Before entering STOP mode, the Processor programmer should verify that the EP bit (in the xSR register) is cleared. This check is needed to ensure that all pending updates from the Processor, including the power mode change when STOP or WAIT is executed, will be updated in the xSR register.

- If the other Processor is in STOP mode or DSM mode, the EP bit (in the xSR register) may be stuck high; in this case, the Processor need not check the EP bit before entering STOP mode.

42.3.6 Event Update Timing

Each processor's MU messaging side (Processor B or Processor A) has a hardware mechanism to send "event update requests" to the other processor's side. An "event" is considered when any information change should be reflected at the Status Register of the receiving processor. The event update latency is the delay between the event being ready at one processor and the resulting update at the Status Register of the other processor.

- The minimum event latency is "1 clock of the sending side" + "2 1/2 clocks of the receiving side". The minimum case is if there is no event pending when the new event occurs.
- The maximum event latency is "6 clocks of the sending side" + "6 1/2 clocks of the receiving side." The maximum case is if the event occurred just after a previous event was sent to the other side. The event update latency will vary between the above-mentioned minimum and maximum latencies, depending on the time at which the subsequent event is triggered.

42.3.7 Interrupts

The MU controls the Processor B interrupt requests to the Processor A, and the Processor A interrupt requests to the Processor B. This section describes all the interrupts that the module generates.

42.3.7.1 Interrupts to the Processors

There are 12 interrupt sources from the MU to the Processors:

- Four receive interrupts (asserted when the Processors receive full bits are set and enabled in the xCR register) for each of the receive registers
- Four transmit interrupts (asserted when the Processor transmit empty bits are set and enabled in the xCR register) for each of the transmit registers
- Four general purpose interrupts (asserted when the GIP bits are set and enabled in the xCR register)

All the interrupts are maskable in the Processor Control Register (xCR). The MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, Receive 0 and Receive 1 interrupts or any of the transmit and general purpose interrupts) can be asserted at one time. The priority of these interrupts should be resolved by the interrupt controller at the chip level.

The General Purpose Interrupt Pending bits (GIP0, GIP1, GIP2, and GIP3) should be cleared by the software (as part of the interrupt service routine) to de-assert the request to the interrupt controller.

42.3.7.2 General Purpose Interrupt Clearing Sequence

When a Processor writes to the general interrupt bit (GIR), the write event is synchronized to the other Processor clock to set the general interrupt request pending bit (GIP). When the GIP bit is set, and if the general purpose interrupt is enabled on the transmitting Processor side (GIE bit is set), then the receiving Processor general purpose interrupt is issued to the transmitting Processor. The transmitting Processor clears this interrupt by writing a “1” on the GIP bit. The interrupt is de-asserted as soon as the GIP bit is written. The write event of the GIP bit is synchronized to the other Processor clock. The synchronized signal clears the GIR bit. The software should not write the GIR bit again until the GIR bit is cleared.

42.3.8 Interrupt Messaging Protocols

42.3.8.1 Messaging Protocols using Interrupts

The example below describes a four-word messaging sequence sent by the Processor to the other Processor.

Functional Description

In this example, the first, second, and third receive interrupts are disabled, and the fourth receive interrupt is enabled. We write registers sequentially for $n = 0, 1, 2, 3$. For $n = 0, 1, 2$, the interrupts are disabled, therefore no interrupt will go to the other core (although interrupt conditions occur). For $n = 3$, the interrupt is enabled, and the last Receive Interrupt request is generated.

1. Write Sequence

- The Processor writes the message information sequentially to its Transmit Registers 0, 1, 2.
- When the write to the Transmit Register 3 occurs, the RF3 bit of the xSR is set after synchronization, and it immediately trigger the Receive 3 interrupt to the other Processor.

2. Read Sequence

- The other Processor receives the Receive 3 interrupt and starts reading the message transferred from the receive registers.
- After Receive Register 3 is read, the interrupt bit is cleared.

Figure 42-3 shows the programmer's model of a messaging protocol using transmit and receive registers. Use Table 42-2 and Figure 42-3 to understand the generalized protocol sequence.

Table 42-2. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A Data write	A data write to the ATRn register by Processor A is immediately reflected in the Processor B BRRn register.
2	Clear Tx Empty bit and Set Rx Full bit	The data write to the ATRn register <ul style="list-style-type: none">• Clears the transmitter empty bit (TE_n) in the Processor A Transmit Status Register• Sets the receiver full bit (RF_n) in the Processor B Receive Status Register
3	Generate Receive Interrupt request	The setting of the receiver full bit (RF _n) in the Receive Status Register generates a Receive Interrupt request to Processor B.
4	Processor B Data read	After receiving the Receive Interrupt request, Processor B performs a data read of the BRRn register.
5	Clear Rx Full bit and Set Tx Empty bit	Reading the data out of the BRRn register <ul style="list-style-type: none">• Clears the receiver full bit (RF_n) in the Processor B Receive Status Register• Sets the transmitter empty bit (TE_n) in the Processor A Transmit Status Register
6	Generate Transmit Interrupt request	The setting of the transmitter empty bit (TE _n) in the Transmit Status Register generates a Transmit Interrupt request to Processor A.

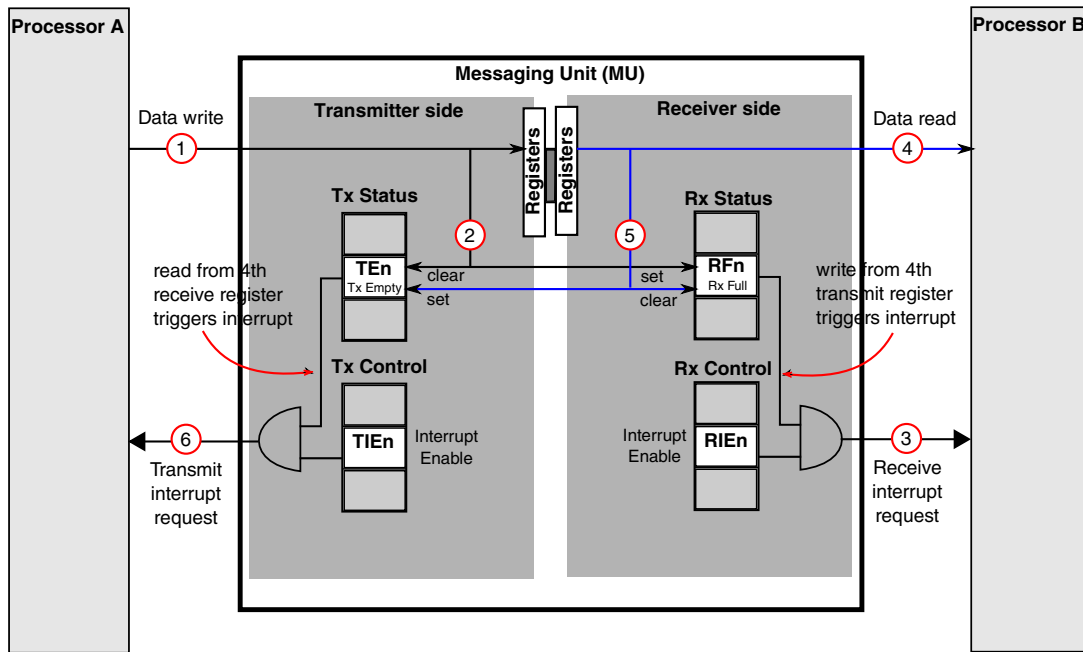

Figure 42-3. Messaging Model Using Transmit and Receive Registers

NOTE

The Transmit registers can be used to pass frame information on long messages written to the shared memory. Such frame information would typically include an initial address, number of words, and perhaps a message type code.

The messaging hardware can be used by software to implement messaging protocols for a wide array of message types. Full support is given for both interrupt and polling management schemes.

42.3.8.2 Messaging Protocols using Event Interrupts

Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the two general interrupts.

Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general purpose interrupt to signal the other processor that the data is ready.

The three flags can be used by a processor to announce to the other processor the program state it is currently in, or to announce similar messages.

[Table 42-3](#) and [Figure 42-4](#) describe the event sequence when the Processor triggers an interrupt.

Table 42-3. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A sets General Interrupt request bit	Processor A sets its associated General Interrupt request bit (GIRn = 1) in the control register (ACR).
2	General Interrupt Request Pending status bit is set	The General Interrupt Request Pending status bit (GIPn) in the status register (BSR) is set to "1"
3	General Interrupt request to Processor B is generated	Setting the GIPn bit generates the General Interrupt request to Processor B (Interrupt Request Enable bit, GIEn, must be set for Processor B)
4	Processor B reads status register	The Processor B reads the GIPn bit in the BSR register.
5	Processor B services the interrupt	-
6	Processor B sets GIPn bit to clear interrupt	The Processor B writes "1" to the corresponding GIPn bit to clear the interrupt
7	GIRn bit is cleared	Setting the GIPn bit to "1" clears the General Interrupt request bit (GIRn) in the Processor A control register (ACR).

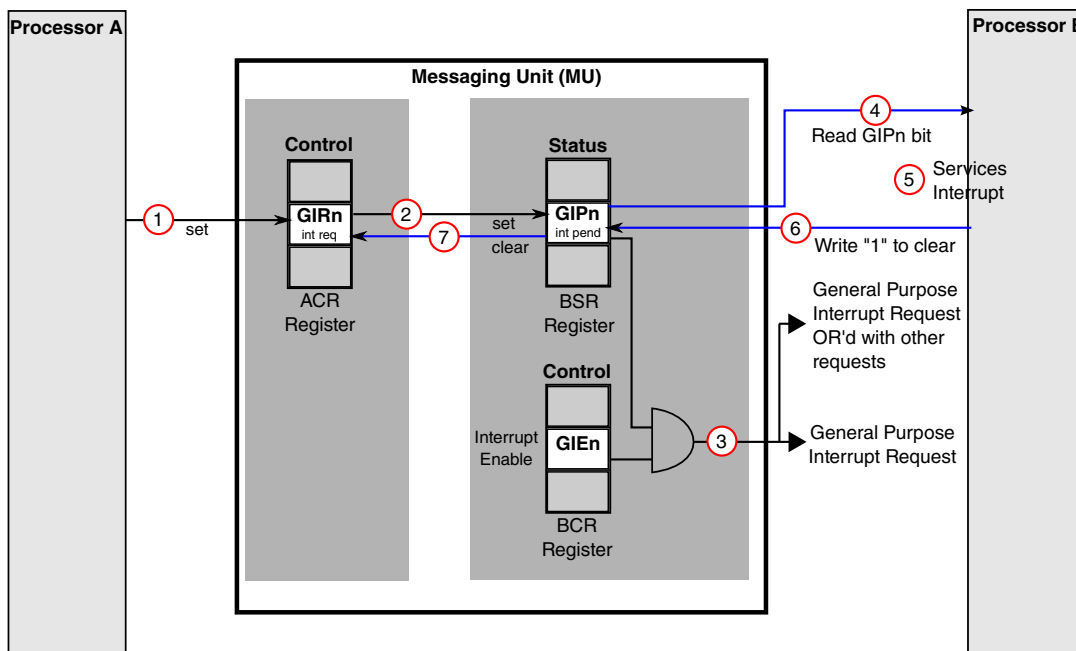

Figure 42-4. Messaging Model Using a General Purpose Interrupt

42.3.9 Exclusive Access to Shared Memory

You can use the MU to signal one processor about its current access to the shared memory, so that the data is not overwritten by the other processor during the exclusive memory access period.

The following tables describe the signaling protocol that the Processor A uses to inform the Processor B about its current access (write) to the shared memory, assuming that the set of bits and registers (GIR0 bit, BRR0 register, BTR0 register, GIR0 bit, ARR0 register, ATR0 register) are reserved to support exclusive access to the shared memory protocol.

Table 42-4. How the Processor A Performs an Exclusive Access to Shared Memory

Sequence	Action	Description
1	Processor A sends GIRn request to Processor B using Processor A control register	When the Processor A wants to perform an exclusive access to the shared memory, the Processor A sends an GIR0 request to the Processor B.
2	Processor A sends an exclusive-access request using a transmit data register (ATRn)	The Processor A will send an exclusive-access request (command, location, and length of target access) to Processor B using a selected transmit data register (ATR0).
3	Processor A waits for a dedicated interrupt from Processor B	The Processor A waits for a dedicated interrupt (as an acknowledgement) triggered by the Processor B before proceeding.
4	Processor A accesses shared memory	After receiving a dedicated interrupt from the Processor B, Processor A proceeds.

Table 42-5. How the Processor B Scans for Transaction Information

Sequence	Action	Description
1	Processor B receives an interrupt from a receive data register (BRRn)	-
2	Processor B reads the receive data register (BRRn)	-
3	Processor B scans the receive data register contents	For transaction information (whether Processor A has requested an exclusive-access)

Table 42-6. How the Processor B Accepts Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B triggers a dedicated interrupt	Processor B acknowledges the Processor A request by triggering a dedicated interrupt (ack) to the Processor A.
2	Processor B sends a code message to Processor A	Along with the acknowledge interrupt, the Processor B sends a code message to the Processor A through the selected transmit register (BTRn). The message informs the Processor A that it can exclusively access the shared memory.

Table 42-7. How the Processor B Rejects Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B ignores Processor A request for exclusive access	If the Processor B does not want to give go-ahead permission to the Processor A, Processor B ignores the exclusive access request.

42.3.10 Packet Data Transfers

The following example describes the packet transfer sequence between the Processor B and Processor A subsystems:

Table 42-8. Packet Data Transfer Sequence

Action	Sequence	Description
Processor B requests DMA	1	The Processor B sends a DMA request to initiate the packet data transfer
DMA data transfer	2	DMA acknowledges.
	3	DMA starts transferring data from the specified Processor B location to the specified shared memory
	4	DMA interrupts the Processor B to signal that the packet transfer has finished.
Processor B informs Processor A that data is in shared memory	5	Using an MU Processor B-side transmit register, the Processor B sends a packet information message to the Processor A to inform the Processor A of the arrival of new packet data that is stored in shared memory . The message contains the command, location, and length of packet data information.
Processor A receives interrupt	6	The Processor A receives an interrupt (assuming its corresponding Processor A MU-side receive interrupt is enabled), and the pending processing task becomes active and processes packet data from memory.
Processor A reads data, writes data	7	The Processor A reads or processes packet data from shared memory.
	8	The Processor A writes the result from packet processing to a separate buffer.
Processor A informs Processor B that transfer is finished	9	After the processing of the packet data finishes, the Processor A informs the Processor B (using the MU Processor A-side transmit register, ATRn).
Processor A sends interrupt to Processor B (request for more data)	10	The Processor B receives the next interrupt from the Processor A, in which the Processor A requests more packet data.

42.3.11 MU Resets

The MU has two sources of reset, and each reset has a different function from the MU or system perspective.

- One asynchronous system that is connected to both sides of the MU interface.
- One programmable hardware reset (MUR bit) in the ACR register (on the Processor A-side).

Table 42-9. MU programmable resets

Reset	Description
Processor A MU reset	<ul style="list-style-type: none"> • Processor A MU Reset bit (MUR) of the ACR register • The MUR reset affects the messaging section on both the Processor A and the Processor B sides. The MUR reset causes all control and status registers to return to their default values and all internal states to be cleared. • It is up to the Processor A software to decide whether to use the MUR reset or not. • The instruction immediately following assertion of the MUR bit should not write to MU registers. Such a write may be overwritten by the reset sequence and the register will remain with the reset value. You should wait at least one instruction (after assertion of the MUR bit) before attempting a write to MU registers.

After issuing MUR bit reset events, the Processor A programmer can verify that the reset sequence on the Processor B-side has ended, by checking the RS bit in the ASR register.

NOTE

MUR bit assertion is a delicate operation because it affects the other side's registers asynchronously. MUR bit assertion may cause unpredictable behavior if, for example, the Processor B is concurrently testing an MU register bit (TE bit in BSR register). Before asserting the MUR bit, you should verify that the Processor B is not presently engaged in an MU signalling activity.

42.4 Software Restrictions

This section describes certain software restrictions when accessing the MU.

42.4.1 General Restrictions

This section lists the restrictions that apply to both the sides (Processor A, Processor B) of the MU.

42.4.1.1 Write-After-Write to a Transmit Register

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver will attempt to retrieve the data.
- Before attempting to write the transmit register again, the transmitter side should wait for a “Transmitter Empty” interrupt, or should poll the “Transmitter Empty” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being read on the receiver side of the MU.

42.4.1.2 Read-After-Read from a Receive Register

A read of a receive register signals the transmitter side that data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a “Receiver Full” interrupt or polling the “Receiver Full” bit in the Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter will attempt to write the data.
- Before attempting to read the receive register again, the receiver side should wait for a “Receiver Full” interrupt, or should poll the “Receiver Full” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being written on the transmitter side of the MU.

42.4.2 Processor Restrictions

This section lists the restrictions that apply each side of the processor in the MU.

42.4.2.1 Before Entering Low Power Mode

Before entering Low Power mode, the Processor should verify that the Processor Event Pending (EP) bit in the Status Register is cleared.

- If the Event Pending bit (EP) is still set to “1”, then the Processor should wait and poll the EP bit until it is cleared, before executing the LPM instruction.

- Note that if the other Processor is in Low Power mode (programmed for clock gating in CCM), the EP bit may be stuck high. In this case, the other Processor clock must be turned ON to get the EP bit cleared before the Processor can enter Low Power mode.
- To discover which power mode the other Processor is in, the Processor can check the PM bits in the xSR register.

42.4.2.2 Before Setting a General Interrupt Request Bit (GIR0–3)

Before setting a General Interrupt Request bit (GIR0–3), you must verify that the GIR_n bit is cleared, which means that a general interrupt is not pending. Generally, setting the GIR_n bit while the bit is set to “1” will be ignored, but in some cases it may issue a second interrupt. This restriction is meant to prevent this indeterministic behavior.

42.4.2.3 Reset Bit Restrictions

The reset bit (MUR, HR) restrictions are:

- Before asserting the MUR bit in the ACR register, verify that the Processor B-side is not engaged in some MU activity.
- Do not write to an MU register in the instruction immediately after the assertion of the MUR bit in the ACR register, because the written data can be overridden by the reset value.

42.5 MU Processor A-side Memory Map/Register Definition

This section contains the detailed register descriptions for the Processor A-side MU registers.

MU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
229_4000	Processor A Transmit Register 0 (MU_ATR0)	32	R/W	0000_0000h	42.5.1/2732
229_4004	Processor A Transmit Register 1 (MU_ATR1)	32	R/W	0000_0000h	42.5.2/2733
229_4008	Processor A Transmit Register 2 (MU_ATR2)	32	R/W	0000_0000h	42.5.3/2733
229_400C	Processor A Transmit Register 3 (MU_ATR3)	32	R/W	0000_0000h	42.5.4/2734
229_4010	Processor A Receive Register 0 (MU_ARR0)	32	R	0000_0000h	42.5.5/2735

Table continues on the next page...

MU memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
229_4014	Processor A Receive Register 1 (MU_ARR1)	32	R	0000_0000h	42.5.6/2735
229_4018	Processor A Receive Register 2 (MU_ARR2)	32	R	0000_0000h	42.5.7/2736
229_401C	Processor A Receive Register 3 (MU_ARR3)	32	R	0000_0000h	42.5.8/2737
229_4020	Processor A Status Register (MU_ASR)	32	R/W	00F0_0080h	42.5.9/2738
229_4024	Processor A Control Register (MU_ACR)	32	R/W	0000_0000h	42.5.10/2741

42.5.1 Processor A Transmit Register 0 (MU_ ATR0)

Use Processor A Transmit Register 0 (ATR0, 32-bit, write-only) to transmit a message or data to the Processor B.

- You can only write to the ATR0 register when the TE0 bit in ASR register is set to “1”.
- Reading the ATR0 register returns all zeros.

Address: 229_4000h base + 0h offset = 229_4000h

MU_ ATR0 field descriptions

Field	Description
ATR0	<p>Processor A Transmit Register 0. (Write-only)</p> <ul style="list-style-type: none"> • Data written to the ATR0 register is reflected on the Processor B-side in the Processor B Receive Register 0 (BRR0). The ATR0 and BRR0 registers are not double-buffered—a write to the ATR0 register overrides the data readable at the BRR0 register. • A write to the transmit register clears a “transmitter empty” bit (TE0) in the Processor A Status Register (ASR) on the transmitter side, and sets a “receiver full” bit (RF0) in the Processor B Status Register (BSR) on the receiver side (optionally triggering an interrupt 0 on the Processor B-side). • Any write to the ATR0 register will update all status information.

42.5.2 Processor A Transmit Register 1 (MU_ATR1)

Use Processor A Transmit Register 1 (ATR1, 32-bit, write-only) to transmit a message or data to the Processor B.

- You can only write to the ATR1 register when the TE1 bit in ASR register is set to “1”.
- Reading the ATR1 register returns all zeros.

Address: 229_4000h base + 4h offset = 229_4004h

The ATR2 and BRR2 registers are not double-buffered—a write to the ATR2 register overrides the data readable at the BRR2 register. • A write to the transmit register clears a “transmitter empty” bit (TE2) in the Processor A Status Register (ASR) on the transmitter side, and sets a “receiver full” bit (RF2) in the Processor B Status Register (BSR) on the receiver side (optionally triggering an interrupt 2 on the Processor B-side). • Any write to the ATR2 register will update all status information.

42.5.4 Processor A Transmit Register 3 (MU_ATR3)

Use Processor A Transmit Register 3 (ATR3, 32-bit, write-only) to transmit a message or data to the Processor B.

- You can only write to the ATR3 register when the TE3 bit in ASR register is set to “1”.
- Reading the ATR3 register returns all zeros.

Address: 229_4000h base + Ch offset = 229_400Ch

MU_ATR3 field descriptions

Field	Description
ATR3	<p>Processor A Transmit Register 3. (Write-only)</p> <ul style="list-style-type: none"> • Data written to the ATR3 register is reflected on the Processor B-side in the Processor B Receive Register 3 (BRR3). The ATR3 and BRR3 registers are not double-buffered—a write to the ATR3 register overrides the data readable at the BRR3 register. • A write to the transmit register clears a “transmitter empty” bit (TE3) in the Processor A Status Register (ASR) on the transmitter side, and sets a “receiver full” bit (RF3) in the Processor B Status Register (BSR) on the receiver side (optionally triggering an interrupt 3 on the Processor B-side). • Any write to the ATR3 register will update all status information.

42.5.5 Processor A Receive Register 0 (MU_ARR0)

Use Processor A Receive Register 0 (ARR0, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR0 register is immediately reflected in the ARR0 register.
- You can only read the ARR0 register when the RF0 bit in the ASR register is set to “1”.
- Writing to the ARR0 register generates an error response to the Processor A.

Address: 229_4000h base + 10h offset = 229_4010h

MU_ARR0 field descriptions

Field	Description
ARR0	<p>Processor A Receive Register 0. (Read-only)</p> <ul style="list-style-type: none"> • Reflects the data written to Processor B Transmit Register 0 (BTR0). • Reading the ARR0 register clears the “receiver full” bit (RF0) in the Processor A Status Register (ASR) on the receiver side, and sets the “transmitter empty” bit (TE0) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the Processor B-side). • Any read of the ARR0 register will update all status information.

42.5.6 Processor A Receive Register 1 (MU_ARR1)

Use Processor A Receive Register 1 (ARR1, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR1 register is immediately reflected in the ARR1 register.
- You can only read the ARR1 register when the RF1 bit in the ASR register is set to “1”.
- Writing to the ARR1 register generates an error response to the Processor A.

Address: 229_4000h base + 14h offset = 229_4014h

Field	Description
ARR1	Processor A Receive Register 1. (Read-only) <ul style="list-style-type: none"> • Reflects the data written to Processor B Transmit Register 1 (BTR1). • Reading the ARR1 register clears the “receiver full” bit (RF1) in the Processor A Status Register (ASR) on the receiver side, and sets the “transmitter empty” bit (TE1) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 1 on the Processor B-side). • Any read of the ARR1 register will update all status information.

42.5.7 Processor A Receive Register 2 (MU_ARR2)

Use Processor A Receive Register 2 (ARR2, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR2 register is immediately reflected in the ARR2 register.
- You can only read the ARR2 register when the RF2 bit in the ASR register is set to “1”.
- Writing to the ARR2 register generates an error response to the Processor A.

Address: 229_4000h base + 18h offset = 229_4018h

MU_ARR2 field descriptions

Field	Description
ARR2	Processor A Receive Register 2. (Read-only) <ul style="list-style-type: none"> • Reflects the data written to Processor B Transmit Register 1 (BTR2). • Reading the ARR2 register clears the “receiver full” bit (RF2) in the Processor A Status Register (ASR) on the receiver side, and sets the “transmitter empty” bit (TE2) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 2 on the Processor B-side). • Any read of the ARR2 register will update all status information.

