTSSM to initiate a speed change to Gen2 or Gen3 after the link is initialized at Gen1 speed. When the speed change occurs, the controller will clear the contents of this field; and a read to this field by your software will return a "0". To manually initiate the speed change: - Write to LINK_CONTROL2_LINK_STATUS2_REG . PCIE_CAP_TARGET_LINK_SPEED in the local device - Deassert this field - Assert this field If you set the default of this field using the DEFAULT_GEN2_SPEED_CHANGE configuration parameter to "1", then the speed change is initiated automatically after link up, and the controller clears the contents of this field. If you want to prevent this automatic speed change, then write a lower speed value to the Target Link Speed field of the Link Control 2 register (LINK_CONTROL2_LINK_STATUS2_OFF . PCIE_CAP_TARGET_LINK_SPEED) through the DBI before link up. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W
16 AUTO_LANE_FLIP_CTRL_EN	Enable Auto flipping of the lanes. You must set the CX_AUTO_LANE_FLIP_CTRL_EN configuration parameter to include the hardware for this feature in the controller. For more details, see the 'Lane Reversal' appendix in the Databook. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
15-13 PRE_DET_LANE	Predetermined Lane for Auto Flip. This field defines which physical lane is connected to logical Lane0 by the flip operation performed in Detect. Allowed values are: - 3'b000: Connect logical Lane0 to physical lane 0 or CX_NL-1 or CX_NL/2-1 or CX_NL/4-1 or CX_NL/8-1, depending on which lane is detected - 3'b001: Connect logical Lane0 to physical lane 1 - 3'b010: Connect logical Lane0 to physical lane 3 - 3'b011: Connect logical Lane0 to physical lane 7 - 3'b100: Connect logical Lane0 to physical lane 15 This field is used to restrict the receiver detect procedure to a particular lane when the default detect and polling procedure performed on all lanes cannot be successful. A notable example of when it is useful to program this field to a value different from the default, is when a lane is asymmetrically broken, that is, it is detected in Detect LTSSM state but it cannot exit Electrical Idle in Polling LTSSM state. Note: This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
12-8 NUM_OF_LANES	Predetermined Number of Lanes. Defines the number of lanes which are connected and not bad. Used to limit the effective link width to ignore "broken" or "unused" lanes that detect a receiver. Indicates the number of lanes to check for exit from Electrical Idle in Polling.Active and L2.Idle. It is possible that the LTSSM might detect a receiver on a bad or broken lane during the Detect Substate. However, it is also

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	possible that such a lane might also fail to exit Electrical Idle and therefore prevent a valid link from being configured. This value is referred to as the "Predetermined Number of Lanes" in section 4.2.6.2.1 of the PCI Express Base 3.0 Specification, revision 1.0. Encoding is as follows: - 0x01: 1 lane - 0x02: 2 lanes - 0x03: 3 lanes - .. When you have unused lanes in your system, then you must change the value in this register to reflect the number of lanes. You must also change the value in the "Link Mode Enable" field of PORT_LINK_CTRL_OFF. The value in this register is normally the same as the encoded value in PORT_LINK_CTRL_OFF. If you find that one of your used lanes is bad then you must reduce the value in this register. For more information, see "How to Tie Off Unused Lanes." For information on upsizing and downsizing the link width, see "Link Establishment." This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
7-0 FAST_TRAINING_SEQ	Sets the Number of Fast Training Sequences (N_FTS) that the controller advertises as its N_FTS during Gen2 or Gen3 link training. This value is used to inform the link partner about the PHY's ability to recover synchronization after a low power state. The number should be provided by the PHY vendor. Do not set N_FTS to zero; doing so can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

11.3.7.1.81 PHY Status Register. (PHY_STATUS_OFF)

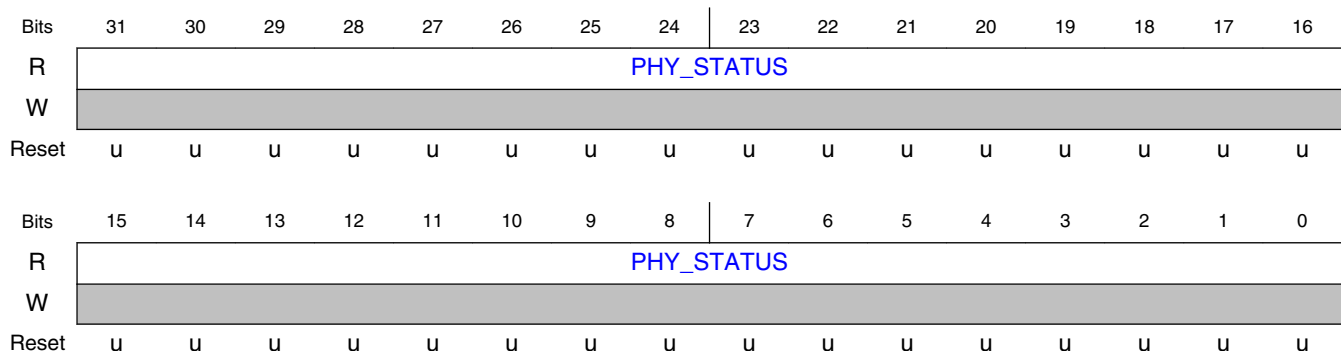

11.3.7.1.81.1 Offset

Register	Offset
PHY_STATUS_OFF	810h

11.3.7.1.81.2 Function

PHY Status Register. Memory mapped register from phy_cfg_status GPIO input pins.

11.3.7.1.81.3 Diagram

11.3.7.1.81.4 Fields

Field	Function
31-0 PHY_STATUS	PHY Status. Data received directly from the phy_cfg_status bus. These is a GPIO register reflecting the values on the static phy_cfg_status input signals. The usage is left completely to the user and does not in any way influence controller functionality. You can use it for any static sideband status signalling requirements that you have for your PHY. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

11.3.7.1.82 PHY Control Register. (PHY_CONTROL_OFF)

11.3.7.1.82.1 Offset

Register	Offset
PHY_CONTROL_OFF	814h

11.3.7.1.82.2 Function

PHY Control Register. Memory mapped register to cfg_phy_control GPIO output pins.

11.3.7.1.82.3 Diagram

11.3.7.1.82.4 Fields

Field	Function
31-0 PHY_CONTROL	PHY Control. Data sent directly to the cfg_phy_control bus. These is a GPIO register driving the values on the static cfg_phy_control output signals. The usage is left completely to the user and does not in any way influence controller functionality. You can use it for any static sideband control signalling requirements that you have for your PHY. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

11.3.7.1.83 Programmable Target Map Control Register. (TRGT_MAP_CTRL_L_OFF)

11.3.7.1.83.1 Offset

Register	Offset
TRGT_MAP_CTRL_OFF	81Ch

11.3.7.1.83.2 Diagram

11.3.7.1.83.3 Fields

Field	Function
31-21 TARGET_MAP_ RESERVED_21 _31	Reserved. Note: The access attributes of this field are as follows: - Dbi: R (sticky)
20-16 TARGET_MAP_ INDEX	The number of the PF Function on which the Target Values are set. This register does not respect the Byte Enable setting. any write will affect all register bits.
15-13 TARGET_MAP_ RESERVED_13 _15	Reserved. Note: The access attributes of this field are as follows: - Dbi: R (sticky)
12-7 —	Reserved.
6 TARGET_MAP_ ROM	Target Value for the ROM page of the PF Function selected by the index number. This register does not respect the Byte Enable setting. any write will affect all register bits.
5-0 TARGET_MAP_ PF	Target Values for each BAR on the PF Function selected by the index number. This register does not respect the Byte Enable setting. any write will affect all register bits.

11.3.7.1.84 Integrated MSI Reception Module (iMRM) Address Register. (MSI_CTRL_ADDR_OFF)

11.3.7.1.84.1 Offset

Register	Offset
MSI_CTRL_ADDR_OFF	820h

11.3.7.1.84.2 Diagram

11.3.7.1.84.3 Fields

Field	Function
31-0 MSI_CTRL_ADDR	Integrated MSI Reception Module Address. System specified address for MSI memory write transaction termination. Within the AXI Bridge, every received Memory Write request is examined to see if it targets the MSI Address that has been specified in this register; and also to see if it satisfies the definition of an MSI interrupt request. When these conditions are satisfied the Memory Write request is marked as an MSI request. Note: This register field is sticky.

11.3.7.1.85 Integrated MSI Reception Module Upper Address Register. (MSI_CTRL_UPPER_ADDR_OFF)

11.3.7.1.85.1 Offset

Register	Offset
MSI_CTRL_UPPER_ADDR_OFF	824h

11.3.7.1.85.2 Diagram

11.3.7.1.85.3 Fields

Field	Function
31-0 MSI_CTRL_UPPER_ADDR	Integrated MSI Reception Module Upper Address. System specified upper address for MSI memory write transaction termination. Allows functions to support a 64-bit MSI address. Note: This register field is sticky.

11.3.7.1.86 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_0_EN_OFF)

11.3.7.1.86.1 Offset

Register	Offset
MSI_CTRL_INT_0_EN_OFF	828h

11.3.7.1.86.2 Diagram

11.3.7.1.86.3 Fields

Field	Function
MSI_CTRL_INT_0_EN 31-0	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.87 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_0_MASK_OFF)

11.3.7.1.87.1 Offset

Register	Offset
MSI_CTRL_INT_0_MASK_OFF	82Ch

11.3.7.1.87.2 Diagram

11.3.7.1.87.3 Fields

Field	Function
MSI_CTRL_INT_0_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.88 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_0_STATUS_OFF)

11.3.7.1.88.1 Offset

Register	Offset
MSI_CTRL_INT_0_STATUS_OFF	830h

11.3.7.1.88.2 Diagram

11.3.7.1.88.3 Fields

Field	Function
31-0 MSI_CTRL_INT_0_STATUS	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.89 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_1_EN_OFF)

11.3.7.1.89.1 Offset

Register	Offset
MSI_CTRL_INT_1_EN_OFF	834h

11.3.7.1.89.2 Diagram

11.3.7.1.89.3 Fields

Field	Function
31-0 MSI_CTRL_INT_1_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.90 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_1_MASK_OFF)

11.3.7.1.90.1 Offset

Register	Offset
MSI_CTRL_INT_1_MASK_OFF	838h

11.3.7.1.90.2 Diagram

11.3.7.1.90.3 Fields

Field	Function
MSI_CTRL_INT_1_MASK (31-0)	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.91 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_1_STATUS_OFF)

11.3.7.1.91.1 Offset

Register	Offset
MSI_CTRL_INT_1_STATUS_OFF	83Ch

11.3.7.1.91.2 Diagram

11.3.7.1.91.3 Fields

Field	Function
MSI_CTRL_INT_1_STATUS	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.92 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_2_EN_OFF)

11.3.7.1.92.1 Offset

Register	Offset
MSI_CTRL_INT_2_EN_OFF	840h

11.3.7.1.92.2 Diagram

11.3.7.1.92.3 Fields

Field	Function
31-0 MSI_CTRL_INT_2_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.93 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_2_MASK_OFF)

11.3.7.1.93.1 Offset

Register	Offset
MSI_CTRL_INT_2_MASK_OFF	844h

11.3.7.1.93.2 Diagram

11.3.7.1.93.3 Fields

Field	Function
31-0 MSI_CTRL_INT_2_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.94 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_2_STATUS_OFF)

11.3.7.1.94.1 Offset

Register	Offset
MSI_CTRL_INT_2_STATUS_OFF	848h

11.3.7.1.94.2 Diagram

11.3.7.1.94.3 Fields

Field	Function
MSI_CTRL_INT_2_STATUS 31-0	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.95 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_3_EN_OFF)

11.3.7.1.95.1 Offset

Register	Offset
MSI_CTRL_INT_3_EN_OFF	84Ch

11.3.7.1.95.2 Diagram

11.3.7.1.95.3 Fields

Field	Function
MSI_CTRL_INT_3_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.96 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_3_MASK_OFF)

11.3.7.1.96.1 Offset

Register	Offset
MSI_CTRL_INT_3_MASK_OFF	850h

11.3.7.1.96.2 Diagram

11.3.7.1.96.3 Fields

Field	Function
31-0 MSI_CTRL_INT_3_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.97 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_3_STATUS_OFF)

11.3.7.1.97.1 Offset

Register	Offset
MSI_CTRL_INT_3_STATUS_OFF	854h

11.3.7.1.97.2 Diagram

11.3.7.1.97.3 Fields

Field	Function
31-0 MSI_CTRL_INT_3_STATUS	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.98 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_4_EN_OFF)

11.3.7.1.98.1 Offset

Register	Offset
MSI_CTRL_INT_4_EN_OFF	858h

11.3.7.1.98.2 Diagram

11.3.7.1.98.3 Fields

Field	Function
31-0 MSI_CTRL_INT_4_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.99 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_4_MASK_OFF)

11.3.7.1.99.1 Offset

Register	Offset
MSI_CTRL_INT_4_MASK_OFF	85Ch

11.3.7.1.99.2 Diagram

11.3.7.1.99.3 Fields

Field	Function
MSI_CTRL_INT_4_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.100 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_4_STATUS_OFF)

11.3.7.1.100.1 Offset

Register	Offset
MSI_CTRL_INT_4_STATUS_OFF	860h

11.3.7.1.100.2 Diagram

11.3.7.1.100.3 Fields

Field	Function
31-0 MSI_CTRL_INT_4_STATUS	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.101 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_5_EN_OFF)

11.3.7.1.101.1 Offset

Register	Offset
MSI_CTRL_INT_5_EN_OFF	864h

11.3.7.1.101.2 Diagram

11.3.7.1.101.3 Fields

Field	Function
31-0 MSI_CTRL_INT_5_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.102 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_5_MASK_OFF)

11.3.7.1.102.1 Offset

Register	Offset
MSI_CTRL_INT_5_MASK_OFF	868h

11.3.7.1.102.2 Diagram

11.3.7.1.102.3 Fields

Field	Function
MSI_CTRL_INT_5_MASK 31-0	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.103 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_5_STATUS_OFF)

11.3.7.1.103.1 Offset

Register	Offset
MSI_CTRL_INT_5_STATUS_OFF	86Ch

11.3.7.1.103.2 Diagram

11.3.7.1.103.3 Fields

Field	Function
MSI_CTRL_INT_5_STATUS 31-0	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.104 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_6_EN_OFF)

11.3.7.1.104.1 Offset

Register	Offset
MSI_CTRL_INT_6_EN_OFF	870h

11.3.7.1.104.2 Diagram

11.3.7.1.104.3 Fields

Field	Function
31-0 MSI_CTRL_INT_6_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.105 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_6_MASK_OFF)

11.3.7.1.105.1 Offset

Register	Offset
MSI_CTRL_INT_6_MASK_OFF	874h

11.3.7.1.105.2 Diagram

11.3.7.1.105.3 Fields

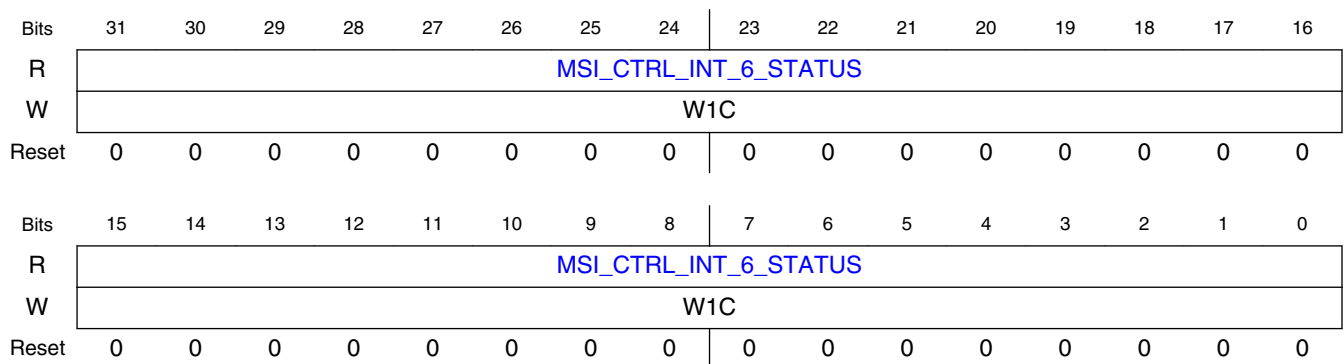

Field	Function
31-0 MSI_CTRL_INT_6_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.106 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_6_STATUS_OFF)

11.3.7.1.106.1 Offset

Register	Offset
MSI_CTRL_INT_6_STATUS_OFF	878h

11.3.7.1.106.2 Diagram

11.3.7.1.106.3 Fields

Field	Function
MSI_CTRL_INT_6_STATUS 31-0	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.107 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_7_EN_OFF)

11.3.7.1.107.1 Offset

Register	Offset
MSI_CTRL_INT_7_EN_OFF	87Ch

11.3.7.1.107.2 Diagram

11.3.7.1.107.3 Fields

Field	Function
MSI_CTRL_INT_7_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.108 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_7_MASK_OFF)

11.3.7.1.108.1 Offset

Register	Offset
MSI_CTRL_INT_7_MASK_OFF	880h

11.3.7.1.108.2 Diagram

11.3.7.1.108.3 Fields

Field	Function
31-0 MSI_CTRL_INT_7_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.7.1.109 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_7_STATUS_OFF)

11.3.7.1.109.1 Offset

Register	Offset
MSI_CTRL_INT_7_STATUS_OFF	884h

11.3.7.1.109.2 Diagram

11.3.7.1.109.3 Fields

Field	Function
31-0 MSI_CTRL_INT_7_STATUS	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.7.1.110 Integrated MSI Reception Module General Purpose IO Register. (MSI_GPIO_IO_OFF)

11.3.7.1.110.1 Offset

Register	Offset
MSI_GPIO_IO_OFF	888h

11.3.7.1.110.2 Diagram

11.3.7.1.110.3 Fields

Field	Function
MSI_GPIO_REG	MSI GPIO Register. The contents of this register drives the top-level GPIO msi_ctrl_io[31:0] Note: This register field is sticky.

11.3.7.1.111 RADM clock gating enable control register. (CLOCK_GATING_CTRL_OFF)

11.3.7.1.111.1 Offset

Register	Offset
CLOCK_GATING_CTRL_OFF	88Ch

11.3.7.1.111.2 Function

RADM clock gating enable control register. Using this register you can disable the RADM clock gating feature. The DWC_pcie_clk_rst.v modules uses the en_radm_clk_g output to gate core_clk and create the radm_clk_g clock input. The controller de-asserts the en_radm_clk_g output when there is no Rx traffic, Rx queues and pre/post-queue pipelines are empty, RADM completion LUT is empty, and there are no FLR actions pending. You must set the RADM_CLK_GATING_EN field to enable this functionality; otherwise the en_radm_clk_g output will always be set to '1'.

11.3.7.1.111.3 Diagram

11.3.7.1.111.4 Fields

Field	Function
31-1 RSVDP_1	Reserved for future use.
0 RADM_CLK_GATING_EN	Enable Radm clock gating feature. - 0: Disable - 1: Enable(default)

11.3.7.1.112 Order Rule Control Register. (ORDER_RULE_CTRL_OFF)

11.3.7.1.112.1 Offset

Register	Offset
ORDER_RULE_CTRL_OFF	8B4h

11.3.7.1.112.2 Diagram

11.3.7.1.112.3 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15-8 CPL_PASS_P	Completion Passing Posted Ordering Rule Control. Determines if CPL can pass halted P queue. - 0: CPL can not pass P (recommended) - 1: CPL can pass P
7-0 NP_PASS_P	Non-Posted Passing Posted Ordering Rule Control. Determines if NP can pass halted P queue. - 0: NP can not pass P (recommended). - 1: NP can pass P

11.3.7.1.113 PIPE Loopback Control Register. (PIPE_LOOPBACK_CONTROL_OFF)

11.3.7.1.113.1 Offset

Register	Offset
PIPE_LOOPBACK_CONTROL_OFF	8B8h

11.3.7.1.113.2 Diagram

11.3.7.1.113.3 Fields

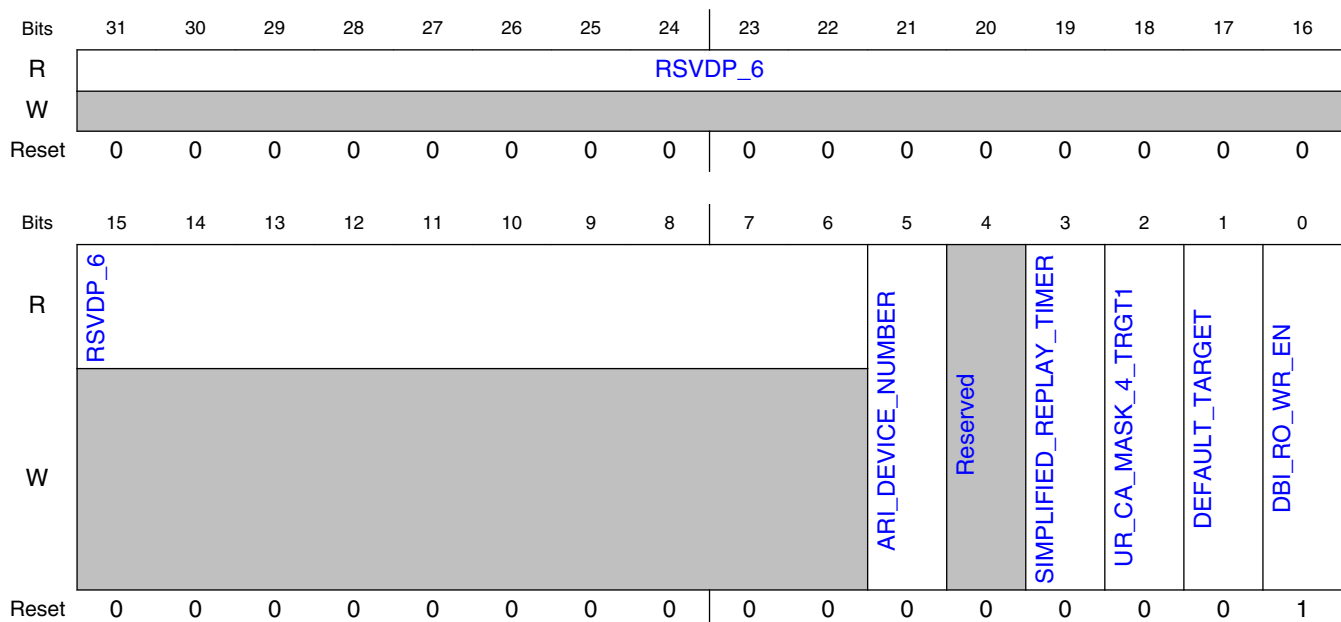

Field	Function
31 PIPE_LOOPBACK	PIPE Loopback Enable. Indicates RMMI Loopback if M-PCIe. Note: This register field is sticky.
30-27 RSVDP_27	Reserved for future use.
26-24 RXSTATUS_VALUE	RXSTATUS_VALUE is an internally reserved field. Do not use.
23-22 RSVDP_22	Reserved for future use.
21-16 RXSTATUS_LANE	RXSTATUS_LANE is an internally reserved field. Do not use. Note: This register field is sticky.
15-0 LPBK_RXVALID	LPBK_RXVALID is an internally reserved field. Do not use. Note: This register field is sticky.

11.3.7.1.114 DBI Read-Only Write Enable Register. (MISC_CONTROL_1_0 FF)

11.3.7.1.114.1 Offset

Register	Offset
MISC_CONTROL_1_0 FF	8BCh

11.3.7.1.114.2 Diagram

11.3.7.1.114.3 Fields

Field	Function
31-6 RSVDP_6	Reserved for future use.
5 ARI_DEVICE_NUMBER	When ARI is enabled, this field enables use of the device ID. Note: This register field is sticky.
4 —	Reserved.
3	Enables Simplified Replay Timer (Gen4). For more details, see "Transmit Replay" in the Controller Operations chapter of the Databook. Simplified Replay Timer Values are: - A value from 24,000 to 31,000

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
SIMPLIFIED_REPLY_TIMER	Symbol Times when Extended Synch is 0b. - A value from 80,000 to 100,000 Symbol Times when Extended Synch is 1b. Must not be changed while link is in use. Note: This register field is sticky.
2 UR_CA_MASK_4_TRGT1	This field only applies to request TLPs (with UR filtering status) that you have chosen to forward to the application (when you set DEFAULT_TARGET in this register). - When you set this field to '1', the core suppresses error logging, Error Message generation, and CPL generation (for non-posted requests). - For more details, refer to the "Advanced Error Handling For Received TLPs" chapter of the Databook. You should set this if you have set the Default Target port logic register to '1'. Default is CX_MASK_UR_CA_4_TRGT1 configuration parameter. Note: This register field is sticky.
1 DEFAULT_TARGET	Default target a received IO or MEM request with UR/CA/CRS is sent to by the controller. - 0: The controller drops all incoming I/O or MEM requests (after corresponding error reporting). A completion with UR status will be generated for non-posted requests. - 1: The controller forwards all incoming I/O or MEM requests with UR/CA/CRS status to your application For more details, see "ECRC Handling" and "Request TLP Routing Rules" in "Receive Routing" section of the "Controller Operations" chapter of the Databook. Default value is DEFAULT_TARGET configuration parameter. Note: This register field is sticky.
0 DBI_RO_WR_EN	Write to RO Registers Using DBI. When you set this field to "1", then some RO and Hwlnit bits are writable from the local application through the DBI. For more details, see "Writing to Read-Only Registers." Note: This register field is sticky.