42.5.8 Processor A Receive Register 3 (MU_ARR3)

Use Processor A Receive Register 3 (ARR3, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR3 register is immediately reflected in the ARR3 register.
- You can only read the ARR3 register when the RF3 bit in the ASR register is set to “1”.
- Writing to the ARR3 register generates an error response to the Processor A.

Address: 229_4000h base + 1Ch offset = 229_401Ch

MU_ARR3 field descriptions

Field	Description
ARR3	<p>Processor A Receive Register 3. (Read-only)</p> <ul style="list-style-type: none"> • Reflects the data written to Processor B Transmit Register 3 (BTR3). • Reading the ARR3 register clears the “receiver full” bit (RF3) in the Processor A Status Register (ASR) on the receiver side, and sets the “transmitter empty” bit (TE3) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 3 on the Processor B-side). • Any read of the ARR3 register will update all status information.

42.5.9 Processor A Status Register (MU_ASR)

Use the Processor A Status Register (ASR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, and to set dual function control-status bits.

- Some dual-purpose bits are set by the MU logic, and cleared by the Processor A-side programmer
- Other dual-purpose bits are set by the Processor A-side programmer, and cleared by the MU logic.

Address: 229_4000h base + 20h offset = 229_4020h

MU_ASR field descriptions

Field	Description
31–28 GIPn	<p>For n = {0, 1, 2, 3} Processor A General Interrupt Request n Pending. (Read-Write)</p> <ul style="list-style-type: none"> • GIPn bit signals the Processor A that the GIRn bit in the BCR register on the Processor B-side was set from “0” to “1”. If the GIEn bit in the ACR register is set to “1”, a General Interrupt n request is issued. • The GIPn bit is cleared by writing it back as “1”. Writing “0”, or writing “1” when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. The proper bit clearing sequence is: clear an Processor A register, set the desired bit in it (Processor A register), and write it to the ASR register, thus clearing the GIPn bit. • GIPn bit is cleared when the MU is reset.

Table continues on the next page...

MU_ASR field descriptions (continued)

Field	Description
	0 Processor A general purpose interrupt n is not pending. (default) 1 Processor A general purpose interrupt n is pending.
27–24 RFn	For n = {0, 1, 2, 3} Processor A Receive Register n Full. (Read-only) <ul style="list-style-type: none"> The RFn bit is set to “1” when the BTRn register is written on the Processor B-side. After the RFn bit is set to “1”, the RFn bit signals the Processor A-side that new data is ready to be read by the Processor A in the ARRn register, and a Receive n interrupt is issued on the Processor A-side (if the RIEn bit in the ACR register has been set to “1”). RFn bit is cleared when the ARRn register is read, and when the MU is reset. 0 ARRn register is not full (default). 1 ARRn register has received data from BTRn register and is ready to be read by the Processor A.
23–20 TEn	For n = {0, 1, 2, 3} Processor A Transmit Register n Empty. (Read-only) <ul style="list-style-type: none"> The TEn bit is set to “1” after the BRRn register is read on the Processor B-side. After the TEn bit is set to “1”, the TEn bit signals the Processor A-side that the ATRn register is ready to be written on the Processor A-side, and a Transmit n interrupt is issued on the Processor A-side (if the TEn bit in the ACR register is set to “1”). TEn bit is cleared after the ATRn register is written on the Processor A-side. TEn bit is set to “1” when the MU is reset. 0 ATRn register is not empty. 1 ATRn register is empty (default).
19–10 -	This field is reserved. Reserved.
9 BRDIP	Processor B Reset De-asserted Interrupt Pending. (Read-Write) <ul style="list-style-type: none"> BRDIP bit signals the Processor A-side that the Processor B-side has come out of reset. BRDIP bit is set to “1” after the MU Processor B-side comes out of reset, after synchronization. The interrupt generated by a Processor B-side reset de-assertion is ORed with the Processor A general purpose interrupt 3. The Processor A general purpose interrupt 3 is issued when the Processor B-side comes out of reset (if the interrupt is enabled). To clear the BRDIP bit, write “1”, which also clears general purpose interrupt 3. When Processor A-side of MU comes out of reset BRDIP bit has value “0”(default).Then Processor A sees the status of Processor B-side and if Processor B-side has come out of reset then BRDIP bit goes high.This takes 5-6 clock cycles.And if you read BRDIP bit now you will see it as high although its reset value was "0". 0 The Processor A general purpose interrupt 3, because of a Processor B-side reset de-assertion, is cleared (default). 1 The Processor B-side is out of reset.
8 FUP	Processor A Flags Update Pending. (Read-only) <ul style="list-style-type: none"> FUP bit is set to “1” when the Processor A-side sends a Flags Update request to the Processor B-side. A Flags Update request is generated when the ABF[2:0] bits of the ACR register change. No flag update changes are allowed while the FUP bit is set to “1”. Any write to the ABF[2:0] bits, while the FUP bit is set to “1”, will not generate a Flags Update event, and the ABF[2:0] bits will stay unchanged. FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU Processor B-side, and during MU reset.

Table continues on the next page...

MU_ASR field descriptions (continued)

Field	Description
	0 No flags updated, initiated by the Processor A, in progress (default) 1 Processor A initiated flags update, processing
7 BRS	<p>Processor B-side Reset State. (Read-only)</p> <ul style="list-style-type: none"> • BRS bit indicates if the Processor B-side of the MU is in a reset state or not. • If the BRS bit is set to “1”, then the Processor B-side of the MU is still in the reset state. • If the BRS bit is cleared, then the Processor B-side of the MU are out of reset. • The BRS bit is set to “1” during: a Processor B system reset, or an MU reset (caused by setting the MUR bit at the ACR register). • The BRS bit is cleared when the reset sequence on the Processor B-side of the MU ends. After issuing any of the reset events mentioned previously, you should verify that the BRS bit is cleared before starting any accesses. • When Processor A side of MU comes out of reset BRS bit has value “1”(default). Then Processor A sees the status of Processor B-side and if Processor B-side has come out of reset then BRS bit goes low. This takes 5-6 clock cycles. And if you read BRS bit now you will see it as low although its reset value was “1” . <p>0 The Processor B-side of the MU is not in reset. 1 The Processor B-side of the MU is in reset.</p>
6–5 -	This field is reserved. Reserved
4 EP	<p>Processor A-Side Event Pending. (Read-only)</p> <ul style="list-style-type: none"> • EP bit is set to “1” when the Processor A-side mechanism sends an event update request to the Processor B-side. • EP bit is cleared when the event update acknowledge is received. An “event” is any hardware message that is reflected in the BSR register on the Processor B-side (for example, “transmit register 0 written”). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically. • To ensure events have been posted to Processor B before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to “1”, you should wait and continue to poll it (EP bit) before entering STOP mode. • Reading the ASR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP or WAIT modes; otherwise, the EP bit may be set by subsequent additional actions. • The EP bit is cleared when the MU resets. <p>0 The Processor A-side event is not pending (default). 1 The Processor A-side event is pending.</p>
3 -	This field is reserved. Reserved.
Fn	<p>For n = {0, 1, 2} Processor A-Side Flag n. (Read-only)</p> <ul style="list-style-type: none"> • Fn bit is the Processor A-side flag that reflects the values written to the BAFn bit in the Processor B control register. • Every time that the BAFn bit is written, the BAFn bit write event updates the Fn bit after the event update latency, which is measured in terms of the number of clocks of the Processor B and the Processor A. <p>0 BAFn bit in BCR register is written 0 (default). 1 BAFn bit in BCR register is written 1.</p>

42.5.10 Processor A Control Register (MU_ACR)

Use the Processor A Control Register (ACR, 32-bit, read-write) to enable the MU interrupts on the Processor A-side, and trigger events and interrupts on the Processor B-side (general purpose interrupt, flag update).

4229_C01C	Processor B Receive Register 3 (MU_BRR3)	32	R	0000_0000h	42.6.8/2748
4229_C020	Processor B Status Register (MU_BSR)	32	R/W	00F0_0080h	42.6.9/2749
4229_C024	Processor B Control Register (MU_BCR)	32	R/W	0000_0000h	42.6.10/2752

42.6.1 Processor B Transmit Register 0 (MU_BTR0)

Use Processor B Transmit Register 0 (BTR0, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR0 register when the TE0 bit in BSR register is set to “1”.
- Reading the BTR0 register returns all zeros.

Address: 4229_C000h base + 0h offset = 4229_C000h

MU_BTR0 field descriptions

Field	Description
BTR0	<p>Processor B Transmit Register 0. (Write-only)</p> <ul style="list-style-type: none"> • Data written to the BTR0 register is reflected on the Processor A-side in the Processor A Receive Register 0 (ARR0). The BTR0 and ARR0 registers are not double-buffered—a write to the BTR0 register overrides the data readable at the ARR0 register. • A write to the transmit register clears a “transmitter empty” bit (TE0) in the Processor B Status Register (BSR) on the transmitter side, and sets a “receiver full” bit (RF0) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 0 on the Processor A-side). • Any write to the BTR0 register will update all status information.

42.6.2 Processor B Transmit Register 1 (MU_BTR1)

Use Processor B Transmit Register 1 (BTR1, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR1 register when the TE1 bit in BSR register is set to “1”.
- Reading the BTR1 register returns all zeros.

Address: 4229_C000h base + 4h offset = 4229_C004h

MU_BTR1 field descriptions

Field	Description
BTR1	<p>Processor B Transmit Register 1. (Write-only)</p> <ul style="list-style-type: none"> Data written to the BTR1 register is reflected on the Processor A-side in the Processor A Receive Register 1 (ARR1). The BTR1 and ARR1 registers are not double-buffered—a write to the BTR1 register overrides the data readable at the ARR1 register. A write to the transmit register clears a “transmitter empty” bit (TE1) in the Processor B Status Register (BSR) on the transmitter side, and sets a “receiver full” bit (RF1) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 1 on the Processor A-side). Any write to the BTR1 register will update all status information.

42.6.3 Processor B Transmit Register 2 (MU_BTR2)

Use Processor B Transmit Register 2 (BTR2, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR2 register when the TE2 bit in BSR register is set to “1”.
- Reading the BTR2 register returns all zeros.

Address: 4229_C000h base + 8h offset = 4229_C008h

MU_BTR2 field descriptions

Field	Description
BTR2	<p>Processor B Transmit Register 2. (Write-only)</p> <ul style="list-style-type: none"> Data written to the BTR2 register is reflected on the Processor A-side in the Processor A Receive Register 2 (ARR2). The BTR2 and ARR2 registers are not double-buffered—a write to the BTR2 register overrides the data readable at the ARR2 register. A write to the transmit register clears a “transmitter empty” bit (TE2) in the Processor B Status Register (BSR) on the transmitter side, and sets a “receiver full” bit (RF2) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 2 on the Processor A-side). Any write to the BTR2 register will update all status information.

42.6.4 Processor B Transmit Register 3 (MU_BTR3)

Use Processor B Transmit Register 3 (BTR3, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR3 register when the TE3 bit in BSR register is set to “1”.
- Reading the BTR3 register returns all zeros.

Address: 4229_C000h base + Ch offset = 4229_C00Ch

MU_BTR3 field descriptions

Field	Description
BTR3	<p>Processor B Transmit Register 3. (Write-only)</p> <ul style="list-style-type: none"> • Data written to the BTR3 register is reflected on the Processor A-side in the Processor A Receive Register 3 (ARR3). The BTR3 and ARR3 registers are not double-buffered—a write to the BTR3 register overrides the data readable at the ARR3 register. • A write to the transmit register clears a “transmitter empty” bit (TE3) in the Processor B Status Register (BSR) on the transmitter side, and sets a “receiver full” bit (RF3) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 3 on the Processor A-side). • Any write to the BTR3 register will update all status information.

42.6.5 Processor B Receive Register 0 (MU_BRR0)

Use Processor B Receive Register 0 (BRR0, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR0 register is immediately reflected in the BRR0 register.
- You can only read the BRR0 register when the RF0 bit in the BSR register is set to “1”.
- Writing to the BRR0 register generates an error response to the Processor B.

Address: 4229_C000h base + 10h offset = 4229_C010h

MU_BRR0 field descriptions

Field	Description
BRR0	Processor B Receive Register 0. (Read-only) <ul style="list-style-type: none"> • Reflects the data written to Processor A Transmit Register 0 (ATR0). • Reading the BRR0 register clears the “receiver full” bit (RF0) in the Processor B Status Register (BSR) on the receiver side, and sets the “transmitter empty” bit (TE0) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the Processor A-side). • Any read of the BRR0 register will update all status information.

42.6.6 Processor B Receive Register 1 (MU_BRR1)

Use Processor B Receive Register 1 (BRR1, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR1 register is immediately reflected in the BRR1 register.
- You can only read the BRR1 register when the RF1 bit in the BSR register is set to “1”.
- Writing to the BRR1 register generates an error response to the Processor B.

Address: 4229_C000h base + 14h offset = 4229_C014h

MU_BRR1 field descriptions

Field	Description
BRR1	Processor B Receive Register 1. (Read-only) <ul style="list-style-type: none"> • Reflects the data written to Processor A Transmit Register 1 (ATR1). • Reading the BRR1 register clears the “receiver full” bit (RF1) in the Processor B Status Register (BSR) on the receiver side, and sets the “transmitter empty” bit (TE1) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 1 on the Processor A-side). • Any read of the BRR1 register will update all status information.

42.6.7 Processor B Receive Register 2 (MU_BRR2)

Use Processor B Receive Register 2 (BRR2, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR2 register is immediately reflected in the BRR2 register.
- You can only read the BRR2 register when the RF2 bit in the BSR register is set to “1”.
- Writing to the BRR2 register generates an error response to the Processor B.

Address: 4229_C000h base + 18h offset = 4229_C018h

MU_BRR2 field descriptions

Field	Description
BRR2	Processor B Receive Register 2. (Read-only) <ul style="list-style-type: none"> • Reflects the data written to Processor A Transmit Register 1 (ATR2). • Reading the BRR2 register clears the “receiver full” bit (RF2) in the Processor B Status Register (BSR) on the receiver side, and sets the “transmitter empty” bit (TE2) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 2 on the Processor A-side). • Any read of the BRR2 register will update all status information.

42.6.8 Processor B Receive Register 3 (MU_BRR3)

Use Processor B Receive Register 3 (BRR3, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR3 register is immediately reflected in the BRR3 register.
- You can only read the BRR3 register when the RF3 bit in the BSR register is set to “1”.
- Writing to the BRR3 register generates an error response to the Processor B.

Address: 4229_C000h base + 1Ch offset = 4229_C01Ch

MU_BRR3 field descriptions

Field	Description
BRR3	<p>Processor B Receive Register 3. (Read-only)</p> <ul style="list-style-type: none"> Reflects the data written to Processor A Transmit Register 3 (ATR3). Reading the BRR3 register clears the “receiver full” bit (RF3) in the Processor B Status Register (BSR) on the receiver side, and sets the “transmitter empty” bit (TE3) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 3 on the Processor A-side). Any read of the BRR3 register will update all status information.

42.6.9 Processor B Status Register (MU_BSR)

Use the Processor B Status Register (BSR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, the Processor A power mode, and to set dual function control-status bits.

- Dual-purpose bits are set by the Processor B-side programmer, and cleared by the MU logic.

MU_BSR field descriptions

Field	Description
31–28 GIPn	For n = {0, 1, 2, 3} Processor B General Interrupt Request n Pending. (Read-Write)

Table continues on the next page...

MU_BSR field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> GIPn bit signals the Processor B that the GIRn bit in the ACR register on the Processor A-side was set from “0” to “1”. If the GIEn bit in the BCR register is set to “1”, a General Interrupt n request is issued. The GIPn bit is cleared by writing it back as “1”. Writing “0”, or writing “1” when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. GIPn bit is cleared when the MU is reset. <p>0 Processor B general purpose interrupt n is not pending. (default) 1 Processor B general purpose interrupt n is pending.</p>
27–24 RFn	<p>For n = {0, 1, 2, 3} Processor B Receive Register n Full. (Read-only)</p> <ul style="list-style-type: none"> RFn bit signals to the Processor B-side that new data was written by the Processor A to the ATRn register, and is ready to be read by the Processor B in the BRRn register. The RFn bit is set to “1” when the ATRn register is written on the Processor A-side. After the RFn bit is set to “1”, the RFn bit signals the Processor B-side that new data is ready to be read by the Processor B in the BRRn register, and a Receive n interrupt is issued on the Processor A-side (if the RIEn bit in the BCR register has been set to “1”). RFn bit is cleared when the BRRn register is read, and when the MU is reset. <p>0 BRRn register is not full (default). 1 BRRn register has received data from ATRn register and is ready to be read by the Processor B.</p>
23–20 TEn	<p>For n = {0, 1, 2, 3} Processor B Transmit Register n Empty. (Read-only)</p> <ul style="list-style-type: none"> When TEEn = “1”, it signals to the Processor B-side that the BTRn register is ready to be written on the Processor B-side. The TEEn bit is set to “1” after the ARRn register is read on the Processor A-side. Setting TEEn bit will issue a transmit n interrupt on the Processor B-side (if the TIEn bit in the BCR register is set to “1”). TEEn bit is cleared after the BTRn register is written on the Processor B-side. TEEn bit is set to “1” when the MU is reset. <p>0 BTRn register is not empty. 1 BTRn register is empty (default).</p>
19–9 Reserved	This field is reserved.
8 FUP	<p>Processor B Flags Update Pending. (Read-only)</p> <ul style="list-style-type: none"> FUP bit is set to “1” when the Processor B-side sends a Flags Update request to the Processor A-side. A Flags Update request is generated when the BAF[2:0] bits of the BCR register change. No flag update changes are allowed while the FUP bit is set to “1”. Any write to the BAF[2:0] bits, while the FUP bit is set to “1”, will not generate a Flags Update event, and the BAF[2:0] bits will stay unchanged. FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU Processor A-side, and during MU reset. <p>0 No flags updated, initiated by the Processor B, in progress (default) 1 Processor B initiated flags update, processing</p>
7 ARS	<p>Processor A Reset State. (Read-only)</p> <ul style="list-style-type: none"> ARS bit indicates if the Processor A-side of the MU is in a reset state or not. If the ARS bit is set to “1”, then the Processor A-side of the MU is still in the reset state.

Table continues on the next page...

MU_BSR field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> If the ARS bit is cleared, then both the Processor A and the Processor A-side of the MU are out of reset. The ARS bit is set to "1" during: a Processor A system reset, or an MU reset (caused by setting the MUR bit at the BCR register). The ARS bit is cleared when the reset sequence on the Processor A-side of the MU ends. After issuing any of the three reset events mentioned previously, you should verify that the ARS bit is cleared before starting any accesses. When Processor B side of MU comes out of reset ARS bit has value "1"(default).Then Processor B sees the status of Processor A side and if Processor A has come out of reset then ARS bit goes low.This takes 5-6 clock cycles.And if you read ARS bit now you will see it as low although its reset value was "1" . <p>0 The Processor A or the Processor A-side of the MU is not in reset. 1 The Processor A or the Processor A-side of the MU is in reset.</p>
6–5 APM	<p>Processor A Power Mode. (Read-only)</p> <ul style="list-style-type: none"> APM[1:0] bits indicate the Processor A power mode. <p>00 The System is in Run Mode. 01 The System is in WAIT Mode. 10 Reserved. 11 The System is in STOP Mode.</p>
4 EP	<p>Processor B-Side Event Pending. (Read-only)</p> <ul style="list-style-type: none"> EP bit is set to "1" when the Processor B-side mechanism sends an event update request to the Processor A-side. EP bit is cleared when the event update acknowledge is received. An "event" is any hardware message that is reflected in the ASR register on the Processor A-side (for example, "transmit register 0 written"). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically. To ensure events have been posted to Processor A before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to "1", you should wait and continue to poll it (EP bit) before entering STOP mode. Reading the BSR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP mode; otherwise, the EP bit may be set by subsequent additional actions. Due to Processor B pipeline effects, three NOP operations (or their timing equivalent) should be given after an instruction that sets an event before the EP bit can reflect this event. The EP bit is cleared when the MU resets. <p>0 The Processor B-side event is not pending (default). 1 The Processor B-side event is pending.</p>
3 Reserved	This field is reserved.
Fn	<p>For n = {0, 1, 2} Processor B-Side Flag n. (Read-only)</p> <ul style="list-style-type: none"> Fn bit is the Processor B-side flag that reflects the values written to the ABFn bit in the Processor A control register. Every time that the ABFn bit is written, the ABFn bit write event updates the Fn bit after the event update latency, which is measured in terms of the number of clocks of the Processor A and the Processor B.

Table continues on the next page...

MU_BSR field descriptions (continued)

Field	Description
0	ABFn bit in ACR register is written 0 (default).
1	ABFn bit in ACR register is written 1.

42.6.10 Processor B Control Register (MU_BCR)

Use the Processor B Control Register (BCR, 32-bit, read-write) to enable the MU interrupts on the Processor B-side, and trigger events and interrupts on the Processor A-side (wake from STOP, hardware reset, flag update).

Chapter 43

Network Interconnect Bus System (NIC-301)

43.1 Overview

This section provides an overview of the NIC-301 (Network Inter-Connect) AXI arbiter IP.

The NIC-301 (by ARM Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 functionality, while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the ARM specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual*.

NOTE

The NIC-301 default settings are configured by Freescale's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

43.1.1 Block diagram

The NIC-301 AXI arbiter (or "CoreLink Network Interconnect") by ARM, provides configurable AXI-based interconnect logic, for connecting a number of masters (initiators) to several slaves (targets), via a configurable bus switches and bridging components.

The bus system is composed of five such instances: PER1, PER2, FAST1, FAST2, and FAST3.

Each instance can include one or more bus switches, with additional logic.

This chapter provides details of the various instances and the selected configuration parameters.

The top level diagram of the bus system is shown in the following figure.

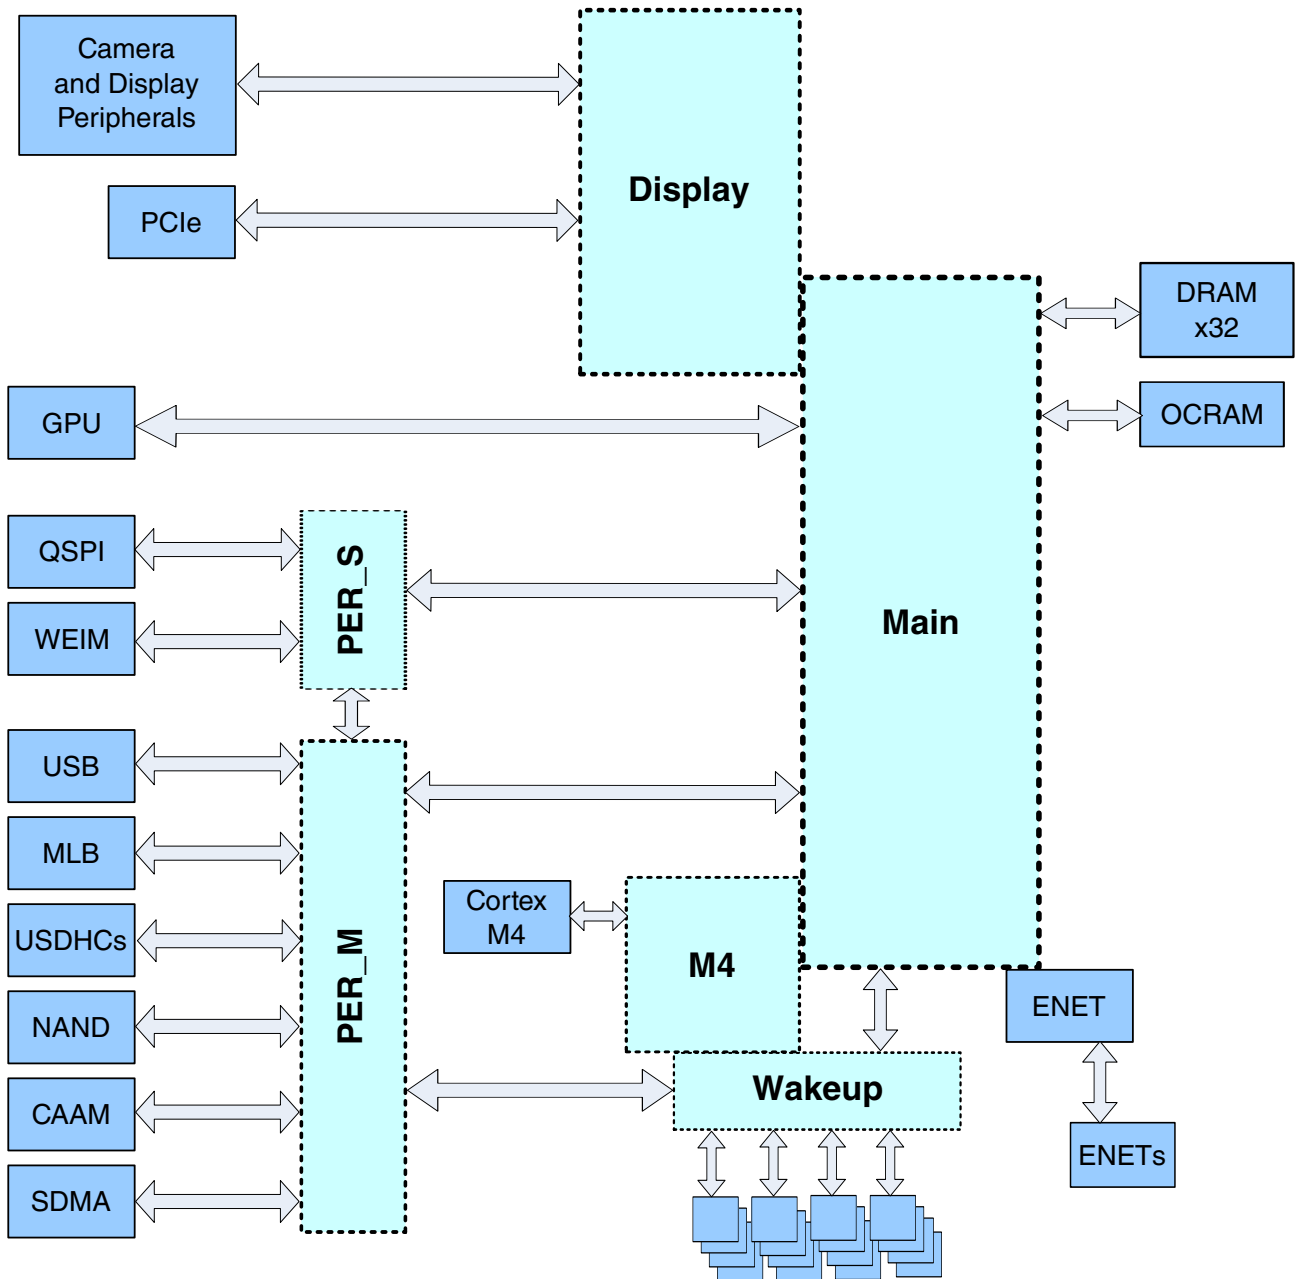

Figure 43-1. NIC-301 Bus System

43.1.2 NIC-301 Main Features

Key features of the NIC-301 module include the following:

- Address space memory mapping, including 'remap' functions.
- Programmer's view, for software-configured parameters, via "GPV" ports.
- Support for cross-clock domain synchronization.