11.3.7.1.115 UpConfigure Multi-lane Control Register. (MULTI_LANE_CONTROL_OFF)

11.3.7.1.115.1 Offset

Register	Offset
MULTI_LANE_CONTROL_OFF	8C0h

11.3.7.1.115.2 Function

UpConfigure Multi-lane Control Register. Used when upsizing or downsizing the link width through Configuration state without bringing the link down. For more details, see the "Link Establishment" section in the "Controller Operations" chapter of the Databook.

11.3.7.1.115.3 Diagram

11.3.7.1.115.4 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7 UPCONFIGURE_SUPPORT	Upconfigure Support. The controller sends this value as the Link Upconfigure Capability in TS2 Ordered Sets in Configuration.Complete state. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.
6 DIRECT_LINK_WIDTH_CHANGE	Directed Link Width Change. The controller always moves to Configuration state through Recovery state when this bit is set to '1'. - If the upconfigure_capable variable is '1' and the PCIE_CAP_HW_AUTO_WIDTH_DISABLE bit in LINK_CONTROL_LINK_STATUS_REG is '0', the controller starts upconfigure or autonomous width downsizing (to the TARGET_LINK_WIDTH value) in the Configuration state. - If TARGET_LINK_WIDTH value is 0x0, the controller does not start upconfigure or autonomous width downsizing in the Configuration state. The controller self-clears this field when the controller accepts this request. This field is reserved (fixed to '0') for M-PCIe.
5-0 TARGET_LINK_WIDTH	Target Link Width. Values correspond to: - 6'b000000: Core does not start upconfigure or autonomous width downsizing in the Configuration state. - 6'b000001: x1 - 6'b000010: x2 - 6'b000100: x4 - 6'b001000: x8 - 6'b010000: x16 - 6'b100000: x32 This field is reserved (fixed to '0') for M-PCIe.

11.3.7.1.116 PHY Interoperability Control Register. (PHY_INTEROP_CTRL_OFF)

11.3.7.1.116.1 Offset

Register	Offset
PHY_INTEROP_CTRL_OFF	8C4h

11.3.7.1.116.2 Function

PHY Interoperability Control Register. This register is reserved for internal use. You should not write to this register and change the default unless specifically instructed by Synopsys support.

11.3.7.1.116.3 Diagram

11.3.7.1.116.4 Fields

Field	Function
31-11 RSVDP_11	Reserved for future use.
10 L1_CLK_SEL	L1 Clock control bit. - 1: Controller does not request aux_clk switch and core_clk gating in L1. - 0: Controller requests aux_clk switch and core_clk gating in L1. Note: This register field is sticky.
9 L1_NOWAIT_P1	L1 entry control bit. - 1: Core does not wait for PHY to acknowledge transition to P1 before entering L1. - 0: Core waits for the PHY to acknowledge transition to P1 before entering L1. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Table continues on the next page...

Field	Function
8 L1SUB_EXIT_M ODE	L1 Exit Control Using phy_mac_pclkack_n. - 1: Core exits L1 without waiting for the PHY to assert phy_mac_pclkack_n. - 0: Core waits for the PHY to assert phy_mac_pclkack_n before exiting L1. Note: This register field is sticky.
7 RSVDP_7	Reserved for future use.
6-0 RXSTANDBY_C ONTROL	Rxstandby Control. Bits 0..5 determine if the controller asserts the RxStandby signal (mac_phy_rxstandby) in the indicated condition. Bit 6 enables the controller to perform the RxStandby/RxStandbyStatus handshake. - [0]: Rx EIOS and subsequent TX-IDLE-MIN - [1]: Rate Change - [2]: Inactive lane for upconfigure/downconfigure - [3]: PowerDown=P1orP2 - [4]: RxL0s.Idle - [5]: EI Infer in L0 - [6]: Execute RxStandby/RxStandbyStatus Handshake This field is reserved (fixed to '0') for M-PCIE. Note: This register field is sticky.

11.3.7.1.117 TRGT_CPL_LUT Delete Entry Control register. (TRGT_CPL_LUT_DELETE_ENTRY_OFF)

11.3.7.1.117.1 Offset

Register	Offset
TRGT_CPL_LUT_DELETE_ENTRY_OFF	8C8h

11.3.7.1.117.2 Function

TRGT_CPL_LUT Delete Entry Control register. Using this register you can delete one entry in the target completion LUT. You should only use this register when you know that your application will never send the completion because of an FLR or any other reason. Note:: The target completion LUT (and associated target completion timeout event) is watching for completions (from your application on XALI0/1/2 or AXI master read channel) corresponding to previously received non-posted requests from the PCIe wire.

11.3.7.1.117.3 Diagram

11.3.7.1.117.4 Fields

Field	Function
31 DELETE_EN	This is a one-shot bit. A '1' write to this bit triggers the deletion of the target completion LUT entry that is specified in the LOOK_UP_ID field. This is a self-clearing register field. Reading from this register field always returns a '0'.
30-0 LOOK_UP_ID	This number selects one entry to delete of the TRGT_CPL_LUT.

11.3.7.1.118 Link Reset Request Flush Control Register. (LINK_FLUSH_CONTROL_OFF)

11.3.7.1.118.1 Offset

Register	Offset
LINK_FLUSH_CONTROL_OFF	8CCh

11.3.7.1.118.2 Diagram

11.3.7.1.118.3 Fields

Field	Function
31-24 RSVD_I_8	This is an internally reserved field. Do not use. Note: This register field is sticky.
23-1 RSVDP_1	Reserved for future use.
0 AUTO_FLUSH_EN	Enables automatic flushing of pending requests before sending the reset request to the application logic to reset the PCIe controller and the AXI Bridge. The flushing process is initiated if any of the following events occur: - Hot reset request. A downstream port (DSP) can "hot reset" an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted. - Warm (Soft) reset request. Generated when exiting from D3 to D0 and <code>cfg_pm_no_soft_rst=0</code> . - Link down reset request. A high to low transition on <code>smlh_req_rst_not</code> indicates the link has gone down and the controller is requesting a reset. If you disable automatic flushing, your application is responsible for resetting the PCIe controller and the AXI Bridge. For more details see "Warm and Hot Resets" section in the Architecture chapter of the Databook. Note: This register field is sticky.

11.3.7.1.119 AXI Bridge Slave Error Response Register. (AMBA_ERROR_RESPONSE_DEFAULT_OFF)

11.3.7.1.119.1 Offset

Register	Offset
AMBA_ERROR_RESPONSE_DEFAULT_OFF	8D0h

11.3.7.1.119.2 Diagram

11.3.7.1.119.3 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15-10 AMBA_ERROR_RESPONSE_MAP	AXI Slave Response Error Map. Allows you to selectively map the errors received from the PCIe completion (for non-posted requests) to the AXI slave responses, slv_resp or slv_bresp. The recommended setting is SLVERR. CRS is always mapped to OKAY. - [0] -- 0: UR (unsupported request) -> DECERR -- 1: UR (unsupported request) -> SLVERR - [1] -- 0: CRS (configuration retry status) -> DECERR -- 1: CRS (configuration retry status) -> SLVERR - [2] -- 0: CA (completer abort) -> DECERR -- 1: CA (completer abort) -> SLVERR - [3]: Reserved - [4]: Reserved - [5]: -- 0: Completion Timeout -> DECERR -- 1: Completion Timeout -> SLVERR The AXI bridge internally drops (processes internally but not passed to your application) a completion that has been marked by the Rx filter as UC or MLF, and does not pass its status directly down to the slave interface. It waits for a timeout and then signals "Completion Timeout" to the slave interface. The controller sets the AXI slave read databus to 0xFFFF for all error responses. Note: This register field is sticky.
9-5 RSVDP_5	Reserved for future use.
4-3 AMBA_ERROR_RESPONSE_CR	CRS Slave Error Response Mapping. Determines the AXI slave response for CRS completions. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - always returns OKAY AXI: - 00: OKAY - 01: OKAY with all FFFF_FFFF data for all CRS completions - 10: OKAY with FFFF_0001 data for CRS completions to vendor ID read requests, OKAY with FFFF_FFFF data for all other CRS completions - 11: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) Note: This register field is sticky.

Table continues on the next page...

Field	Function
2 AMBA_ERROR_RESPONSE_VENDORID	Vendor ID Non-existent Slave Error Response Mapping. Determines the AXI slave response for errors on reads to non-existent Vendor ID register. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - 0: OKAY (with FFFF data). The controller ignores the setting in the bit when bit 0 of this register is '0'. - 1: ERROR AXI: - 0: OKAY (with FFFF data). - 1: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) Note: This register field is sticky.
1 RSVDP_1	Reserved for future use.
0 AMBA_ERROR_RESPONSE_GLOBAL	Global Slave Error Response Mapping. Determines the AXI slave response for all error scenarios on non-posted requests. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - 0: OKAY (with FFFF data for non-posted requests) and ignore the setting in bit [2] of this register. - 1: ERROR for normal link (data) accesses and look at bit [2] for other scenarios. AXI: - 0: OKAY (with FFFF data for non-posted requests) - 1: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) The error response mapping is not applicable to Non-existent Vendor ID register reads. Note: This register field is sticky.

11.3.7.1.120 Link Down AXI Bridge Slave Timeout Register. (AMBA_LINK_TIMEOUT_OFF)

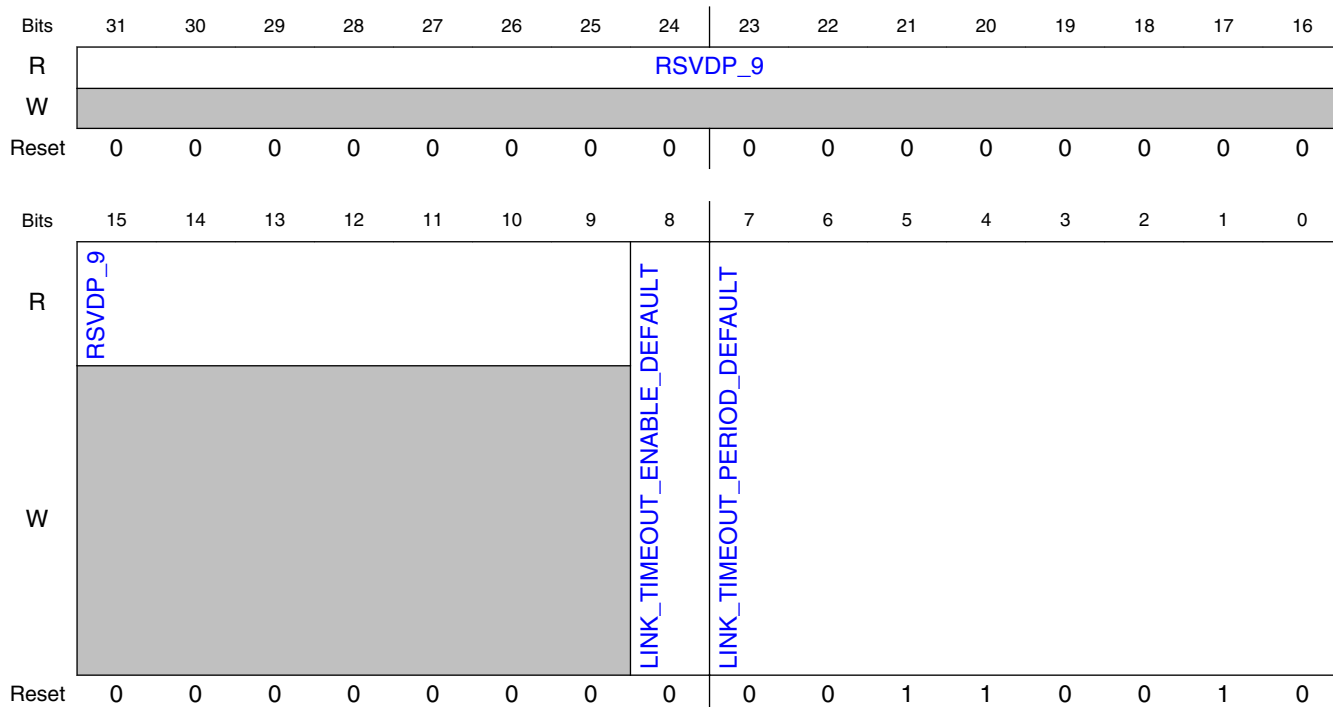

11.3.7.1.120.1 Offset

Register	Offset
AMBA_LINK_TIMEOUT_OFF	8D4h

11.3.7.1.120.2 Function

Link Down AXI Bridge Slave Timeout Register. If your application AXI master issues outbound requests to the AXI bridge slave interface before the PCIe link is operational, the controller starts a "flush" timer. The timeout value of the timer is set by this register. The timer will timeout and then flush the bridge TX request queues after this amount of time. The timer counts when there are pending outbound AXI slave interface (or DMA) requests and the PCIe TX link is not transmitting any of these requests. For more details, see the "AXI Bridge Initialization, Clocking and Reset" section in the AXI chapter of the Databook.

11.3.7.1.120.3 Diagram

11.3.7.1.120.4 Fields

Field	Function
31-9 RSVDP_9	Reserved for future use.
8 LINK_TIMEOUT_ENABLE_DEFAULT	Disable Flush. You can disable the flush feature by setting this field to "1". Note: This register field is sticky.
7-0 LINK_TIMEOUT_PERIOD_DEFAULT	Timeout Value (ms). The timer will timeout and then flush the bridge TX request queues after this amount of time. The timer counts when there are pending outbound AXI slave interface requests and the PCIe TX link is not transmitting any of these requests. The timer is clocked by core_clk. For an M-PCIe configuration: - Time unit of this field is 4 ms. - Margin of error for RateA clock is < 1%. - Margin of error for RateB clock is between 16% and 17%. Note: This register field is sticky.

11.3.7.1.121 AMBA Ordering Control. (AMBA_ORDERING_CTRL_OFF)

11.3.7.1.121.1 Offset

Register	Offset
AMBA_ORDERING_CTL_OFF	8D8h

11.3.7.1.121.2 Diagram

11.3.7.1.121.3 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7 AX_MSTR_ZEROLREAD_FW	AXI Master Zero Length Read Forward to the application. The DW PCIe controller AXI bridge is able to terminate in order with the Posted transactions the zero length read, implementing the PCIe express flush semantics of the Posted transactions. - 0x0: The zero length Read is terminated at the DW PCIe AXI bridge master - 0x1: The zero length Read is forward to the application.
6-5 RSVDP_5	Reserved for future use.
4-3 AX_MSTR_ORDR_P_EVENT_SELECTOR	AXI Master Posted Ordering Event Selector. This field selects how the master interface determines when a P write is completed when enforcing the PCIe ordering rule, "NP must not pass P" at the AXI Master Interface. The AXI protocol does not support ordering between channels. Therefore, NP reads can pass P on your AXI bus fabric. This can result in an ordering violation when the read overtakes a P that is going to the same address. Therefore, the bridge master does not issue any NP requests until all outstanding P writes reach their destination. It does this by waiting for the all of the write responses on

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	the B channel. This can affect the performance of the master read channel. For scenarios where the interconnect serializes the AXI master "AW", "W" and "AR" channels, you can increase the performance by reducing the need to wait until the complete Posted transaction has effectively reached the application slave. - 00: B'last event: wait for the all of the write responses on the B channel thereby ensuring that the complete Posted transaction has effectively reached the application slave (default). - 01: AW'last event: wait until the complete Posted transaction has left the AXI address channel at the bridge master. - 10: W'last event: wait until the complete Posted transaction has left the AXI data channel at the bridge master. - 11: Reserved Note 2: This setting will not affect: - MSI interrupt catcher and P data ordering. This is always driven by the B'last event. - DMA read engine TLP ordering. This is always driven by the B'last event. - NP write transactions which are always serialized with P write transactions.
2 RSVDP_2	Reserved for future use.
1 AX_SNP_EN	AXI Serialize Non-Posted Requests Enable. This field enables the AXI Bridge to serialize same ID Non-Posted Read/Write Requests on the wire. Serialization implies one outstanding same ID NP Read or Write on the wire and used to avoid AXI RAR and WAW hazards at the remote link partner. For more details, see the "Optional Serialization of AXI Slave Non-posted Requests" section in the AXI chapter of the Databook.
0 RSVDP_0	Reserved for future use.

11.3.7.1.129.3 Fields

Field	Function
31-10 RSVDP_10	Reserved for future use.
9-0 AUX_CLK_FREQ	The aux_clk frequency in MHz. This value is used to provide a 1 us reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk. Frequencies lower than 1 MHz are possible but with a loss of accuracy in the time counted. If the actual frequency (f) of aux_clk does not exactly match the programmed frequency (f_prog), then there is an error in the time counted by the controller that can be expressed in percentage as: $err\% = (f_prog/f-1)*100$. For example if f=2.5 MHz and f_prog=3 MHz, then $err\% = (3/2.5-1)*100 = 20\%$, meaning that the time counted by the controller on aux_clk will be 20% greater than the time in us programmed in the corresponding time register (for example T_POWER_ON). Note: This register field is sticky.

11.3.7.1.130 L1 Substates Timing Register. (L1_SUBSTATES_OFF)

Field	Function
31-8 RSVDP_8	Reserved for future use.
7-6 L1SUB_T_PCLKACK	Max delay (in 1us units) between a MAC request to remove the clock on mac_phy_pclkreq_n and a PHY response on phy_mac_pclkack_n. If the PHY does not respond within this time the request is aborted. Range is 0..3 Note: This register field is sticky.
5-2 L1SUB_T_L1_2	Duration (in 1us units) of L1.2. Range is 0.15. Note: The timeout value can vary by 50%. Note: This register field is sticky.
1-0 L1SUB_T_POWER_OFF	Duration (in 1us units) of L1.2.Entry. Range is 0.3. Note: The timeout value can vary by 50%. Note: This register field is sticky.

11.3.7.1.131 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_0)

11.3.7.1.131.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_0	8000_0000h

11.3.7.1.131.2 Diagram

11.3.7.1.131.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0 unless multifunction operation in the controller is enabled (CX_NFUNC > 1). - When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.7.1.132 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_0)

11.3.7.1.132.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_0	8000_0004h

11.3.7.1.132.2 Diagram

11.3.7.1.132.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_M ODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBS TITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.
22 INHIBIT_PAYLO AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTIT UTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.133 iATU Lower Base Address Register. (IATU_LWR_BASE_AD DR_OFF_OUTBOUND_0)

11.3.7.1.138.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.3.7.1.139 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFFSET_INBOUND_0)

11.3.7.1.139.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFFSET_INBOUND_0	8000_0104h

11.3.7.1.139.2 Diagram

11.3.7.1.139.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_M ODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_ MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_C ODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_ LOC_TRANS_ EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_M ATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_M ATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_ EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.140 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_0)

11.3.7.1.140.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_0	8000_0108h

11.3.7.1.140.2 Function

iATU Lower Base Address Register. The CX_ATU_MIN_REGION_SIZE configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ bits are zero.

11.3.7.1.140.3 Diagram

11.3.7.1.140.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(CX_ATU_MIN_REGION_SIZE) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(CX_ATU_MIN_REGION_SIZE)

11.3.7.1.141 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_0)

11.3.7.1.141.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_INBOUND_0	8000_010Ch

11.3.7.1.141.3 Fields

Field	Function
31-0 UPPER_BASE_ RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. Note: This register field is sticky.

11.3.7.1.142 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_INBOUND_0)

11.3.7.1.142.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_INBOUND_0	8000_0110h

11.3.7.1.142.2 Diagram

11.3.7.1.142.3 Fields

Field	Function
31-16 LIMIT_ADDR_R W	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_H W	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.3.7.1.143 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_0)

11.3.7.1.143.1 Offset

Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_0	8000_0114h

11.3.7.1.143.2 Diagram

11.3.7.1.143.3 Fields

Field	Function
31-16 LWR_TARGET_R W	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(CX_ATU_MIN_REGION_SIZE) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ in address match mode. - Field size depends on $\log_2(\text{BAR_MASK} + 1)$ in BAR match mode.

11.3.7.1.144 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_1)

11.3.7.1.144.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_1	8000_0200h

11.3.7.1.144.2 Diagram

11.3.7.1.144.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0 unless multifunction operation in the controller is enabled (CX_NFUNC > 1). - When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.7.1.145 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFFSET_OUTBOUND_1)

11.3.7.1.145.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFFSET_OUTBOUND_1	8000_0204h

11.3.7.1.145.2 Diagram

11.3.7.1.145.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
22 INHIBIT_PAYLOAD AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTITUTE EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.146 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_1)

	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.3.7.1.152 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_1)

11.3.7.1.152.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_1	8000_0304h

11.3.7.1.152.2 Diagram

11.3.7.1.152.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_M ODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_ MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_C ODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_ LOC_TRANS_ EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_M ATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_M ATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_ EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the <code>iatu_region_ctrl_1_OFF_inbound</code> register (<code>=>TYPE[4:3]=2'b10</code>) will be translated. Message type match mode overrides any value of <code>MATCH_MODE</code> field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the <code>CX_TPH_ENABLE</code> configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.153 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_1)

11.3.7.1.153.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_1	8000_0308h

11.3.7.1.153.2 Function

iATU Lower Base Address Register. The `CX_ATU_MIN_REGION_SIZE` configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ bits are zero.

11.3.7.1.153.3 Diagram

11.3.7.1.153.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$

11.3.7.1.154 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_1)

11.3.7.1.154.1 Offset

11.3.7.1.154.3 Fields

Field	Function
31-0 UPPER_BASE_ RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. Note: This register field is sticky.

11.3.7.1.155 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_INBOUND_1)

11.3.7.1.155.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_INBOUND_1	8000_0310h

11.3.7.1.155.2 Diagram

11.3.7.1.155.3 Fields

Field	Function
31-16 LIMIT_ADDR_R W	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_H W	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.3.7.1.156 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_1)

11.3.7.1.156.1 Offset

Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_1	8000_0314h

11.3.7.1.156.2 Diagram

11.3.7.1.156.3 Fields

Field	Function
31-16 LWR_TARGET_R W	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(CX_ATU_MIN_REGION_SIZE) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ in address match mode. - Field size depends on $\log_2(\text{BAR_MASK} + 1)$ in BAR match mode.

11.3.7.1.157 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_2)

11.3.7.1.157.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_2	8000_0400h

11.3.7.1.157.2 Diagram

11.3.7.1.157.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0 unless multifunction operation in the controller is enabled (CX_NFUNC > 1). - When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.7.1.158 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFFSET_OUTBOUND_2)

11.3.7.1.158.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFFSET_OUTBOUND_2	8000_0404h

11.3.7.1.158.2 Diagram

11.3.7.1.158.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
22 INHIBIT_PAYLOAD AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTITUTE EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.159 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_2)

11.3.7.1.159.1 Offset

11.3.7.1.165.2 Diagram

11.3.7.1.165.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_M ODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_ MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_C ODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_ LOC_TRANS_ EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_M ATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_M ATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_ EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.166 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_2)

11.3.7.1.166.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_2	8000_0508h

11.3.7.1.166.2 Function

iATU Lower Base Address Register. The CX_ATU_MIN_REGION_SIZE configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ bits are zero.

11.3.7.1.166.3 Diagram

11.3.7.1.166.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$

11.3.7.1.167 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_2)

11.3.7.1.167.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_INBOUND_2	8000_050Ch

11.3.7.1.167.2 Diagram

11.3.7.1.167.3 Fields

Field	Function
31-0 UPPER_BASE_ RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. Note: This register field is sticky.

11.3.7.1.168 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_INBOUND_2)

11.3.7.1.168.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_INBOUND_2	8000_0510h

11.3.7.1.168.2 Diagram

11.3.7.1.168.3 Fields

Field	Function
31-16 LIMIT_ADDR_R W	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_H W	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.3.7.1.169 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_2)

11.3.7.1.169.1 Offset

Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_2	8000_0514h

11.3.7.1.169.2 Diagram

11.3.7.1.169.3 Fields

Field	Function
31-16 LWR_TARGET_R W	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(CX_ATU_MIN_REGION_SIZE) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ in address match mode. - Field size depends on $\log_2(\text{BAR_MASK} + 1)$ in BAR match mode.