43.1.3 Modes and Operations

The NIC-301 supports a normal functional mode only, as described in [Normal Mode](#).

43.2 External Signals

The NIC-301 has no external I/O interfaces.

43.3 Memory Map and Register Definition

This section includes the block memory map and detailed register descriptions.

Access to NIC-301 registers is provided through the global programmer's view (GPV) ports. Each GPV port provides access to the configuration registers of certain IP as listed in [Table 43-6](#). The GPV base addresses are listed in the table below:

Table 43-1. CA9 GPV ports memory allocations

GPV	Allocation	Size	Chip Address	
			Start	End
GPV_6	"m4" configuration port	1MB	0110_0000	011F_FFFF
GPV_5	"display" configuration port	1MB	0100_0000	010F_FFFF
GPV_4	"enet" configuration port	1MB	00F0_0000	00FF_FFFF
GPV_3	"per_m" configuration port	1MB	00E0_0000	00EF_FFFF
GPV_2	"per_s" configuration port	1MB	00D0_0000	00DF_FFFF
GPV_1	"wakeUp" configuration port	1MB	00C0_0000	00CF_FFFF
GPV_0	"main" configuration port	1MB	00B0_0000	00BF_FFFF

Table 43-2. CM4 GPV ports memory allocations

GPV	Allocation	Size	Chip Address	
			Start	End
GPV_6	"m4" configuration port	1MB	4110_0000	411F_FFFF
GPV_5	"display" configuration port	1MB	4100_0000	410F_FFFF
GPV_4	"enet" configuration port	1MB	40F0_0000	40FF_FFFF
GPV_3	"per_m" configuration port	1MB	40E0_0000	40EF_FFFF
GPV_2	"per_s" configuration port	1MB	40D0_0000	40DF_FFFF
GPV_1	"wakeup" configuration port	1MB	40C0_0000	40CF_FFFF
GPV_0	"main" configuration port	1MB	40B0_0000	40BF_FFFF

43.3.1 Memory Map

The NIC-301 memory map, is dependent on the selected configuration option at time of creation.

A "template" map is provided in [Table 43-3](#) below. For specific features, see the configuration tables in [NIC-specific parameters](#) to check whether specific options are selected.

43.3.2 Configuration programmers model

The GPV's contain configuration registers, partitioned into a number of individual 4KB blocks.

The general structure of the registers is provided by the following tables:

- Address map of the programmers model, [Table 43-3](#)
- AMIB Registers, [Table 43-4](#)
- ASIB Registers, [Table 43-5](#)

Table 43-3. Address map of the programmers model

Address Offset from Base Address	Registers	Notes
0x000F_F000	Internal interface p registers	Maximum p = 61 Note ¹
	...	
0x000C_4000	Internal interface 2 registers	
0x000C_3000	Internal interface 1 registers	
0x000C_2000	Internal interface 0 registers	

Table continues on the next page...

Table 43-3. Address map of the programmers model (continued)

Address Offset from Base Address	Registers	Notes
0x000C_1000	Slave interface m registers	Maximum m = 127 Note ²
	...	
0x0004_4000	Slave interface 2 registers	
0x0004_3000	Slave interface 1 registers	
0x0004_2000	Slave interface 0 registers	
0x0004_1000	Master interface n registers	Maximum n = 63 Note ³
	...	
0x0000_4000	Master interface 2 registers	
0x0000_3000	Master interface 1 registers	
0x0000_2000	Master interface 0 registers	
0x0000_1000	ID registers	
0x0000_0000	Address control registers	Configurable base address ⁴

1. Index refers to BI registers index
2. Index refer to ASIB registers index
3. Index refer to AMIB registers index
4. Reserved for internal use

43.3.2.1 Address control and ID registers

Registers at offsets 0x0–0xFFC are reserved for internal use.

43.3.2.2 AMBA master interface block (AMIB) configuration registers

The table below lists only the registers that affect the user. All other addresses are treated as "reserved".

Table 43-4. AMIB Registers

Offset	Register	Access	Width	Reset Value
0x024	fn_mod2 Bypass merge. This register is only present if upsizing or downsizing. See upsizing/downsizing data width functions in AMBA Network Interconnect TRM.	RW	1	0
0x040	wr_tidemark	RW	4	Note ¹

1. Reset value varies, default value chosen at RTL creation time is designed to suit normal operation.

43.3.2.3 ASIB (AMBA slave interface block) configuration registers

The table below lists only the registers that affect the user. All other addresses are treated as "reserved".

Table 43-5. ASIB Registers

Offset	Register	Access	Width	Reset Value
0x040	wr_tidemark Valid only for AXI slaves with WFIFO >=4.	RW	1	Note ¹
0x100	read_qos	RW	4	Note ²
0x104	write_qos	RW	4	Note ³

1. Reset value varies, default value chosen at RTL creation time is designed to suit typical operation cases.
2. QoS default is set at RTL creation time, and is listed in specific NIC-301 configuration tables in [NIC-specific parameters](#), as parameters "QoS qv_value" in ASIB / AMIB parameter tables.
3. QoS default is set at RTL creation time, and is listed in specific NIC-301 configuration tables in [NIC-specific parameters](#), as parameters "QoS qv_value" in ASIB / AMIB parameter tables.

43.3.3 Register Descriptions

The NIC-301 registers are dependent upon the selected configuration, the type of ports, hardware-selected features and whether they have a GPV view. The addressing is associated to a specific port, by looking at the port's index number, under "apb_slave" column.

The memory map template is provided in the [Configuration programmers model](#) above.

43.3.3.1 QoS registers' address look-up example

The flow below describes the steps needed in determining the memory addresses for GPU3D QoS read/write registers:

- Look up the GPU3D port index ("apb_slave"¹ column in [Table 43-6](#)): index 66. Note that the GPU3D is listed under GPV_1 interface.
- Look up the GPV_1 base address: 0x00C0_0000, in [Table 43-1](#).
- The master/slave ports configuration base address, is always obtained by: "GPV base" + ("APB index" x 0x1000), regardless of whether it is a slave or a master port. This is somewhat contrary to the way indexes are presented in the "Address map of the NIC-301 programmers model" in the ARM documentation as shown in [Table 43-3](#), where, instead, the indexes are provided in absolute values (of 0x1000 jumps), starting from the GPV base address.

1. The "slave", "master" type is assumed from NIC-301 point of view.

Hence, for the GPU3Dport (index '66'), the "slave interface" programming base address is 0x00C4_2000 (= GPV_1 base + 66 x 0x1000).

- To access any of the slave/master interface registers (in this example - the QoS read/write ones), their offset(s) must be added, as shown in [Table 43-5](#) :

"0x100" for Read_QoS and "0x104" for Write_QoS, in our example.

Final addresses obtained for QoS registers for the GPU3D primary port (index 66), are as follows:

- Read QoS: "0x00C4_2100"
- Write QoS: "0x00C4_2104"

43.3.4 NIC-specific parameters

This section details the configuration parameters of the NIC-301.

General notes:

1. All accesses to GPV_4 port, must be of "Supervisor" type.
2. The associated master/slave port interface ID (for each "GPV_N") is specified by the "apb_slave" / "apb_master" ² index. The slave/master interface, configuration register's start address is obtained by the following:

Start address (for "apb" index= "n") = GPV_N base + (n x 0x1000).

3. The security features of NIC-301 are not used, since master-slaves permissions are controlled by the CSU security policy/scheme.

Chapter 44

On-Chip OTP Controller (OCOTP_CTRL)

44.1 Overview

This section contains information describing the requirements for the on-chip eFuse OTP controller along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

44.1.1 Features

The OCOTP provides the following features :

- 32-bit word restricted program and read to 4 kbit of eFuse OTP(512 x 8).
- Loading and housing of fuse content into shadow registers.
- Memory-mapped (restricted) access to 4 kbit of shadow registers.
- Generation of HWV_FUSE (hardware visible fuse bus) and the HWV_REG bus which is made of up of volatile PIO register based "fuses". The HWV_REG bits come from the SCS (Software Controllable Signals) register.
- Generation of STICKY_REG which is consist of sticky register bits.
- Provide program-protect and read-protect eFuse.
- Provide override and read protection of shadow register.
- CRC32 test for read-lock fuse content.

44.2 Clocks

The table found here describes the clock sources for OCOTP.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 44-1. OCOTP Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

44.3 Top-Level Symbol and Functional Overview

The figure found here shows the OCOTP system level diagram.

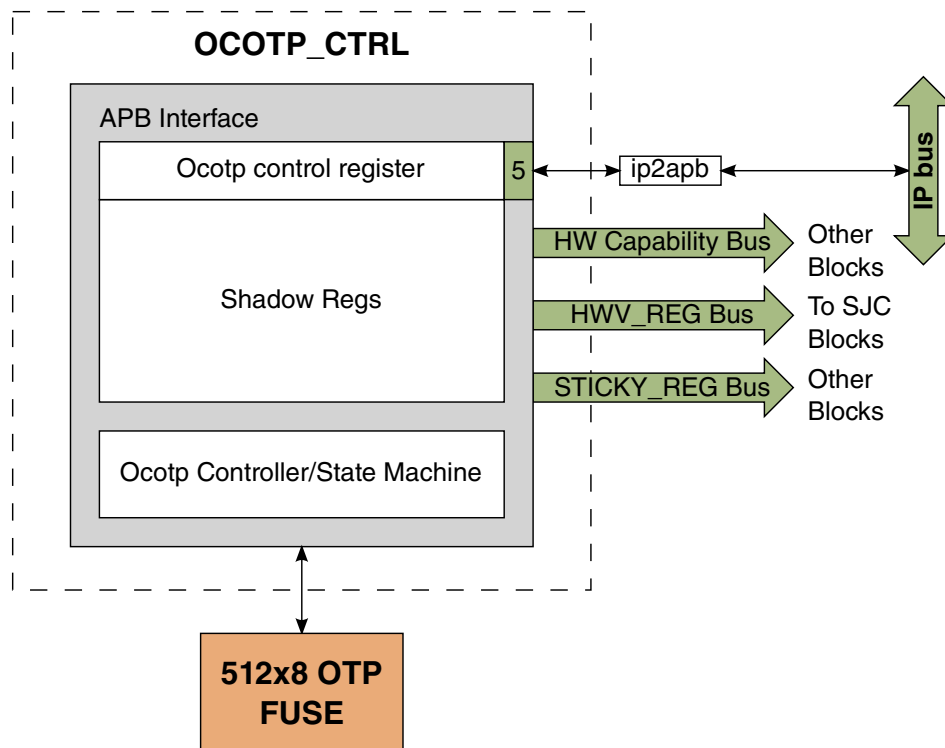

Figure 44-1. OCOTP System Level Diagram

44.3.1 Operation

The IP bus interface of the OCOTP provides two functions.

- Configure control registers for programming and reading fuse word.
- Override and read shadow registers.

For efuse, program can only be performed on bit and read is based on byte. OCOTP configuration for program and read are performed on 32-bit words for SW convenience. For writes, the 32-bit word reflects the "write-mask". Bit fields with 0 will not be programmed and bit fields with 1 will be programmed. OCOTP will program bit field with 1 in the fuse word one bit by one bit. For reads, OCOTP will read 4 times to get 4 bytes in the fuse word in order.

In this document, 4-kbit fuse are divided into 16 banks by function. Each bank has 8 fuse words. In physical, 4k bits fuse are in one 512x8 efusebox.

44.3.1.1 Shadow Register Reload

All fuse words in efusebox are shadowed. Therefore, fuse information is available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers (including HW_OCOTP_LOCK) without having to reset the device. To force a reload, complete the following steps:

1. Set the HW_OCOTP_TIMING[STROBE_READ] and HW_OCOTP_TIMING[RELAX] field value appropriately (as explained in a later section).
2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a new access can be requested.
3. Set the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit. OCOTP will read all the fuse one by one and put it into corresponding shadow register.
4. Wait for HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[RELOAD_SHADOWS] to be cleared by the controller.

The controller will automatically clear the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

44.3.1.2 Fuse and Shadow register read

All shadow registers are always readable through the APB bus except some secret keys regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write , read or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

To read fuse words directly from fusebox correctly complete the following steps:

1. Program HW_OCOTP_TIMING[STROBE_READ] and HW_OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the ipg_clk. OTP read will work at maximum bus frequencies as long as the HW_OCOTP_TIMING parameters are set correctly.
2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
3. Write the requested address to HW_OCOTP_CTRL[ADDR].
4. Set HW_OCOTP_READ_CTRL[READ_FUSE] to 1. OCOTP will auto read 4 bytes in requested word address in fusebox one by one. Then put read value into HW_OCOTP_READ_FUSE_DATA register.
5. Once complete, the controller will clear BUSY. A read request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read HW_OCOTP_READ_FUSE_DATA register to get fuse word value. HW_OCOTP_READ_FUSE_DATA will be 0xBADABADA when HW_OCOTP_CTRL[ERROR] is set.

44.3.1.3 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The LOCK shadow register also has no shadow or fuse lock bits but it is always read only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank correctly complete the following steps:

1. Program HW_OCOTP_TIMING[STROBE_PROG] and HW_OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the ipg_clk. OTP writes will work at maximum bus frequencies as long as the HW_OCOTP_TIMING parameters are set correctly.

2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested address to HW_OCOTP_CTRL[ADDR] and program the unlock code into HW_OCOTP_CTRL[WR_UNLOCK]. This must be programmed for each write access. The lock code is documented in the register description. Both the unlock code and address can be written in the same operation.
4. Write the data to the HW_OCOTP_DATA register. This will automatically set HW_OCOTP_CTRL[BUSY] and clear HW_OCOTP_CTRL[WR_UNLOCK]. To protect programming same OTP bit twice, before program OCOTP will automatically read fuse value in OTP and use read value to mask program data. The controller will use masked program data to program a 32-bit word in the OTP per the address in HW_OCOTP_CTRL[ADDR]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of HW_OCOTP_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to HW_OCOTP_CTRL[ADDR] will not affect an active write operation. It should also be noted that during the programming HW_OCOTP_DATA will shift right (with zero fill). This shifting is required to program the OTP serially. During the write operation, HW_OCOTP_DATA cannot be modified.
5. Once complete, the controller will clear BUSY. A write request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds per word. Write latencies is based on amount of bit filed which is 1. For example : program half fuse bits in one word need 10 us x 16.

For further details of OTP read/write operations see [eFUSE].

HW_OCOTP_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while HW_OCOTP_CTRL[RELOAD_SHADOWS] is set. In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed to from a shadow register which has been read locked.
- A program is performed to a fuse word which has been locked.
- A read is performed to from a fuse word which has been read locked.

44.3.1.4 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations following a write must be separated by 2 us after the clearing of HW_OCOTP_CTRL_BUSY following the write. This guarantees programming voltages on-chip to reach a steady state when exiting a write sequence. This includes reads, shadow reloads, or other writes.

A recommended software sequence to meet the postamble requirements is as follows:

- Issue the write and poll for BUSY (as per [Fuse Shadow Memory Footprint](#)).
- Once BUSY is clear, use HW_DIGCTL_MICROSECONDS to wait 2 us.
- Perform the next OTP operation.

44.3.2 Fuse Shadow Memory Footprint

The OTP memory footprint shows in the following figure. The registers are grouped by lock region. Their names correspond to the PIO register and fusemap names.

i.MX 6SoloX Applications Processor Reference Manual, Rev. 0, 2/2015

44.3.3 OTP Read/Write Timing Parameters

There are three timing fields contained in the HW_OCOTP_TIMING register that specify counter limit values, which are used to time how long the state machine remains in the various states, as well as specify the STROBE signal timing.

TheyBoth two timing parameters are all specified in ipg_clk cycles. Since the ipg_clk frequency can be set to a range of values, these parameters must be adjusted with the clock to yield the appropriate delay.

The HW_OCOTP_TIMING[RELAX] field specifies how long to remain in states to meet setup and hold timing requirement in fuse spec. This parameter should be set by the following equation:

$$t_{RELAX} = t_{HP_PG} = (HW_OCOTP_TIMING[RELAX]+1)/ipg_frequency > 16.2ns$$

HW_OCOTP_TIMING[RELAX] field is used to create other setup and hold timing delays in addition to tHP_PG. For all timing to be met, this is the max delay that must be programmed.

Except for setup and hold timing delay, there are 2 timing parameters for STROBE signal pulse width in program and read.

The HW_OCOTP_TIMING[STROBE_PROG] field specifies the period of the STROBE signal for fuse writes and is given in units of ipg_clk cycles. This value should be specified so that the requirement for the time when the STROBE signal is asserted high is met: $9000ns < t_{PGM} < 11000ns$ is met. Even though a range is given for tPGM, it is advised in [eFUSE] to program for a value of 10000ns. Therefore, this field should be set according to the following equation:

$$t_{PGM} = ((HW_OCOTP_TIMING[STROBE_PROG]+1) - 2*(HW_OCOTP_TIMING[RELAX]+1))/ipg_frequency = 10000ns.$$

The HW_OCOTP_TIMING[STROBE_READ] field specifies the period of the STROBE signal for fuse reads and is given in units of ipg_clk cycles. This field should be set according to the following equation:

$$t_{RD} = ((HW_OCOTP_TIMING[STROBE_READ]+1) - 2*(HW_OCOTP_TIMING[RELAX]+1))/ipg_frequency > 36ns.$$

The figure below illustrates the relationship between the STROBE signal in programming and reading mode, as well as the timing PIO register fields that affect it. The implementation uses one counter to generate the STROBE waveform within one period and a second counter counts the number of cycles to create for programming the designated word.

Figure 44-3. STROBE Signal Creation and Timing

44.3.4 Hardware Visible Fuses

The `hwv_fuse` bus emanates from the OCOTP block and goes to various other blocks inside the chip. This bus is made up of the shadow register bits for banks 0, 1, 2 and 4.

Only a subset of these fuse bits are currently used by the hardware. The fuse bits are initially copied from the eFuse banks after reset is deasserted. When all fuse bits are loaded into their shadow registers, the OCOTP asserts the `fuse_latched` output signal.

The `hwv_reg` bus also comes from the OCOTP. Its source is the `HW_OCOTP_SCS` register. This register has 1 defined bit, the `HAB_JDE` bit, that is connected to the SJC block. The SCS bits are intended to be used as volatile fuse bits under software control. Additional bits will be defined as needed in future implementations.

The system-wide reset sequence must be coordinated by the system reset controller, so that the `hwv_fuse` and `hwv_reg` buses are stable and reflect the values of the fuses before they are used by the rest of the system.

44.3.5 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time `HW_OCOTP_CTRL_BUSY` is set. The load time is similar to that of a "reload shadow" operation.

44.3.6 Secure JTAG control

The JTAG control fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are envisioned, as shown in the table below.

Table 44-2. JTAG Security Level Control Bits

Security Mode	JTAG_SMODE	Description
No Debug	2'b11	The highest security level.
Secure JTAG	2'b01	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	Low Security, all JTAG features are enabled.

44.4 Fuse Map

See the Fusemap chapter of this reference manual for more information.

44.5 OCOTP Memory Map/Register Definition

OCOTP Hardware Register Format Summary

OCOTP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

44.5.1 OTP Controller Control Register (OCOTP_CTRLn)

The OCOTP Control and Status Register specifies the copy state, as well as the control required for random access of the OTP memory

OCOTP_CTRL: 0x000

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the HW_OCOTP_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and HW_OCOTP_READ_CTRL register. Read value is saved in HW_OCOTP_READ_FUSE_DATA register.

EXAMPLE

Empty Example.

Address: 21B_C000h base + 0h offset + (4d × i), where i=0d to 3d

OCOTP Memory Map/Register Definition

OCOTP_CTRLn field descriptions

Field	Description
31–16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: This register must be unlocked on a write-by-write basis (a write is initiated when HW_OCOTP_DATA is written), so the UNLOCK bitfield must contain the correct key value during all writes to HW_OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY). 0x3E77 KEY — Key needed to unlock HW_OCOTP_DATA register.
15–13 -	This field is reserved. Reserved
12–11 -	This field is reserved. Reserved
10 RELOAD_SHADOWS	Set to force re-loading the shadow registers (HW/SW capability and LOCK). This operation will automatically set BUSY. Once the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 ERROR	Set by the controller when an access to a locked region(OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface is active and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a one to the SCT clear address space and not by a general write.

Table continues on the next page...

OCOTP_CTRLn field descriptions (continued)

Field	Description
8 BUSY	OTP controller status bit. When active, no new write access or read access to OTP(including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7 -	This field is reserved. Reserved
ADDR	OTP write and read access address register. Specifies one of 128 word address locations (0x00 - 0x7f). If a valid access is accepted by the controller, the controller makes an internal copy of this value. This internal copy will not update until the access is complete.

44.5.2 OTP Controller Timing Register (OCOTP_TIMING)

The OCOTP Data Register is used for OTP Programming

This register specifies timing parameters for programming and reading the OCOTP fuse array.

EXAMPLE

Empty Example.

Address: 21B_C000h base + 10h offset = 21B_C010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				WAIT				STROBE_READ				RELAX				STROBE_PROG															
W	0				0				1				0				1															
Reset	0	0	0	0	0	0	0	1	0	1	0	0	0	1	1	0	0	0	0	1	0	0	1	0	1	0	0	1	1	0	0	1

OCOTP_TIMING field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.
27–22 WAIT	This count value specifies time interval between auto read and write access in one time program. It is given in number of ipg_clk periods.
21–16 STROBE_READ	This count value specifies the strobe period in one time read OTP. $Trd = ((STROBE_READ+1) - 2*(RELAX+1)) / ipg_clk_freq$. It is given in number of ipg_clk periods.
15–12 RELAX	This count value specifies the time to add to all default timing parameters other than the Tpgm and Trd. It is given in number of ipg_clk periods.
STROBE_PROG	This count value specifies the strobe period in one time write OTP. $Tpgm = ((STROBE_PROG+1) - 2*(RELAX+1)) / ipg_clk_freq$. It is given in number of ipg_clk periods.