11.3.7.1.170 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_3)

11.3.7.1.170.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_3	8000_0600h

11.3.7.1.170.2 Diagram

11.3.7.1.170.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0 unless multifunction operation in the controller is enabled (CX_NFUNC > 1). - When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.7.1.171 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFFSET_OUTBOUND_3)

11.3.7.1.171.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFFSET_OUTBOUND_3	8000_0604h

11.3.7.1.171.2 Diagram

11.3.7.1.171.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
22 INHIBIT_PAYLOAD AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTITUTE EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.172 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_3)

11.3.7.1.172.1 Offset

22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by CX_ATU_MAX_REGION_SIZE. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.3.7.1.178 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_3)

11.3.7.1.178.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_3	8000_0704h

11.3.7.1.178.2 Diagram

11.3.7.1.178.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

PCI Express Controller (PCIe)

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_M ODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_ MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_C ODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_ LOC_TRANS_ EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_M ATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_M ATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_ EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.3.7.1.179 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_3)

11.3.7.1.179.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_3	8000_0708h

11.3.7.1.179.2 Function

iATU Lower Base Address Register. The CX_ATU_MIN_REGION_SIZE configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ bits are zero.

11.3.7.1.179.3 Diagram

11.3.7.1.179.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(CX_ATU_MIN_REGION_SIZE) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(CX_ATU_MIN_REGION_SIZE)

11.3.7.1.180 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_3)

11.3.7.1.180.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_INBOUND_3	8000_070Ch

11.3.7.1.180.3 Fields

Field	Function
31-0 UPPER_BASE_ RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. Note: This register field is sticky.

11.3.7.1.181 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_INBOUND_3)

11.3.7.1.181.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_INBOUND_3	8000_0710h

11.3.7.1.181.2 Diagram

11.3.7.1.181.3 Fields

Field	Function
31-16 LIMIT_ADDR_R W	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_H W	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.3.7.1.182 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_3)

11.3.7.1.182.1 Offset

Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_3	8000_0714h

11.3.7.1.182.2 Diagram

11.3.7.1.182.3 Fields

Field	Function
31-16 LWR_TARGET_R W	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(CX_ATU_MIN_REGION_SIZE) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ in address match mode. - Field size depends on $\log_2(\text{BAR_MASK} + 1)$ in BAR match mode.

11.3.7.1.183 DMA Arbitration Scheme for TRGT1 Interface. (DMA_CTRL_DATA_ARB_PRIOR_OFF)

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 —	Reserved.
15-1 RSVDP_1	Reserved for future use.
0 DMA_WRITE_E NGINE	<p>DMA Write Engine Enable. - 1: Enable - 0: Disable (Soft Reset) For normal operation, you must initially set this bit to "1", before any other software setup actions. You do not need to toggle or rewrite to this bit during normal operation. You should set this bit to "0" when you want to "Soft Reset" the DMA controller write logic. There are three possible reasons for resetting the DMA controller write logic: - The "Abort Interrupt Status" bit is set (in the "DMA Write Interrupt Status Register" (DMA_WRITE_INT_STATUS_OFF), and any of the bits in the "DMA Write Error Status Register" (DMA_WRITE_ERR_STATUS_OFF) are set. Resetting the DMA controller write logic re-initializes the control logic, ensuring that the next DMA write transfer is executed successfully. - You have executed the procedure outlined in "Stop Bit" , after which, the "Abort Interrupt Status" bit is set and the Channel Status field (CS) of the DMA write "DMA Channel Control 1 Register " (DMA_CH_CONTROL1_OFF_WRCH_0) is set to "Stopped." Resetting the DMA controller write logic re-initializes the control logic ensuring that the next DMA write transfer is executed successfully. - During software development, when you incorrectly program the DMA write engine. To "Soft Reset" the DMA controller write logic, you must: - De-assert the DMA write engine enable bit. - Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA write engine enable bit returns a "0". - Assert the DMA write engine enable bit. This "Soft Reset" does not clear the DMA configuration registers. The DMA write transfer does not start until you write to the "DMA Write Doorbell Register" (DMA_WRITE_DOORBELL_OFF). Note: The access attributes of this field are as follows: - Dbi: R/W</p>

11.3.7.1.186 DMA Write Doorbell Register. (DMA_WRITE_DOORBELL_OFF)

11.3.7.1.186.1 Offset

Register	Offset
DMA_WRITE_DOORBELL_OFF	8008_0010h

11.3.7.1.186.2 Diagram

11.3.7.1.186.3 Fields

Field	Function
31 WR_STOP	Stop. Set in conjunction with the Doorbell Number field. The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the "DMA Channel Control 1 Register" (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). For more information, see "Stopping the DMA Transfer (Software Stop)." Note: The access attributes of this field are as follows: - Dbi: R/W
30-3 RSVDP_3	Reserved for future use.
2-0 WR_DOORBELL_NUM	Doorbell Number. You must write the channel number to this register to start the DMA write transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. You do not need to toggle or write any other value to this register to start a new transfer. The range of this field is 0x0 to 0x7, and 0x0 corresponds to channel 0. Also note that a write to this field triggers the controller to exit L1 substates. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.187 DMA Write Engine Channel Arbitration Weight Low Register. (DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF)

11.3.7.1.187.1 Offset

Register	Offset
DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF	8008_0018h

11.3.7.1.187.2 Function

DMA Write Engine Channel Arbitration Weight Low Register. The 5-bit channel weight (for write channels 0-3) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.

11.3.7.1.187.3 Diagram

11.3.7.1.192.2 Function

DMA Read Engine Channel Arbitration Weight High Register. The 5-bit channel weight (for read channels 4-7) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.

11.3.7.1.192.3 Diagram

11.3.7.1.192.4 Fields

Field	Function
31-20 RSVDP_20	Reserved for future use.
19-15 READ_CHANNE L7_WEIGHT	Channel 7 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Dbi: R/W
14-10 READ_CHANNE L6_WEIGHT	Channel 6 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Dbi: R/W
9-5 READ_CHANNE L5_WEIGHT	Channel 5 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Dbi: R/W
4-0 READ_CHANNE L4_WEIGHT	Channel 4 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.193 DMA Write Interrupt Status Register. (DMA_WRITE_INT_ST ATUS_OFF)

11.3.7.1.193.1 Offset

Register	Offset
DMA_WRITE_INT_ST ATUS_OFF	8008_004Ch

11.3.7.1.193.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 WR_ABORT_INT_STATUS	Abort Interrupt Status. The DMA write channel has detected an error, or you manually stopped the transfer as described in "Error Handling Assistance by Remote Software". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA write interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 RSVDP_8	Reserved for future use.
7-0 WR_DONE_INT_STATUS	Done Interrupt Status. The DMA write channel has successfully completed the DMA transfer. For more details, see "Interrupts and Error Handling". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA write interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to

11.3.7.1.210.3 Fields

Field	Function
31-24 DATA_POISONING	Data Poisoning. The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. The CX_FLT_MASK_UR_POIS filter rule does not affect this behavior. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You

Table continues on the next page...

Field	Function
	must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
23-16 CPL_TIMEOUT	Completion Time Out. The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling" . - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
15-8 CPL_ABORT	Completer Abort. The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
7-0 UNSUPPORTED_REQ	Unsupported Request. The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

11.3.7.1.211 DMA Read Linked List Error Enable Register. (DMA_READ_LINKED_LIST_ERR_EN_OFF)

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-17 —	Reserved.
16 RD_CHANNEL_LLLAIE	Read Channel LL Local Abort Interrupt Enable (LLLAIE). You enable the read channel Local Abort interrupt through this bit. The LIE and RIE bits in the LL element enable the read channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 RSVDP_8	Reserved for future use.
7-1 —	Reserved.
0 RD_CHANNEL_LLRAIE	Read Channel LL Remote Abort Interrupt Enable (LLRAIE). You enable the read channel Remote Abort interrupt through this bit. The LIE and RIE bits in the LL element enable the read channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.212 DMA Read Done IMWr Address Low Register. (DMA_READ_DONE_IMWR_LOW_OFF)

11.3.7.1.212.1 Offset

Register	Offset
DMA_READ_DONE_IMWR_LOW_OFF	8008_00CCh

11.3.7.1.212.2 Diagram

11.3.7.1.212.3 Fields

Field	Function
DMA_READ_DONE_IMWR_LOW_REG	The DMA uses this field to generate bits [31:0] of the address field for the Done IMWr TLP. Bits [1:0] must be "00" as this address must be dword aligned. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.213 DMA Read Done IMWr Address High Register. (DMA_READ_DONE_IMWR_HIGH_OFF)

11.3.7.1.220.3 Fields

Field	Function
31-30 DMA_AT	Address Translation TLP Header Bit (AT) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
29-27 DMA_TC	Traffic Class TLP Header Bit (TC) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
26 DMA_RESERVED5	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
25 DMA_RO	Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
24 DMA_NS_SRC	Source No Snoop TLP Header Bit (DMA_NS_SRC). The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
23 DMA_NS_DST	Destination No Snoop TLP Header Bit (DMA_NS_DST). The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
22-17 DMA_RESERVED2	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
16-12	Function Number (FN). The controller uses this field when generating the requester ID for the MRd/MWr DMA TLP. When you have enabled SR-IOV, then this field is ignored if you have set the VFE field in the

Table continues on the next page...

Field	Function
DMA_FUNC_NUM	"DMA Write Channel Control 2 Register" (DMA_CH_CONTROL2_OFF_WRCH_0). Note: The access attributes of this field are as follows: - Dbi: R/W
11-10 DMA_RESERVED1	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
9 LLE	Linked List Enable (LLE). - 0: Disable linked list operation - 1: Enable linked list operation Note: The access attributes of this field are as follows: - Dbi: R/W
8 CCS	Consumer Cycle State (CCS). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Dbi: R/W
7 DMA_RESERVED0	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
6-5 CS	Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is as follows: - 00: Reserved - 01: Running. This channel is active and transferring data. - 10: Halted. An error condition has been detected, and the DMA has stopped this channel. - 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Write Doorbell Register" (DMA_WRITE_DOORBELL_OFF) or "DMA Read Doorbell Register" (DMA_READ_DOORBELL_OFF).
4 RIE	Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
3 LIE	Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
2 LLP	Load Link Pointer (LLP). Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W
1 TCB	Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
0 CB	Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.221 DMA Write Transfer Size Register. (DMA_TRANSFER_SIZE_OFF_WRCH_0)

11.3.7.1.221.1 Offset

Register	Offset
DMA_TRANSFER_SIZE_OFF_WRCH_0	8008_0208h

11.3.7.1.221.2 Diagram

11.3.7.1.221.3 Fields

Field	Function
31-0 DMA_TRANSFER_SIZE	DMA Transfer Size. You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.222 DMA Write SAR Low Register. (DMA_SAR_LOW_OFF_WRCH_0)

11.3.7.1.222.1 Offset

Register	Offset
DMA_SAR_LOW_OFF_WRCH_0	8008_020Ch

11.3.7.1.222.2 Diagram

11.3.7.1.222.3 Fields

Field	Function
SRC_ADDR_REG_LOW	Source Address Register (Lower 32 bits). Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. - DMA Read: The SAR is the address of the remote memory. - DMA Write: The SAR is the address of the local memory. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.223 DMA Write SAR High Register. (DMA_SAR_HIGH_OFF_WRC H_0)

11.3.7.1.223.1 Offset

Register	Offset
DMA_SAR_HIGH_OFF_WRCH_0	8008_0210h

11.3.7.1.226.3 Fields

Field	Function
31-0 LLP_LOW	Lower bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list after the previous element is consumed. - When the current element is a data element; this field is incremented by 6. - When the current element is a link element; this field is overwritten by the LL Element Pointer of the element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.227 DMA Write Linked List Pointer High Register. (DMA_LLPHIGH_OFF_WRCH_0)

11.3.7.1.227.1 Offset

Register	Offset
DMA_LLPHIGH_OFF_WRCH_0	8008_0220h

11.3.7.1.227.2 Diagram

11.3.7.1.227.3 Fields

Field	Function
31-0 LLP_HIGH	Upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list as elements are consumed. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.228 DMA Read Channel Control 1 Register. (DMA_CH_CONTR OL1_OFF_RDCH_0)

11.3.7.1.228.1 Offset

Register	Offset
DMA_CH_CONTROL1_ OFF_RDCH_0	8008_0300h

11.3.7.1.228.2 Diagram

11.3.7.1.228.3 Fields

Field	Function
31-30 DMA_AT	Address Translation TLP Header Bit (AT) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
29-27 DMA_TC	Traffic Class TLP Header Bit (TC) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
26 DMA_RESERV ED5	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
25 DMA_RO	Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
24 DMA_NS_SRC	Source No Snoop TLP Header Bit (DMA_NS_SRC). The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
23 DMA_NS_DST	Destination No Snoop TLP Header Bit (DMA_NS_DST). The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
22-17 DMA_RESERV ED2	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
16-12 DMA_FUNC_N UM	Function Number (FN). The controller uses this field when generating the requester ID for the MRd/MWr DMA TLP. When you have enabled SR-IOV, then this field is ignored if you have set the VFE field in the "DMA Read Channel Control 2 Register" (DMA_CH_CONTROL2_OFF_RDCH_0). Note: The access attributes of this field are as follows: - Dbi: R/W
11-10 DMA_RESERV ED1	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
9 LLE	Linked List Enable (LLE). - 0: Disable linked list operation - 1: Enable linked list operation Note: The access attributes of this field are as follows: - Dbi: R/W
8 CCS	Consumer Cycle State (CCS). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Dbi: R/W
7 DMA_RESERV ED0	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
6-5 CS	Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is as follows: - 00: Reserved - 01: Running. This channel is active and transferring data. - 10: Halted. An error condition has been detected, and the DMA has stopped this channel. - 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Read Doorbell Register" (DMA_WRITE_DOORBELL_OFF) or "DMA Read Doorbell Register" (DMA_READ_DOORBELL_OFF).
4 RIE	Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W

Table continues on the next page...

Field	Function
3 LIE	Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
2 LLP	Load Link Pointer (LLP). Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W
1 TCB	Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
0 CB	Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.7.1.235.2 Diagram

11.3.7.1.235.3 Fields

Field	Function
31-0 LLP_HIGH	Upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list as elements are consumed. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4 PCI Express PHY (PCIE_PHY)

11.4.1 Overview

This block provides information regarding PCIe PHY and its features. PCIe PHY supports 6.0 Gbps data rate and complies to PCI Express base specification 2.1. The functions that are performed by the transceiver include serializing the 8B/10B encoded data for transmission, de-serializing received code groups, and word alignment.

When transmitting, the transceiver accepts two or four 10-bit 8B/10B encoded transmit characters, latches them and serializes the data onto the PCIE_TX_P/PCIE_TX_N differential outputs at 1.5 / 2.5 / 3.0 / 5.0 / 6.0 Gbps. It also performs 8B/10B encoding for 8-bit data from the PIPE interface.

When receiving, the transceiver also samples received serial data on the PCIE_RX_P / PCIE_RX_N differential inputs, deserializes it into two or four 10-bit received characters and detects the K28.5 character (0011111010 or 1100000101) for word alignment. It also applies 8B/10B decoding for 8-bit data to the PIPE interface. PCIe PHY core contains on-chip PLL circuitry for synthesis of the baud-rate transmitting clocks, and extraction of the retimed clocks from the received serial stream.

11.4.1.1 Block Diagram

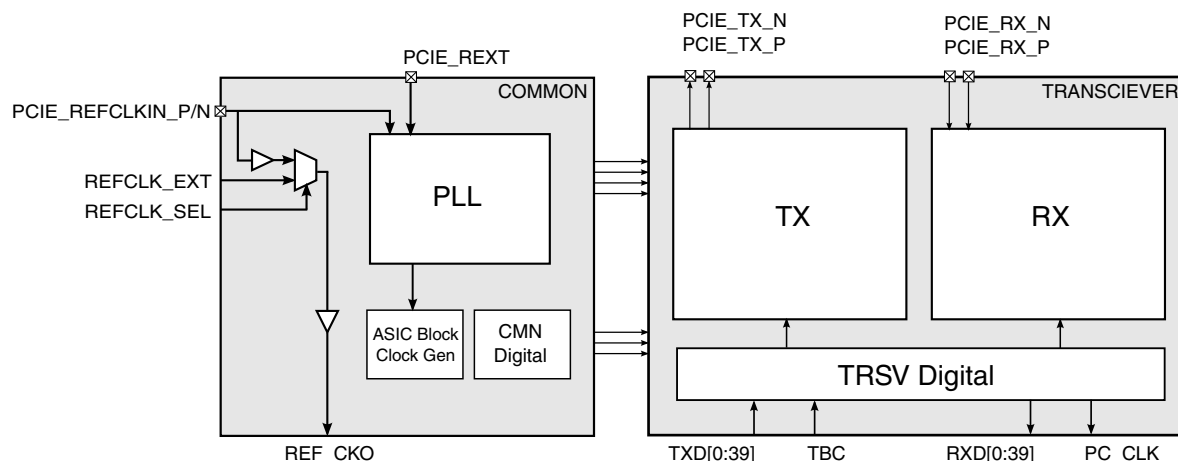

Figure 11-53. Block Diagram

11.4.1.2 Features

The following list the key features of the PCIe PHY:

- 1.5 / 2.5 / 3.0 / 5.0 / 6.0 Gbps Serializer / Deserializer
- Compliant with PCI Express Base Specification 2.1
- Compliant with PIPE Specification 2.0
- 8 / 16 / 20 / 40-bit CMOS Interface for Transmitter and Receiver
- 25 / 100 MHz Reference Clock
- K28.5 Detection for Word Alignment
- 8B/10B Encoding / Decoding
- Receiver Detection
- 28 nm CMOS Process (LN28LPP)
- Supports Spread Spectrum Clocking in Transmitter and Receiver

11.4.2 PCIe PHY Signals

11.4.2.1 External Signal

The following table describes the external signals and power supplies to PCIe PHY.

Table 11-54. External I/O and Power

Signal	Description	Pad	Mode	Direction
PCIE_TX_P	Positive-side transmitted differential output from the PHY. Terminal transmit NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_TX_P	Not multiplexed	O
PCIE_TX_N	Negative-side transmitted differential output from the PHY. Terminal transmit NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_TX_N	Not multiplexed	O
PCIE_RX_P	Positive-side received differential input from the PHY. Terminal receive NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_RX_P	Not multiplexed	I

Table continues on the next page...

Table 11-54. External I/O and Power (continued)

Signal	Description	Pad	Mode	Direction
PCIE_RX_N	Negative-side received differential input from the PHY. Terminal receive NRZ data rate of 1.5 - 6.0 Gbps.	PCIE_RX_N	Not multiplexed	I
PCIE_REXT	External reference resistor input.	PCIE_REXT	Not multiplexed	IO
PCIE_REFCLKOUT_P	100 MHz Positive-side Reference Clock Differential Output for PCIe.	PCIE_REFCLKOUT_P	Not multiplexed	O
PCIE_REFCLKOUT_N	100 MHz Negative-side Reference Clock Differential Output for PCIe.	PCIE_REFCLKOUT_N	Not multiplexed	O
PCIE_REFCLKIN_P	100 MHz Positive-side Reference Clock Differential Input for PCIe.	PCIE_REFCLKIN_P	Not multiplexed	I
PCIE_REFCLKIN_N	100 MHz Negative-side Reference Clock Differential Input for PCIe.	PCIE_REFCLKIN_N	Not multiplexed	I
PCIE_VP	1.0 V (or 1.1 V) Power for Common block of the PHY	PCIE_VP	Not multiplexed	Supply
PCIE_VPH	1.8 V Voltage Regulator / Bias Power for Common block of the PHY	PCIE_VPH	Not multiplexed	Supply
PCIE_VP_TX	1.0 V (or 1.1 V) Power for Transmitter block of the PHY	PCIE_VP_TX	Not multiplexed	Supply
PCIE_VPH_TX	1.8 V Voltage Regulator for Transmitter block of the PHY	PCIE_VPH_TX	Not multiplexed	Supply
PCIE_VP_RX	1.0 V (or 1.1 V) Power for Receiver block of the PHY	PCIE_VP_RX	Not multiplexed	Supply
PCIE_VPH_RX	1.8 V Voltage Regulator for Receiver block of the PHY	PCIE_VPH_RX	Not multiplexed	Supply
PCIE_GND	Ground for the PHY	PCIE_GND	Not multiplexed	Ground

11.4.2.2 Interface Signals

This section describes the interface signals to PCIe PHY.

Table 11-55. Interface Signals Description

Signal	Description
REF_CKO	Buffered Reference Clock Output. REF_CKO is 25 or 100 MHz according to the reference clock input frequency.
REFCLK_SEL	Internal Reference Clock Enable. When driven high, REFCLK_EXT is the reference clock of PHY.
REFCLK_EXT	Internal Reference Clock Input. REFCLK_EXT is the reference clock from logic. The nominal frequency is 25 / 100 MHz.
HIGH_SPEED	Maximum Speed Selection. When driven high, the maximum data rate is Gen2 PCIe. When driven low, the maximum data rate Gen1 PCIe.
TXD	<i>Transmit Data</i>
RXD	<i>Receive Data</i>
TBC	<i>PIPE Interface Input Data Clock</i> TBC is the transmit byte clock used to latch all input data on the PIPE interface. Transitions of TXD and other inputs occur at rising edge of TBC. TBC is 250 MHz both 2.5 Gbps and 5.0 Gbps, when HIGH_SPEED is high. TBC is required to be frequency locked to reference clock from PCIE_REFCLKIN_P/N or REFCLK_EXT. The exact timing relationship between TBC and reference clock is not tightly specified, however the TBC should be derived from the PC_CLK (PCLK) clock.
RBC	<i>Receive Byte Clock.</i> RBC is locked to the received data. RBC is 75 MHz at 1.5 Gbps, 150 MHz at 3.0 Gbps, and 300 MHz at 6.0 Gbps. The parallel output data are valid on the rising edge of RBC.
PC_CLK	<i>PIPE Interface Output Data Clock.</i> All output data movement across the parallel interface is synchronized to this clock. This clock operates at 250 MHz regardless of the Rate control input. The rising edge of the clock is the reference for all output signals. Spread spectrum modulation on this clock is allowed.

11.4.2.3 Reference Clock

Reference Clock input jitter should be tightly controlled to ensure very high-speed clock operation and its jitter characteristics. Jitter performance of the PCIe PHY is dependent on a low-jitter reference clock source. It can use Crystal Oscillator input, PCIE_REFCLKIN_P/N, or internal clock input, REFCLK_EXT as a Reference Clock

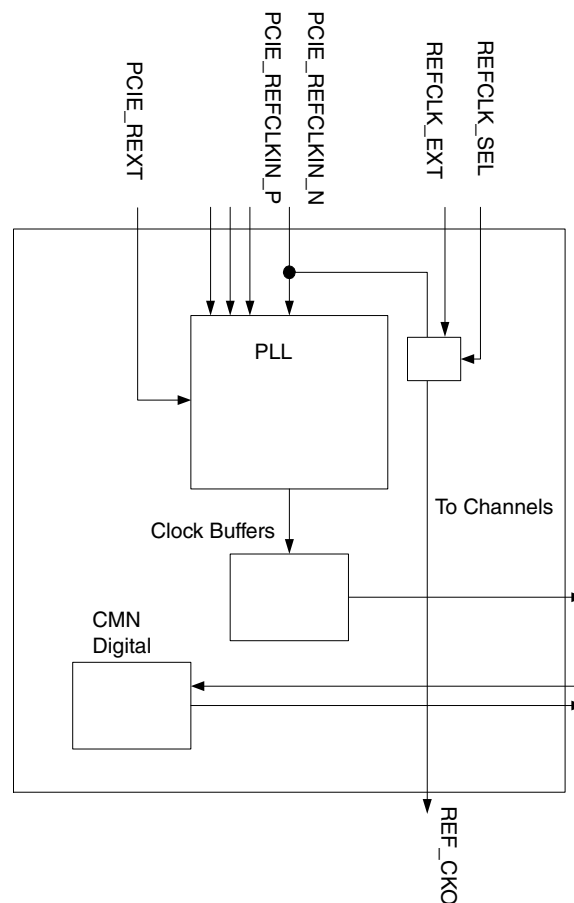

input. For more detail, please refer to the datasheet. When the REFCLK_EXT is used, the external IO pin of PCIE_REFCLKIN_P/N cannot be floating and proper powerdown control should be considered.

For the reference clock differential output for the PCIe PHY (PCIE_REFCLKOUT_P and PCIE_REFCLKOUT_N), the external resistors should be connected to ground in the PCB board. It is open drain structure.