44.5.3 OTP Controller Write Data Register (OCOTP_DATA)

The OCOTP Data Register is used for OTP Programming

OCOTP Memory Map/Register Definition

This register is used in conjunction with HW_OCOTP_CTRL to perform one-time writes to the OTP. Please see the "Software Write Sequence" section for operating details.

EXAMPLE

Empty Example.

Address: 21B_C000h base + 20h offset = 21B_C020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

OCOTP_READ_FUSE_DATA field descriptions

Field	Description
DATA	The data read from OTP

44.5.6 Sticky bit Register (OCOTP_SW_STICKY)

Some SW sticky bits .

Some sticky bits are used by SW to lock some fuse area , shadow registers and other features.

EXAMPLE

Empty Example.

OCOTP Memory Map/Register Definition

Address: 21B_C000h base + 50h offset = 21B_C050h

OCOTP_SW_STICKY field descriptions

Field	Description
31-5 -	This field is reserved. Reserved
4 JTAG_BLOCK_RELEASE	Set by ARM during Boot and before test mode entry. * 0 (Default) - JTAG is blocked (subject to other conditions). * 1 - JTAG block is released (subject to other controls). Once this bit is set, it is always high unless a POR is issued.
3 BLOCK_ROM_PART	Set by ARM during Boot and before test mode entry, if ROM_PART_LOCK=1. * 0 (Default) - Secret part of Boot ROM is not hidden (subject to other conditions). * 1 - Secret part of Boot ROM is hidden. Once this bit is set, it is always high unless a POR is issued.
2 FIELD_RETURN_LOCK	Shadow register write and OTP write lock for FIELD_RETURN region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
1 SRK_REVOKE_LOCK	Shadow register write and OTP write lock for SRK_REVOKE, MC_ERA and AP_BI_VER regions. When set, the writing of these region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
0 -	This field is reserved. Reserved.

44.5.7 Software Controllable Signals Register (OCOTP_SCSn)

HW_OCOTP_SCS: 0x060

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their default values after POR.

EXAMPLE

Empty Example.

Address: 21B_C000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SPARE															HAB_JDE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_SCSn field descriptions

Field	Description
31 LOCK	When set, all of the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a POR is issued.
30–1 SPARE	Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	<p>HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB.</p> <p>The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled.</p> <p>Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by POR. 0: JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms). 1: JTAG debugging is enabled by the HAB (though this signal may be gated off).</p> <p>1 JTAG debugging is enabled by the HAB (though this signal may be gated off)</p>

44.5.8 OTP Controller Version Register (OCOTP_VERSION)

This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

Empty Example.

OCOTP Memory Map/Register Definition

Address: 21B_C000h base + 90h offset = 21B_C090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
R	MAJOR								MINOR								STEP																	
W	0																																	
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

44.5.9 Value of OTP Bank0 Word0 (Lock controls) (OCOTP_LOCK)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 0 (ADDR = 0x00).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 400h offset = 21B_C400h

OCOTP Memory Map/Register Definition

OCOTP_LOCK field descriptions

Field	Description
31–30 GP3	Status of shadow register and OTP write lock for gp3 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
29–23 -	This field is reserved. Reserved
22 MISC_CONF	Status of shadow register and OTP write lock for misc_conf region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
21–20 -	This field is reserved. Reserved
19–18 ANALOG	Status of shadow register and OTP write lock for analog region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
17–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14 SRK	Status of shadow register and OTP write lock for srk region. When set, the writing of this region's shadow register and OTP fuse word are blocked.

Table continues on the next page...

OCOTP_LOCK field descriptions (continued)

Field	Description
13–12 GP2	Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
11–10 GP1	Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
9–8 MAC_ADDR	Status of shadow register and OTP write lock for mac_addr region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
7 -	This field is reserved. Reserved
6 SJC_RESP	Status of shadow register read and write, OTP read and write lock for sjc_resp region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
5–4 MEM_TRIM	Status of shadow register and OTP write lock for mem_trim region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
3–2 BOOT_CFG	Status of shadow register and OTP write lock for boot_cfg region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
TESTER	Status of shadow register and OTP write lock for tester region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

44.5.10 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP_CFG0)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 1 (ADDR = 0x01).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 410h offset = 21B_C410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

OCOTP_CFG0 field descriptions

Field	Description
BITS	This register contains 32 bits of the Unique ID and SJC_CHALLENGE field. Reflects value of OTP Bank 0, word 1 (ADDR = 0x01). These bits become read-only after the HW_OCOTP_LOCK_TESTER[1] bit is set.

44.5.11 Value of OTP Bank0 Word2 (Configuration and Manufacturing Info.) (OCOTP_CFG1)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

shadowed memory mapped access to OTP Bank 0, word 2 (ADDR = 0x02).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 420h offset = 21B_C420h

OCOTP_CFG1 field descriptions

Field	Description
BITS	This register contains 32 bits of the Unique ID and SJC_CHALLENGE field. Reflects value of OTP Bank 0, word 2 (ADDR = 0x02). These bits become read-only after the HW_OCOTP_LOCK_TESTER[1] bit is set.

44.5.12 Value of OTP Bank0 Word3 (Configuration and Manufacturing Info.) (OCOTP_CFG2)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 3 (ADDR = 0x03).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 430h offset = 21B_C430h

OCOTP_CFG2 field descriptions

Field	Description
BITS	Reflects value of OTP Bank 0, word 3 (ADDR = 0x03). These bits become read-only after the HW_OCOTP_LOCK_TESTER[1] bit is set.

44.5.13 Value of OTP Bank0 Word4 (Configuration and Manufacturing Info.) (OCOTP_CFG3)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

Non-shadowed memory mapped access to OTP Bank 0, word 4 (ADDR = 0x04).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 440h offset = 21B_C440h

OCOTP_SRK5 field descriptions

Field	Description
BITS	Shadow register for the hash of the Super Root Key word5 (Copy of OTP Bank 3, word 5 (ADDR = 0x21)). These bits become read-only after the HW_OCOTP_LOCK_SRK bit is set.

44.5.31 Shadow Register for OTP Bank3 Word6 (SRK Hash) (OCOTP_SRK6)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS].

Shadowed memory mapped access to OTP Bank 3, word 6 (ADDR = 0x1E).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 5E0h offset = 21B_C5E0h

OCOTP_SRK6 field descriptions

Field	Description
BITS	Shadow register for the hash of the Super Root Key word6 (Copy of OTP Bank 3, word 6 (ADDR = 0x22)). These bits become read-only after the HW_OCOTP_LOCK_SRK bit is set.

44.5.32 Shadow Register for OTP Bank3 Word7 (SRK Hash) (OCOTP_SRK7)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS].

Shadowed memory mapped access to OTP Bank 3, word 7 (ADDR = 0x1F).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 5F0h offset = 21B_C5F0h

OCOTP_SRK7 field descriptions

Field	Description
BITS	Shadow register for the hash of the Super Root Key word7 (Copy of OTP Bank 3, word 7 (ADDR = 0x23)). These bits become read-only after the HW_OCOTP_LOCK_SRK bit is set.

44.5.33 Value of OTP Bank4 Word0 (Secure JTAG Response Field) (OCOTP_RESP0)

Copied from the OTP automatically after reset. Can be re-loaded by setting HW_OCOTP_CTRL[RELOAD_SHADOWS]

Shadowed memory mapped access to OTP Bank 4, word 0 (ADDR = 0x20).

EXAMPLE

Empty Example.

Address: 21B_C000h base + 600h offset = 21B_C600h

Chapter 45

On-Chip RAM Memory Controller (OCRAM)

45.1 Overview

There are 2 OCRAM controllers implemented in i.MX 6SoloX. One controller is for the normal 128KB on-chip RAM. The other controller is for the 256KB L2 cache of ARM platform.

The L2 cache can be configured into "OCRAM mode" and used in the same way as normal OCRAM. The on-chip RAM block is implemented as a slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory controller, it supports only one AXI port with memory banks. For the AXI port, the read and write transactions are handled by two independent modules. As it is possible to have simultaneous read and write request from the AXI bus, each memory bank has an arbiter with round-robin scheme. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.

The 4 memory banks are organized with lower 2 bits of address which is AXI bus address and is 64 bits aligned interleaved. This allows a read access and a write access can be processed at the same time if they are targeted to different memory banks.

Various options are provided for adding pipeline or wait-states in read/write access, in order to ensure flexible timing control at both high and low frequencies.

The internal block diagram is shown in the figure below.

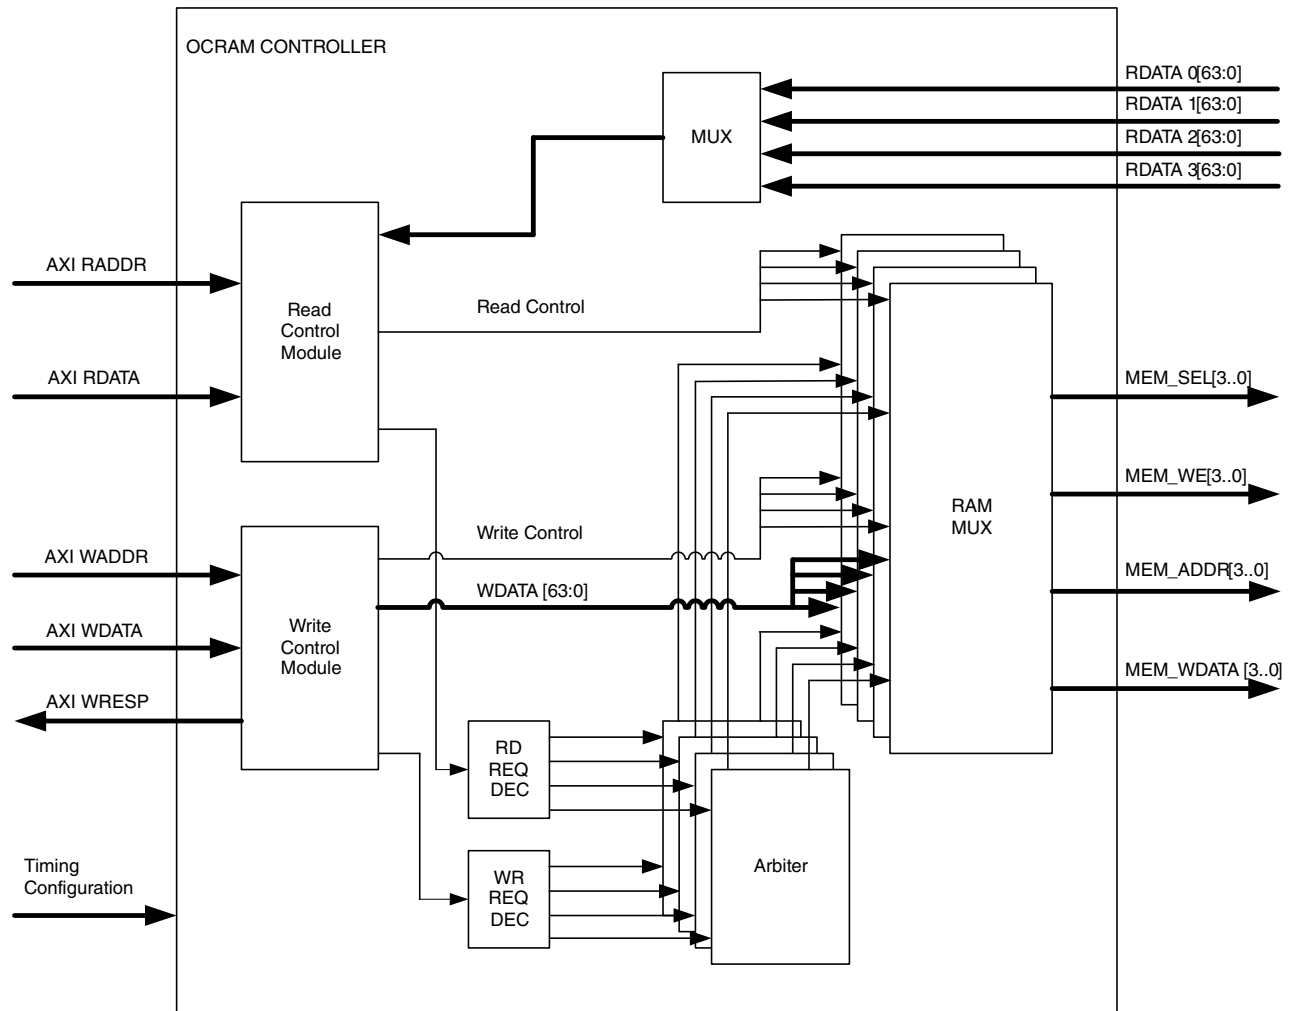

Figure 45-1. On-chip RAM Block Diagram

45.2 Basic Functions

45.2.1 Read/Write Arbitration

The arbiter is used to handle the read/write request from the read control module and write control module. It grants read/write access to the memory cell according to the internal arbitration state and the request/switch signal from the read control module and write control module. Generally, the arbitration is using the round-robin method.

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

45.2.2 TrustZone

TrustZone is also supported on this block.

When SECURE_ENBL bit in the General Purpose Register (IOMUXC_GPR10) bits [10:4] and [26:20] is set, the STARTADDR and ENDADDR bit-fields in this register establish the region of OCRAM that can only be accessed (both read and write) according to the execution mode policy described in CSU chapter, [Peripheral access policy](#). If this bit is cleared to zero, the entire OCRAM can be accessed in either secure or non-secure mode. The TrustZone bits shows in [Programmable Registers](#).

NOTE

The ENDADDR is not configurable and its value is the last address of the OCRAM space. The STARTADDR granularity is of 4KB.

45.3 Advanced Features

This section describes some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

All of the features can be disabled/enabled by programming the corresponding fields of the General Purpose Register (IOMUXC.GPR3) bits [24:21] and bits [3:0] in the IOMUX chapter.

45.3.1 Read Data Wait State

When the wait state is enabled, it will cost 2 cycles for each read access, (each beat of a read burst).

This can avoid the potential timing problem caused by the relatively longer memory access time at higher frequency.

When this feature is disabled, it only costs 1 clock cycle to finish a read transaction, that is, to get read data back in the next cycle of read request becomes valid on the bus.

For the normal ocram, the read data wait state is configurable via IOMUXC.GPR3[21]. For the L2 cache as ocram, the read data wait state is configurable via IOMUXC.GPR3[0].

45.3.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

For the normal ocram, the read address pipeline is configurable via IOMUXC.GPR3[22]. For the L2 cache as ocram, the read address pipeline is configurable via IOMUXC.GPR3[1].

45.3.3 Write Data Pipeline

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

For the normal ocram, the write data pipeline is configurable via IOMUXC.GPR3[23].
For the L2 cache as ocram, the write data pipeline is configurable via IOMUXC.GPR3[2].

45.3.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

For the normal ocram, the write address pipeline is configurable via IOMUXC.GPR3[24].
For the L2 cache as ocram, the write address pipeline is configurable via IOMUXC.GPR3[3]

45.4 Programmable Registers

There are no programmable registers in this block; however, OCRAM configurable bits can be found in the IOMUX Controller (IOMUXC) general purpose registers found here.

- TrustZone bits: IOMUXC_GPR10
- WAIT state / Pipeline bits: IOMUXC_GPR3
- L2 Cache OCRAM enable bits: IOMUXC_GPR11

Chapter 46

PCI Express (PCIe)

46.1 Overview

PCI Express includes the following cores:

- PCI Express Dual Mode (DM) core
- PCI Express Root Complex (RC) core
- PCI Express Endpoint (EP) core

NOTE

Throughout this chapter, content that is specific to a core is identified by using the abbreviated core name; for example, DM, RC, EP. Content that applies to the DM core specifically in either RC mode or EP mode is further qualified by using RC Mode or EP Mode. Content that applies to all cores is not identified as being specific to any core; rather, the term core or cores is used.

46.1.1 Terms and Abbreviations

The following terms are used throughout this chapter:

Table 46-1. Terms and Abbreviations

Term	Description
DM	PCI Express Dual Mode (DM) core
RC	PCI Express Root Complex (RC) core
EP	PCI Express Endpoint (EP) core
PCIe	PCI Express
CXPL	Common Xpress Port Logic: An internal Port Logic core module that implements the majority of the PCI Express protocol
x1/x2/x4/x8/x16	1/2/4/8/16 lanes

Table continues on the next page...

Table 46-1. Terms and Abbreviations (continued)

PIPE	PHY Interface for the PCI Express Architecture
NW	Number of double words; 1 stands for a 32-bit DWORD
DW	Data width: 32, 64, or 128 bits
NF	Number of functions; 1 stands for one function
TLP	Transaction Layer Packet
DLLP	Data Link Layer Packet
VC	Virtual Channel
BAR	Base Address Register
XADM	Transmit application-dependent module.
RADM	Receive application-dependent module.
PMC	Power management controller.
RAMI	External RAM interface.
Core	Identifies the entire core. The core includes the native PCIe-core and AXI/AHB bridge if present.
Native PCIe core	Identifies the basic PCIe core which has its own non-standard, proprietary dedicated bus interface to the application.
CDM	Configuration Dependent Module This is an internal block in the native core that houses the PCI configuration registers and some user-accessible registers that reside in the core. In general, an application may use our core, but will add other registers that are unique to their applications. Those new application registers will be referred to as External Application Registers (EAR).
LBC	Local Bus Controller This is an internal block that resides in the native core. It allows the DBI interface (from the application side) or the wire side interface (via the radm_TRGT0 interface) to access the core's Configuration Dependent Module (CDM) registers and/or the External Application Registers (EAR). (For additional details on this module, please refer to the native core documentation.)
ELBI	External Local Bus Interface This is an interface on the native core that processes read/write access to the external application registers (EAR). For applications that require external registers, the application can access the EAR through the bridge or an entirely different interface (outside the scope of this core). (For additional details on this interface, please refer to the native core's documentation.)
DBI	Data Bus Interface This bus is internal to the native core. This interface is used to access the core's internal registers (CDM) or the external application's device-specific registers attached to the PCIe native core ELBI interface.
VMI	Vendor Message Interface.
Inbound traffic	PCIe transactions that enter the native core from the wire side of the core (PCIe wire). These transactions will be delivered to the application side.
Outbound traffic	Transactions that enter the native core from the application side of the core. These are passed to the native core, where they will be sent out onto the PCIe wire.
MTU	Maximum Transfer Unit Specifies the maximum packet payload size supported. This indicates the maximum allowed transfer size for a write or completion.
Page boundary	Specifies the address page boundary size supported by the bridge. No packet can have an address that crosses the specified address boundary.
big-endian	Data format in which most significant byte comes first; normal order of bytes in a word.

Table continues on the next page...

Table 46-1. Terms and Abbreviations (continued)

RBYP	Receive Bypass Interface
RTRGT1	Receive Target 1 Interface
RCPL	Receive Completion Interface
XALI0/1/2	Transmit Application Client Interfaces
SII	System Information Interface.
iATU	Internal Address Translation Unit.

46.2 Architecture

This information describes the architecture of the PCI Express core.

The topics for this section are:

- [Common Xpress Port Logic \(CXPL\)](#)
- [Transmit Application-Dependent Module \(XADM\)](#)
- [Receive Application-Dependent Module \(RADM\)](#)
- [Configuration-Dependent Module \(CDM\)](#)
- [Power Management Controller \(PMC\)](#)
- [Local Bus Controller \(LBC\) and Data bus Interface \(DBI\)](#)
- [Message Generation](#)
- [Debug and Diagnostics](#)

The Common Xpress Port Logic (CXPL) module implements the basic functionality for the PCI Express Physical, Link, and Transaction Layers. In addition to the CXPL, there are several top-level modules that provide the configuration and mode-specific features:

- [Transmit Application-Dependent Module \(XADM\)](#)
- [Receive Application-Dependent Module \(RADM\)](#)
- [Configuration-Dependent Module \(CDM\)](#)
- [Power Management Controller \(PMC\)](#)
- [Local Bus Controller \(LBC\) and Data bus Interface \(DBI\)](#)
- [Message Generation](#)

Figure 46-1. DM Core Block Diagram (with AXI Bridge Module)

NOTE

- Optional internal (iATU) and external (xATU) Address Translation Units/Interfaces not shown.
- Narrow arrows represent response signal paths to requests (broad arrows)
- In RC mode the ELBI pins are present but not operational.

For definitions of acronyms used for block and interface names, see [Terms and Abbreviations](#).

Table 46-2. Core Interface Summary

Interface	Function
Transmit Client 0 Interface (XALI0)	Transmit interface for outbound Request or Completion TLPs.
Transmit Client 1 Interface (XALI1)	Additional application transmit interface, identical to XALI0. The usage of XALI0 and XALI1 is up to the application. For example, an application may use XALI0 for Requests and XALI1 for Completions.
Receive Completion Interface (RCPL)/Bypass Interface (RBYP)	When the core is configured in single or multiple queue architecture, RCPL delivers Completions received by the core to the application client that requested them. When the core is configured in segmented buffer queue mode, Bypass delivers all transactions that are configured as bypass.
Receive Target 1 Interface (RTRGT1)	Delivers inbound Requests received by the core after the Requests are qualified by the filter rules of the core.
Data Bus Interface (DBI)	Delivers an RD/WR request from application logic such as EEPROM to internal registers of the core or application registers at ELBI.
Message Signaled Interrupt (MSI) Interface	Allows the application to request a transmission of an MSI independent from the client interfaces. MSI interface is used only in EP mode.
MSI-X Interface	Allows the application to request a transmission of an MSI-X independent from the client interfaces. MSI-X interface is used only in EP mode.
Vendor Message Interface (VMI)	Allows the application to request a transmission of a vendor message independent from the client interfaces.
System Information Interface (SII)	Exchanges system information between the core and the application.
PIPE	Standard PIPE interface between the PCI Express PHY and the core.
RAM Interface (RAMI)	Optional top-level interface to connect external RAMs for the retry buffer and receive queues. If you do not select the optional top-level RAMI, the RAMs reside inside the top-level hierarchy of the core.

46.2.1 Common Xpress Port Logic (CXPL)

The CXPL module implements a large portion of the Transaction Layer logic, all of the Data Link Layer logic, and the MAC portion of the Physical Layer, including the Link Training and Status State Machine (LTSSM).

The CXPL connects to the external PHY through the PIPE.

Important aspects of the CXPL and overall core implementation include:

- Layer 3 (Transaction Layer) functionality is split between the XADM, RADM, CDM, and CXPL.

- Layer 1(Physical Layer) is split across the PIPE such that the MAC functionality is in the core and the PHY functionality is implemented in the PIPE-compliant PHY.the PHY module resides outside of the core, interfacing through the standard PIPE.
- Receive and transmit path functionality is decoupled except where communication between the two is required (such as Flow Control and other low-level Link management functions).

CXPL contains six modules, three for transmission and three for reception, as shown in the figure below.

- RTLH: Receive Transaction Layer Handler
- XTLH: Transmit Transaction Layer Handler
- RDLH: Receive Data Link Layer Handler
- XDLH: Transmit Data Link Layer Handler
- RMLH: Receive MAC Layer Handler
- XMLH: Transmit MAC Layer Handler

CXPL is compliant with the PCI Express 3.0 Specification with regards to the physical layer, data link layer and transaction layer.

1. PCS soft logic and timing model for mixed signal PMA

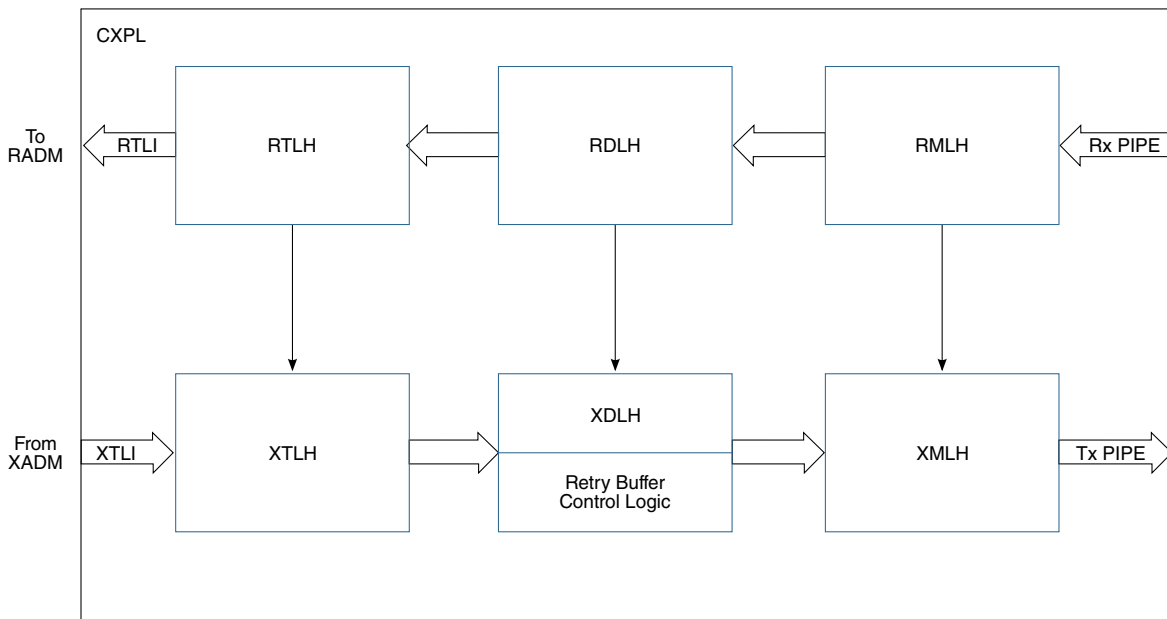

Figure 46-2. CXPL Module Block Diagram

46.2.2 Transmit Application-Dependent Module (XADM)

The XADM sits between the application logic and the CXPL core and implements the mode-specific functionality of the PCI Express Transaction Layer for packet transmission.

The figure below is a block diagram of the XADM. Its functions include arbitration, TLP formation, and credit checking.

The transmit path uses a cut-through architecture. It does not implement transmit buffering/queues (other than the retry buffer). Depending on system design, an externally-implemented transmit queue can be used to handle rate matching if the CXPL and application transfer rates are different. For relevant information on this in the context of using the AHB/ AXI Bridge as an application to the XADM.

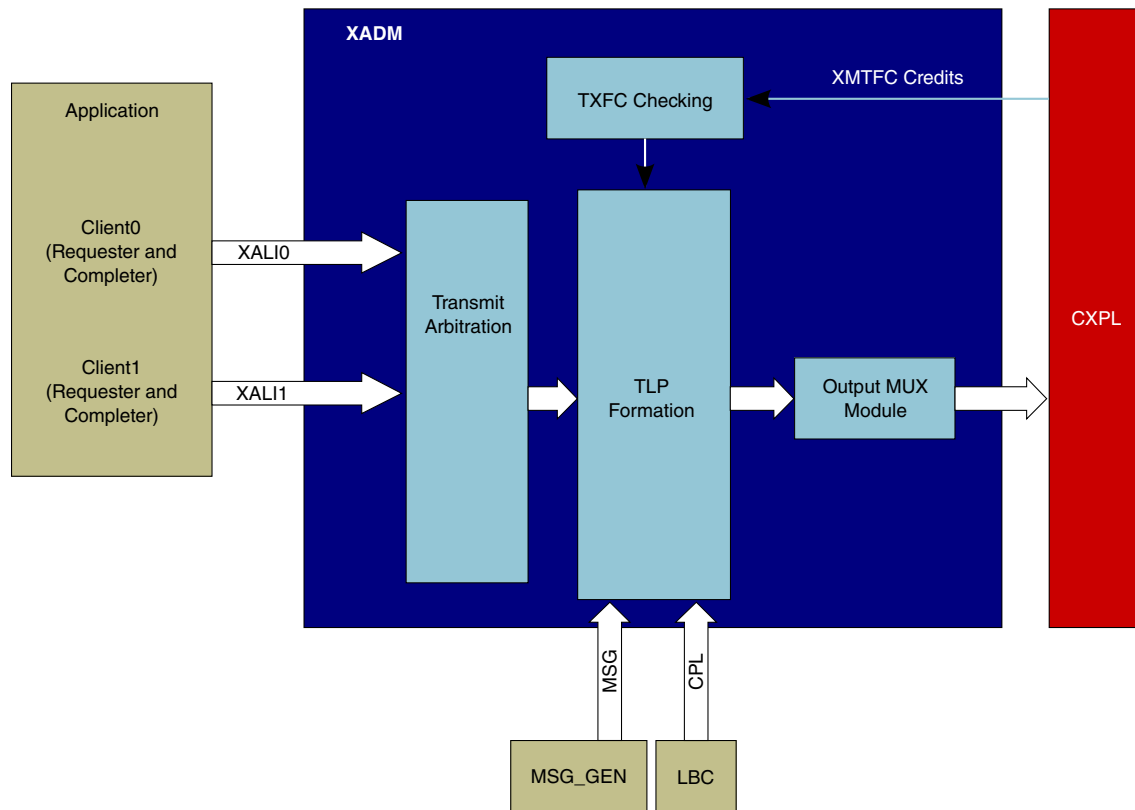

Figure 46-3. XADM Block Diagram

46.2.2.1 Arbitration

XADM provides the arbitration of TLP transmission between the following:

- The transmit client interfaces (XALI0, XALI1)
- Internally generated Messages from the MSG_GEN, triggered by PME, INTx (EP mode), errors, or application logic
- Internally generated Completions:
 - EP mode: Internally generated Completions are responses for type 0 Configuration Read and Write Requests from upstream components, memory or I/O-mapped application register space Read and Write Requests, or responses to error conditions (Unsupported Requests).
 - RC mode: Internally generated Completions are Unsupported Request or Completer Abort, as required by the incoming Request filtering function of the RADM.

In general, all internally generated TLP requests have higher priority than client interfaces.

For details about how the arbitration methods work and how to configure the arbitration methods, see [Transmit TLP Arbitration](#).

46.2.2.2 Credit Checking

The core checks that enough FC credits are available in the remote device for the specific type of transaction (P, NP, CPL) before allowing a transmission of a TLP. TLPs that passed the credit check are arbitrated according to the supported arbitration method. Internally generated Completions and Messages are also gated by the arbitration logic, though at highest priority, and must also pass the FC credit test before they are accepted for transmission.

46.2.3 Receive Application-Dependent Module (RADM)

The RADM sits between the application logic and the CXPL core and implements the mode-specific functionality of the PCI Express Transaction Layer for TLP packet reception.

The figure below shows a block diagram of the RADM. The RADM serves four major functionalities as following:

- Sort/Filter received TLPs
- Completion Lookup Table (CLT), which is used for Completion tracking and Completion timeout monitoring of transmitted Non-Posted requests.
- Provide queuing (or bypass) of the received TLP
- Output received TLP to the core's receive interface (Demux function)

The filtering rules and routing for all TLP receive options are configurable for all TLPs received.

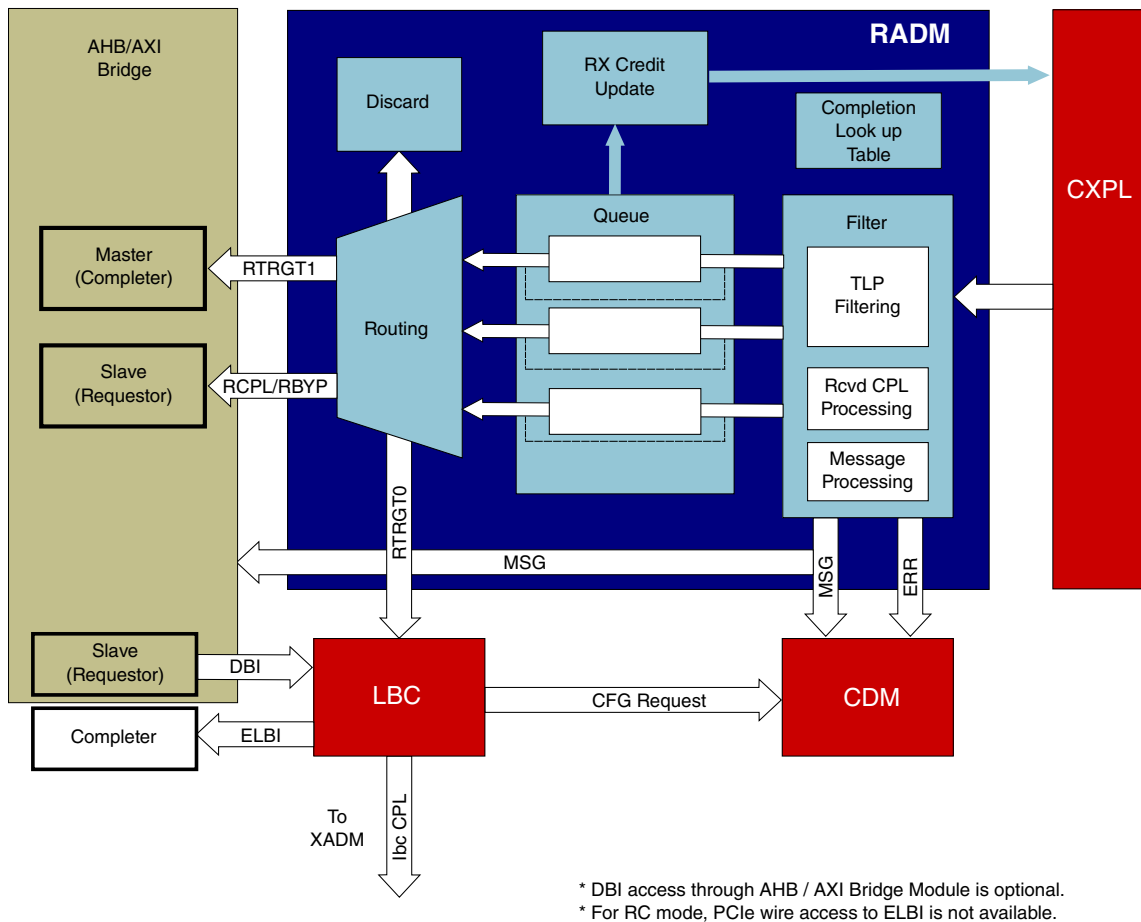

Figure 46-4. RADM Block Diagram

46.2.3.1 Posted and Non-Posted Request and Completion TLP Processing

The RADM filter passes the Posted and Non-Posted Request and Completion transactions (such as Write Transactions and Memory Reads) directly to the application through the RTRGT1 interface or to RTRGT0 for internal modules, as determined by the filtering and routing rules for the current operating mode, as described in [Receive Filtering](#).

The RADM filter segregates Posted and Non-Posted TLPs into valid supported and valid un-supported Requests, and forwards them to the queue. The filter processes each Request and determines each TLP's destination along with other controls that may be needed to generate TLPs.

For Requests that the core forwards to the RTRGT1 or Bypass interface, the application must process the Request and generate the Completion.

For Requests that the core forwards to RTRGT0, the core automatically generates the Completion. The core automatically executes any required ELBI access before generating the Completion.

46.2.3.1.1 TLP Routing

The RADM demux is designed to mux out a received TLP to the RTRGT1 and RCPL/RBYP interfaces from single queue or multiple queue (DM/RC/EP) configurations. The filter determines the destination and the action for each TLP, then sends this to the queue. The demux decides whether to discard or forward the TLP onto the RTRGT1, RTRGT0, RCPL or RBYP interfaces.

For more details see [Receive Routing](#) and [Queue to Port Mapping](#).

46.2.3.2 Received Completion TLP Processing

Received Completions are filtered against the completion lookup table content before presenting the Completion to the queue.

The RADM also implements a Completion time-out mechanism (via the Completion Lookup Table) and notifies the application when an expected Completion-corresponding to a transmitted Non Posted TLP-does not arrive within a specified time.

The Completion Lookup Table (and Completion Timeout event) should not be confused with the Target Completion Lookup table (and Target Completion Timeout event) .

The Target Completion Lookup Table is watching for received application completions (on XALI0/1) corresponding to previously received Non Posted requests.

The Completion Lookup Table is watching for received PCIe completions corresponding to previously transmitted Non Posted requests.

Typically, infinite Completion credits are advertised and the received completion is configured in bypass mode which means that there is no queue in the core to store completions.

NOTE

It is fully expected that the application will have enough buffering space ready for its requests, so no backpressure mechanism is needed. By default, the Completion queue operates in bypass mode.

Completions can be configured in store and forward mode if the application has chosen to do so. If a completion lookup has failed or other completion filtering has failed, the core will assert an abort signal at the end of the transaction. If the core is configured to have Completions in bypass mode, it is the application's responsibility to roll back any actions at the application's queue when an abort signal is asserted. If the core is configured with Completions enqueued, the Completion will be discarded by the core and flow control credits will be updated, as necessary, when an abort signal is detected.

46.2.3.3 Message Processing

The RADM filter provides a Message interface (grouped as part of the SII) to handle the Message TLPs received from the upstream component. The RADM filter processes the Message and decodes the header before sending it to the application logic on the SII. You can also select a configuration option to send the entire Message TLP to the application in addition to providing the decoded Message on the SII. For more details see [Message Reception](#).

46.2.4 Configuration-Dependent Module (CDM)

The CDM implements the standard PCI Express configuration space and the core-specific register space. The CDM also requests the Message generation module to send Messages, as required, including MSI and interrupts.

The specific PCI Express configuration structures implemented in the CDM include the following:

PCI-Compatible Configuration Registers

- RC mode: Type 1 header
- EP mode: Type 0 header

PCI Capability Structures:

- PCI Power Management Capability Structure
- MSI Capability Structure

- MSI-X Capability Structure
- VPD (Vital Product Data) Capability

PCI Express Capability Structure

PCI Express Extended Capabilities:

- Advanced Error Reporting Capability
- Virtual Channel Capability
- Device Serial Number Capability
- Power Budgeting Extended Capability

The configured device type (determined by the device_type[3:0] input signal) affects the behavior of the Message generation engine, error reporting mechanism, as well as some PCI Express configuration space registers.

The CDM communicates with application's host bus controller through the DBI. The host bus controller controls accesses to registers within each CDM in multiple instances of the core in a multi-port design.

46.2.5 Local Bus Controller (LBC) and Data bus Interface (DBI)

This following topics are covered in this section:

- [Overview \(LBC\)](#)
- [ELBI](#)
- [CDM Register Space Layout](#)
- [PCI Configuration Header and Capability Registers \(in CDM\)](#)
- [Port Logic \(PL\) Registers \(in CDM\)](#)
- [PCIe Wire Access \(EP mode\)](#)
- [PCIe Wire Access \(RC mode\)](#)
- [DBI Access](#)
- [LBC/DBI Feature Availability](#)
- [LBC/DBI Size Limitations](#)
- [AXI DBI Limitations](#)

46.2.5.1 Overview (LBC)

The LBC module provides a mechanism for a link partner PCIe device (in EP mode only) or a local CPU (through the DBI) to access internal registers (in the CDM) .

NOTE

In RC mode:

The application can access CDM registers through the DBI.

PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

Figure 46-5 shows the location of the LBC within the PCIe core and its role in routing transactions.

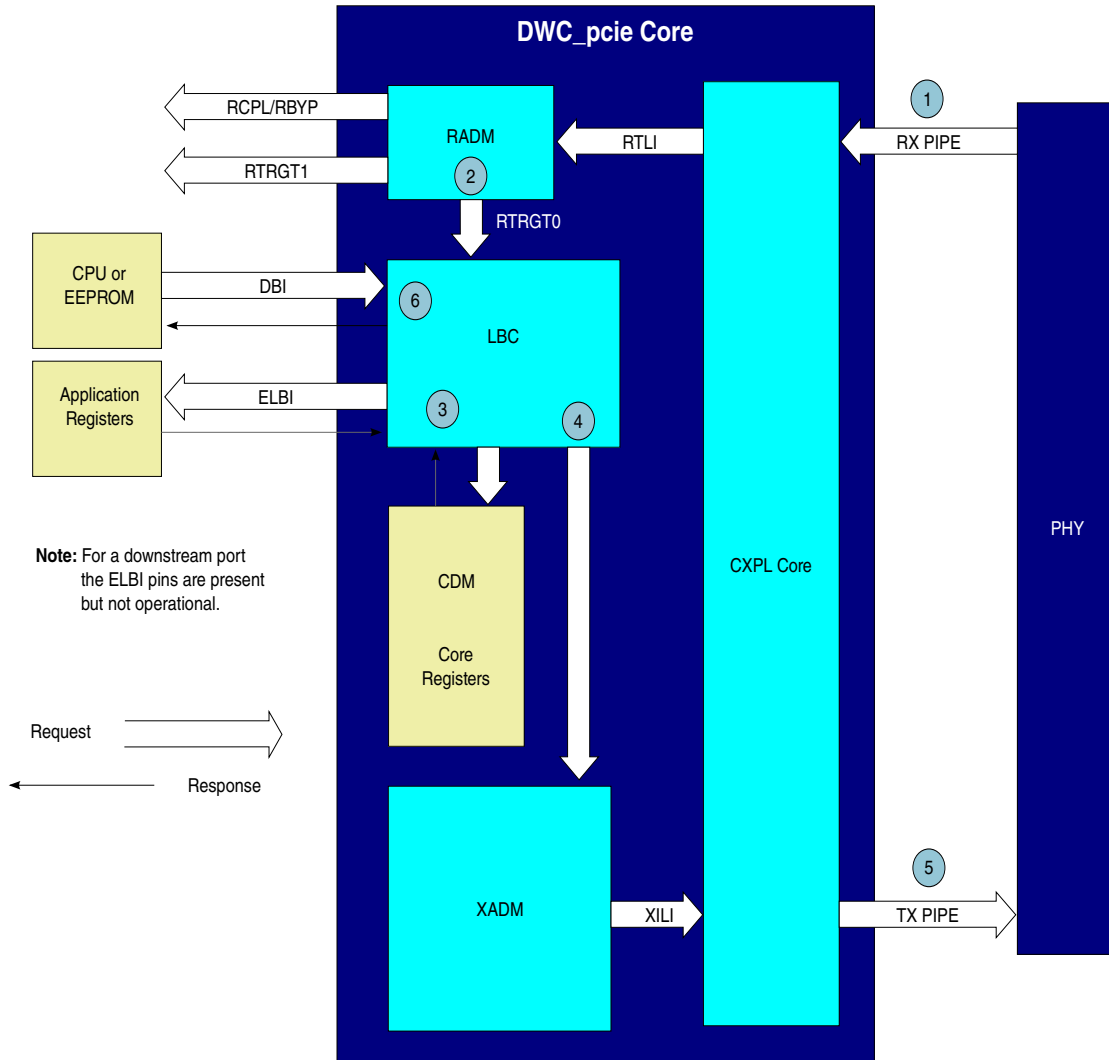

Figure 46-5. LBC Context

The LBC provides a Switched access function to internal registers (in the CDM) from the local application processor (CPU) via the DBI or the remote application software (off the PCIe RX wire) via RTRGT0. Figure 46-6 illustrates the four possible request paths through the LBC.

For more information on the filtering and routing of received inbound TLPs, see [Receive Routing](#).

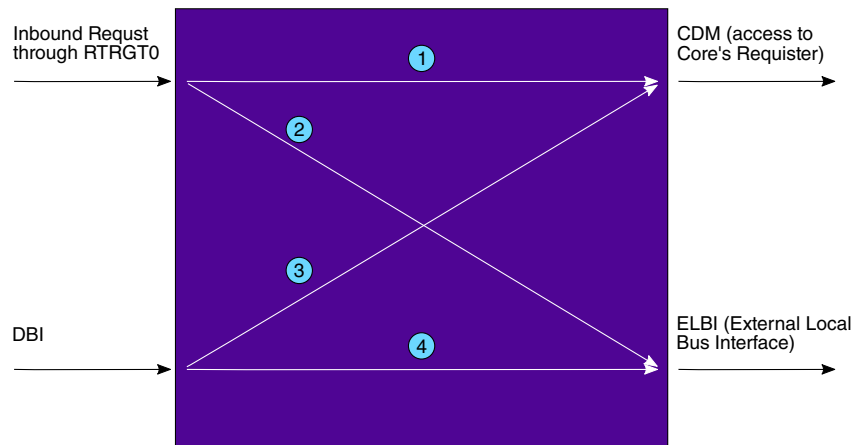

Figure 46-6. LBC Switch

NOTE

In RC mode PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

46.2.5.1.1 Simultaneous Transactions

The LBC is single-threaded and therefore, the DBI and RTRGT0 cannot use the LBC at the same time. For example, a request on the DBI will not be accepted, during a RTRGT0 transaction, until both parts of that transaction - [1] request and [2] response (completion generation) - are completed.

If the DBI and RTRGT0 present a request at the same time (regardless of the target/destination of each request), then the LBC will grant access to the RTRGT0.

46.2.5.2 ELBI

You can connect external application registers to the ELBI. These can be accessed by PCIe request TLPs over the PCIe link or by the DBI.

NOTE

In RC mode PCIe wire access (through RTRGT0) to the ELBI is NOT possible.

46.2.5.3 CDM Register Space Layout

The core has 4096 bytes of PCI Express configuration space per function distributed as per the figure below. This address space is fully accessible from the DBI without any restrictions.

In EP mode it can be accessed from the PCIe wire using CFG requests. Under certain configurations, the Port Logic and ELBI Register spaces can also be accessed from the PCIe wire with MEM and IO requests.

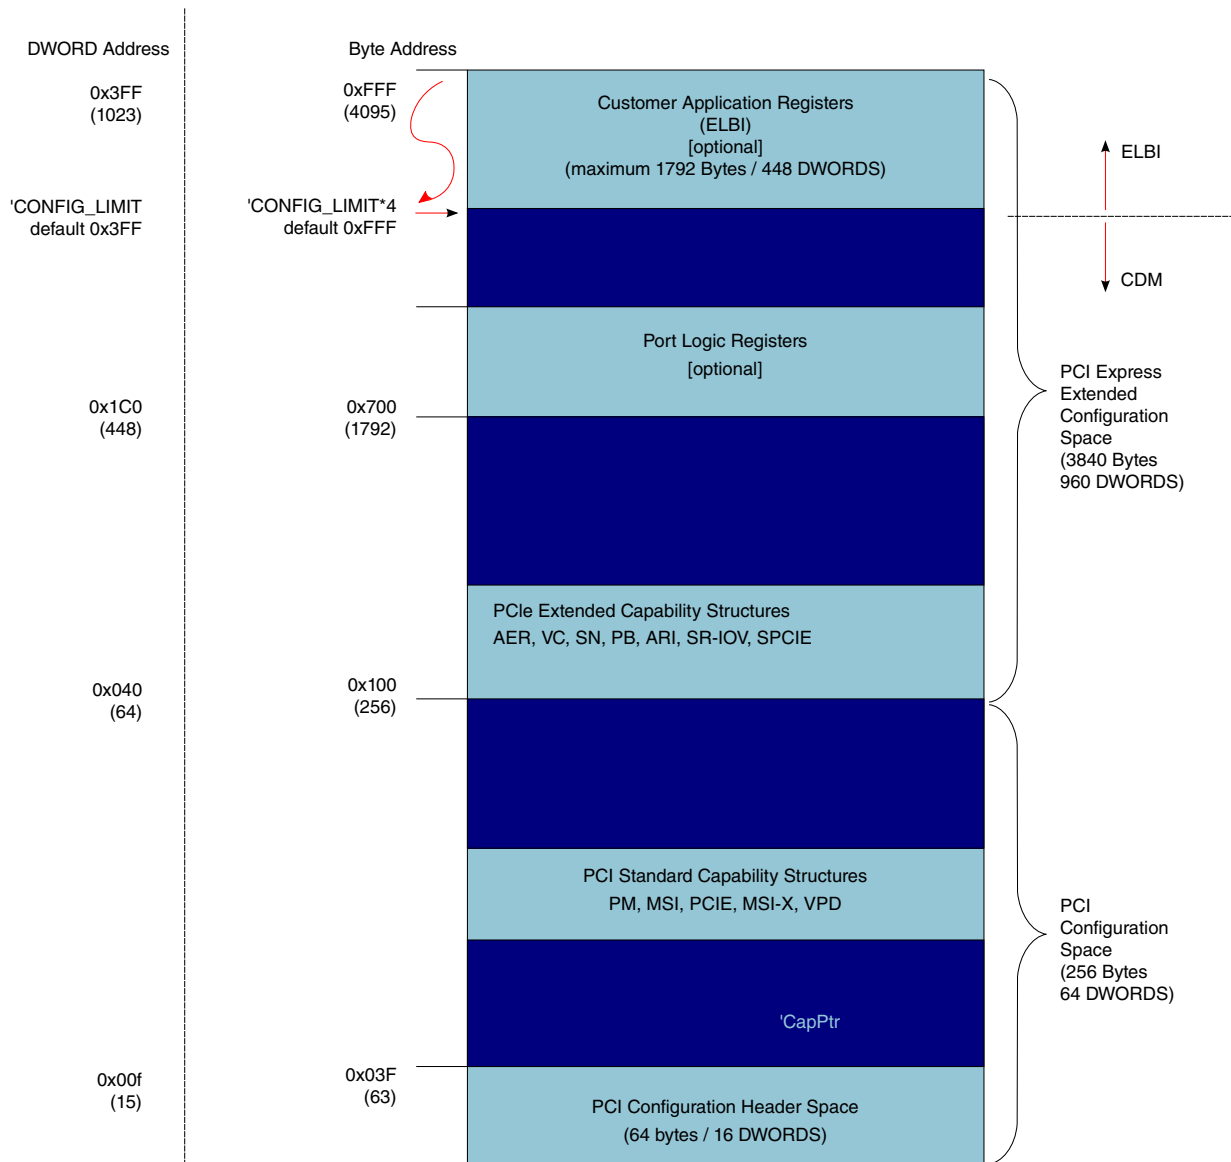

Figure 46-7. PCIe Core Configuration Space Address Map (per function)

A CFG TLP has a 6-bit Register Number Field and a 4-bit Extended Register Number field allowing 1024 DWORDS (4096 bytes) to be accessed.