11.4.3 Functional Description

11.4.3.1 Common Block

Figure 11-54. Common Block Diagram

11.4.3.1.1 Phase Locked Loop (PLL)

In the PCIe PHY core, the PLL is locked at the multiple frequency of reference clock (PCIE_REFCLKIN_P/N) and generates all internal multi-phase clocks for transceiver. These clocks are based on the supplied PCIE_REFCLKIN_P/N.

11.4.3.2 Transceiver block

Figure 11-55. Transceiver Block Diagram

11.4.3.2.1 Serializer

The PCIe PHY core accepts two or four 10-bit parallel characters from the link layer on the TXD[0:19] or TXD[0:39] bus which are latched into the input latch. This data will be serialized and transmitted on the PCIE_TX_P / PCIE_TX_N differential outputs at 1.5 / 3.0 / 6.0 Gbps, with bit TXD [0] transmitted first.

11.4.3.2.2 Clock and Data Recovery (CDR)

The PCIe PHY core accepts high-speed differential serial inputs on the PCIE_RX_P / PCIE_RX_N pins, extracts the retimed clocks and recovers the data. The serial bit stream should be encoded so as to provide DC balance and limited run length using 8B/10B

encoding. The PCIe PHY core clock recovery circuitry is completely monolithic and requires no external components. For proper operation, the baud rate of the data stream to be recovered should meet the PCIe specification.

The retimed serial bit stream is converted into two or four 10-bit parallel output characters on the RXD[0:19] or RXD[0:39] of which the RXD[0] is received first. The PCIe PHY core provides retimed clock, RBC. The RBC is generated from one of the high-speed clocks which is phase locked to the reference clock. The serial data is retimed by the internal high-speed clocks, and deserialized.

Even if serial input data is not present, or does not meet the required baud rate, the PCIe PHY core will continue to produce retimed clock, RBC, which locks to the REF_CLK, reference clock.

11.4.3.2.3 Word Alignment

The PCIe PHY core provides K28.5 character recognition and data word alignment. When synchronization is enabled, the PCIe PHY core constantly examines the serial data for the presence of the K28.5 character (0011111010 / 1100000101).

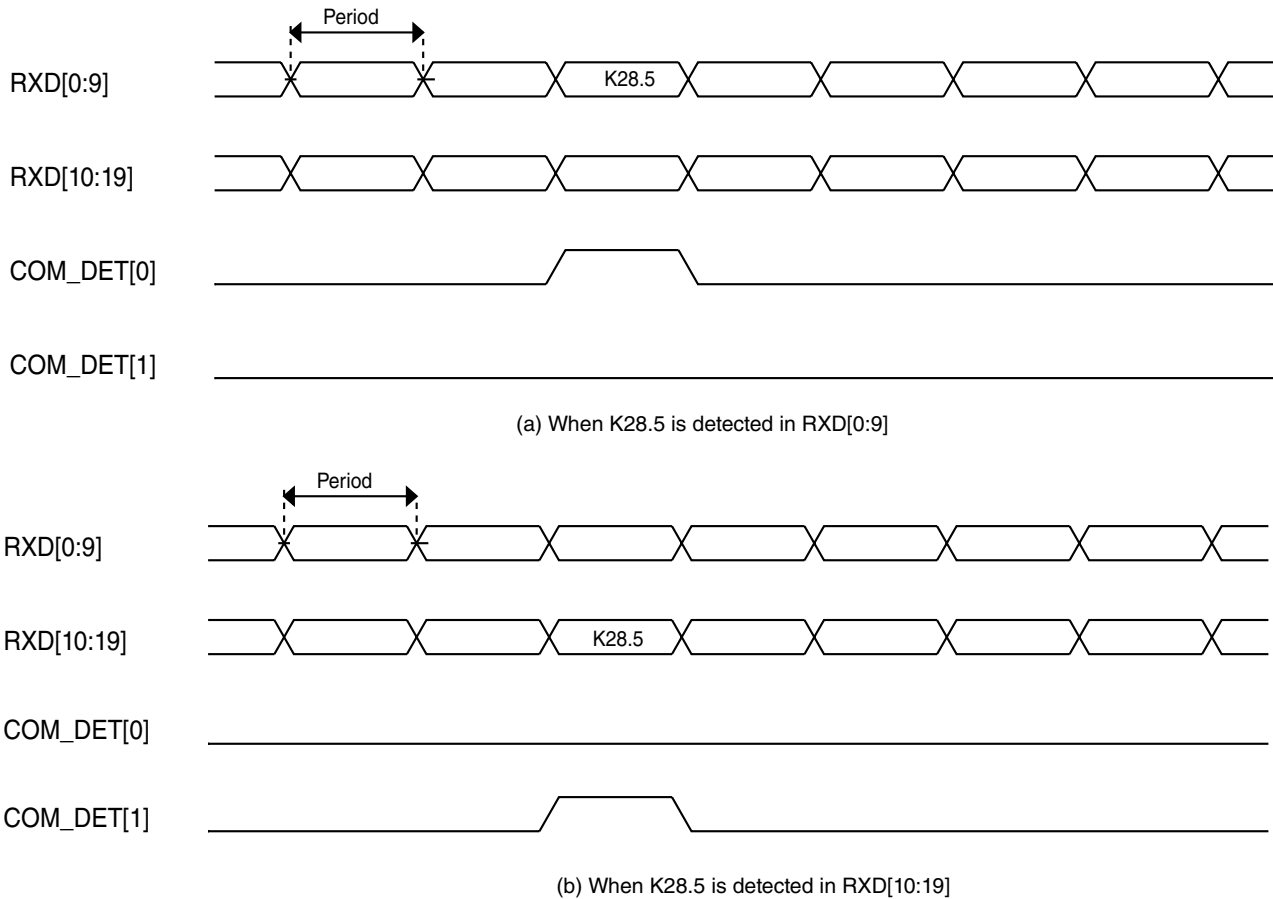

Figure 11-56. Detection of a K28.5 Character

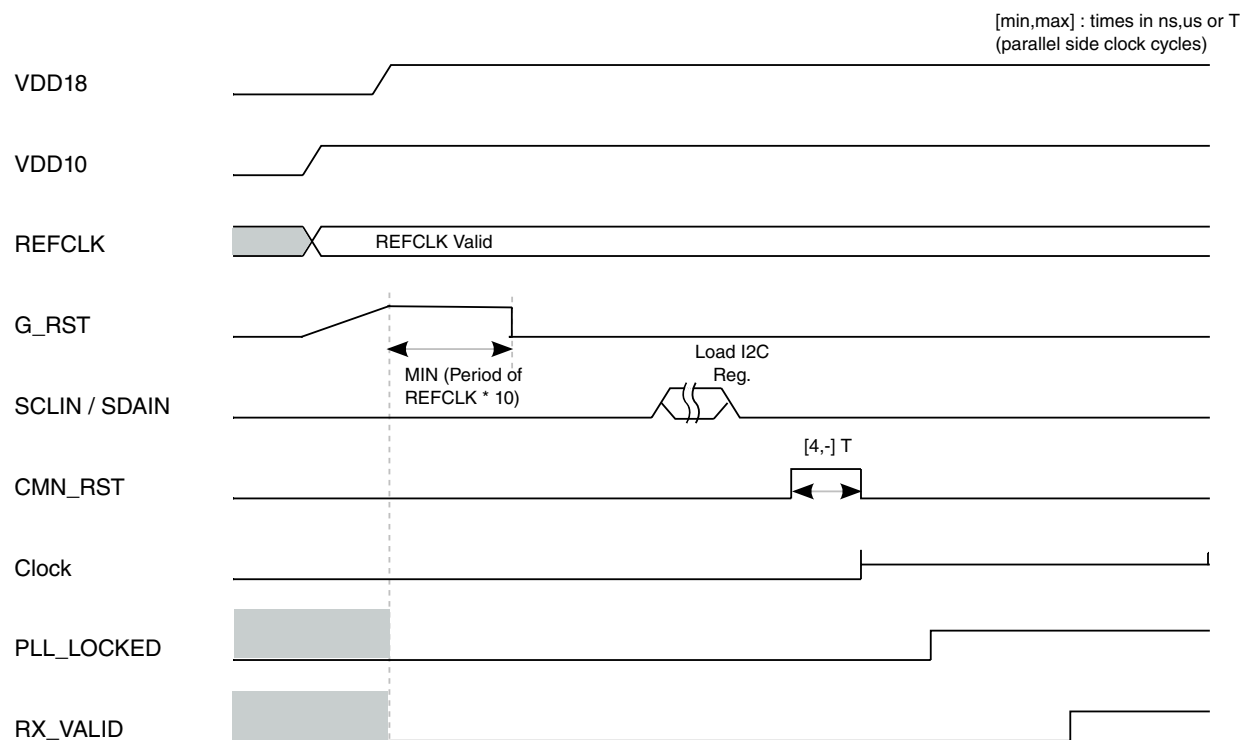

11.4.3.2.4 Driver

Driver amplifies the level of received signal from Serializer to the level that is enough to drive the transmission line. The launch amplitude can be controlled by DRV_LVL [2:0]. Driver features the pre-emphasis that is effective to reduce ISI jitter caused by the loss of transmission line. The pre-emphasis level can be controlled by EMP_LVL [3:0].

11.4.3.3 Start-up sequence

To start PCIe PHY operation, RESET (G_RST) should be invoked at the power up. G_RST should be pulsed after the power-up following by REFCLK input and setting the asynchronous control inputs. The PHY powerdown and up sequences could be added

after G_RST sequence for the initialization. The timing restrictions for RESET signal and the typical timing information for the related output signals are shown in the following figure.

Note: All times (widths and delays) are approximate. The order of events is accurate.

Figure 11-57. Start-up Sequence

NOTE

Before the PHY initialization sequences, all the input signals including REFCLK and power / ground for the PHY should be active and stable. After the PHY initialization sequences (for example, after $\text{RX_VALID} = 1$), the Link controller initialization including reset could be started (for example, PHY signals to the LINK controller must be neglected before the PHY initialization sequences is fully completed).

11.4.3.4 Interface power states

The interface power states are defined as described in the following table. For the power states such as Partial or Slumber, greater power savings can be achieved at a cost of increased exit latency.

Table 11-56. Interface Power States

State	Description
PHYRDY (or L0)	The Phy logic and main PLL are both on and active. The interface is synchronized and capable of receiving and sending data.
Partial (or L1)	The Phy logic is powered, but is in a reduced power state. This state allows an additional power savings over normal mode at the cost of additional resume latency. The exit latency from this state shall be no longer than 10 μ s (Usually less than 2 μ s in Samsung PCIe PHY). However, when Automatic Partial to Slumber Transitions are enabled the exit latency from this state shall be no longer than the maximum Slumber exit latency.
Slumber (or L2)	The Phy logic is powered but is in a reduced power state. Power can be aggressively conserved in this mode. Most of the Transmitter and Receiver may be shut off. Main power and clocks are not guaranteed, but REF_CLK is available. The exit latency from this state shall be no longer than 10 ms (Usually less than 500 μ s in PCIe PHY).

NOTE

For the PCIe interface, recommended L0s Exit Latency and L1 Exit Latency is less than 64 ns and between 1 μ s and 2 μ s respectively. L0s state in the PCIe application is intended as a power savings state between L0 and L1.

11.4.3.5 Multi-channel support

- When the PCIe PHY is implemented to support four channels. Register map demonstrates how this 4-channel PCIe PHY is configured. One CMU block includes the main PLL, bias generator, termination calibration, and the reference clock I/O buffer. 4-channel TRSV block contains the full TX and RX parts including serializer, deserializer, clock and data recovery and high-speed I/Os. This SoC only support one channel phy.
- For the logic sides, interface signal ports are provided for each channel and named with channel number such as "*_CH[n]" (For example, *_CH0, *_CH1, *_CH2, and *_CH3).
- VDD10 power has to turn on first and then VDD18 power turns on. It is needed to protect damage of thin transistor from unknown situation when 1.8 V power supply only applied to the PHY.
- VDD18 turn on time has to wait at least 0.1 μ s after VDD10 turns on. But if ramp up time of VDD10 is much slower than 0.1 μ s, waiting time also has to be increased to meet following figure.

Figure 11-58. Power Up Sequence

11.4.4 PCIe PHY Register

The PCIe PHY has programmable test features that are controlled by registers. These internal registers can be accessible through the APB or I2C interface. The PHY comprises CMU part and TRSV part. Only one CMU block exists for the PHY, and one or more TRSV blocks can be implemented according to the system requirements.

This phy only has channel 0 (CH0). Address is word address, SOC Address = Base Address + 4 * (word address). For each word only byte0 is useful, byte3 ~ 1 are all read zero.

11.4.4.1 PHY Register for CMN Block

The PCIe PHY share a common (CMN) block for the clock and bias generation. The following tables list the capabilities implemented by the PHY design team for internal use.

PCIE_PHY_CMN memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

11.4.4.2 PHY Register for Transceiver Block

The PCIe PHY has a common (CMN) block and multi-lanes of transceiver (TRSV) can be supported for the application for the high-speed serial data transmission and clock-data recovery. The following descriptions list the capabilities implemented by the PHY design team for internal use. The addresses of register in this chapter are for the transceiver ch0 and addition offset is required for another channel such as ch1 ~ 3.

Field	Description
31–8 Reserved	This field is reserved.
7 DRVR_PDH	TX Driver Option 0 Default for PCIe 1 Reduce Power consumption
6–5 Reserved	This field is reserved.
EMP_LVL[4:0]	TX De-emphasis Level Control NOTE: <ul style="list-style-type: none"> For the TX properties such as amplitude and de-emphasis, please use default setting for the first time evaluation. If the PHY is connected through a long cable, (or media), generally high pre-emphasis level setting would be better. But there would be optimization setting points according to the cable length. TX amplitude and de-emphasis ratio can be calculated as follows. Vtx-noemp-pkpk means differential peak to peak amplitude when there is no de-emphasis. Vtx-diff-pkpk means differential peak to peak amplitude which is included de-emphasis. And Vtx-deemp-pkpk means differential inner flatted peak to peak amplitude which is reduced by de-emphasis.

Table continues on the next page...

NOTE

- TX and RX parallel data also can have bit and / or byte order change to be flexible with connection errors between the PHY and the LINK controller.
- This BIST mode would be used for ATE test and addition features such as loopback mode can be controlled with the proper register settings. Make sure the powerdown mode control pins are not enabled. (i.e. these powerdown mode pins should be controllable by register in the SoC). These loopback mode are not Compliance mode which is usually implemented in the LINK controller side. When LB_EN is "high", Loopback mode works. This LB_EN is used with LB_MODE[1:0]. If you would like to use TX to RX serial loopback, you should set LB_EN = "1" and LB_MODE = "00'.

11.5 Universal Serial Bus Controller (USB)

11.5.1 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification* (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of three independent USB controller cores: two On-The-Go (OTG) controller cores, and one Host-only controller core. Each controller core connects to its dedicated on-chip USB PHY instance using a UTMI interface. See [Features](#) for more details. All three controller cores are single-port cores.

The following figure is a block diagram of USB.

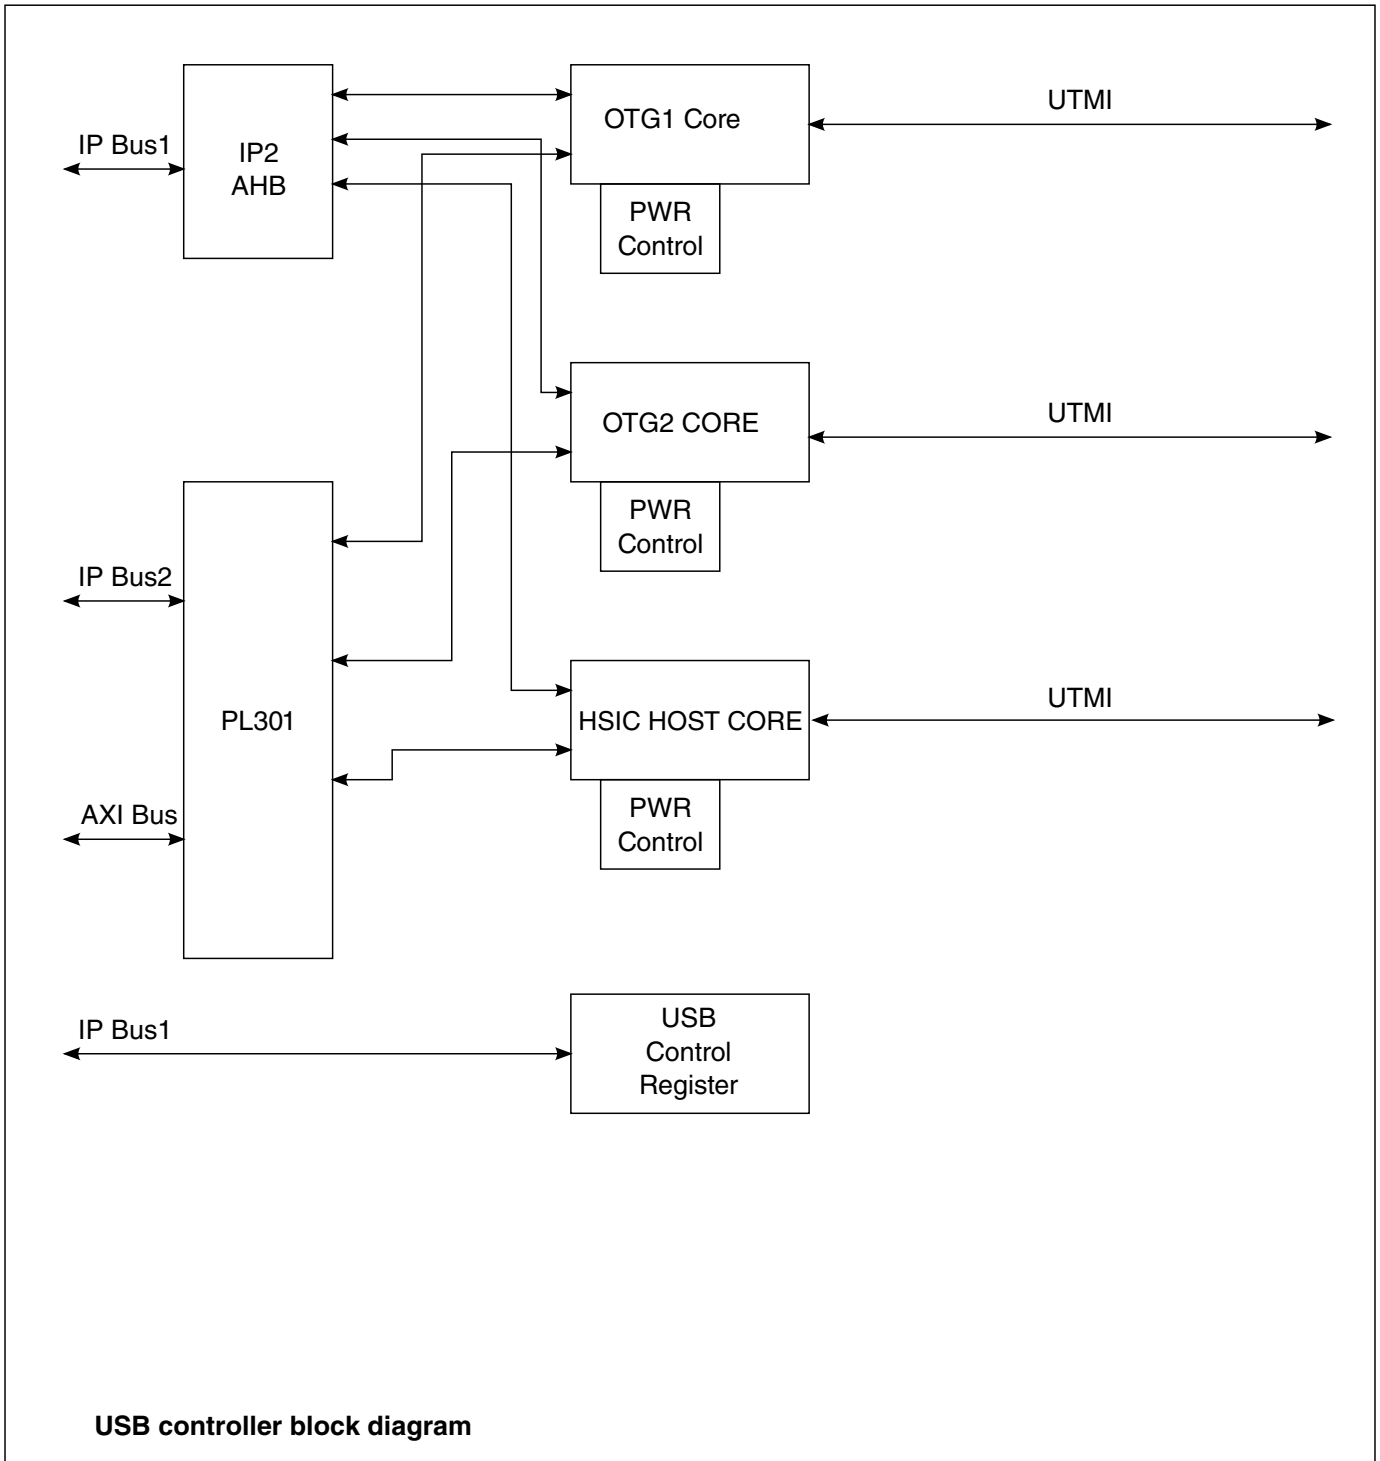

Figure 11-59. USB block diagram

11.5.1.1 Features

There are three USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.
- Controller Core 2 is also named 'HSIC'.

The following list provides features of each of the controller cores.

- USB 2.0 Controller Core 0
 - High-Speed/Full-Speed/Low-Speed OTG core
 - HS/FS/LS UTMI compliant interface connected to on-chip UTMI PHY
 - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
 - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
 - Hardware support for OTG signaling, Session Request Protocol (SRP), Host Negotiation Protocol (HNP), and Attach Detection Protocol (ADP). ADP support includes dedicated timer hardware and register interface.
 - Up to 8 bidirectional endpoints
 - Supports charger detection with USB_OTG1_CHD_B pin and register interface
- USB 2.0 Controller Core 1
 - High-Speed/Full-Speed/Low-Speed OTG core
 - HS/FS/LS UTMI compliant interface connected to on-chip UTMI PHY
 - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
 - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
 - Hardware support for OTG signaling, Session Request Protocol (SRP), Host Negotiation Protocol (HNP), and Attach Detection Protocol (ADP). ADP support includes basic register interface only.
 - Up to 8 bidirectional endpoints
 - Supports charger detection with register interface only
- USB 2.0 Controller Core 2
 - High-Speed Host-Only core
 - HS UTMI interface connects to on-chip HSIC PHY
- Low-power mode with local and remote wake-up capability
- Embedded DMA controller in each core

11.5.1.2 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps, Host mode only).

The HSIC controller core supports High Speed operation (other USB speeds are not defined for HSIC).

This chapter explains the operation modes.

11.5.1.2.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode. The Host-only HSIC controller core can operate in Host mode only.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC.PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
 - This port supports on-chip UTMI transceiver only.
- OTG2 port
 - This port supports on-chip UTMI transceiver only.
- Host1 Port
 - This port supports on-chip HSIC transceiver only.

Interface for on-board HSIC compatible USB peripherals.

11.5.1.2.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local Arm platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see [USB Power Control](#).

11.5.2 External Signals

The table found here describes the external signals of USB.

Table 11-57. USB External Signals

Signal	Description	Pad	Mode	Direction
USB_OTG1_ID	OTG1 ID Signal	GPIO1_IO02	ALT7	I
		GPIO1_IO12	ALT7	
		I2C4_SCL	ALT4	
		SD2_WP	ALT4	
USB_OTG1_OC	External Input for VBUS overcurrent detectoin	GPIO1_IO04	ALT1	I
		UART3_RXD	ALT1	
USB_OTG1_PWR	To control PMIC to supply VBUS voltage	GPIO1_IO05	ALT1	O

USB_OTG1_REXT	External reference resistor input.	USB_OTG1_REXT	No muxing	IO
USB_OTG2_DN	OTG2 DN Signal	USB_OTG2_DN	No muxing	IO
USB_OTG2_DP	OTG2 DP Signal	USB_OTG2_DP	No muxing	IO
USB_OTG2_ID	OTG2 ID Signal	USB_OTG2_ID	No muxing	I
USB_OTG2_REXT	External reference resistor input.	USB_OTG2_REXT	No muxing	IO

11.5.3 Functional Description

These sections describe the functionality of the various building blocks of the USB.