46.2.5.3.1 PCI Configuration Header and Capability Registers (in CDM)

The PCI Configuration Header and Capability Registers in [Figure 46-7](#) are PCIe core configuration registers specified by the PCI Express 3.0 Specification. Access from the PCIe wire is possible with CFG requests (in EP mode only).

These registers are fully accessible from the DBI without any restrictions.

NOTE

From the PCIe wire (through RTRGT0) in EP mode only:

You can Memory-Map the Port Logic (PL) Register Space.

You cannot Memory-Map the PCI and PCIe Configuration Register Spaces. You must always access them with a CFG request.

NOTE

In RC mode:

PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

NOTE

From the DBI:

You can access without any restriction the Port Logic (PL) Register Space.

You can access without any restriction the PCI and PCIe Configuration Register Spaces.

46.2.5.3.2 Port Logic (PL) Registers (in CDM)

The Port Logic Registers in [Figure 46-7](#) are PCIe core configuration registers not specified by the PCI Express 3.0 Specification, but are specific to the configuration and operation of the PCIe IP core.

In EP mode, access from the PCIe wire is with CFG requests. There is no access from the PCIe wire in RC mode. These registers are fully accessible from the DBI without any restrictions.

46.2.5.3.3 Memory Mapping PL Registers

Port Logic Registers (which by default are accessed by CFG requests) can also (at the same time) be accessed by MEM requests through the use of the `ENABLE_MEM_MAP_PL_REG`, `PL_FUNC_NUM` and `PL_BAR_NUM` configuration parameters. These can be used to map the Port Logic Registers to any BAR of any function.

All MEM requests that match `PL_BAR_NUM` (when `ENABLE_MEM_MAP_PL_REG=1`) and whose address offset is in the range `0x700-0x8FF` will be routed to the Port Logic Registers.

NOTE

The BAR corresponding to `PL_BAR_NUM` must also be mapped/assigned to `RTRGT0`.

46.2.5.4 PCIe Wire Access (EP mode)

By default¹, CFG requests are routed to `RTRGT0` and then to CDM via LBC.

By default, BAR-matched MEM/IO requests are routed to `RTRGT1`.

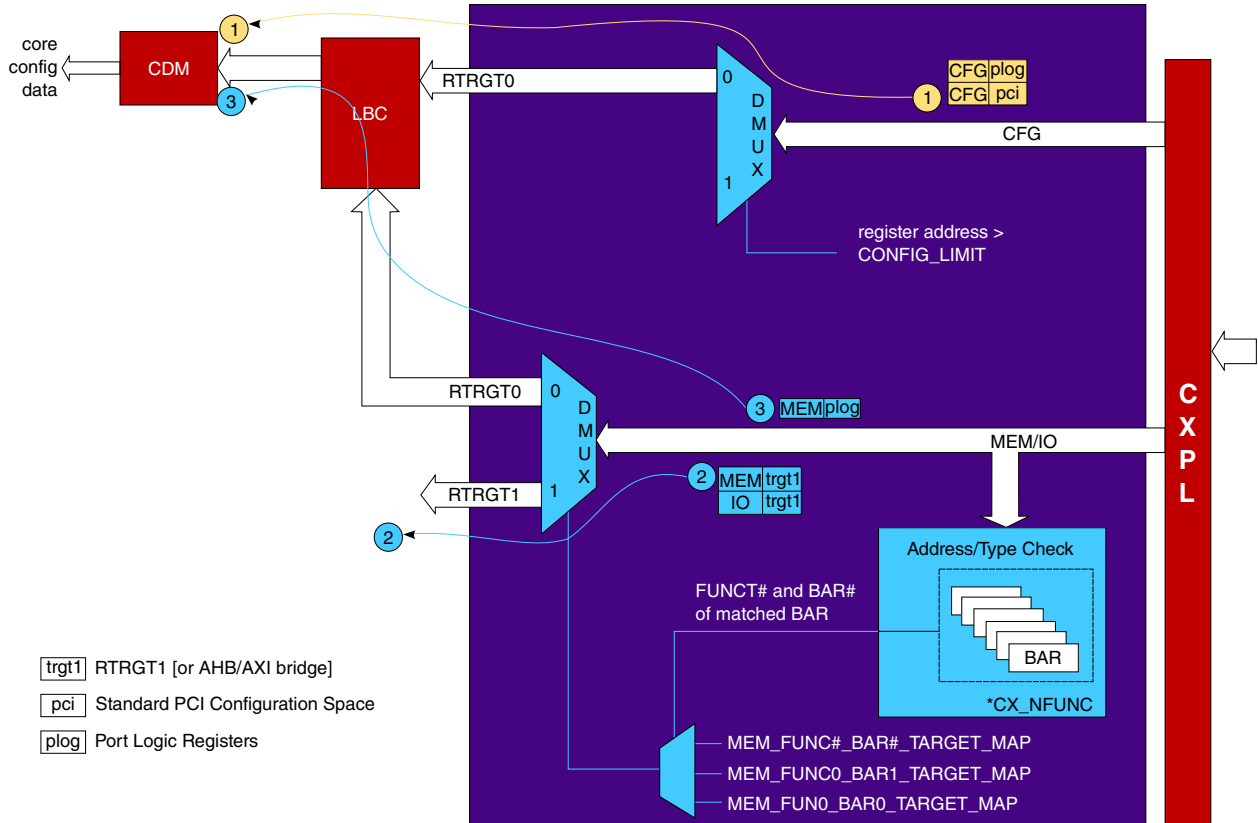

Figure 46-8. Request TLP Routing - Typical Use Model

Looking in detail at the typical routing of inbound PCIe requests (the numbers refer to the paths identified by the circled numbers in the above diagram).

CFG requests—either to Standard PCI Configuration Space or Port Logic Registers—are always routed to the CDM. This is because CONFIG_LIMIT by default is set to 0x3FF (top of the CFG register address space).

BAR-matched MEM/IO requests are routed to RTRGT1. MEM_FUNC#_BAR#_TARGET_MAP for each enabled BAR is set by default to RTRGT1.

Port Logic Registers (which by default are accessed by CFG requests—see [1] above) can also be accessed by MEM requests through the use of the ENABLE_MEM_MAP_PL_REG, PL_FUNC_NUM and PL_BAR_NUM configuration parameters. These can be used to map the Port Logic Registers to any BAR.

To see all routing possibilities, refer to [Receive Routing](#).

46.2.5.5 PCIe Wire Access (RC mode)

To see all routing possibilities, see [Receive Routing](#).

NOTE

In RC mode the application can access CDM registers through the DBI.

PCIe wire access (through RTRGT0) to the CDM registers is NOT possible.

46.3 Core Operations

This section describes the operations of the PCI Express core.

46.3.1 Initialization

Immediately after reset the DM core goes into either EP mode or RC mode depending on the state of the `device_type` input.

The internal configuration registers in the CDM assume their default reset values as listed in the following sections:

- [PCIe Registers \(EP mode\)](#)
- [PCIe Registers \(RC mode\)](#)
- [PCIe Registers: Port Logic](#)

The application must keep the `app_ltssm_enable` signal deasserted after reset until the application is ready to establish a Link and start receiving and transmitting TLPs. If the application needs to update configuration registers in the CDM as part of the initialization process, then the application must keep `app_ltssm_enable` deasserted until it has programmed all the necessary configuration registers through the DBI.

After initializing the necessary configuration registers, the application can assert `app_ltssm_enable` to allow the LTSSM to begin Link establishment. The LTSSM begins Link negotiation after the `core_rst_n` and `phy_mac_phystatus` signals are deasserted and `app_ltssm_enable` is asserted.

Core Operations

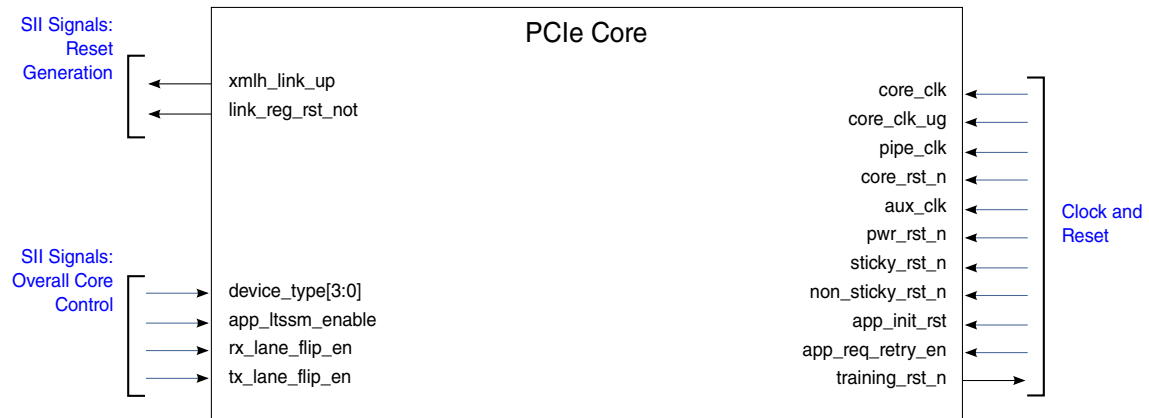

Figure 46-9. I/O Interfaces involved in Initialization

Figure 46-10. PCI Express Initialization Steps

46.3.2 Link Establishment

The core and a PCI Express compliant PHY combine to provide a complete solution for setting up and maintaining a compliant PCI Express Link.

The core implements the LTSSM function according to the *PCI Express 3.0 specification*.

In general, the process for establishing a Link is as follows:

1. Upon power-up (or directly out of reset), it is assumed that the power supply becomes stable and the PLLs reach frequency lock before the devices attempt to establish a valid Link. Once in a valid state, the SerDes either communicates a ready status to the core or simply begins transmitting and receiving valid data.
2. Per the *PCI Express 3.0 specification*, once bit and symbol synchronization are complete, the core initiates the following sequence to establish a Link (assuming a valid and properly functioning Link partner):

Receiver detection on available Lanes for the Port.

Exchange of Training Sequences to determine Link configuration (for example, Link speed, number of Lanes, and order).

Once both partners reach a valid negotiated state, the Link state is set up and the LTSSM is in L0.

1. Once Link up is achieved, the data link modules take over to manage the Link and initialize Flow Control.
2. After Flow Control initialization is complete, the data link modules signal the transaction layer modules that the link is ready to allow transmission/reception of TLP traffic.
3. During normal operation, the LTSSM and data link modules continue to manage the underlying Link integrity while data traffic is communicated across the PCI Express Link.

NOTE

The power management implementation also affects Link establishment.

46.3.3 Transmit TLP Processing

Information found here describes the flow of transmit TLPs through the core.

The topics for this section are:

- [Transmit Overview](#)
- [Transmit TLP Arbitration](#)
- [Transmit Retry](#)
- [Transmit DLLP Priorities](#)

It may helpful to first review the following sections: [Common Xpress Port Logic \(CXPL\)](#) and [Transmit Application-Dependent Module \(XADM\)](#).

46.3.3.1 Transmit Overview

Generally, all types of transmit TLPs (Posted, Non-Posted, and Completion) generated by the application travel through the core in the following flow:

1. The application presents a transaction transmission request with header information and payload (if applicable) on one of the transmit client interfaces (for example, XALI0).
2. The XADM forms the transaction into a TLP and checks the TLP against the current Flow Control credit availability. If the TLP passes the Flow Control checks and wins the arbitration with TLPs from the other the client interfaces, then the TLP goes to the CXPL.
3. The XTLH module inserts an ECRC (if applicable) and snoops/stores the necessary TLP information for Completion lookup (for Non-Posted requests only).
4. The XDLH inserts the Sequence Number and LCRC into the TLP and the retry buffer stores the TLP.
5. The XMLH inserts start and end delimiters and performs data scrambling.
6. The XMLH presents the packet to the PHY through the PIPE interface.
7. The PHY receives the packet, performs 8b10b encoding, and serialization, then sends the packet for transmission on the Link

The core does not check for TLP errors; instead it sends the TLP as presented on the XALI interface.

The native PCIe core does not check that the TLP payload size is less than the 'Maximum Payload Size' limit. However, the AXI bridge module does guarantee that this limit is not exceeded.

The native PCIe core does not check that the TLP payload size is less than CX_MAX_MTU limit. Exceeding this limit will overflow the retry buffer, resulting in data corruption. However, the AXI/AHB bridge module does guarantee that this limit is not exceeded.

46.3.3.2 Transmit TLP Arbitration

The transmit arbitration mechanisms supported by the core are as follows:

- Client-based round robin arbitration
- Strict priority client-based arbitration
- VC-based priority arbitration

To configure the transmit arbitration algorithm, use the 'Transmit Arbitration Method' configuration parameter (`^CX_XADM_ARB_MODE`).

Regardless of the transmit arbitration method selected, Messages (both internally-generated and Messages requested through the VMI) always have the highest priority, followed by internally-generated Completions. The priority order for all transmitted TLPs is:

1. Internally generated Messages
2. Internally-generated Completions
3. Transmit TLPs from Client0, Client1, and Client2 according to the selected arbitration method

46.3.3.2.1 Client-Based Arbitration

When you configure the core to use client-based arbitration (`^CX_XADM_ARB_MODE = 1`), the XADM uses round-robin arbitration between the two transmit client interfaces.

46.3.3.3 Transmit Retry

There is a Retry Buffer (RB) in the core that stores a copy of each transmitted TLP until an Ack is received. The RB consists of two buffers: retry buffer and start-of-TLP (SOT) buffer.

NOTE

The Retry Buffer does not function as a transmit queue. The core transmits TLPs immediately after they pass arbitration. The copy in the Retry Buffer is only sent in the event that the TLP must be re-transmitted.

The retry buffer is implemented with a single port RAM. The depth of the retry buffer is selected during hardware configuration either by enabling automatic buffer sizing or by setting the depth explicitly. The retry buffer width is set automatically (data bus width plus extra control bits).

The selected retry buffer size determines the size of the SOT buffer. The SOT buffer stores the starting address of each unacknowledged TLP stored in the retry buffer. The SOT buffer is implemented with a single port RAM and is indexed by the Sequence Number of the TLP whose starting address is being stored or retrieved.

The minimum depth of the SOT buffer is also a user configuration option. The selected size must allow the retry buffer to store the maximum number of shortest TLPs (3 DWORDs).

When a Nak is received or the replay timer times out, a replay is initiated. A replay is terminated by two conditions:

- When the replay of all TLPs in the retry buffer is finished, or
- An Ack DLLP is received that acknowledges all TLPs in the retry buffer

The replay timer tracks the TLP replay time. It stays at 0 when every TLP has received an Ack and starts to count when a TLP is transmitted and the LTSSM is not in the training state. The replay timer is reset to 0 when an Ack or Nak is received that acknowledges a TLP that is in the retry buffer.

46.3.3.4 Transmit DLLP Priorities

The order of priority to transmit pending DLLPs is:

1. High-priority DLLPs
2. TLPs
3. Low-priority DLLPs

46.3.4 Receive TLP Processing

The information found here describes the flow of receive TLPs through the core.

46.3.4.1 Receive Overview

It may helpful to first review the following sections: [Common Xpress Port Logic \(CXPL\)](#) and [Receive Application-Dependent Module \(RADM\)](#).

Generally, received transactions travel through the core in the following flow:

1. The PHY receives a stream of bits and aligns/forms them into 10-bit symbols (Gen1/2)
2. The PHY decodes the 10b stream into an 8b stream (Gen1/2)
3. The PHY crosses the clock domain from RX to TX and presents the stream to the PIPE.
4. The RMLH descrambles and deskews the incoming data, checks for receiver (Gen1/2) then extracts packets.
5. The RDLH strips off the LCRC and Sequence Number.
6. The RTLH strips off the ECRC (if applicable), checks for a malformed TLP, and forms a transaction across the RTLI interface to the RADM.

7. The RADM filters the transaction based on the transaction type (Posted, Non-Posted, or Completion) and the rules described in Receive Filtering.
8. Filtered transactions are sent to RADM queues.
9. Transactions residing in the RADM queues are presented to the application or locally handled by the LBC module, depending upon the filter result

46.3.4.2 Receive Filtering

The core contains a filter module that is responsible for the tasks listed here.

- Determine the status of a received TLP using filtering rules.
- Determine the destination interfaces of a received TLP based on the status from applying the filter rules.
- Signal the application for the status of the received TLP by driving signals such as DLLP abort, TLP abort and ECRC error.

The core filters and routes received TLPs according to a set of rules determined by the TLP type based on the *PCI Express Base 3.0 Specification* and user-configurable filtering options. The filtering rules for a received TLP are affected by I/O signals (run-time options), and register values (run-time options).

The application can mask some of the filtering and error handling rules by setting the corresponding bits in Symbol Timer Register and Filter Mask Register 1 and Filter Mask Register 2.

There are three types of the filtering rules in the core:

- 3.4.2.1: rules that are applicable for all TLP received
- 3.4.2.2: rules that are dependent on the type of the TLP based on PCIe specification
- 3.4.2.3: rules that are not from the PCIe specification but requested by specific applications.

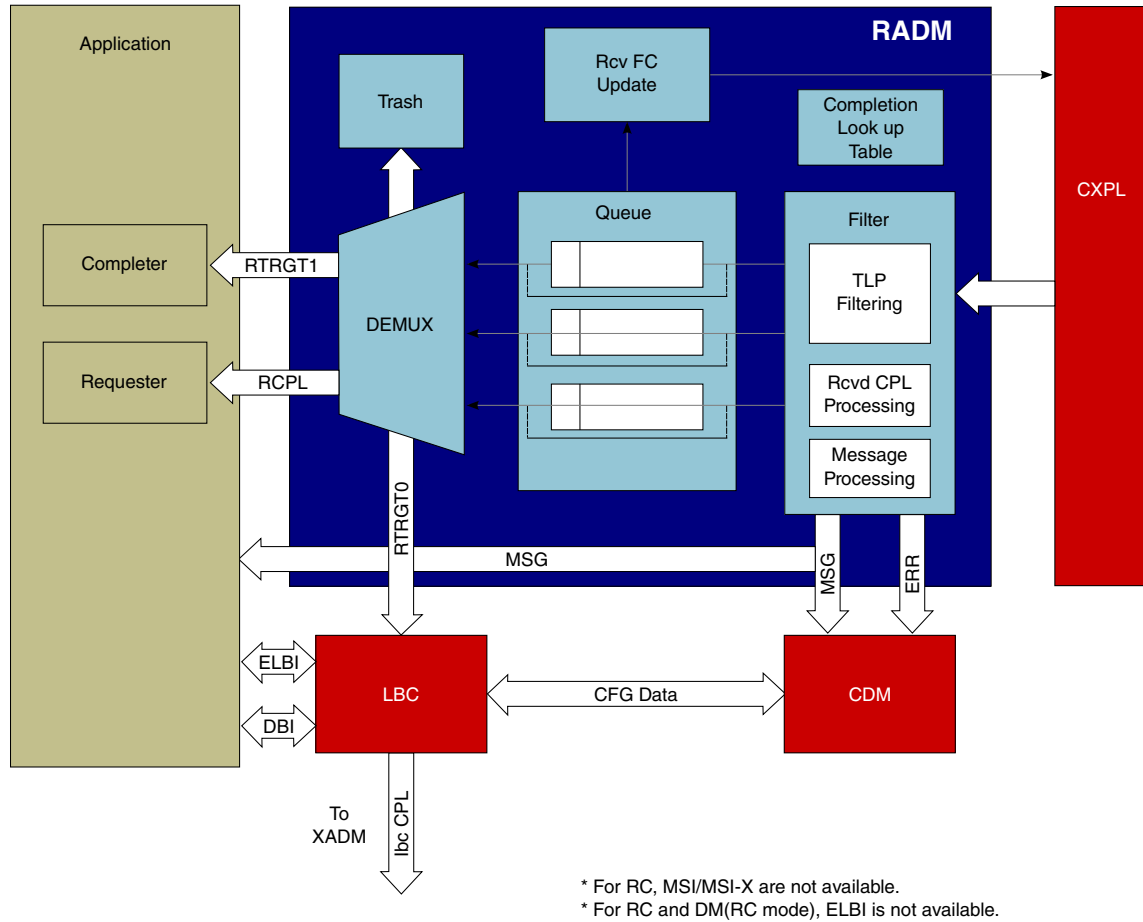

Figure 46-11. RADM Block Diagram

46.3.4.2.1 Filtering Rules Applicable for all TLPs Received

The general rules listed here apply to all incoming TLPs.

- The core discards all incoming TLPs that have an invalid Type field. This TLP is treated as a 'TLP ABORT'.
- By default, a request TLP with the poison bit set (EP=1) is considered an Unsupported Request (UR) and discarded, as the poison rule mask bit (CX_FLT_MASK_UR_POIS) is not set in the Symbol Timer Register and Filter Mask Register 1. You can control the end result of a poisoned TLP by setting this mask bit, and having the poisoned TLP sent to your application.
- A locally terminated TLP with ECRC error detected is discarded in store-and-forward mode and an ECRC error reported only when the filter mask CX_FLT_MASK_ECRC_DISCARD bit is not set. For more information see [ECRC Handling](#).
- Filter rules have no effect on received TLPs when 'DLLP ABORT' signal is asserted.

- If a completion of a non-posted request is not received within a completion timeout period, this request will be treated as a completion timeout, and a non-advisory error will be reported.
- For messages to be accepted and decoded, the incoming Message must be one of the valid Message types with the correct payload length based on *PCIe 3.0 Specification*. Valid Messages will be decoded and passed onto the SII interface as necessary.

See [Error Handling](#) for more details.

The filtering rules for an incoming Request TLP are affected by the configuration parameters (compile-time options), I/O signals (run-time options), and register values (run-time options).

NOTE

In many cases, the standard filtering rules may be 'masked' or ignored by setting the corresponding bit in the Symbol Timer Register and Filter Mask Register 1 and Filter Mask Register 2, which take their default values from the `DEFAULT_FILTER_MASK_1` and `DEFAULT_FILTER_MASK_2` configuration parameters.

46.3.4.2.2 Filtering Rules Based on TLP Type Defined in PCIe Specification

PCIe TLPs are categorized as Requests and Completions. The table found here describes the filtering rules for Request and Completion TLPs and the results of the core's filter.

If a received TLP passes all of the filter rules for Request and Completion TLPs, then it is considered to have no errors, and the TLP will be routed to the destination that is configured. Details on routing are provided in Receive Routing.

Notation of filter results:

1. UR = Unsupported Request

CA = Completer Abort

CRS = Configuration Request Retry Status

SU = Successful

UC = Unexpected Completion

MLF = Malformed

'-' = Filtering rule does not apply to TLP type

MA = Master Abort

TA = Target Abort

46.3.4.2.2.1 EP MODE FILTERING RULES**Table 46-3. Result of Filtering Rules Applied to Request TLPs and Completion (CPL) TLPs: EP Mode**

Filtering Rule	TLP Type					
	MRd IORd	MWr IOWr	CFG	MSG	CPL with UR/CA/ CRS status	CPL with SU status
PowerState is not in D0.	UR	UR	SU	SU	UC	UC
Address is not within any configured Memory BAR or IO BAR if it is an IO request.	UR	UR	-	-	-	-
TLP header poison bit is set and the filter mask CX_FLT_MASK_UR_POIS bit is not set.	UR	UR	UR	UR	SU	SU
Address within a BAR that is configured to RTRGT0 and TLP DW length > 1.	CA	CA	-	-	-	-
MRd with lock and filter mask CX_FLT_MASK_LOCKED_RD_AS_UR bit is not set.	UR	-	-	-	-	-
The function number of a completer ID within a CFG request does not match an implemented function within the receiver device and the filter mask CX_FLT_MASK_UR_FUNC_MISMATCH bit is not set.	-	-	UR	-	-	-
Configuration type1 TLP request and the filter mask CX_FLT_MASK_CFG_TYPE1_REQ_AS_UR is not set.	-	-	UR	-	-	-
Application requests the core filter to return CRS by asserting signal app_req_retry_en.	-	-	CRS	-	-	-
Not Valid Message for EP device	-	-	-	UR/MLF	-	-
Illegal payload length of a message.	-	-	-	UR	-	-
Vendor MSG Type0 with filter mask CX_FLT_MASK_VENMSG0_DROP bit not set.	-	-	-	UR	-	-

1. DM (in RC mode) should not expect to receive a CFG or IO request.

46.3.4.2.3 Filtering Rules Not Defined in PCIe Specification

There are additional filtering rules that are designed to provide enhanced filter support for certain applications.