11.5.3.1 USB 2.0 Controller Core 1

The USB 2.0 Controller 1 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

11.5.3.1.1 Host Mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

11.5.3.1.2 Peripheral (Device) Mode

- Up to eight bidirectional endpoints
- High/full-speed operation
- Support of HNP, ADP, and SRP
- Remote wake-up capability

11.5.3.2 USB 2.0 Controller Core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation with ULPI interface. It also supports High Speed operation with HSIC interface.

This USB core's signals connect directly to I/O pins (HSIC interface).

11.5.3.3 USB Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the Arm platform from core sleep mode by generating an interrupt.

11.5.3.3.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0".
2. Set the "SUSPEND" bit in USB_PORTSC1
3. Set the "PHCD" bit in USB_PORTSC1
4. Set all PWD bits in USBPHY_x_PWD
5. Set CLKGATE in USBPHY_x_CTRL

NOTE

Step 3,4,5 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS)
2. Set the "PHCD" bit on USB_PORTSC1
3. Set all PWD bits in USBPHY_x_PWD
4. Set CLKGATE in USBPHY_x_CTRL

NOTE

Step 2,3,4 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

11.5.3.3.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) will be generated to Arm platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the Arm platform clocks if they were stopped during the suspend.

11.5.3.3.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see [Port Status & Control \(USB_PORTSC1\)](#).

11.5.3.3.2.2 USB OTG Power Domains

Figure 11-60. USB OTG Power Domains

11.5.3.3.2.2.1 Power Overview

USB controller and USB OTG PHY are in different power domains. USB controller locates in megamix power domain. USB OTG PHY has three powers: VDD33, VDD18, and DVDD (1.0 V).

- VDD33 comes from external of the chip, which may be from VBUS or 3.3 V power supply depend on the board design.
- VDD18 is generated by on-chip regulator vreg18 from VDD33.
- DVDD is generated by on-chip regulator inside the Auxiliary Charger Detector from VDD33.

All three OTG PHY power supplies turn on/off at same time.

Auxiliary Charger Detector can detect each power to control related power isolations and generate reset signal for the PHY.

11.5.3.3.2.2.2 Wake-up in Power Down Mode

NOTE

USB controller or OTG PHY can only power down during USB disconnect mode, power down any part when device/host is connected will cause unknown result.

11.5.3.3.2.2.2.1 Power Down USB Controller

When USB controller is power down, it can be wake-up by changes on PHY port. This is completed by the wake-up logic in the wakeupmix (it is always on power domain).

NOTE

This wake-up does not generate any interrupts, the wake-up event is only used to power up the system (includes USB controller), software re-initials the USB controller like a system power up event.

The wake-up source in the USB controller power down mode includes following:

- ID
- VBUS/SESS_VLD
- DP/DM

The related enable signals come from USB_x_CTRL1, software set related enable signals before USB controller is power down. The latch based isolation cells keep these enable values.

11.5.3.4 Interrupts

11.5.3.4.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the [Interrupt Enable Register \(USB_USBINTR\)](#) for details.

11.5.3.4.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

11.5.4 USB Operation Model

This section describes the detailed application knowledge for Host1, OTG1, and OTG2 ports. It can be generally divided in two parts, one is for Host and the other is for Device. Host port applies to all host ports, and to OTG port when operating in Host mode. Device part only applies to OTG port when operating in Device mode.

11.5.4.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

Table 11-58. Interface Register Sets

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

11.5.4.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

NOTE

Depending on implementation, "x" can have the following values: UOG1, UOG2, UH.

Table 11-59. Device/Host Capability Registers

NOTE

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

11.5.4.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

11.5.4.1.3 OTG Operations**11.5.4.1.3.1 Register Bits**

In the previous section, the Register interface has behaviors described for device mode and behaviors described for host mode. However, for OTG operations it is necessary to perform tasks independent of the controller mode.

NOTE

The only way to transit the controller mode out of host or device mode is with the controller reset bit. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset as well as independent of the controller mode.

The following figure shows the controller mode.

Figure 11-61. Controller Mode

To this end, listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

11.5.4.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

11.5.4.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the `USB_PERIODICLISTBASE` address register and the `USB_FRINDEX` register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.

The `USB_PERIODICLISTBASE` address register is combined with the `USB_FRINDEX` register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

Figure 11-62. Periodic Schedule Organization

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

Table 11-60. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	----	---	---	---	---	---	---	---	---	---	---	--

Table continues on the next page...

Table 11-60. Format of Frame List Element Pointer (continued)

Frame List Link Pointer	0	Typ	03-00H
-------------------------	---	-----	--------

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 11-61. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

11.5.4.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

Figure 11-63. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNC_LIST_ADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

11.5.4.2.3 Isochronous (High-Speed) Transfer Descriptor (iTID)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 11-62. Isochronous Transaction Descriptor (iTID)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

These fields may be modified by the host controller if the I/O field indicates an OUT.

11.5.4.2.3.1 Next Link Pointer

The first DWord of an iTD is a pointer to the next schedule data structure.

The following table describes the Next Schedule Element pointer field.

Table 11-63. Next Schedule Element Pointer

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iT D/siT D) or Queue Head (QH).

Table continues on the next page...

Table 11-63. Next Schedule Element Pointer (continued)

4-3 Reserved	These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

11.5.4.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

Table 11-64. iTD Transaction Status and Control

Bit	Description								
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:								
	<table border="1"> <thead> <tr> <th>Bit</th> <th>Definition</th> </tr> </thead> <tbody> <tr> <td>31</td> <td>Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.</td> </tr> <tr> <td>30</td> <td>Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.</td> </tr> <tr> <td>29</td> <td>Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.</td> </tr> </tbody> </table>	Bit	Definition	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.	29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.
Bit	Definition								
31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.								
30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.								
29	Babble Detected. Set to one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.								

Table continues on the next page...

Table 11-64. iTD Transaction Status and Control (continued)

Bit	Description
28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0±zero length data, 1±one byte, 2±two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent PG field to produce the starting buffer address for this transaction.

11.5.4.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 11-65. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

Table continues on the next page...

Table 11-65. iTD Buffer Pointer Page 0 (Plus) (continued)

Bit	Description
Endpoint Number (Endpt)	
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

Table 11-66. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint (<i>wMaxPacketSize</i>). This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the <i>Multi</i> field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 11-67. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame. 10b Two transactions to be issued for this endpoint per micro- frame. 11b Three transactions to be issued for this endpoint per micro- frame.

Table 11-68. iTD Buffer Pointer Page 3-6

Bit	Description

Bit	Description
11-0 Reserved	These bits reserved for future use and should be set to zero.

11.5.4.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

Table 11-69. Split Transaction Isochronous Transfer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. 04-0B: Static Endpoint State

2. 0C-13: Transfer results

Host Controller Read/Write

Host Controller Read Only

11.5.4.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

Table 11-70. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

11.5.4.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 11-71. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O). 0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 11-72. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.

Table continues on the next page...

Table 11-72. Micro-frame Schedule Control (continued)

Bit	Description
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame C-Mask</i> field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the <i>Active</i> and <i>SplitX-state</i> fields in the <i>Status</i> byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the <i>mFrame S-mask</i> field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

11.5.4.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

Table 11-73. siTD Transfer Status and Control

Bit	Description
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the <i>CurrentOffset</i> field to construct a data buffer pointer (0 selects <i>Page 0</i> pointer and 1 selects <i>Page 1</i>). The host controller is not required to write this field back when the siTD is retired (<i>Active</i> bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	μ Frame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.
7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 11-73. siTD Transfer Status and Control (continued)

Bit	Description
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction.
1	Split Transaction State (SplitXstate). The bit encodings are: Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
0	Reserved. Bit reserved for future use and should be set to zero.

11.5.4.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 11-74. Buffer Page Pointer List (plus)

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field <i>P</i> (see siTD Transfer State) specifies the <i>current</i> active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit (<i>P</i> field)). The host controller is not required to write this field back when the siTD is retired (<i>Active</i> bit transitioned from a one to a zero).
Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.	
11-5 (Page 1)	Reserved
4-3 (Page 1)	Transaction position (TP). This field is used with T-count to determine whether to send <i>all</i> , <i>first</i> , <i>middle</i> , or <i>last</i> with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning

Table continues on the next page...

Table 11-74. Buffer Page Pointer List (plus) (continued)

Bit	Description
	00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full-speed that is greater than 188 bytes. 10b Mid. This is the <i>middle</i> payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the <i>last</i> payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

11.5.4.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

Table 11-75. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

11.5.4.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

Table 11-76. Queue element transfer descriptor data structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. 08-0F: Transfer Results

Host Controller Read/Write

Host Controller Read Only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

11.5.4.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

Table 11-77. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

11.5.4.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 11-78. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

11.5.4.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

Table 11-79. TD Token (DWord 2)

Bit	Description
31 Data Toggle	This is the data toggle sequence bit. The use of this bit depends on the setting of the <i>Data Toggle Control</i> bit in the queue head.
30-16 Total Bytes to Transfer	<p>This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that <i>Total Bytes To Transfer</i> be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.</p> <p>Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</p>
15 Interrupt On Complete (IOC)	If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.
14-12 Current Page (C_Page)	This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.
11-10 Error Counter (CERR)	<p>This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the <i>Halted</i> bit to a one, and error status bit for the error that caused <i>CERR</i> to decrement to zero. An interrupt is generated if the <i>USB Error Interrupt Enable</i> bit in the <i>USBINTR</i> register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.</p> <p>Transaction Error - Decrement Data Buffer Error - No Decrement³ Stalled - No Decrement¹ Babble Detected - No Decrement¹ No Error - No Decrement²</p>
Error	Decrement Counter
1	Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented
2	If the <i>EPS</i> field indicates a HS device or the queue head is in the Asynchronous Schedule (and <i>PIDCode</i> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <i>CERR</i> to extend the total number of errors for this transaction. For example, <i>CERR</i> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.

Table continues on the next page...

Table 11-79. TD Token (DWord 2) (continued)

Bit	Description
	See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <i>PIDCode</i> indicates a SETUP.
3	Data buffer errors are host problems. They don't count against the device's retries.
	NOTE: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.
9-8 PID Code	This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:
00b	OUT Token generates token (E1H)
01b	IN Token generates token (69H)
10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, <i>μFrame S-mask</i> field in.
11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:
Bit	Status Field Description
7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overflow) or is unable to supply data fast enough during transmission (under run). If an overflow condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
4	Babble Detected. Set to a one by the Host Controller during status update when "babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the <i>Halted</i> bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.

Table continues on the next page...

Table 11-79. TD Token (DWord 2) (continued)

Bit	Description	
	2	Missed Micro-Frame. This bit is ignored unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	<p>Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the <i>QH.EPS</i> field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint.</p> <p>1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.</p>
	0	<p>Ping State (P)/ERR. If the <i>QH.EPS</i> field indicates a High-speed device and the <i>PID_Code</i> indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are:</p> <p>Value Meaning</p> <p>0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint.</p> <p>1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint.</p> <p>If the <i>QH.EPS</i> field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.</p>

11.5.4.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the *C_Page* field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 11-80. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field <i>C_Page</i> specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using <i>C_Page</i> (similar to an array index to

Table continues on the next page...

Table 11-80. qTD Buffer Pointer(s) (DWords 3-7) (continued)

	select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

11.5.4.2.6 Queue Head

The table located in this section shows the Queue Head structure layout.

The following table shows the queue head structure layout.

Table 11-81. Queue Head Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

- 4. 14-27: Transfer results.

Host Controller Read/Write

Host Controller Read Only

11.5.4.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

Table 11-82. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

11.5.4.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- **Endpoint Characteristics.** These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- **Endpoint Capabilities.** These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- **Split Transaction Characteristics.** This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 11-83. Endpoint Characteristics: Queue Head DWord 1

Bit	Description										
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.										
27	Control Endpoint Flag (C). If the <i>QH.EPS</i> field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.										
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (<i>wMaxPacketSize</i>). The maximum value this field may contain is 0x400 (1024).										
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.										
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.										
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are: <table border="1" data-bbox="310 1272 1472 1479"> <thead> <tr> <th>Value</th> <th>Meaning</th> </tr> </thead> <tbody> <tr> <td>00b</td> <td>Full-Speed (12 Mbits/sec)</td> </tr> <tr> <td>01b</td> <td>Low-Speed (1.5 Mbits/sec)</td> </tr> <tr> <td>10b</td> <td>High-Speed (480 Mbits/sec)</td> </tr> <tr> <td>11b</td> <td>Reserved</td> </tr> </tbody> </table> This field must not be modified by the host controller.	Value	Meaning	00b	Full-Speed (12 Mbits/sec)	01b	Low-Speed (1.5 Mbits/sec)	10b	High-Speed (480 Mbits/sec)	11b	Reserved
Value	Meaning										
00b	Full-Speed (12 Mbits/sec)										
01b	Low-Speed (1.5 Mbits/sec)										
10b	High-Speed (480 Mbits/sec)										
11b	Reserved										
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.										
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the periodic schedule , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the <i>EPS</i> field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the <i>EPS</i> field indicates a high-speed device yields undefined results.										
6-0	Device Address. This field selects the specific device serving as the data source or sink.										

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 11-84. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	<p>High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are:</p> <p>Value Meaning</p> <p>00b Reserved. A zero in this field yields undefined results.</p> <p>01b One transaction to be issued for this endpoint per micro-frame.</p> <p>10b Two transactions to be issued for this endpoint per micro-frame.</p> <p>11b Three transactions to be issued for this endpoint per micro-frame.</p>
29-23	<p>Port Number. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address <i>Hub Addr</i> below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.</p>
22-16	<p>Hub Addr. This field is ignored by the host controller unless the <i>EPS</i> field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.</p>
15-8	<p>Split Completion Mask (μFrame C-Mask). This field is ignored by the host controller unless the <i>EPS</i> field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the <i>Active</i> and <i>SplitX-state</i> fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the μFrame C- Mask field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.</p>
7-0	<p>Interrupt Schedule Mask (μFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the μFrame S-mask field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the <i>EPS</i> field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the <i>PID_Code</i> field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the <i>EPS</i> field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.</p>

11.5.4.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the

duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

Table 11-85. Current qTD Link Pointer

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

Table 11-86. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt) μ RW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from <i>RL</i> before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from <i>RL</i> during an overlay.
6	31	Data Toggle. The <i>Data Toggle Control</i> controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the <i>EPS</i> field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.

Table continues on the next page...

Table 11-86. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9) (continued)

9	11-5	S-bytes. Software must ensure that the S-bytes field in a qTD is zero before activating the qTD. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.
---	------	--

11.5.4.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See [Host Controller Operational Model for FSTNs](#) for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

Table 11-87. Frame Span Traversal Node Structure Layout

11.5.4.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 11-88. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved

Table continues on the next page...

Table 11-88. FSTN Normal Path Pointer Field Descriptions (continued)

2-1	<p>QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/ siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are:</p> <p>Value Meaning</p> <p>00b iTD (isochronous transfer descriptor)</p> <p>01b QH (queue head)</p> <p>10b siTD (split transaction isochronous transfer descriptor)</p> <p>11b FSTN (Frame Span Traversal Node)</p>
0	<p>Terminate (T).</p> <p>1 = Link Pointer field is not valid. 0 = Link Pointer is valid.</p>

11.5.4.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FSTN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 11-89. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	<p>Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator.</p> <p>0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.</p>

11.5.4.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

11.5.4.3.1 Host Controller Initialization

After initial power-on or HCRreset (hardware or through HCRreset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

Table 11-90. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if <i>Asynchronous Schedule Park Capability is one</i>)
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNC_LISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/PPC set to one); 00003000h (w/PPC set to zero)

To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate

with devices through the asynchronous schedule, system software must write the USB_ASYNCLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

11.5.4.3.2 Port Routing and Control

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

NOTE

The USB controllers do not require nor support companion controllers to support Full and Low Speed device. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to [Embedded Transaction Translator Function](#) for details.

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

Figure 11-64. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.¹

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See [Host Controller Structural Parameters \(USB_HCSPARAMS\)](#)

11.5.4.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

Table 11-91. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC. The EHCI HC has access to the additional port status and control bits defined in this specification (see). The EHCI HC can temporarily release control of the port to a companion HC by setting the <i>PortOwner</i> bit in the PORTSC1 register to one.

11.5.4.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and

identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.

- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from 1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

11.5.4.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

Figure 11-65. Port Owner Handoff State Machine

11.5.4.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

11.5.4.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

11.5.4.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

Table 11-92. Port Power Enable Control Rules

CF	CHC ¹ (PP)	EHC ² (PP)	Owner	PPE ³	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.

Table continues on the next page...

Table 11-92. Port Power Enable Control Rules (continued)

1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

11.5.4.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to [Table 11-93](#) for summary behavior for over-current detection

when the host controller is halted (suspended from a device component point of view).

11.5.4.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the Arm platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

11.5.4.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see [Port Status & Control \(USB_PORTSC1\)](#)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 µsec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a

port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 11-93. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, the USB_PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNTNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNTNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

11.5.4.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the `USB_PERIODICLISTBASE` register (see [Frame List Base Address \(USB_PERIODICLISTBASE\)](#))/ [Device Address \(USB_DEVICEADDR\)](#). The `USB_PERIODICLISTBASE` register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in [Host Data Structures](#). In each micro-frame, if the periodic schedule is enabled (see [Periodic scheduling threshold](#)) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the `USB_PERIODICLISTBASE` and the `USB_FRINDEX` registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

Figure 11-66. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register `USB_ASYNC_LIST_ADDR` to access the asynchronous schedule, see the figure below.

Figure 11-67. General Format of Asynchronous Schedule List

The `USB_ASYNC_LIST_ADDR` register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the `USB_ASYNC_LIST_ADDR` register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See [Asynchronous Schedule](#) for complete operational details.

11.5.4.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

11.5.4.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in [Figure 11-68](#). The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and Last Start curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

Figure 11-68. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 11-94. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in [Figure 11-68](#) was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```

Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
    Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
    Rvalue = FALSE
End If
Return rvalue
End
    
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the

running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the $f(x)$ plot was getting close to the LastStart line.

11.5.4.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

Figure 11-69. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in [USB Frame Index \(USB_FRINDEX\)](#) and initially illustrated in [Schedule Traversal Rules](#). Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller

periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

Figure 11-70. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in [USB Frame Index \(USB_FRINDEX\)](#), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be

accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. [USB Frame Index \(USB_FRINDEX\)](#) provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 11-95. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]
N	N	111b	N+1	N	000b
N+1	N	000b	N+1	N+1	001b
N+1	N+1	001b	N+1	N+1	010b

11.5.4.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule.

The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero.

The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions.

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

Figure 11-71. Example Periodic Schedule

11.5.4.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in [Isochronous \(High-Speed\) Transfer Descriptor \(iTD\)](#). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

11.5.4.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of

Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Size. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

11.5.4.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

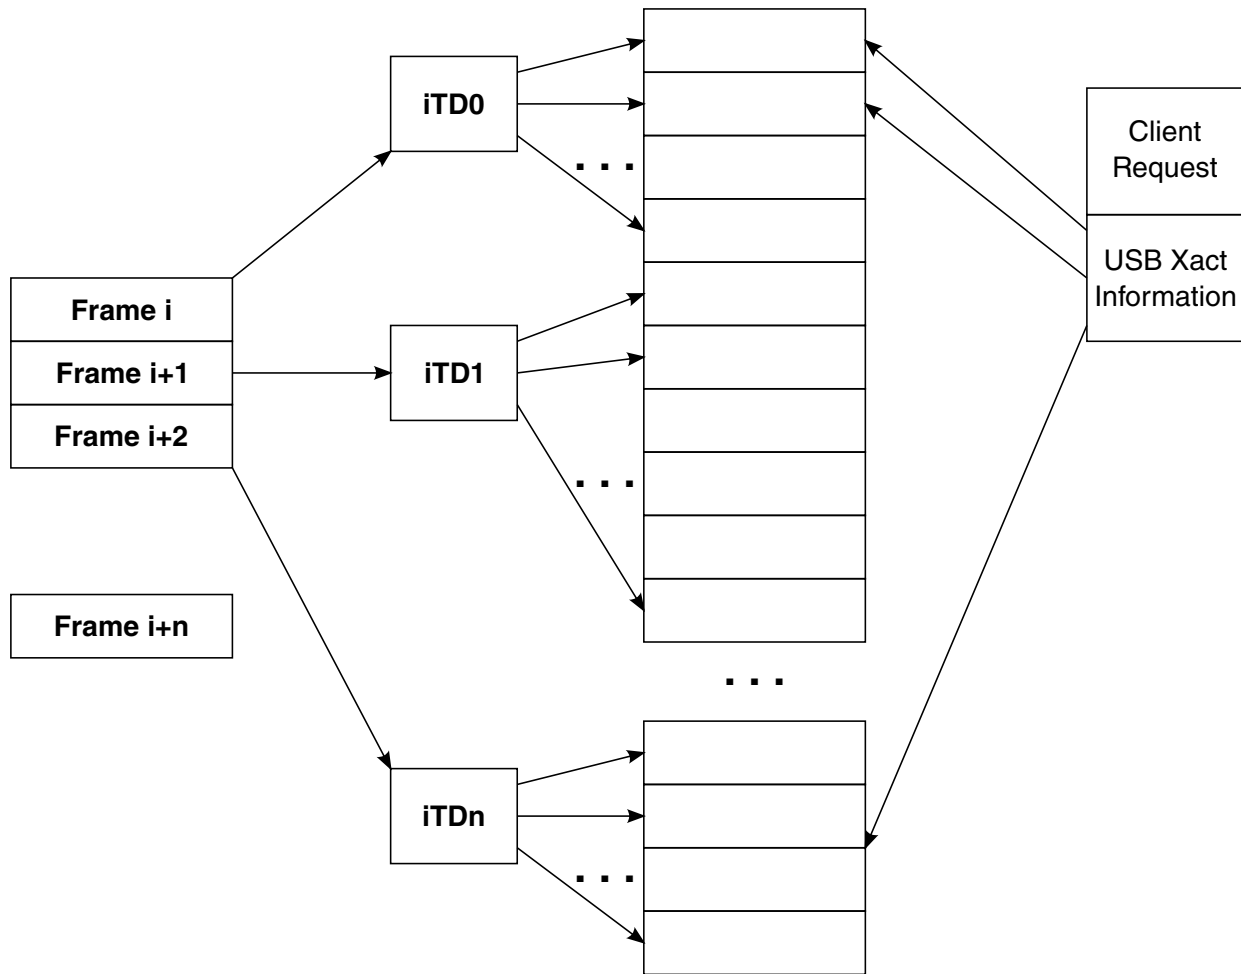

Figure 11-72. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

11.5.4.3.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

11.5.4.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see [Empty Asynchronous Schedule Detection](#))
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in [Figure 11-67](#). Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iT or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

11.5.4.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```

InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadCurrent is a pointer to a queue head that is
-- already in the active list
-- pQHeadNew is a pointer to the queue head to be added
--
-- This algorithm links a new queue head into a existing
-- list
--
pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer
pQueueHeadCurrent.HorizontalPointer = physicalAddressOf (pQueueHeadNew)
End InsertQueueHead

```

11.5.4.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```

UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadPrevious is a pointer to a queue head that
-- references the queue head to remove

```

Universal Serial Bus Controller (USB)

```
-- pQHeadToUnlink is a pointer to the queue head to be
-- removed
-- pQheadNext is a pointer to a queue head still in the
-- schedule. Software provides this pointer with the
-- following strict rules:
--     if the host software is one queue head, then
--     pQHeadNext must be the same as
--     QueueheadToUnlink.HorizontalPointer. If the host
--     software is unlinking a consecutive series of
--     queue heads, QHeadNext must be set by software to
--     the queue head remaining in the schedule.
--
-- This algorithm unlinks a queue head from a circular list
--
pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer
pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
```

End UnlinkQueueHead

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

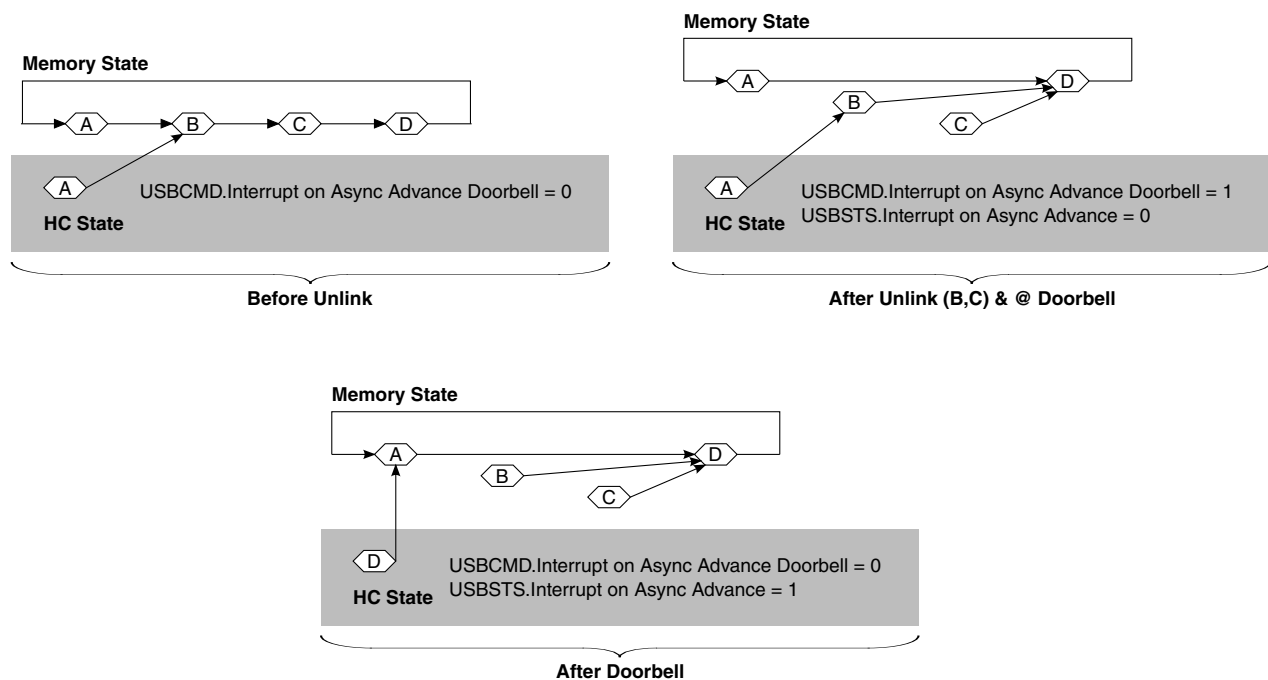

Figure 11-73. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

11.5.4.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see Table 11-81) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see *Asynchronous schedule traversal: Start Event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

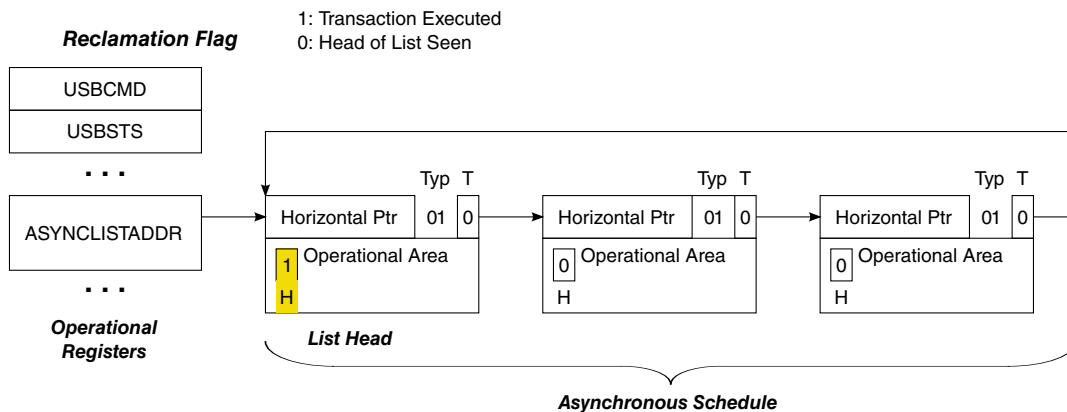

Figure 11-74. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

11.5.4.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

11.5.4.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting?*

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 μ sec. The value is derived based on the analysis in [Example Derivation for AsyncSchedSleepTime](#). The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

Figure 11-75. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 11-96. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the <i>AsynchronousTraversalSleepTimer</i> to <i>AsynSchedSleepTime</i> .
B	When the <i>AsynchronousTraversalSleepTimer</i> expires, the host controller sets the <i>Reclamation</i> bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see Nak Count Reload Control).
C	The host controller cancels the sleep timer (<i>AsynchronousTraversalSleepTimer</i>).

11.5.4.3.8.4.2 *Asyn Sched Not Active*

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Asyn Sched Active or Asyn Sched Sleeping states when the end-of-micro-frame event is detected.

11.5.4.3.8.4.3 *Asyn Sched Active*

This state is entered from the Asyn Sched Not Active state when the periodic schedule is not active. It is also entered from the Asyn Sched Sleeping states when the *AsynSchedSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

11.5.4.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

11.5.4.3.8.4.5 Example Derivation for AsyncSchedSleepTime

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 11-97. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 μ s provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 μ s sleep period would allow the host controller to get the NAK results on the first complete-split.

11.5.4.3.8.5 Asynchronous schedule traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in [Restarting Asynchronous Schedule Before EOF](#). Asynchronous schedule *Start Events* are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see [Restarting Asynchronous Schedule Before EOF](#)).

11.5.4.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see [Empty Asynchronous Schedule Detection](#)) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see [Fetch Queue Head](#)).

The host controller is required to set the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented in [Asynchronous schedule traversal: *Start Event*](#), occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see [Execute Transaction](#)). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

11.5.4.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head.

See [Queue Head Initialization](#) for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the *NakCnt* field adjustment rules.

Table 11-98. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement <i>NakCnt</i>	N/A (protocol error)
OUT	decrement <i>NakCnt</i>	No Action ¹ Start
Split	decrement <i>NakCnt</i>	N/A (protocol error)
Complete Split	No Action	Decrement <i>NakCnt</i>

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in [Nak Count Reload Control](#) .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all *NakCnt*'s go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see [Empty Asynchronous Schedule Detection](#)).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see [Asynchronous schedule traversal: Start Event](#). Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

11.5.4.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see [Execute Transaction](#)). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see [Table 11-81](#)) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see [Asynchronous schedule traversal: Start Event](#) for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see [Figure 11-74](#)).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the *RL* field (see [Table 11-81](#)) is set to zero.

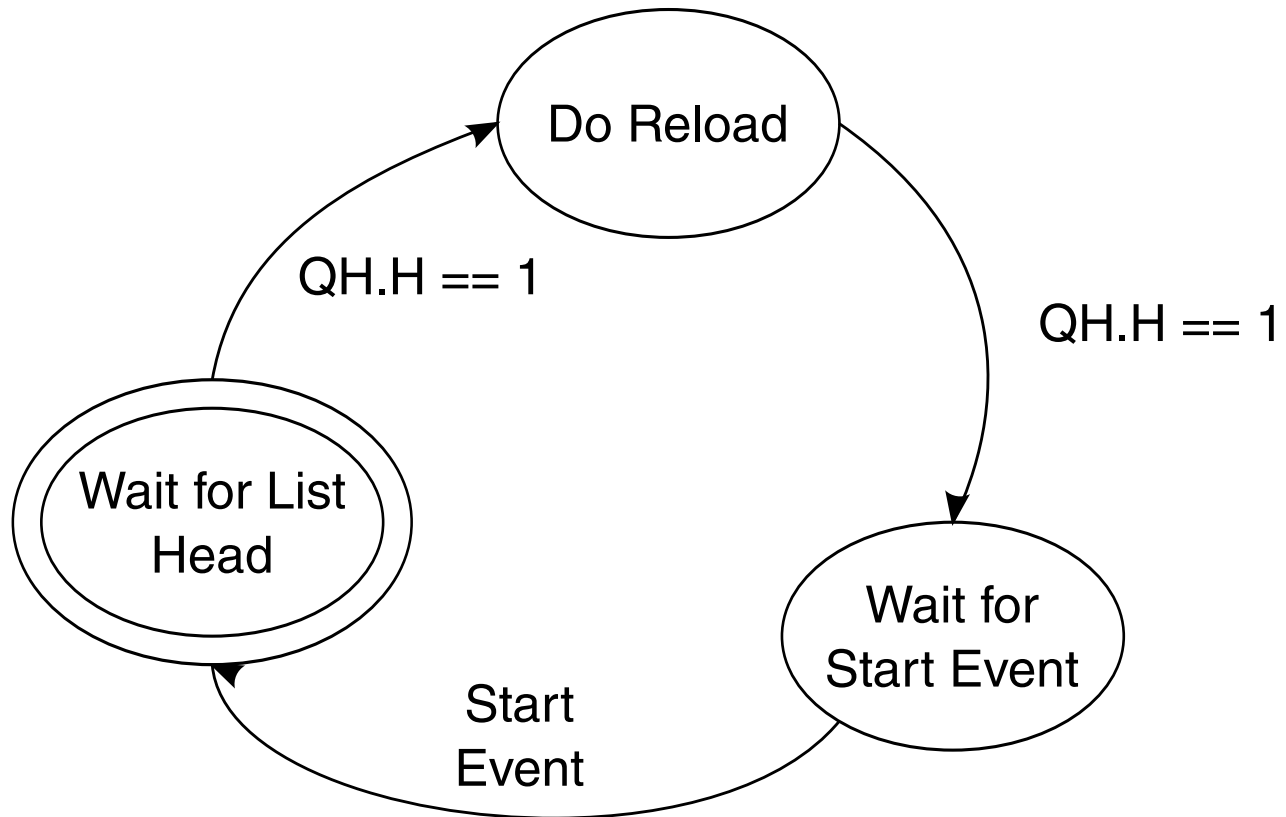

Figure 11-76. Example HC State Machine for Controlling Nak Counter Reloads

11.5.4.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in [Asynchronous schedule traversal: Start Event](#) occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

11.5.4.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

11.5.4.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

11.5.4.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in [Table 11-81](#)). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

Figure 11-77. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see [Execute](#)

[Transaction](#)) describes the basic requirements for all endpoints. [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

11.5.4.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see [Next Asynch. Address \(USB_ASYNCLISTADDR\)](#))/ [Endpoint List Address \(USB_ENDPTLISTADDR\)](#) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in [Table 11-81](#).

While in this state, the host controller performs operations to implement empty schedule detection (see [Empty Asynchronous Schedule Detection](#)) and Nak Counter reloads (see [Operational Model for Nak Counter](#)). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in [Empty Asynchronous Schedule Detection](#)). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in [Operational Model for Nak Counter](#).

This state is complete when the queue head has been read on-chip.

11.5.4.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control (dte)* bit (see [Table 11-83](#)).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

11.5.4.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see [Split Transactions for Asynchronous Transfers](#) and [Split Transaction Interrupt](#) .

11.5.4.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

11.5.4.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state ([Operational Model for Nak Counter](#)). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

11.5.4.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#) for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,⁴ or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction (see [Transaction Fit - A Best-Fit Approximation Algorithm](#)) for example method for implementing the frame boundary test).

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See [Buffer Pointer List Use for Data Streaming with qTDs](#) .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in [Transaction Error](#) .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
 - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to [Split Transactions](#) for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

11.5.4.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB_n_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset*, and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB_n_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

11.5.4.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in [Execute Transaction](#) apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB_n_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB_n_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB_n_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in [Execute Transaction](#). It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asynchronous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 11-99. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction. ^{1, 2}
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.

Table continues on the next page...

Table 11-99. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction. ²
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. ²
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

11.5.4.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see [Table 11-99](#)).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

11.5.4.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or

- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

11.5.4.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical

page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

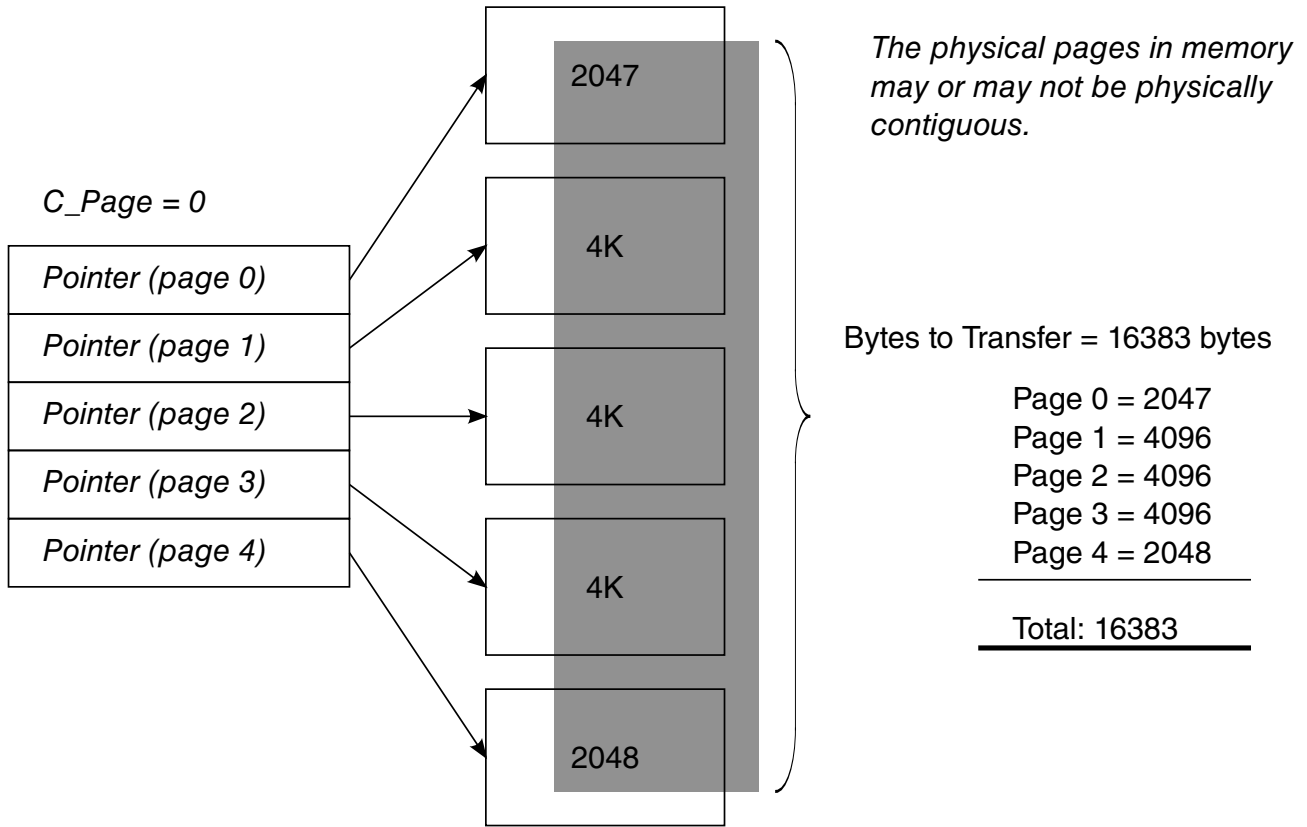

Figure 11-78. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

11.5.4.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 11-100. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 01h	A queue head for the <i>bInterval</i> of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the <i>S-Mask</i> field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on <i>S-Mask</i> = 02h	Another example of a queue head with a <i>bInterval</i> of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the <i>S-Mask</i> is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

11.5.4.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete (IOC)* bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

11.5.4.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 11-101. Ping Control State Transition Table

Event	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr ¹	Do Ping
Do Ping	PING	Stall	N/C ² Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT

Table continues on the next page...

Table 11-101. Ping Control State Transition Table (continued)

Do OUT	OUT	XactErr ¹	Do Ping
Do OUT	OUT	Stall	N/C ²

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 11-102. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

11.5.4.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see [Split Transaction Isochronous Transfer Descriptor \(siTD\)](#)). Control, Bulk and Interrupt are managed using the queuing data structures (see [Queue Head](#)). The interface data structures need to be programmed with the device address and the

Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

11.5.4.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type (C)* bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

Figure 11-79. Host Controller Asynchronous Schedule Split-Transaction State Machine

11.5.4.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

11.5.4.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (*XactErr*). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller **MUST** ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host

controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).

11.5.4.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#), but only occurs on the completion of a split transaction.

11.5.4.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^CX labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

Figure 11-80. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

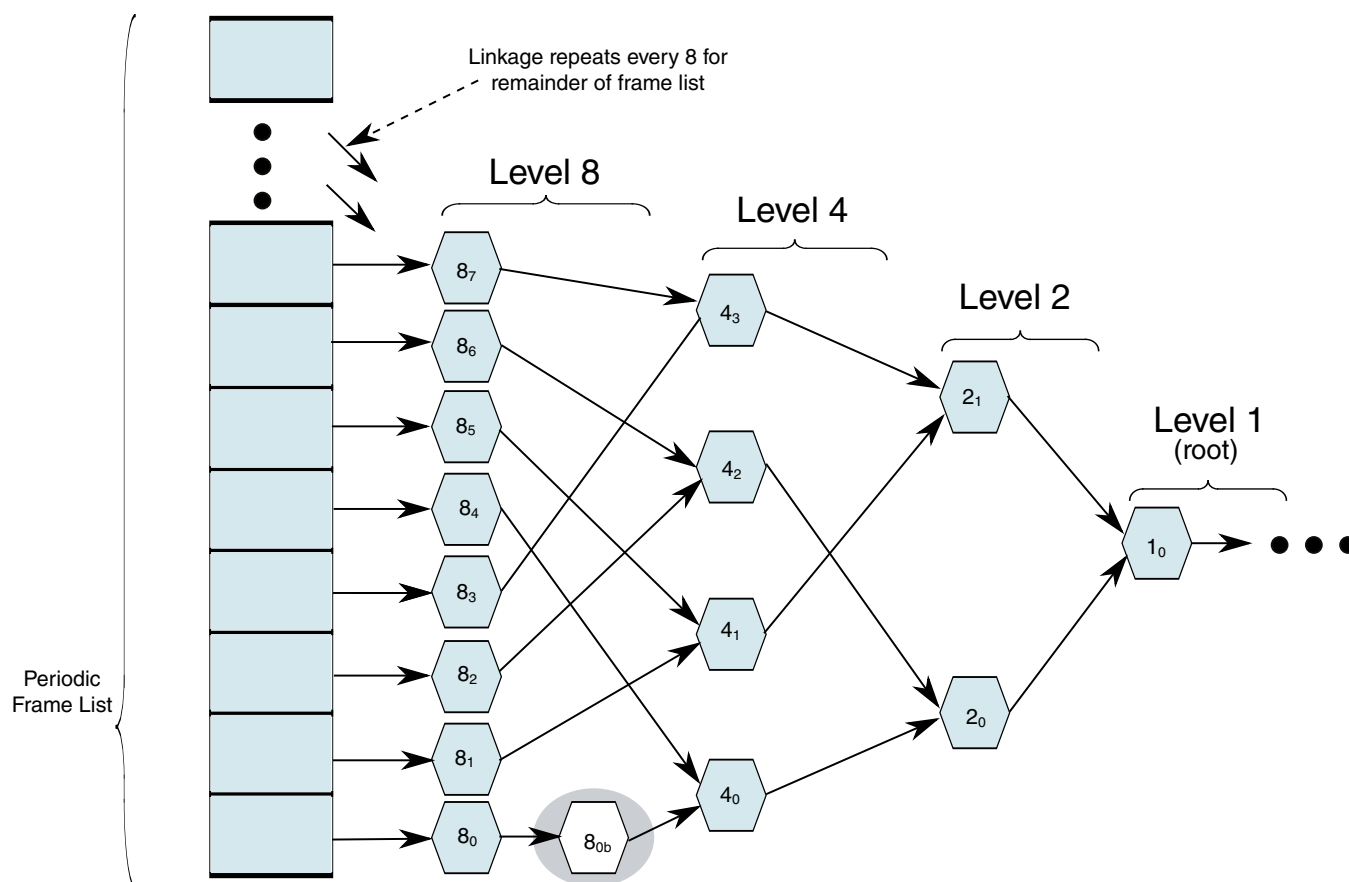

Figure 11-81. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b} . It would then have to move 4_1 and everything linked after into the same path as 4_0 . This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. [Host Controller Operational Model for FSTNs](#) defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see [Table 11-79](#)). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 11-80](#), case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to [Figure 11-80](#), case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

11.5.4.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see [siTD Back Link Pointer](#)).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See [Execute Transaction](#) and [Tracking Split Transaction Progress for Interrupt Transfers](#) for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
 - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See [Periodic Isochronous - Do Complete Split](#) for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

Figure 11-82. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {83,0, 83,1, 83,2, Save-A, 82,2, 82,3, 42, 41, 40, 20, 21, 10, ...}

$2_0, \text{Restore-N}, 4_3, 2_1, \text{Restore-N}, 1_0 \dots \}$. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: $\{8_{2,0}, 8_{2,1}, 8_{2,2}, 8_{2,3}, 4_2, 2_0, \text{Restore-N}, 1_0 \dots \}$.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: $\{8_{3,0}, 8_{3,1}, 8_{3,2}, \text{Save-A}, 4_3, 2_1, \text{Restore-N}, 1_0 \dots \}$.

11.5.4.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
 - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer* and *T-bit* equal to zero.
 - *Back Path Link Pointer.Type* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
 - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer's T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

11.5.4.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog-mask* bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.

- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

11.5.4.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit* is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, $cMicroFrameBit = (1 \text{ shifted-left}(FRINDEX[2:0]))$). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at *Do_Start* and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to *Do_Complete*. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the *Do_Complete* state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the *Do_Complete* state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

Figure 11-83. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section [Periodic Isochronous - Do Complete Split](#) for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX[7:3]*. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the
-- 'previous bit' is set in C-mask, check C-prog-mask to
-- make sure it
-- happened.
If (previousBit bitAND QH.C-mask) then
    If not(previousBit bitAND QH.C-prog-mask) then
        rvalue = FALSE;
    End if
End If
-- If the C-prog-mask already has a one in this bit position,
```

```
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
  rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section [Periodic Isochronous - Do Start Split](#)). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *CErr* is non-zero). If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section [Managing Control/Bulk/Interrupt Transfers through Queue Heads](#)).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- **ERR.** There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- **STALL.** The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 11-103. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame. Host controller should continue walking the schedule.
A not(C)	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted. If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> . In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A not(B) C	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	<i>QH.FrameTag</i> test failed. This means that exactly one or more <i>H-Frames</i> have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If <i>PIDCode</i> is an IN, then the Queue head must be halted. If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> . In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If <i>PIDCode</i> is an IN, then the Queue head must be halted. If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> . In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one. Note: When executing in the context of a <i>Recovery Path</i> mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

Table 11-103. Interrupt IN/OUT Do Complete Split State Execution Criteria

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a <i>Recovery Path</i> mode.
--	--	--

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see [Figure 11-80](#)).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c ([Figure 11-80](#)).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases ([Figure 11-80](#)).