- Core to handle the received posted or non-posted requests with zero byte length. When a zero-byte request TLP is received, also called "flush" command, the core can drop¹ the zero-byte request. This is designed to support some applications that can not handle a zero-byte request. Applications can dynamically program a bit in the filter mask CX_FLT_MASK_HANDLE_FLUSH bit to turn on/off this rule. If the core is programmed to handle the flush, it will be the completer's task to return completion status.
- Core to detect oversize read request and return UR for the read request. Some applications may have a buffer limit and are not able to handle lengthy read requests. The core over-size read request detection rule can be turned on when an application can identify a maximum read request size that it can tolerate.

46.3.4.3 Receive Routing

46.3.4.3.1 EP Mode

The possible destinations of a posted or non-posted Request TLP are RTRGT1 interface, RTRGT0 interface and Core Discard (dropped¹ or terminated). By default:

- CFG requests are routed to RTRGT0 and then to CDM via LBC.
- BAR-matched MEM/IO requests are routed to RTRGT1.
- MSG requests are decoded internally, signalled on the SII interface and then terminated.

Figure 46-12. Default Request TLP Routing (assuming no TLPs with CA/CRS/UR completion status)

The possible destinations of a Completion TLP are RCPL interface, RBYP interface, RTRGT1 interface, and Core Discard.

In general, a TLP type that is configured as bypass will be sent to either the RBYP interface, or RCPL interface if it is a completion. A TLP type that is configured as a cut-through or store-forward will be sent to RTRGT1 interface.

Because the core supports three types of queue architecture (single queue, multiple queue, segmented buffer queue architecture) and three buffer modes (bypass, cut-through, store-forward mode), a configuration of the core receive queue structure will affect the destination of a received TLP.

NOTE

By default, all Configuration Requests that pass filtering go to RTRGT0 for configuration register access. However, the application can configure the core to direct certain

configuration TLPs to the RTRGT1 interface - see [PCIe Wire Access \(EP mode\)](#) for more details. The application is responsible for generating Completions for Configuration Requests that are routed to RTRGT1.

Figure 46-13. Configurable Request TLP Routing (assuming SC completion status).

46.3.4.3.2 RC mode

The possible destinations of a posted or non-posted Request TLP are RTRGT1 interface and Core Discard (dropped or terminated). By default:

- MEM requests outside of the memory range AND prefetchable memory range as determined by the corresponding Base and Limit fields in the Type-1 header, are routed to RTRGT1.
- MSG requests are decoded internally, signalled on the SII interface and then terminated.

- An RC does not expect to receive CFG or IO requests.
- BARs should be disabled and not used.

The possible destinations of a Completion TLP are RCPL interface, RBYP interface, RTRGT1 interface, and Core Discard.

In general, a TLP type that is configured as bypass will be sent to the RBYP interface. A TLP type that is configured as a cut-through or store-forward will be sent to RTRGT1 interface. Because the core supports three types of queue architecture (single queue, multiple queue, segmented buffer queue architecture) and three buffer modes (bypass, cut-through, store-forward mode), a configuration of the core receive queue structure will affect the destination of a received TLP.

46.3.4.3.3 ECRC Handling

The setting of the `CX_FLT_MASK_ECRC_DISCARD` bit (default value is 0) in the Symbol Timer Register and Filter Mask Register 1 can be used to prevent an ECRC contributing to a CA status and thereby preventing all associated downstream effects such as error handling.

By default, all incoming IO or MEM requests with UR/CA/CRS status will be dropped/terminated and an Advisory Non-Fatal Error is signalled. For Non Posted (NP) requests, a CPL with CA is generated. See [Advisory Non-Fatal Error Messages](#).

If you set the `DEFAULT_TARGET` parameter to 'Forward' (default is 'Drop'), then all incoming IO or MEM requests with UR/CA/CRS status will not be dropped but will be forwarded to the application. Setting `CX_MASK_UR_CA_4_TRGT1` (default is 0) at the same time, will suppress error reporting for TLPs (with UR/CA status) that are being routed to the application on AXI Bridge master.

A completion TLP with ECRC errors is only dropped by the RADM in the native core when CPL queue mode is store-forward and queue architecture is single or multiple queue. See [Completion TLP Routing Rules](#) for more details.

46.3.4.3.4 Request TLP Routing Rules

The next table shows the applicability of routing rules for Request TLPs, and indicates whether the destination is as stated by the rule when the conditions of the rule are met.

By default all error-free MSG requests are decoded internally, signalled on the SII interface and then terminated. To have the decoded message *also* sent to the application/AMBA interface then see [Routing of Received Messages to SII and optionally to](#)

Application. When a MSG request is filtered with UR/CA/CRS status, the TLP is always terminated. Only MSG requests filtered with SC status, can potentially be forwarded to the application.

For a full analysis of what error conditions contribute towards an UR or CA status, see **Receive Filtering**. For example, an ECRC error contributes towards a CA status whereas an UR status can be generated by detecting the EP bit set in the TLP header or having an IO/MEM request not match against any of the BARs.

In many cases, the standard routing rules may be 'masked' or ignored by setting the corresponding bit in the Symbol Timer Register and Filter Mask Register 1 and Filter Mask Register 2. For example, see **Message Reception**.

NOTE

RTRGT1 is the application interface and it is connected to the AXI bridge master interface.

Notation of routing results:

Yes = destination is as specified in rule when conditions of rule are met

no = destination is not as specified in rule even when conditions of rule are met

- = routing rule has no affect because it does not apply to TLP type

Table 46-7. Routing Rules for Request TLPs (EP Mode)

Routing Rule	MRd	MWr	CFG	IO	Vendor MSG Type0	Vendor MSG Type1	Other MSG
When a request is filtered with SU status, and is in BAR range, MEM_FUNC#_BAR#_TARGET_MAP parameter determines the destination.	Yes	Yes	no	Yes	-	-	-
When a request is filtered with UR/CA/CRS status, and the DEFAULT_TARGET parameter is 0, the TLP is dropped. For NP requests, a CPL is also generated.	Yes	Yes	Yes	Yes	Yes	Yes	Yes
When a request is filtered with UR/CA/CRS status, and the DEFAULT_TARGET parameter is 1, the TLP is dropped.	no	no	no	no	Yes	Yes	Yes
When a request is filtered with UR/CA/CRS status, and the DEFAULT_TARGET parameter is 1, the destination is RTRGT1 interface.	Yes	Yes	Yes	Yes	no	no	no
When a CFG request is filtered with SU status and the CFG register address is > CONFIG_LIMIT, TARGET_ABOVE_CONFIG determines the destination.	-	-	Yes	-	-	-	-

Table continues on the next page...

Table 46-7. Routing Rules for Request TLPs (EP Mode) (continued)

When a CFG request is filtered with SU status and the CFG register address is < CONFIG_LIMIT, RTRGT0 interface is the destination.	-	-	Yes	-	-	-	--
The TLP is dropped, when the filter mask CX_FLT_MASK_MSG_DROP bit is not set and the non-Vendor MSG is filtered with SU status.	-	-	-	-	no	no	Yes
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG0_DROP bit is 0 and the VEN0 MSG is filtered with SC status.	-	-	-	-	Yes	no	no
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG1_DROP bit is 0 and the VEN1 MSG is filtered with SC status.	-	-	-	-	no	Yes	no
RTRGT1 interface is the destination when none of the previous rules are satisfied and the MSG is filtered with SU status.	-	-	-	-	Yes	Yes	Yes

Table 46-8. Routing Rules for Request TLPs (RC mode)

Routing Rule	MRd	MWr	¹ CFG	¹ IO	Vendor MSG Type0	Vendor MSG Type1	Other MSG
When a request is filtered with SU status, and is not in BAR range, RTRGT1 is the destination.	Yes	Yes	no	Yes	-	-	-
² When a request is filtered with SU status, and is in BAR range, MEM_FUNC#_BAR#_TARGET_MAP parameter determines the destination.	Yes	Yes	no	no	-	-	-
When a request is filtered with UR/CA status, the TLP is dropped. For NP requests, a CPL is also generated.	Yes	Yes	Yes	Yes	Yes	Yes	Yes
The TLP is dropped, when the filter mask CX_FLT_MASK_MSG_DROP bit is 0 and the non-Vendor MSG is filtered with SU status.	-	-	-	-	no	no	Yes
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG0_DROP bit is 0 and the VEN0 MSG is filtered with SU status.	-	-	-	-	Yes	no	no
The TLP is dropped, when the filter mask CX_FLT_MASK_VENMSG1_DROP bit is 0 and the VEN1 MSG is filtered with SU status.	-	-	-	-	no	Yes	no
RTRGT1 interface is the destination when none of the previous rules are satisfied and the MSG is filtered with SU status.	-	-	-	-	Yes	Yes	Yes

1. DM (in RC mode) should not expect to receive a CFG or IO request.
2. BARs are not normally used in RC application.

46.3.4.3.5 Completion TLP Routing Rules

The table found here shows the applicability of routing rules for Completion TLPs, and indicates whether the destination is as stated by the rule when the conditions of the rule are met.

In summary, under error conditions, CPLs are never dropped but always forwarded to the application except when:

1. 'suggested' completion or error status is any of the following:
 - UC
 - 'DLLP abort'
 - 'ECRC error'

and

2. queue mode is store-forward and
3. queue architecture is single or multiple queue.

Table 46-9. Routing Rules for Completion TLPs.

Routing Rule	Filter Status of the Completion (CPL)	
	SC / UR / CA / CRS	UC / 'DLLP abort' / 'ECRC error'
Core Drop is the destination when queue mode is store-forward and queue architecture is single queue or multiple queue	no	yes
RCPL interface is the destination when queue mode is <any> and queue architecture is single queue or multiple queue	yes	yes
RBYP interface is the destination when queue mode is by-pass and queue architecture is segment buffer queue.	yes	no
RTRGT1 interface is the destination when queue mode is cut-through and queue architecture is segment buffer queue.	yes	no
RTRGT1 interface is the destination when queue mode is store-forward and queue architecture is segment buffer queue.	yes	no
Core Drop is the destination when queue mode is <any> and queue architecture is segment buffer queue.	no	yes

46.3.4.4 Receive Queuing

The core support three configurable queue architectures per VC: single queue, multiple queue, and segmented queue.

Each queue architecture supports three buffering modes: bypass mode, cut-through mode, and store-and-forward mode. The buffering mode is selectable for each TLP type: posted, non-posted and completion. The configurability is dependent on the queuing architecture.

The single queue architecture has one header buffer and one data buffer; and the header and data buffers are used as a single FIFO for buffering all posted, non-posted and completion TLP.

The multiple queue architecture has a single header and data buffer per posted, non-posted and completion TLP type.

The segmented queue architecture has one header buffer and one data buffer, but these two buffers are segmented by posted, non-posted and completion TLP type (versus single queue architecture).

For all queuing modes, RAM modules are either instantiated inside the top-level module of the core or connected externally, which is configurable.

46.3.4.4.1 Queuing Architecture

The queue architecture is specified by the user using the `CX_RADMQ_MODE` configuration parameter..

46.3.4.4.1.1 SEGMENTED-BUFFER RECEIVE QUEUE CONFIGURATION (CX_RADMQ_MODE=2)

The segmented-buffer queue architecture is designed for applications that want to enforce an ordering rule other than FIFO. This is the only queue architecture that can strictly adhere to the ordering rules of the *PCI Express Specification*. This queue architecture is relatively large in area. The segmented-buffer configuration uses a single memory module pair (header and data) for all TLP types and all VCs.

In the segmented-buffer configuration:

- The memory width is set automatically.
- The memory is divided into segments for Posted, Non-Posted, and Completion queues for each VC. The depth of each segment is set during hardware configuration,
- The operating mode is selected (bypass, cut-through, or store-and-forward) independently for each TLP type of each VC during hardware configuration. The operating mode (per TLP type and VC) can be controlled dynamically by writing to the Port Logic registers. If a TLP type is configured to be cut-through or store-and-forward, then it will be routed to the RTGT interfaces. If a TLP type is configured to be bypassed, then it will be routed to the `radm_bypass` interface. Once a Posted Request is configured in bypass mode, the application should not expect to send a Posted-write to the ELBI interface.

- The number of advertised credits is selected independently for each TLP type and each VC during hardware configuration. The number can be selected dynamically by writing to the Port Logic registers.
- The receive queue priority for VCs can be set to either strict priority (higher-numbered VCs have higher priority) or round robin during hardware configuration; and the priority at runtime can be set by writing to the Port Logic registers.
- The ordering rules for TLP types can be set during hardware configuration and at runtime by writing to the Port Logic registers. The choices are either strict priority (Posted first, Completion second, Non-Posted third) or priority determined according to ordering rules set forth in the PCI Express 3.0 Specification.

46.3.4.4.2 Queue Modes

The queue mode for each P/NP/CPL queue is specified using the `RADM_P_QMODE_VC0`, `RADM_NP_QMODE_VC0` and `RADM_CPL_QMODE_VC0` configuration parameters.

It is possible to change the Queue Mode (during device setup by software) by writing to the appropriate queue control register.

BYPASS MODE (`RADM_P/NP/CPL_QMODE_VC0=4`)

Queues in bypass mode are completely bypassed.

In the case of aborted TLPs, the core asserts either `radm_trgt1/cpl/bypass_dllp_abort` or `radm_trgt1/cpl/bypass_tlp_abort` to the application. The application is responsible for rolling back any actions that were performed on behalf of the aborted TLP.

CUT-THROUGH MODE (`RADM_P/NP/CPL_QMODE_VC0=2`)

In cut-through mode, the queue presents data to the application as soon as the first data for a packet is placed into the queue.

In the case of aborted TLPs, the application is responsible for rolling back any actions that were performed on behalf of the aborted TLP. The `radm_trgt1/cpl/bypass_dllp_abort` and `radm_trgt1/cpl/bypass_tlp_abort` signals are presented to the application at the same time as the `eot` signal.

STORE-AND-FORWARD MODE (`RADM_P/NP/CPL_QMODE_VC0=1`)

In store-and-forward mode, only valid TLPs are forwarded to the application logic. Therefore, no rollback functionality is required by the application. All TLPs with `radm_trgt1/cpl/bypass_dllp_abort` or `radm_trgt1/cpl/bypass_tlp_abort` asserted will be dropped¹ by the receive queues of the core.

Flow Control credits are returned by the queue as packets are read out (even when the TLP was aborted and not presented to the application).

NOTE

Error handling by the application is dependent on the choice of queue mode. See [Dependency upon Queue Architecture and Mode](#).

46.3.4.4.3 Order Enforcement

The ordering of TLPs within the same VC depends on the queuing architecture as follows:

- In the segmented-buffer configuration, either PCIe ordering rules or strict priority ordering are provided.
- In segmented buffer mode, you may select either strict VC priority (same as for single- and multi- buffer) or round robin.

For more information of packet ordering in relation to buffering/queue mode and architecture see:

- [App Note: Order Enforcement Using the PCIe Core](#)
- [Inbound Order Enforcement for AXI Bridge](#)

46.3.4.4.4 Queue to Port Mapping

Tables found here indicate which interfaces (ports) are used to deliver requests and completions depending on the queue architecture and buffer mode selected.

For Posted (P) and Non Posted (NP) TLP's, the destination (RTRGT1/RTRGT0) depends on the BAR setup, and if the TLP is of CFG type or not.

See [Receive Routing](#) for more details on routing for TLP's under error conditions.

QUEUE TO PORT MAPPING WHEN AHB/AXI BRIDGE PRESENT

RTRGT1 is connected to the AXI/AHB Bridge master interface (request) channel. RCPL and RBYP are connected to the AXI/AHB Bridge slave interface (response) channel. See [Receive Routing](#) for more details on routing for TLP's under error conditions.

Table 46-10. Segmented Queue Architecture (CX_RADMQ_MODE == 2) Queue to Port Mapping

Queue Mode	Posted	Non Posted	CPL
------------	--------	------------	-----

Table continues on the next page...

Table 46-10. Segmented Queue Architecture (CX_RADMQ_MODE == 2) Queue to Port Mapping (continued)

(RADM_P/NP/CPL_QMODE_VC0)	TLP Queue	TLP Queue	Queue
Store and Forward (1)	RTRGT1 / RTRGT0	RTRGT1 / RTRGT0	¹ RTRGT1
Cut Through (2)	n/a	n/a	n/a
Bypass (4)	n/a	n/a	RBYP

1. Use this feature if you want to maintain PCI Express ordering rules within the AHB/AXI Bridge module after packets have left the RADM receive queues in the native PCIe core. For more information see [Ordering Enforcement Hardware Lock Feature](#).

46.3.5 Error Handling

An overview and additional information regarding error handling can be found here.

46.3.5.1 Error Handling Overview

Errors are classified into two levels:

- Correctable Error (CORR). This means that the PCIe core has a way of automatically handling the error. There is no loss of information. For example, Link CRC (LCRC) that is fixed by replaying the DLL.
- Uncorrectable Error (UNCORR). The PCIe core can not fix these and they are classified as:
 - Fatal Error (FATAL). The link is not functioning correctly and may require a link reset.
 - Non-Fatal Error (NONFATAL). The problem is not related to link operation.

The core implements the types of error handling found here.

- PCIe Baseline Capability. These reporting capabilities are a minimum set, and are required of all PCI Express devices. Error notification takes two forms:
 - Messages sent to Root Complex (RC).
 - Completion Status errors.

This also covers mapping of PCIe errors to legacy PCI generic error handling such as PERR# and SERR#. Many of the PCIe errors are mapped into the Status register in the PCI Compatible Configuration Space Header.

- PCIe Advanced Error Reporting (AER) Capability. Allows more sophisticated error reporting, control, masking and logging using the PCIe extended AER capability register structure.

The PCIe core supports Advisory reporting for both the Baseline and AER capabilities, which is configurable with-holding of reporting for Non-Fatal errors (NONFATAL).

For an RC port, the reporting of most errors is internal to the root port. No external error notifications are generated. One exception to this (for example) is Unsupported Request (UR) completion status.

46.3.5.2 PCIe Baseline Capability

Reporting of errors is achieved by sending a notification to the RC (a CPL with UR/CA/CRS status for Non Posted requests, and optionally an error Msg).

The decision to send an error MSG is controlled by a complex set of associated control and status bits. The status is also logged in the Device Status Register for the following errors: Unsupported Request (UR), FATAL, NONFATAL and CORR.

MESSAGES SENT TO ROOT COMPLEX (RC).

Messages sent to the RC are of the ERR_CORR, ERR_NONFATAL, and ERR_FATAL types.

COMPLETION STATUS ERRORS.

Completion Status errors for Non Posted requests may be any of the following:

- Unsupported Request (UR)
- Configuration Request Retry Status (CRS)
- Completer Abort (CA)

REPORTING THROUGH THE DEVICE STATUS REGISTER

The PCI Express Capability Register Structure provides the following support for Baseline Error Reporting.

- Enable/disable error reporting (Device Control Register).
- Provide error status (Device Status Register) for:
 - UR
 - Correctable Error (CORR).
 - Fatal Error (FATAL).
 - Non-Fatal Error (NONFATAL).
- A method for software to force Link Retraining (Device Control Register).

46.3.5.3 Advanced Error Reporting (AER)

The decision to send an error MSG is controlled by a complex set of associated control and status bits. For more details, see the flow diagram in [Error Detection](#). AER allows more sophisticated error reporting, control, masking and logging using the optional extended AER capability register structure. By default, AER is enabled (AER_ENABLE parameter), and may not be disabled unless you disable ECRC support in the core (CX_ECRC_ENABLE parameter).

AER REGISTERS

The AER registers are described in the Advanced Error Reporting Capability Registers section described in . All possible errors are enabled, masked and assigned a severity.

There are two sets of registers:

- Error Enable Register
- Error Severity Register
- Error Mask Register.

The Correctable set of registers handles (for example) errors arising from bad DLLPs or TLPs.

The Uncorrectable set of registers handles (for example) errors arising from UR, ECRC, Malformed TLPs, Buffer Overflow, UC, CA, Completion Timeout and Poisoned TLP.

SEVERITY PROGRAMMING

The Uncorrectable Error Severity register allows each uncorrectable error to be programmed to Fatal or Non-Fatal. The transmission of these error Messages by class (correctable, non-fatal, fatal) is enabled using the Reporting Enable fields of the Device Control register or the SERR# Enable bit in the PCI Command register.

The Uncorrectable Error Mask register and Correctable Error Mask register allows each error condition to be masked independently. If Messages for a particular class of error are not enabled by the combined settings in the Device Control register and the PCI Command register, then no Messages of that class will be sent regardless of the values for the corresponding mask register. If an individual error is masked when it is detected, its error status bit is still affected, but no error reporting Message is sent to the Root Complex, and the Header Log and First Error Pointer registers are unmodified.

46.3.5.3.1 Advisory Non-Fatal Error Messages

The PCIe core supports Advisory reporting which is the configurable with-holding of reporting for Non- Fatal errors.

- With Baseline Error Reporting, the core produces no error message.
- With AER, the core can instead, signal a non-fatal error with ERR_COR, which serves as an advisory notification to software.

It will always signal a fatal error with ERR_FATAL

UR/CA ADVISORY

The PCIe core generally sends a CPL with UR/CA status to signal a uncorrectable error for a Non-Posted Request. If the severity of the UR/CA error is non-fatal, the PCIe core will handle this case as an Advisory Non-Fatal Error.

By default, the PCIe core will signal the non-fatal error (if enabled) by sending an ERR_COR Message.

If AER is disabled (AER_ENABLE=0), the PCIe core sends no error Message for this case. Even though there was an uncorrectable error for this specific transaction, the PCIe core will handle this case as an Advisory Non-Fatal Error, since the Requester upon receiving the Completion with UR/CA Status is responsible for reporting the error (if necessary) using a Requester-specific mechanism.

UC ADVISORY

When the PCIe core receives an UC and the severity of the UC error is non-fatal, the PCIe core will handle this case as an Advisory Non-Fatal Error. By default, the PCIe core will signal the error (if enabled) by sending an ERR_COR Message.

If AER is disabled (AER_ENABLE=0), the PCIe core sends no error Message for this case.

46.3.5.4 Error Source Classification

The table found here indicates how some of the more common low level errors are classified.

Table 46-11. Possible Causes for Typical Errors

Error Type	Possible Cause
UR (Unsupported Request)	<ul style="list-style-type: none"> •Poisoned TLP (EP=1) •No BAR match •MRd length > max read request size

Table continues on the next page...

Table 46-11. Possible Causes for Typical Errors (continued)

UC (Unexpected Completion)	<ul style="list-style-type: none"> •TAG mismatch. •Requester ID (RID) mismatch.
CPL TimeOut	Remote device hung.
CA (Completion Abort)	ECRC
Malformed TLP (MLF)	Bad TLP header caused by bad link.
Buffer OverFlow	Credit miscalculation by some PCIe device.
Bad DLLP	LCRC

For a full analysis of what error conditions contribute towards an UR or CA status, see [Receive Filtering](#).

NOTE

In many cases, the standard operation may be 'masked' or ignored by setting the corresponding bit in the Symbol Timer Register and Filter Mask Register 1, which take its default value from the `DEFAULT_FILTER_MASK_1` configuration parameter.

NOTE

For example, A TLP with the poison bit set (EP=1) is considered an Unsupported Request (UR) only when the UR poison rule mask bit is not set.

46.3.5.5 Error Detection

Built into the core are all mandatory error detections, some optional error detections, and the error report mechanism based on the *PCI Express Specification*.

The core also has an option for the application to turn off the filter rules and perform its own error checking. For more details, see [Receive Filtering](#).

The following general rules apply to all incoming TLPs:

- The core discards all incoming TLPs that have an invalid Type field. This TLP is treated as a 'TLP-ABORT'.
- A locally terminated TLP with ECRC error detected is discarded in store-and-forward mode and an ECRC error reported only when the filter mask `CX_FLT_MASK_ECRC_DISCARD` bit is not set.
- Filter rules have no affect on received TLP when 'DLLP-ABORT' signal is asserted.

- If a completion of a non-posted request is not received within a completion timeout period, this request will be treated as a completion timeout, and a non-advisory error will be reported. See [Advanced Error Reporting \(AER\)](#) for more details.
- 'DLLP-ABORT' is asserted as a result of one of two conditions:
 - a. A data link layer error is detected (e.g. LCRC). A retry from a remote device will occur.
 - b. UC or completion with ECRC error is detected. This condition is valid only when the application has configured the core with infinite credits. Because the completion buffer of the core or application has limited resources defined for expected completions, it is necessary to avoid overflowing the completion buffer by unexpected completions. Therefore 'DLLP-ABORT' is asserted to notify the core completion buffer (if completion is in store-forward mode) or application's completion buffer to rewind their buffer pointers when a completion with ECRC error or unexpected completion is detected.
- 'TLP-ABORT' is asserted as a result of one of three conditions:
 - Malformed TLP
 - UC
 - ECRC

The figure below provides a flow chart of the error detections for a packet received from the PCIe wire.

Signals in this figure are internal to the core (except those prefixed with `radm_*`)

The signals `radm_cpl_dllp_abort` and `radm_cpl_tlp_abort` are intended for use with the Completion queue configured in either bypass or cut-through mode so that the core can notify the application of errors detected as the TLP is received.

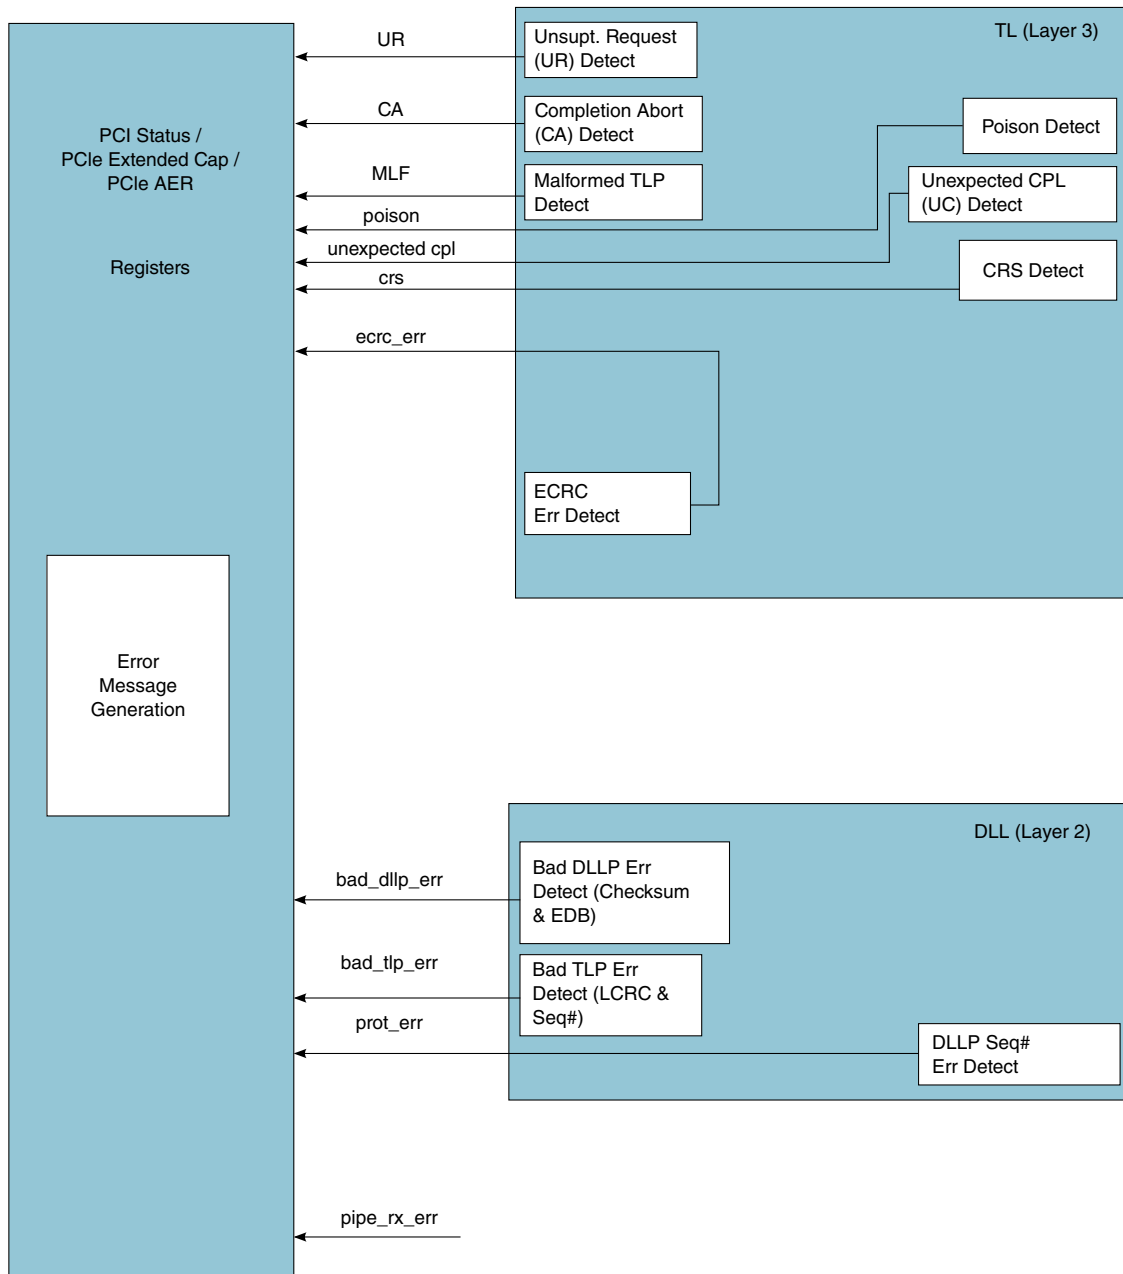

Figure 46-14. Flow Chart of Error Detections

46.3.5.6 Application Error Reporting Interface

The application may optionally generate an Error Message through either of the following methods:

- Directly at the application interface see [Message Generation](#).

- It may instruct the PCI Express core to do so through the 'Application Error Reporting Interface'signals app_* .
- You must set the APP_RETURN_ERR_EN configuration parameter to enable the 'Application Error Reporting Interface'.

If you mask detection of Completion timeout errors, through setting the CPL_TIMEOUT_ERR_MASK configuration parameter, then the core will not automatically report Completion timeout errors. The application must check for Completion timeouts and report Completion timeout errors using the app_err_bus input signal.

NOTE

Your application may want to send an error message to the remote link partner if (for example) your application detected an error during the execution of an inbound/received Posted TLP, for example a MWr

46.3.5.7 Handling of General Errors with the AXI Bridge.

PCIe Advanced Error Reporting (AER) is not supported in the AXI bridge.

AER is only supported with respect to the native PCIe core. Errors detected by the AHB/AXI bridge are not reported as part of AER.

46.3.5.8 AXI

The slv_resp_err_map and mstr_resp_err_map bits are tied to 1. The corresponding CPL error will be SLVERR AXI Error Response. The corresponding CPL status error will be UR (Unsupported Request) PCIe CPL Status.

46.3.5.9 Handling of ECRC/LCRC Errors for IO/MEM with the AXI Bridge.

46.3.5.9.1 Link CRC (LCRC) - a correctable Error

When an LCRC error occurs on an inbound packet (request or completion), the core will automatically discard that packet and wait for the remote device to replay the packet.

The native core will signal (via radm_*_dllp_abort) to the AHB/AXI bridge that an LCRC error has occurred.

The AXI bridge will not signal an error to the application but will wait for the replayed packet to arrive.

46.3.5.9.2 End-to-end CRC (ECRC) - an Uncorrectable Non-Fatal Error

REQUESTS

By default, a request TLP with ECRC errors is dropped by the RADM filter in the native core and an Advisory Non-Fatal Error is signalled. For Non Posted (NP) requests, a CPL with CA is generated. See [Advisory Non-Fatal Error Messages](#).

If you set the `DEFAULT_TARGET` and `CX_MASK_UR_CA_4_TRGT1` parameters to 1 (default values are 0), then, a request TLP with ECRC errors will not be dropped but will be forwarded (without any error reporting) to the application on AXI bridge master.

See [ECRC Handling](#) for more details.

COMPLETIONS

A completion TLP with ECRC errors is only dropped by the RADM in the native core when CPL queue mode is store-forward and queue architecture is single or multiple queue. However, for the AHB/AXI bridge, when the queue architecture is single or multiple queue, the CPL queue mode is restricted to bypass. Therefore a completion TLP with ECRC errors is always forwarded to the AHB/AXI bridge.

When the AXI/AHB bridge receives a CPL with ECRC errors, it will not transmit it to the application through the AHB/AXI master. Instead, the bridge will wait for the subsequent 'completion timeout' (see [Received Completion TLP Processing](#)) generated by the core. It is this timeout that will cause the bridge to issue an ERROR response to the application on each beat of the burst corresponding to the original AHB/AXI request.

46.3.6 Messages

Information found here describes the processing of messages through the core.

NOTE

For a proper understanding of Messages you should be familiar with Message Request Rules of the PCI Express Base Specification.

Similar to MWr, messages (Msg/MsgD) are Posted transactions. The 8-bit 'Message Code' field defines what class of message the TLP is. Some examples of typical message classes are given in the following table.

Table 46-12. Some Message classes based on the Message code

Message Code [7:0]	Message Class	TLP Type	Note
0001_xxxx	Power Management	Msg	
0010_0xxx	Legacy PCI Interrupt	Msg	Assert/deassert for each of INT A/B/C/D.
0011_00xx	Error Signalling	Msg	ERR_CORR, ERR_NONFATAL, ERR_FATAL are encoded using 30h, 31h, 33h.
0111_11xx	Vendor Defined	Msg / MsgD	
Other classes (used by PCIe core) include Locked Transaction, Slot Power Limit.			

NOTE

Message Signalled Interrupts (MSI/MSI-X) are not messages (Msg/MsgD) but MWr TLPs. See [Interrupts](#) for more details.

46.3.6.1 Message Generation

Messages that are transmitted by the PCI Express core can potentially be derived from the following eight sources. Referring to the circled numbers in the following diagrams, outbound messages can be created either by:

the core automatically as follows:

- 'Power Management' messages.
- 'Error Signalling' messages.

or

the customer application as follows:

- Direct supply of message TLPs at AXI bridge master. An internal or external internal address translation unit (ATU) can convert IO/MEM TLPs to MSG TLPs.
- 'Locked Transaction' messages through the 'SII Message' interface [RC mode].
- 'Legacy PCI Interrupt' messages through the 'SII Interrupt' interface.
- 'Error Signalling' messages through the 'SII Transmit Control' interface (app_err* I/O).

or

the host/client software as follows [RC mode]:

- Triggering the sending of 'Slot Power Limit' messages by writing to the Slot Capabilities Register.

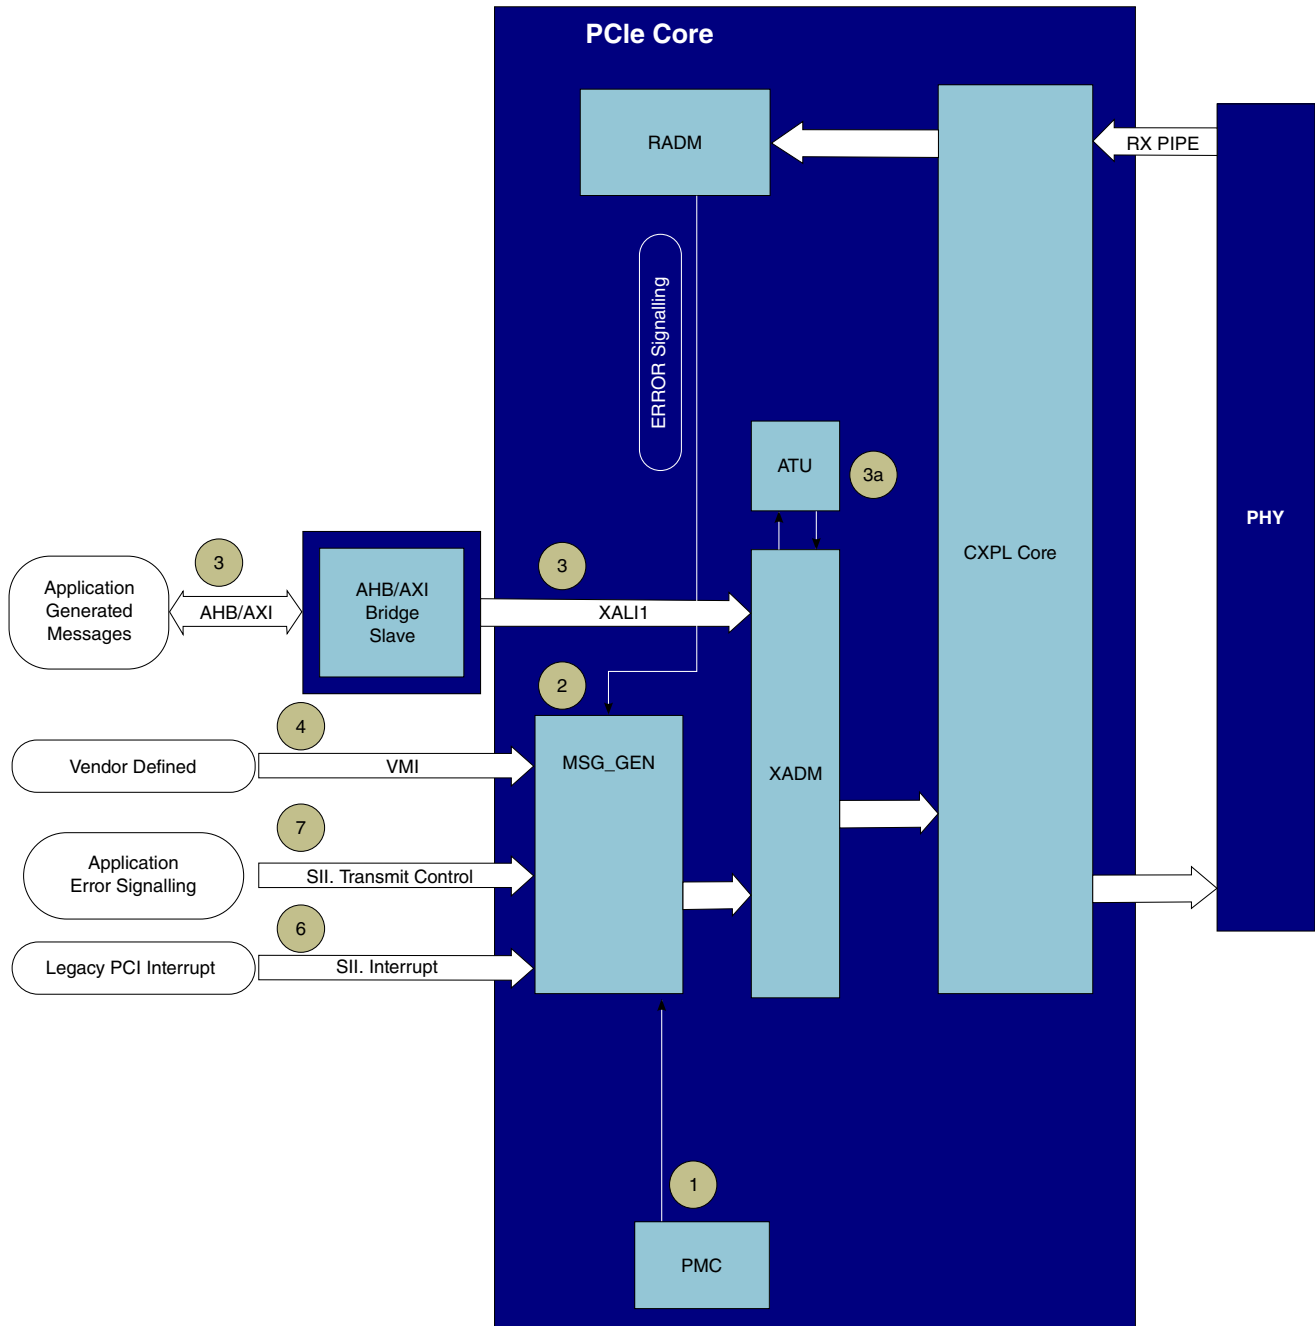

Figure 46-15. Message Transmission: EP mode

See [Terms and Abbreviations](#) for definitions of acronyms used for block and interface names.

Figure 46-16. Message Transmission: RC mode

Table 46-13. Message Transmission. The 'Index' refers to the numbers in the previous diagrams

Index	Message Source (Type)	EP Mode	RC Mode

Table continues on the next page...

Table 46-13. Message Transmission. The 'Index' refers to the numbers in the previous diagrams (continued)

1	Power Management controller in the core (Msg).	PM_PME ¹	PME_Turn_Off ² See Power Management .
2	Error Signalling inside the core (Msg).	COR_ERR / ERR_NONFATAL / ERR_FATAL. See Error Handling for more details.	n/a
3	Direct Supply of any class of Message (Msg/MsgD).	XALI0/1/2 or AHB/AXI See Application Msg/MsgD Programming Examples for details on how to generate a message at the XALI0/1/2 (or AHB/AXI) interfaces.	
3a	Indirect Supply of any class of Message (Msg/MsgD).	See Outbound iATU Operation for more details on generating Msg/MsgD from MWr/IOWr using an internal or external address translation unit (ATU).	
5	Locked Transaction (Msg).	n/a	Unlock Message, triggered by Root Complex application logic via the app_unlock_msg pin.
6	Legacy PCI Interrupt (Msg).	'SII Interrupt' pins sys_int and dp_intx (see PCI Legacy Interrupt).	n/a
7	Error Signalling from the application (Msg).	The core generates Error Signalling Messages in response to application requests on the SII app_err* I/O . It is also possible to generate Error Messages via the client interfaces. See items 3 and 3a in this table.	
8	Slot Power Limit (Msg).	n/a	Set_Slot_Power_Limit Support Message, triggered by writing to the Slot Capabilities Register via the DBI.

1. Triggered by your EP application through the outband_pwrup_cmd or apps_pm_xmt_pme pin.
2. Triggered by your RC application through the apps_pm_xmt_turnoff pin.
3. MsgD not possible on VMI. See [Vendor Defined Message \(VDM\) Generation](#).

46.3.6.1.1 Vendor Defined Message (VDM) Generation

VDMs can be generated by your application using any of the following methods (numbered 4, 3 and 3a in [Table 46-13](#)).

- Direct supply of IO/MEM TLPs AXI bridge master to be converted to VDM by either of the following.
- The internal Address Translation Unit (iATU) can convert IO/MEM TLPs to VDM TLPs.

46.3.6.1.1.1 Application Msg/MsgD Programming Examples

The tables found here enumerate the different ways your application can generate Msg and MsgD TLPs.

NOTE

xATU = "External Address Translation Unit" and iATU = "Internal Address Translation Unit (iATU)".

Table 46-14. Msg (message without payload) Generation Methods

Application Interface	Description	Application I/O Signals
AXI	Direct Supply using a Msg transaction.	slv_awmisc_info[4:0]='MSG' slv_wstrb[3:0]='0000'
	Indirect Supply (iATU) using a MWr ¹ transaction. The iATU needs to be configured to translate MWr to Msg TLPs.	slv_awmisc_info[4:0]='MEM' slv_wstrb[3:0]='0000'

1. Or IOWr

NOTE

xATU = "External Address Translation" and iATU = "Internal Address Translation (iATU)".

Table 46-15. MsgD (Vendor Specific Message with payload) Generation Methods

Application Interface	Description	Application I/O Signals
AXI	Direct supply using an MsgD transaction.	slv_amisc_info[4:0]='MSG'
	Indirect Supply (xATU) using a MWr transaction.	slv_amisc_info[4:0]='MEM' xtranslated_enable =1 xtranslated_addr_in_d[8]=1 xtranslated_addr_in_d[7:0]=Message Code xtranslated_type_in_d = 10xxx
	Indirect Supply (iATU) using a MWr ¹ transaction. The iATU needs to be configured to translate MWr to MsgD TLPs.	slv_amisc_info[4:0]='MEM'

1. Or IOWr

46.3.6.1.2 AHB/AXI Message Address and Size Limitations

Limitations existing in the current implementation of the AHB/AXI bridge module can be found here.

NOTE

- Vendor Messages must not be decomposed in the inbound or outbound direction.
- You must ensure that Vendor Defined Messages generated by your application or remote link partner, do not trigger decomposition as described in [AXI Decomposition Rules](#).

Table 46-16. Processing of Inbound Messages when AHB/AXI and PCIe Core Address Widths are different

AHB/AXI Address Bus Width	PCIe Core Address Bus Width	Notes
MASTER_BUS_ADDR_WIDTH	FLT_Q_ADDR_WIDTH	
32	64	The upper 32 bits of the data field (bytes ¹ 8-11) are not forwarded by the bridge master.
64	32	The upper 32 bits of data field (bytes 8-11) will be forced to '0'.

46.3.6.2 Message Reception

The PCI Express core can receive the following types of messages. The index in the first column refers to the circled numbers in the following diagrams.

Table 46-17. Message Reception. The 'Index' refers to the numbers in the following diagrams

Index	Message Source (Type)	EP Mode	RC Mode
1	Power Management (Msg).	PME_Turn_Off See Power Management .	PM_PME PME_TO_Ack
1a	Slot Power Limit (Msg).	Set_Slot_Power_Limit Support Message.	n/a
2	Error Signalling from downstream component (Msg).	n/a	COR_ERR / ERR_NONFATAL / ERR_FATAL.
3	Vendor Defined (Msg/MsgD).		
4	Locked Transaction (Msg).	Unlock Message.	n/a
5	Legacy PCI Interrupts from downstream devices (Msg).	n/a	See PCI Legacy Interrupt .

Figure 46-17. Message Reception: EP mode

Figure 46-18. Message Reception: RC mode

See [Terms and Abbreviations](#) for definitions of acronyms used for block and interface names.

46.3.6.2.1 Message Reception IO Interfaces

The RADM filter provides a Message interface - that is grouped as part of the System Information Interface (SII) - to handle the Message TLPs received from the upstream component. The RADM filter processes the Message and decodes the header before sending it to the application logic on the SII.

46.3.6.2.2 Routing of Received Messages to SII and optionally to Application

The RADM filter processes *every* received message and decodes the header before sending it to the application logic on the System Information Interface (SII).

In addition, power management messages are processed by the PCIe core Power Management Controller (PMC).

By default, all received messages are dropped¹ (serviced internally) and *not* passed to the application on AXI bridge master.

To have all decoded messages *also* sent to the application interface (AXI bridge master), the register fields must be set to '1'. These registers allow you to override any decisions (regarding MSG routing) made at configuration time by the FLT_DROP_MSG, DEFAULT_FILTER_MASK_1 and DEFAULT_FILTER_MASK_2 configuration parameters .

Table 46-18. Controlling the Routing of Received Messages

Register	Bit	Function	Default Value
Filter Mask Register 1	29	Mask the dropping of Non-Vendor Messages 0: Drop 1: Do not drop	DEFAULT_FILTER_MASK_1[13] = ! FLT_DROP_MSG = 0
Filter Mask Register 2	0	Mask the dropping of Vendor Type 0 Messages 0: Drop ¹ 1: Do not drop	DEFAULT_FILTER_MASK_2[0] = 0
Filter Mask Register 2	1	Mask the dropping of Vendor Type 1 Messages 0: Drop 1: Do not drop	DEFAULT_FILTER_MASK_2[1] = 0

1. Vendor TYPE0 Messages are dropped with UR error reporting.

For the masking (of the dropping) of Vendor messages, it is not possible to differentiate between 'Vendor Message without Payload (Msg)' and 'Vendor Message with Payload (MsgD)'.

Full details of the Filter Mask Registers are at Symbol Timer Register and Filter Mask Register 1 and Filter Mask Register 2.

When a MSG request is filtered with UR/CA/CRS status, the TLP is always dropped. Only MSG requests filtered with SC status, can potentially be forwarded to the application on AXI bridge master.

46.3.6.2.3 Accessing Header and Payload Fields of Received Messages

Format of Received Messages on the Application RTRGT1 Interface

In addition to normal TLP header information, the last two DWORDS of the message header (bytes¹ 8-15) are presented on `radm_trgt1_addr[FLT_Q_ADDR_WIDTH-1:0]` when `radm_trgt1_hv` is asserted.

Format of Received Messages on the Application AHB/AXI Master Interface

In addition to normal TLP header information, the last two DWORDS of the message header (bytes¹ 8-15) are presented on the master address bus as follows:

- AHB/AXI address[31:0] = 4th DWORD = bytes 12-15
- AHB/AXI address[63:32] = 3rd DWORD = bytes 8-11

The TYPE field of `mstr_awmisc_info/mstr_req_misc_info` indicates the type of message TLP received. The remote link partner should not use the last DWORD of a Msg/MsgD header (bytes