11.5.4.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

11.5.4.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iT_D, Section [Isochronous \(High-Speed\) Transfer Descriptor \(iT_D\)](#)) (see Section [Managing Isochronous Transfers Using iT_Ds](#) for the operational model of iT_Ds) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

11.5.4.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section [Split Transaction Scheduling Mechanisms for Interrupt](#) apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The S^X and C^X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

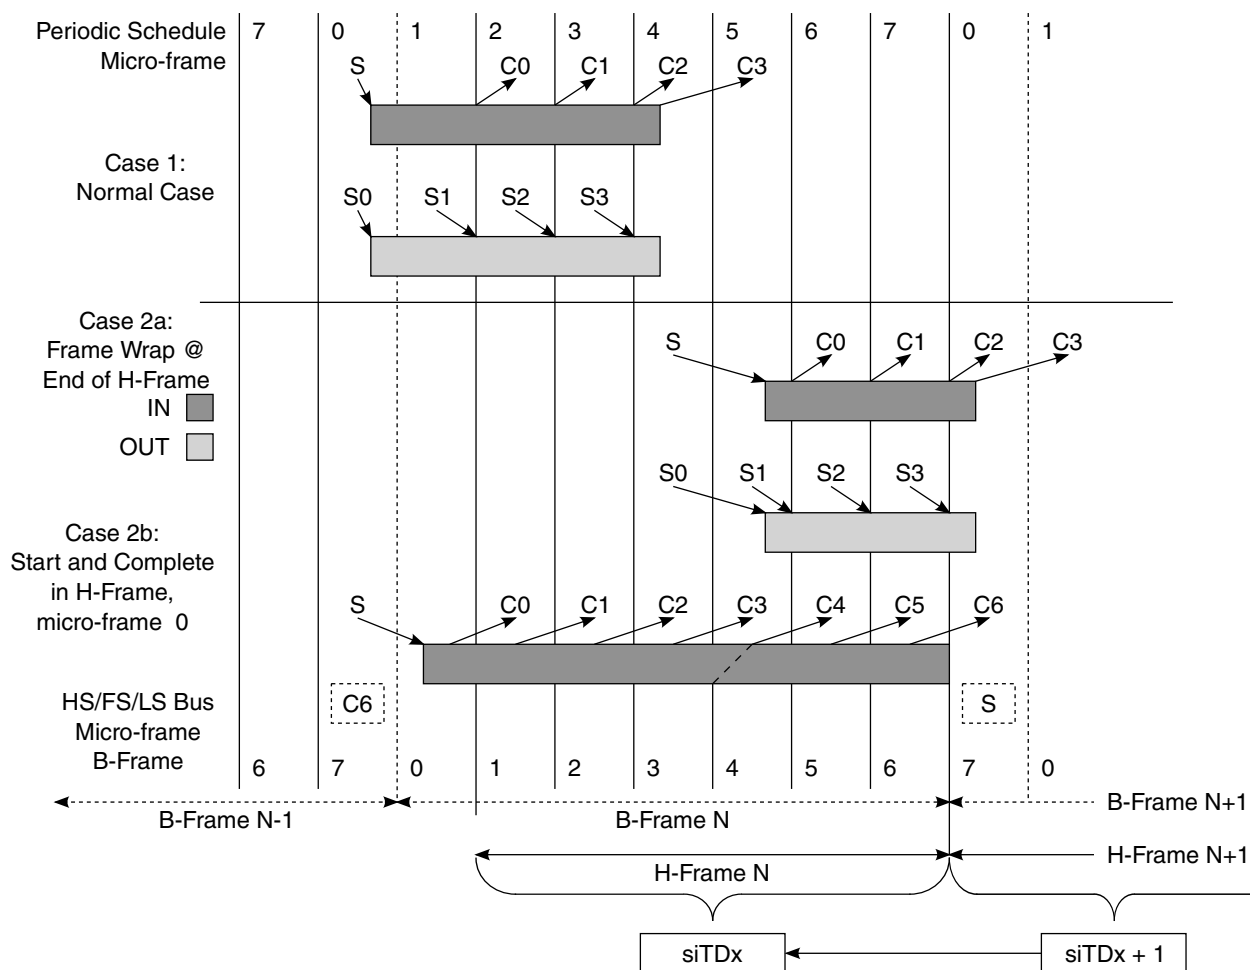

Figure 11-84. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to N complete-splits. The scheduling boundary cases are:

- *Case 1:* The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see [Figure 11-85](#)). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in [Section Split Transaction Execution State Machine for Interrupt](#).
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-84](#), case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by `USB_n_FRINDEX[2:0]` is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-84](#), case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

Complete Split, and the current micro-frame as indicated by *USB_n_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN and OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

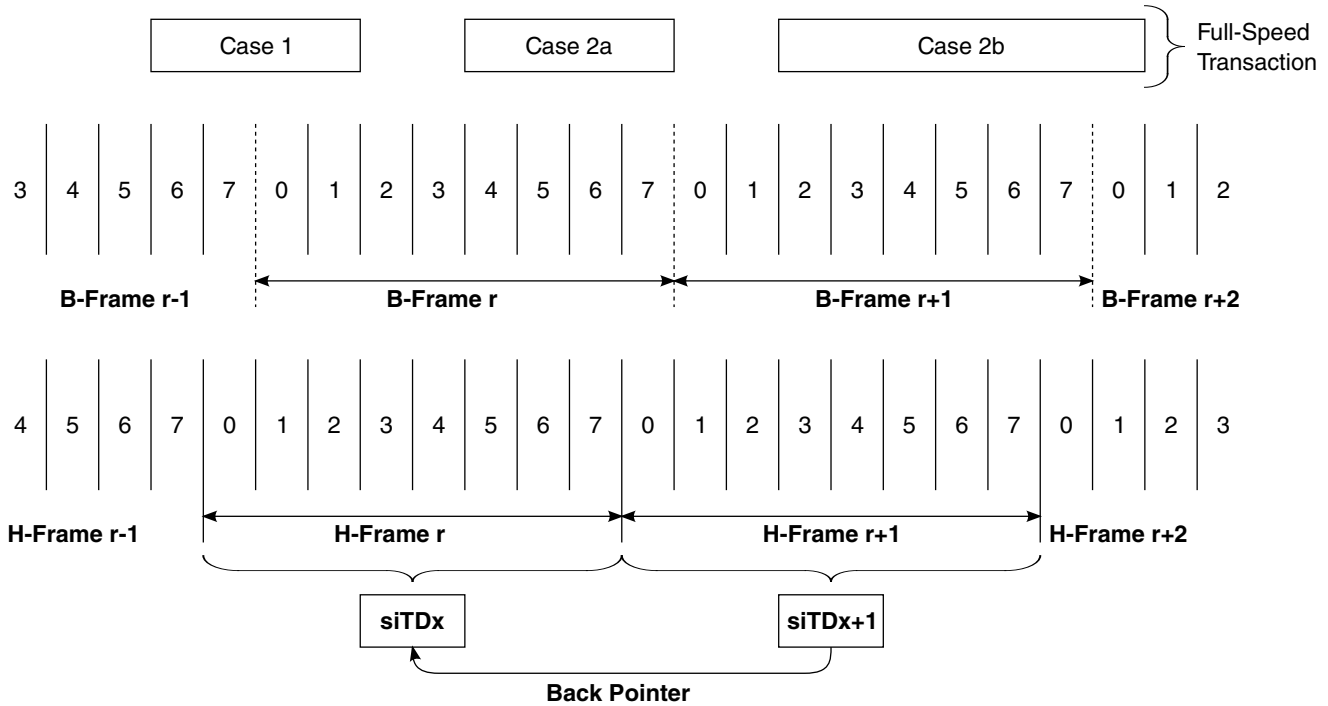

Figure 11-85. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1:* One $siTD$ is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single H -Frame.
- *Case 2a, 2b:* Although both INs and OUTs can have these footprints, OUTs always take only one $siTD$ to schedule. However, INs (for these boundary cases) require two $siTD$ s to complete the scheduling of the isochronous split transaction $siTD_x$ is used to always issue the start-split and the first N complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of H -Frame $_{Y+1}$, or micro-frame 0 of H -Frame $_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from H -Frame $_{Y+2}$ is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described in Section [Periodic Isochronous - Do Complete Split](#).

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame N* and the last complete-split would need to occur in micro-frame 1 of *H-Frame N+1*. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

11.5.4.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction *N* are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position (TP)* and *Transaction Count (T-count)*. If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section [Periodic Isochronous - Do Start Split](#) for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section [Asynchronous - Do Complete Split](#) for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

11.5.4.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section [Tracking Split Transaction Progress for Interrupt Transfers](#), plus the variable *cMicroFrameBit* defined in Section [Split Transaction Execution State Machine for Interrupt](#) to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

Figure 11-86. Split Transaction State Machine for Isochronous

11.5.4.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see [Figure 11-85](#)) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 11-104. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

Table 11-105. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when <i>T-count</i> starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when <i>T-count</i> starts at greater than 2.
MID	!=1	MID	<i>TP</i> stays at MID while <i>T-count</i> is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in [Table 11-105](#).

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section [Split Transaction for Isochronous - Processing Examples](#).

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit()* algorithm defined in [Periodic Isochronous - Do Complete Split](#) can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

11.5.4.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section [Periodic Isochronous - Do Complete Split](#)). The sequence in which this test is applied depends on the current value of *USB_n_FRINDEX[2:0]*. If *USB_n_FRINDEX[2:0]* is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
    Boolean rvalue = TRUE;
    previousBit = cMicroFrameBit rotate-right(1)
    -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
    -- to send a complete split in the previous micro-frame. So, if the
    -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
    -- happened.
    if previousBit bitAND siTD.C-mask then
        if not (previousBit bitAND siTD.C-prog-mask) then
            rvalue = FALSE
        End if
    End if
    Return rvalue
End Algorithm
```

If Test A is true and *USB_n_FRINDEX[2:0]* is zero or one, then this is a case 2a or 2b scheduling boundary (see [Figure 11-84](#)). See Section [Periodic Isochronous - Do Complete Split](#) for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer*,
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section [Periodic Isochronous - Do Complete Split](#) . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing *C-mask* with *C-prog-mask*. A zero result indicates that all complete-splits have been executed.

- **MDATA (and Last).** See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-masks* incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- **NYET (and not Last).** See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- **MDATA (and not Last).** The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame *X* to *X+1* and during micro-frame *X*, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame *X*. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

11.5.4.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see [Figure 11-84](#)) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 11-106. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer	All bits in the status field	C-prog-mask
P (page select)		
Current Offset		
TP (transaction position)		
T-count (transaction count)		

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When *cMicroFrameBit* is a 1h and the *siTDX.Back Pointer.T-bit* is a zero, or
- If *cMicroFrameBit* is a 2h and *siTDX.S-mask[0]* is a zero

When either of these conditions apply, then the host controller must use the transaction state from *siTD_{X-1}*.

In order to access *siTD_{X-1}*, the host controller reads on-chip the siTD referenced from *siTD_X.Back Pointer*.

The host controller must save the entire state from *siTD_X* while processing *siTD_{X-1}*. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If *siTD_{X-1}* is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see [Table 11-106](#)) of *siTD_{X-1}* is appropriately advanced based on the results and written back to memory. If the resultant state of *siTD_{X-1}*'s *Active* bit is a one, then the host controller returns to the context of *siTD_X*, and follows its next pointer to the next schedule item. No updates to *siTD_X* are necessary.

If *siTD_{X-1}* is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If *siTD_{X-1}*'s *Active* bit is a zero, (because it was zero when the host controller first visited *siTD_{X-1}* via *siTD_X*'s back pointer, it transitioned to zero as a result of a detected error, or the results of *siTD_{X-1}*'s complete-split transaction transitioned it to zero), then the host controller returns to the context of *siTD_X* and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and *siTD_X.S-mask[0]* is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of *siTD_X*, then follows *siTD_X.Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows *siTD_X.Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of *siTD_{X-1}* will have its *Active* bit set to zero when the host controller returns

to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

11.5.4.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see [Figure 11-77](#)).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 11-107. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that siTD_{X+1}'s *Back Pointer.T-bit* is a zero, saves the state of siTD_{X+1} and fetches siTD_X. It executes the complete split transaction using the transaction state of siTD_X. If the siTD_X split transaction is complete, siTD's *Active* bit is set to zero and results written back to siTD_X. The host controller retains the fact that siTD_X is retired and transitions the *SplitXState* in the siTD_{X+1} to Do Start Split. At this point, the host controller is prepared to execute the start-split for siTD_{X+1} when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section [Periodic Isochronous - Do Complete Split](#)), that is, before all the scheduled complete-splits have been executed, the host controller will transition *siTD_X.SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, siTD_{X+1} does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame* X+2, micro-frame 0, the host controller detects that siTD_{X+2}'s *Back Pointer.T-bit* is a zero, saves the state of siTD_{X+2} and fetches siTD_{X+1}. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of siTD_{X+2}, and traverses its next pointer without any state change updates to siTD_{X+2}. S

During *H-Frame* X+2, micro-frame 1, the host controller detects siTD_{X+2}'s *S-mask[0]* is a zero, saves the state of siTD_{X+2} and fetches siTD_{X+1}. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of siTD_{X+2} and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for siTD_{X+2} when it reaches micro-frame 4.

11.5.4.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant ping-pong of main memory is known to create Arm platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the Arm platform, based on recent history usage. In the more aggressive power saving modes, the Arm platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the Arm platform power management software can detect this activity over time and inhibit the transition of the Arm platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the Arm platform power management software from placing the Arm platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the Arm platform power management to get the Arm platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the Arm platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the Arm platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

11.5.4.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SEO_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB_n_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCRreset* to a one.

11.5.4.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section [Host System Error](#) details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, Arm platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to read the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINTR register, see Section) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section) from a one to a zero.

11.5.4.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

11.5.4.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 11-108. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1 ¹
Timeout	-1	XactErr set to a one.	1 ¹
Bad PID ²	-1	XactErr set to a one.	1 ¹
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see [Halting a Queue Head](#).
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

11.5.4.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see [Halting a Queue Head](#)). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for

a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

11.5.4.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

11.5.4.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDS, siTDS, and queue heads (qTDS)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB_n_USBSTS register is also set to a one.

11.5.4.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB_n_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

11.5.4.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section [Interrupt on Async Advance](#)).

11.5.4.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

11.5.4.3.15.2.2 *Frame List Rollover*

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

11.5.4.3.15.2.3 *Interrupt on Async Advance*

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section [Removing Queue Heads from Asynchronous Schedule](#).

11.5.4.3.15.2.4 *Host System Error*

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
 - *Host System Error* bit is to a one.
 - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 11-109. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCRreset* in the USB.USBCMD register before re-initializing and restarting the host controller.

11.5.4.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

11.5.4.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

11.5.4.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

11.5.4.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the register.

11.5.4.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 11-110. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

11.5.4.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
 - Hub Address = 0
 - Transactions to direct attached device/hub.
 - QH.EPS = Port Speed
 - Transactions to a device downstream from direct attached FS hub.

- QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)

- All FS ISO transactions:
 - Hub Address = 0
 - siTD.EPS = 00 (full speed)
 - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

11.5.4.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. <http://www.usb.org>) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

11.5.4.4.1.5.1 Micro-frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

11.5.4.4.1.5.2 *Split State Machines*

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 11-111. Summary of the Conditions of Handshakes¹

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

11.5.4.4.1.5.3 *Asynchronous Transaction Scheduling and Buffer Management*

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

11.5.4.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

11.5.4.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

11.5.4.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits
 - EOF (and not started in micro-frames 6)
 - Idle for more than 4 micro-frames
- Abort of pending complete-splits
 - EOF
 - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

11.5.4.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
 - EOF (and not started in micro-frames 6)
 - Idle for more than 4 micro-frames
- Abort of pending complete-splits
 - EOF
 - Idle for more than 4 micro-frames

11.5.4.4.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes

the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

11.5.4.4.1.5.5 *Multiple Transaction Translators*

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the register.

11.5.4.4.2 **Device Operation**

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

11.5.4.4.2.1 **USB_USBMODE Register**

Given that the dual-role controller is initialized in neither host nor device mode, the [USB Device Mode \(USB_USBMODE\)](#) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

11.5.4.4.2.2 **Non-Zero Fields the Register File**

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

11.5.4.4.2.3 **SOF Interrupt**

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See [USB Status Register \(USB_USBSTS\)](#) and [Interrupt Enable Register \(USB_USBINTR\)](#) registers.

11.5.4.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

11.5.4.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

11.5.4.4.4 Miscellaneous variations from EHCI

11.5.4.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the [Port Status & Control \(USB_PORTSC1\)](#) register providing a capability that is not defined by EHCI.

11.5.4.4.4.2 Discovery

11.5.4.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the [Port Status & Control \(USB_PORTSC1\)](#) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.

- This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

11.5.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

11.5.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

11.5.4.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

Figure 11-87. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

11.5.4.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 11-112. Endpoint Queue Head (dQH)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

11.5.4.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

[Table 11-113](#) describes the endpoint capabilities.

Table 11-113. Endpoint Capabilities/Characteristics

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. NOTE: Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where the total transfer length is a multiple of the Maximum Packet Length. This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bits reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

11.5.4.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

11.5.4.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 11-114. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

11.5.4.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 11-115. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

11.5.4.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section [Managing Transfers with Transfer Descriptors](#).

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 11-116. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Pointer (Page 1)	0 Frame Number
Buffer Pointer (Page 2)	Reserved
Buffer Pointer (Page 3)	Reserved
Buffer Pointer (Page 4)	Reserved

Host Controller Read/Write

Host Controller Read Only

The following table describes the dTD Pointer.

Table 11-117. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 11-118. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	<p>Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction.</p> <p>The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H).</p> <p>If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.</p> <p>It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of <i>Maximum Packet Length</i>. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less than <i>Maximum Packet Length</i>.</p>
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.

Table continues on the next page...

Table 11-118. dTD Token (continued)

11-10	<p>Multiplier Override (MultiO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO.</p> <p>Example:</p> <p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default]</p> <p>Three packets are sent: {Data2(8); Data1(7); Data0(0)}</p> <p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2</p> <p>Two packets are sent: {Data1(8); Data0(7)}</p> <p>For maximal efficiency, software should compute MultiO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultiO should be 1.</p> <p>Note: Non-ISO and Non-TX endpoints must set MultiO = "00".</p>
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	<p>Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are:</p> <p>Bit Status Field Description</p> <p>7 Active.</p> <p>6 Halted.</p> <p>5 Data Buffer Error.</p> <p>3 Transaction Error.</p> <p>4, 2, 0 Reserved.</p>

The table below describes the dTD Buffer Page Pointer List.

Table 11-119. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

11.5.4.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

11.5.4.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
 - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

- For information on device queue heads, refer to section [Device Data Structures](#).
- Configure USB.ENDPOINTLISTADDR Pointer.
 - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
 - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
 - For a list of available interrupts refer to the [Interrupt Enable Register \(USB_USBINTR\)](#) and the [USB Status Register \(USB_USBSTS\)](#) register tables.
- Set Run/Stop bit to Run Mode.
 - After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and

adjust the software state as described in the Bus Reset section of the Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

11.5.4.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS* or *defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

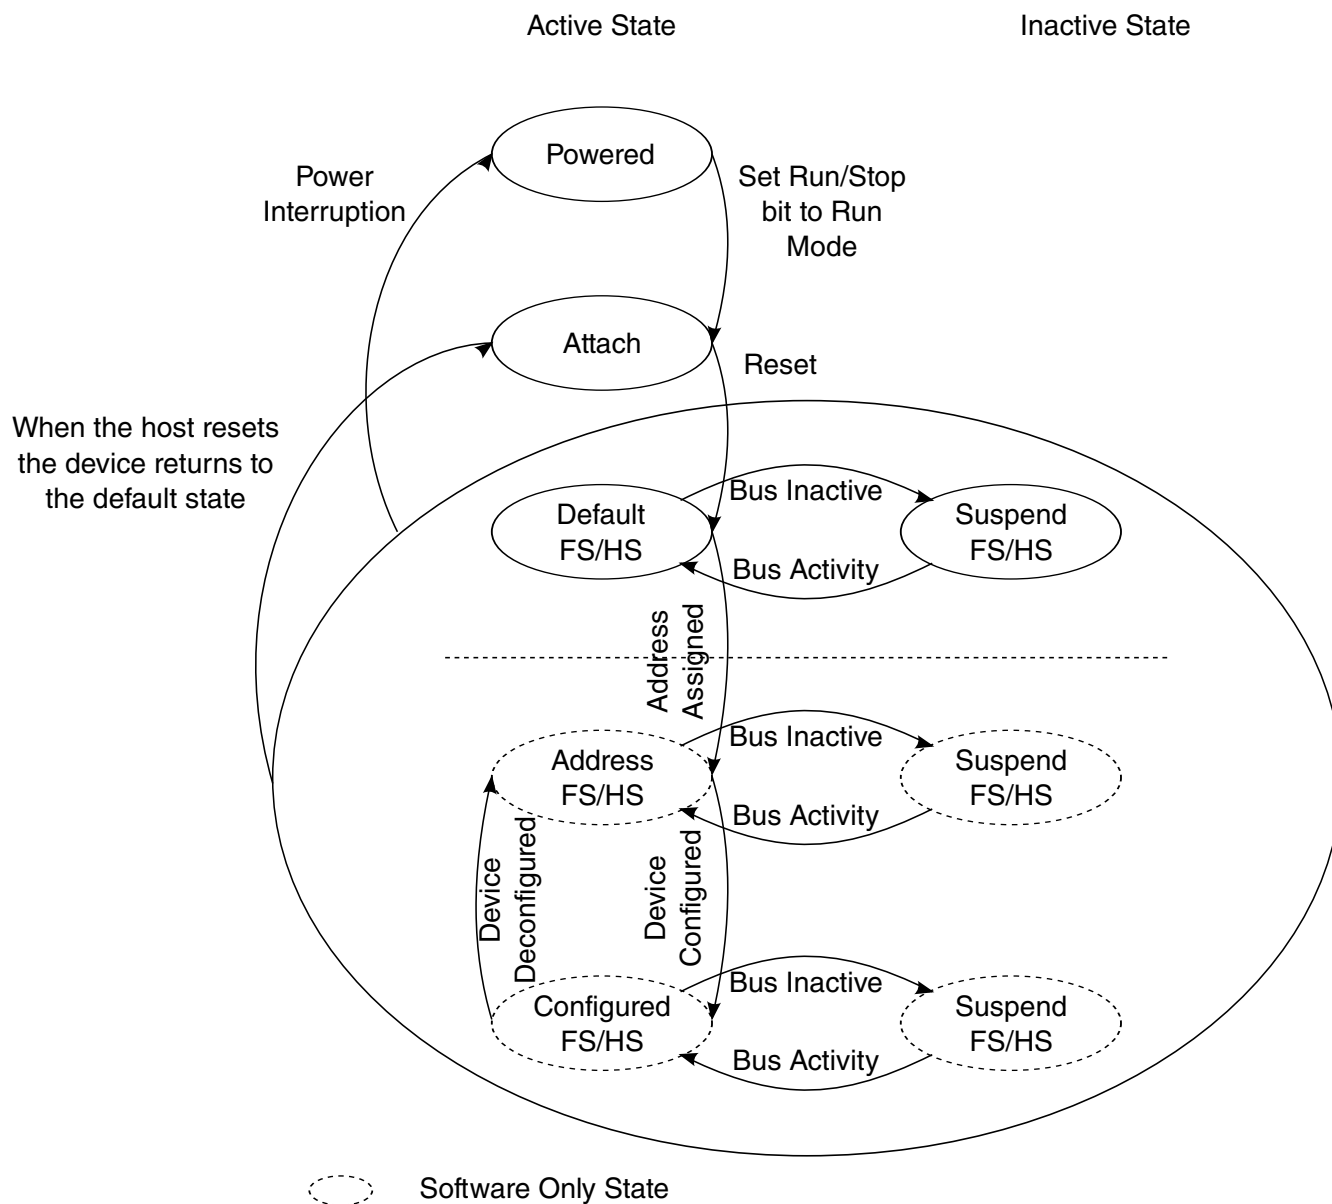

Figure 11-88. Device State Diagram

States *powered*, *attach*, *defaultFS/HS*, *suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 11-120. Device Controller State Information Bits

Bit	Register
DCSuspend	
USB Reset Received	
Port Change Detect	
High-Speed Port	

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

11.5.4.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the [Endpoint Status \(USB_ENDPTSTAT\)](#) register and writing the same value back to the [Endpoint Status \(USB_ENDPTSTAT\)](#) register.

Clear all the endpoint complete status bits by reading the [Endpoint Complete \(USB_ENDPTCOMPLETE\)](#) register and writing the same value back to the [Endpoint Complete \(USB_ENDPTCOMPLETE\)](#) register.

Cancel all primed status by waiting until all bits in the [Endpoint Prime \(USB_ENDPTPRIME\)](#) are 0 and then writing 0xFFFFFFFF to [Endpoint Flush \(USB_ENDPTFLUSH\)](#).

Read the reset bit in the [Port Status & Control \(USB_PORTSC1\)](#) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the [Port Status & Control \(USB_PORTSC1\)](#) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

11.5.4.6.2.2 Suspend/Resume

The details of suspend and resume are explained in these sections.

11.5.4.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the [Port Status & Control \(USB_PORTSC1\)](#) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

11.5.4.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the [Port Status & Control \(USB_PORTSC1\)](#) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

11.5.4.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk*, *interrupt*, and

isochronous. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

11.5.4.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 11-121. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

11.5.4.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 11-122. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

11.5.4.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

11.5.4.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

11.5.4.6.3.3.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

11.5.4.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

11.5.4.6.3.3.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

11.5.4.6.4 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN

requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

11.5.4.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

$$N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1$$

With Zero Length Termination (ZLT) = 1

$$N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length})$$

Table 11-123. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

Table 11-124. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

11.5.4.6.4.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

Table 11-125. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

11.5.4.6.4.2 Control Endpoint Operation Model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

11.5.4.6.4.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in [USB Device Mode \(USB_USBMODE\)](#). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting [Endpoint Setup Status \(USB_ENDPTSETUPSTAT\)](#) to determine that a setup packet was received on a particular pipe:
 - a. Write 1 to clear corresponding bit [Endpoint Setup Status \(USB_ENDPTSETUPSTAT\)](#).
 - b. Write 1 to Setup Tripwire (SUTW) in [USB Command Register \(USB_USBCMD\)](#) register.
 - c. Duplicate contents of dQH.SetupBuffer into local software byte array.
 - d. Read Setup TripWire (SUTW) in [USB Command Register \(USB_USBCMD\)](#) register. (if set - continue; if cleared - goto 2)
 - e. Write 0 to clear Setup Tripwire (SUTW) in [USB Command Register \(USB_USBCMD\)](#) register.
 - f. Process setup packet using local software byte array copy and execute status/handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

11.5.4.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the [Endpoint Prime \(USB_ENDPTPRIME\)](#) register is zero and the associated bit in the [Endpoint Status \(USB_ENDPTSTAT\)](#) register is a one. If a prime fails, ie. The [Endpoint Prime \(USB_ENDPTPRIME\)](#) bit goes to zero and the [Endpoint Status \(USB_ENDPTSTAT\)](#) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status ([Endpoint Status \(USB_ENDPTSTAT\)](#)) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

11.5.4.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

11.5.4.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 11-126. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSEERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

11.5.4.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
 - MULT counter reaches zero.
 - Fulfillment Error [*Transaction Error* bit is set]
 - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
 - MULT counter reaches zero.
 - Non-MDATA Data PID is received**
 - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
 - Overflow Error:
 - Packet received is > maximum packet length. [*Buffer Error* bit is set]
 - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
 - Fulfillment Error [*Transaction Error* bit is set]
 - # Packets Occurred > 0 AND # Packets Occurred < MULT
 - CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame

operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

11.5.4.6.4.3.1 *Isochronous Pipe Synchronization*

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

11.5.4.6.4.3.2 *Isochronous Endpoint Bus Response Matrix*

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 11-127. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

NULL Packet = Zero Length Packet

11.5.4.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

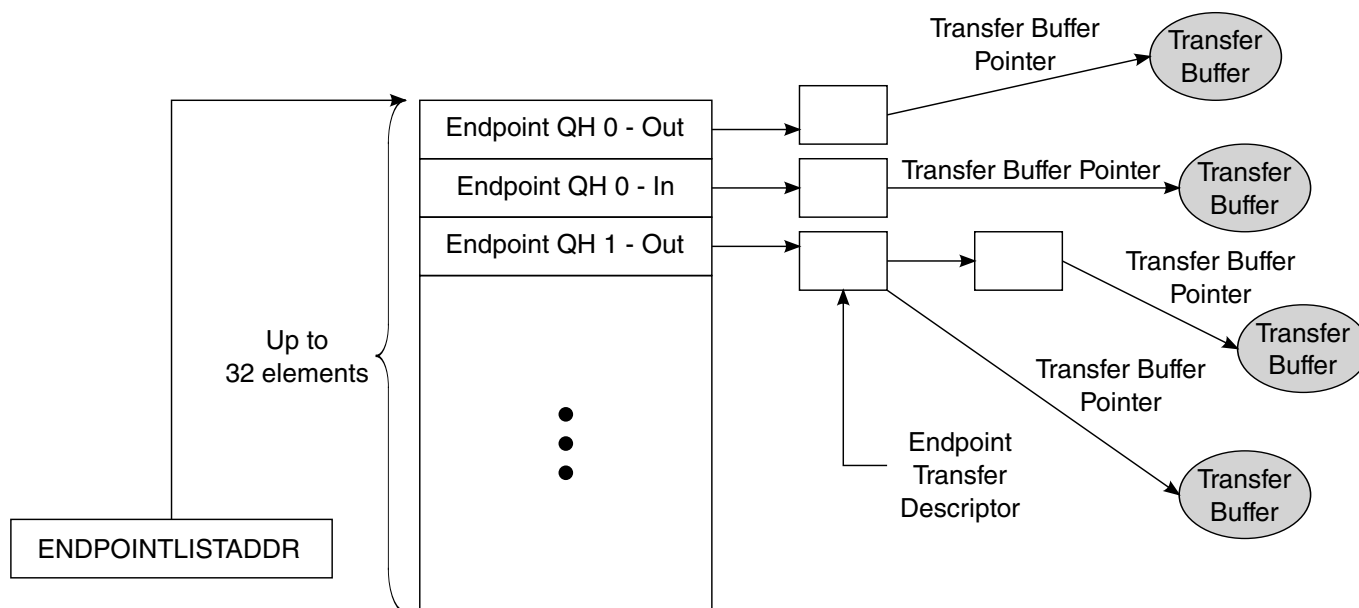

Figure 11-89. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by `USB.ENDPOINTLISTADDR` contains a group of all dQH's in a sequential list as shown in [Figure 11-89](#). The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section [Software Link Pointers](#)).

In addition to the current and next pointers and the dTD overlay examined in section [Operational Model For Packet Transfers](#), the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

11.5.4.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

11.5.4.6.5.2 Operational Model For Setup Transfers

As discussed in section [Control Endpoint Operation Model](#), setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
 - After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.
3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section [Flushing/De-priming an Endpoint](#).
 4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

11.5.4.6.6 Managing Transfers with Transfer Descriptors**11.5.4.6.6.1 Software Link Pointers**

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

Figure 11-90. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

11.5.4.6.6.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

11.5.4.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
 - a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
 - b. Clear active & halt bit in dQH (in case set from a previous error).
 - c. Prime endpoint by writing 1 to correct bit position in .
- Case 2: Link list is not empty
 - a. Add dTD to end of linked list.
 - b. Read correct prime bit in - if 1 DONE.
 - c. Set ATDTW bit in USBCMD register to 1.
 - d. Read correct status bit in . (store in tmp. variable for later)
 - e. Read ATDTW bit in USBCMD register.
 - If 0 goto 3.
 - If 1 continue to 6.
 - f. Write ATDTW bit in USBCMD register to 0.
 - g. If status bit read in (3) is 1 DONE.
 - h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

11.5.4.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the [Device Error Matrix](#).

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

11.5.4.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in .
2. Wait until all bits in are '0'.

- Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
- Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using . A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint is successfully flushed.

11.5.4.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 11-128. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 11-129. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

11.5.4.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

11.5.4.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 11-130. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 11-89 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt ¹ - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 11-89 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

11.5.4.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 11-131. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

11.5.4.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

Table 11-132. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

11.5.5 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registers are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to [Register Interface](#).

NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- USBNC_USB_" prefix in register name indicates it is a USB non-core register.

USBNC memory map

11.5.5.1 USBNC_n_CTRL1

The USB_n_PHY_CTRL1 register controls the integration specific features of the USB PHY modules. These features are not directly related to basic USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: 30B1_0000h base + 200h offset + (65536d × i), where i=0d to 2d

USBNC_n_CTRL1 field descriptions

Field	Description
31 WIR	Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG1 port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE"). 1 Wake-up Interrupt Request received 0 No wake-up interrupt request received
30 Reserved	This field is reserved.
29 WKUP_DPDM_EN	Wake-up on DPDM change enable 1 (Default) DPDM changes wake-up to be enabled, it is for device only. 0 DPDM changes wake-up to be disabled only when VBUS is 0.
28–18 Reserved	This field is reserved.
17 WKUP_VBUS_EN	Wake-up on VBUS change enable 1 Enable 0 Disable
16 WKUP_ID_EN	Wake-up on ID change enable 1 Enable 0 Disable
15 WKUP_SW	Software Wake-up 1 Force wake-up 0 Inactive
14 WKUP_SW_EN	Software Wake-up Enable 1 Enable 0 Disable
13–11 Reserved	This field is reserved. Reserved. Do not write to.
10 WIE	Wake-up Interrupt Enable This bit enables or disables the OTG1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
9 PWR_POL	Power Polarity This bit should be set according to PMIC Power Pin polarity. 1 PMIC Power Pin is High active. 0 PMIC Power Pin is Low active.
8 OVER_CUR_POL	Polarity of Overcurrent The polarity of OTG1/OTG2 port overcurrent event

Table continues on the next page...

USBNC_n_CTRL1 field descriptions (continued)

Field	Description
	1 Low active (low on this signal represents an overcurrent condition) 0 High active (high on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Disable Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection
Reserved	This field is reserved.

11.5.5.2 USBNC_n_CTRL2

The USB_OTGx_PHY_CTRL2 register allows observation of the UTMI Clock Valid status along with control of selected inputs to the USB OTG PHY transceiver.

Some of these input signals may be used for USB out-of-band signaling. Customers should use caution when overriding any UTMI signals since that will interfere with normal USB data communication.

Address: 30B1_0000h base + 204h offset + (65536d × i), where i=0d to 2d

USBNC_n_CTRL2 field descriptions

Field	Description
31 UTMI_CLK_VLD	Indicate whether PHY clock is valid. Write 1 to clear 0 UTMI clock to USB PHY is not toggling (Default) 1 UTMI clock to USB PHY has toggled several times
30–28 Reserved	This field is reserved.
27–23 Reserved	This field is reserved. 0B11110 Default
22–21 Reserved	This field is reserved. Customers should not change the value of this bit field.
20 DIG_ID_SEL	Selects whether the USB OTG ID pin function is connected to the PHY's USB_OTG*_ID pin or a GPIO pin. The ID pin state is observed on USBNC_n_PHY_STATUS[ID_DIG]. 0 Use the USB_OTG*_ID pin for the USB OTG ID pin detection function(default) 1 Use the pin configured by the IOMUXC_USB_OTG*_ID_SELECT_INPUT register for the USB OTG ID pin detection function
19–16 Reserved	This field is reserved. Customers should not change the value of this bit field.
15 DMPULLDOWN_OVERRIDEEN	Enables override of control of the DM pulldown resistor instead of the state set by the USB controller. 0 USB controller enables/disables the DM pulldown resistor in the USB PHY. 1 Use the value set by the USBNC_n_CTRL2[DMPULLDOWN_OVERRIDE] bit field to enable/disable the DM pulldown resistor in the USB PHY.
14 DMPULLDOWN_OVERRIDE	Controls state of DM pulldown resistor if USBNC_n_CTRL2[DMPULLDOWN_OVERRIDEEN] is set to 1'b1. 0 DM pulldown resistor disabled 1 DM pulldown resistor enabled

Table continues on the next page...

USBNC_n_CTRL2 field descriptions (continued)

Field	Description
13 DPPULLDOWN_ OVERRIDEEN	Enables override of control of the DP pulldown resistor instead of using the state set by the USB controller. 0 USB controller enables/disables the DP pulldown resistor in the USB PHY. 1 Use the value set by the USBNC_n_CTRL2[DPPULLDOWN_OVERRIDE] bit field to enable/disable the DP pulldown resistor in the USB PHY.
12 DPPULLDOWN_ OVERRIDE	Controls state of DP pulldown resistor if USBNC_n_CTRL2[DPPULLDOWN_OVERRIDEEN] is set to 1'b1. 0 DP pulldown resistor disabled 1 DP pulldown resistor enabled
11 XCVRSEL_ OVERRIDEEN	Enables override of control of the UTMI XcvrSelect signals to the USB OTG PHY instead of using the state normally set by the USB controller. 0 The state of the UTMI XcvrSelect signals to the USB PHY is set by the USB controller. 1 The state of the UTMI XcvrSelect signals to the USB PHY is set by the values in the USBNC_x_CTRL2[XCVRSEL_OVERRIDE] bit field.
10–9 XCVRSEL_ OVERRIDE	Controls the state of the UTMI XcvrSelect signals to the USB OTG PHY if the value of USBNC_x_CTRL2[XCVRSEL_OVERRIDEEN] is set to 1'b1. See the <i>UTMI+ Specification</i> for descriptions of the functions of the XcvrSelect signals.
8 OPMODE_ OVERRIDEEN	Enables override of control of the UTMI OpMode signals to the USB OTG PHY instead of using the state normally set by the USB controller. 0 The state of the UTMI OpMode signals to the USB PHY is set by the USB controller. 1 The state of the UTMI OpMode signals to the USB PHY is set by the values in the USBNC_x_CTRL2[OPMODE_OVERRIDE] bit field.
7–6 OPMODE_ OVERRIDE	Controls the state of the UTMI XcvrSelect signals to the USB OTG PHY if the value of USBNC_x_CTRL2[OPMODE_OVERRIDEEN] is set to 1'b1. See the <i>UTMI+ Specification</i> for descriptions of the functions of the OpMode signals.
5 TERMSEL_ OVERRIDEEN	Enables override of control of the UTMI TermSelect signal to the USB OTG PHY instead of using the state normally set by the USB controller. 0 The state of the UTMI TermSelect signal to the USB PHY is set by the USB controller. 1 The state of the UTMI TermSelect signal to the USB PHY is set by the value in the USBNC_x_CTRL2[TERMSEL_OVERRIDE] bit field.
4 TERMSEL_ OVERRIDE	Controls the state of the UTMI TermSelect signal to the USB OTG PHY if the value of USBNC_x_CTRL2[TERMSEL_OVERRIDEEN] is set to 1'b1. See the <i>UTMI+ Specification</i> for descriptions of the function of the TermSelect signal.
3 LOWSPEED_EN	Set if AUTURESUME_EN is set and works on low speed. 0 Default
2 AUTURESUME_ EN	Auto Resume Enable This bit field is for UTMI OTG PHY host mode only (UH core does not have this feature since HSIC PHY does not support auto resume). To set USB, it will send resume with 32 KHz clock when it detects remote wakeup from device. This feature is useful if device drives a very short remote wakeup (minimal value is 1 ms for USB2 spec) and system 24 MHz is off during suspend mode. 0 Default

Table continues on the next page...

USBNC_n_CTRL2 field descriptions (continued)

Field	Description
VBUS_SOURCE_SEL	VBUS source select used to detect a VBUS wakeup event. This bit field is for UTMI OTG PHY only (UH core and HSIC PHY have no such feature). 2'b00 vbus_valid others sess_valid

11.5.5.3 USB OTG PHY Configuration Register 1 (USBNC_n_PHY_CFG1)

The USB_OTGx_PHY_CFG1 register allows control of selected inputs to the USB OTG PHY.

Most of these signals are used for parametric tuning of the USB transceiver functions.

One signal is used to allow persistent control of the USB_OTG1_CHD_B external pin.

Address: 30B1_0000h base + 230h offset + (65536d × i), where i=0d to 1d

USBNC_n_PHY_CFG1 field descriptions

Field	Description
31 CHRGDET_Megamix	USB_OTG1_CHD_B output control This signal controls the state of the USB_OTG1_CHD_B external pin together with the CHRGDET (USBNC_USB_OTG1_PHY_STATUS[29] signal during periods when the SOC is fully powered. If either CHRGDET_Megamix or CHRGDET are set to 1'b1, then USB_OTG1_CHD_B will be pulled low. If both CHRGDET_Megamix and CHRGDET are set to 1'b0, then USB_OTG1_CHD_B will be pulled high by its external open-drain pull-up resistor.

Table continues on the next page...

USBNC_n_PHY_CFG1 field descriptions (continued)

Field	Description
	<p>Note: The instance of this bit field for the USB OTG2 PHY does not produce results on an external pin. The R/W register bit may still be used as a memory location to store results of Battery Charger detection tests for USB OTG2 PHY.</p> <p>0 The external state of USB_OTG1_CHD_B is only controlled by the state of the CHRGET signal</p> <p>1 The external state of USB_OTG1_CHD_B is forced low</p>
30 TXPREEMPULSESETUNE0	<p>HS Transmitter Pre-Emphasis Duration Control</p> <p>This signal controls the duration for which the HS pre-emphasis current is sourced on the the USB_OTG*_DP and USB_OTG*_DN pins. The HS Transmitter pre-emphasis duration is defined in terms of unit amounts. One unit of pre-emphasis duration is approximately 580ps and is defined as 1X pre-emphasis duration. This signal is valid only if TXPREEMPAMPTUNE (USBNC_USB_OTGx_PHY_CFG1[29:28]) is NOT set to 2'b00.</p> <p>0 2X, long pre-emphasis current duration (design default)</p> <p>1 1X, short pre-emphasis current duration</p>
29–28 TXPREEMPAMPTUNE0	<p>HS Treansmitter Pre-Emphasis Current Control</p> <p>This signal controls the amount of current sourced to the USB_OTG*_DP and USB_OTG*_DN pins after a J-to-K or K-to-J transition. The HS Transmitter pre-emphasis current is defined in terms of unit amounts. One unit amount is approximately 600uA and is defined as 1X pre-emphasis current.</p> <p>00 HS Transmitter pre-emphasis is disabled</p> <p>01 HS Transmitter pre-emphasis circuit sources 1X pre-emphasis current (design default)</p> <p>10 HS Transmitter pre-emphasis circuit sources 2X pre-emphasis current</p> <p>11 HS Transmitter pre-emphasis circuit sources 3X pre-emphasis current</p>
27–26 TXRESTUNE0	<p>USB Source Impedance Adjustment</p> <p>In some applications, there can be significant series resistance on the USB DP/DN path between the USB_OTG*_DP/USB_OTG*_DN pins tns and the USB cable. This bus adjusts the driver source impedance to compensate for that added resistance.</p> <p>Note: Any setting other than the design default can cause HS/FS signal integrity changes along with variation across process, voltage, and temperature conditions that affect compliance with USB 2.0 specification limits.</p> <p>00 Source impedance is increased by approximately 1.5 Ω</p> <p>01 Design default</p> <p>10 Source impedance is decreased by approximately 2 Ω</p> <p>11 Source impedance is decreased by approximately 4 Ω</p>
25–24 TXRISETUNE0	<p>HS Transmitter Rise/Fall Time Adjustment</p> <p>This bus adjust the rise/fall times of the high-speed transmitter waveform.</p> <p>00 -10%</p> <p>01 Design default</p> <p>10 +15%</p> <p>11 +20%</p>
23–20 TXVREFTUNE0	<p>HS DC Voltage Level Adjustment</p> <p>This bus adjust the high-speed transmitter DC level voltage.</p>

USBNC_n_PHY_CFG2 field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 DRVVBUS0	VBUS Valid Comparator Enable This signal controls the USB OTG PHY VBUS Valid comparator which indicates whether the voltage on the USB_OTG*_VBUS pin is below the VBUS Valid threshold. The VBUS Valid threshold is nominally 4.75V on this USB PHY. The VBUS Valid threshold can be adjusted using the USBNC_OTGn_PHY_CFG1[OTGTUNE0] bit field. Status of the VBUS Valid comparator, when it is enabled, is reported on the USBNC_OTGn_PHY_STATUS[VBUS_VLD] bit. When OTGDISABLE0 (USBNC_USB_OTGx_PHY_CFG2[10]) is set to 1'b0 and DRVVBUS0 is set to 1'b1, the Bandgap circuitry and VBUS Valid comparator are powered, even in Suspend or Sleep mode. DRVVBUS0 should be reset to 1'b0 when the internal VBUS Valid comparator is not required, to reduce quiescent current in Suspend or Sleep mode. 0 The VBUS Valid comparator is disabled 1 The VBUS Valid comparator is enabled
15 VBUSVLDEXT	External VBUS Valid Indicator

Table continues on the next page...

USBNC_n_PHY_CFG2 field descriptions (continued)

Field	Description
	<p>This signal is used if a VBUS Valid signal generated from a circuit outside the USB OTG PHY is desired.</p> <p>If the USB OTG PHY is configured for Device mode and VBUSVLDEXTSEL0 (USBNC_USB_OTGx_PHY_CFG2[14] is set to 1'b1, VBUSVLD indicated whether the VBUS signal on the USB cable is valid and enables the pull-up resistor on USB_OTG1_DP.</p> <p>This signal has no effect when the USB OTG PHY is configured for Host mode.</p> <p>0 The VBUS signal sensed outside the USB OTG PHY is not valid, and the pull-up resistor on USB_OTG*_DP is disabled</p> <p>1 The VBUS signal sensed outside the USB OTG PHY is valid, and the pull-up resistor on USB_OTG*_DP is enabled</p>

13 ADPPRBENB0	<p>ADP Probe Enable</p> <p>This signal determines whether the ADP (Attach Detection Protocol) Probe comparator on the USB_OTG*_VBUS pin is enabled.</p> <p>The ADP Probe threshold is > 0.6V and < 0.75V on this USB PHY.</p> <p>0 ADP Probe comparator is disabled</p> <p>1 ADP Probe comparator is enabled</p>
12 ADPDISCHRG0	<p>VBUS Input ADP Discharge Enable</p> <p>This signal controls discharging the USB_OTG*_VBUS pin during ADP.</p> <p>The I_{ADP_SINK} current is >1.1mA and <2.0mA.</p> <p>0 Disables discharging USB_OTG*_VBUS during ADP</p> <p>1 Enables discharging USB_OTG*_VBUS during ADP</p>
11 ADPCHRG0	<p>VBUS Input ADP Charge Enable</p> <p>This signal controls charging the USB_OTG*_VBUS pin during ADP.</p> <p>The I_{ADP_SRC} current is >1.1mA and <1.65mA.</p> <p>0 Disables charging USB_OTG*_VBUS during ADP</p> <p>1 Disables charging USB_OTG*_VBUS during ADP</p>
10 OTGDISABLE0	<p>OTG Block Disable</p> <p>This signal powers down the VBUS Valid comparator. It does not control power to the Session Valid comparator, ADP Probe and Sense comparators, or the ID detection circuitry.</p>

USBNC_n_PHY_CFG2 field descriptions (continued)

Field	Description
	0 The OTG block is powered up 1 The OTG block is powered down
9 TXBITSTUFFENH0	High-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAINH[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
8 TXBITSTUFFEN0	Low-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAIN[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 LOOPBACKENB0	Loopback Test Enable This signal places the USB OTG PHY in Loopback mode, which enables the receive and transmit logic concurrently. Loopback mode is for test purposes only; it cannot be used for normal operation. 0 During data transmission, the receive logic is disabled 1 During data transmission, the receive logic is enabled
5 SLEEPM0	Sleep Mode Assertion Asserting this signal places the USB OTG PHY in Sleep mode according to the USB 2.0 Link Power Management (LPM) addendum to the USB 2.0 specification. In Sleep mode, the transmitter is tri-stated and the USB OTG PHY circuits used in this SOC are powered down. Note: The USB controller used in this SOC does not support LPM operation. Leave this bit set to 1'b1 for normal operation. 0 Sleep mode 1 Normal operating mode
4 ACAENB0	ACA USB_OTG*_ID Pin Resistance Detection Enable This signal enables the circuitry to detect resistance on the USB_OTG*_ID pin if the USB cable is connected to an ACA (Accessory Charger Adaptor). When ACAENB0 is set to 1'b1, IDPULLUP0 (USB_OTGSC[26]) is overridden and set to 1'b0 internally to the USB OTG PHY. The RID* results are reported in USBNC_USB_OTGx_PHY_STATUS[28:24]. 0 Disables detection of resistance on the USB_OTG*_ID pin 1 Enables detection of resistance on the USB_OTG*_ID pin
3 DCDENB	Data Contact Detection Enable This signal enables current sourcing on the USB_OTG*_DP pin and pull-down resistance on the USB_OTG*_DN pin for Data Contact Detect (DCD) per the USB Battery Charging Specification revision 1.2.

Table continues on the next page...

USBNC_n_PHY_CFG2 field descriptions (continued)

Field	Description
	<p>Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 IDP_SRC current and R_{DM_DWN} pull-down resistance are disabled 1 IDP_SRC current and R_{DM_DWN} pull-down resistance are enabled</p>
2 VDATSRCENB0	<p>Battery Charging Source Select</p> <p>This signal is used to enable the VD*_SRC voltage source and ID*_SINK current sink per the USB Battery Charging Specification revision 1.2.</p> <p>Pin selection for the voltage source and the current sink are controlled by USBNC_USB_OTGx_PHY_CFG2[0].</p> <p>Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 VD*_SRC and ID*_SINK are disabled 1 VD*_SRC and ID*_SINK are enabled</p>
1 VDATDETENB0	<p>Battery Charging Attach / Connect Detection Enable</p> <p>This signal is used to enable attach/connect detection per the USB Battery Charging Specification revision 1.2.</p> <p>Results are reported by using the single-ended receiver status in USBNC_USB_OTGx_PHY_STATUS[1:0].</p> <p>Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 IDP_SRC current source compliant to VLGC_HI connected to USB_OTG*_DP pin is disabled 1 IDP_SRC current source compliant to VLGC_HI connected to USB_OTG*_DP pin is enabled</p>
0 CHRGSEL	<p>Battery Charging Source Select</p> <p>This signal is used to select the Battery Charging detection connections per the USB Battery Charging Specification revision 1.2. It determines which of USB_OTG*_DP / USB_OTG*_DN has the VD*_SRC voltage source and which has the ID*_SINK current sink.</p> <p>Results are reported in USBNC_USB_OTGx_PHY_STATUS[29].</p> <p>Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 VDP_SRC is connected to USB_OTG*_DP and IDM_SINK is connected to USB_OTG*_DN. Used for Primary Detection. 1 VDM_SRC is connected to USB_OTG*_DN and IDP_SINK is connected to USB_OTG*_DP. Used for Secondary Detection.</p>

11.5.5.5 USB OTG PHY Status Register (USBNC_n_PHY_STATUS)

The USB_OTGx_PHY_STATUS register allows visibility of selected outputs of the USB OTG PHY.

These signals are used for some VBUS detection, ADP (Attach Detection Protocol), and Battery Charging ACA (Accessory Charging Adaptor) functions.

Address: 30B1_0000h base + 23Ch offset + (65536d × i), where i=0d to 1d
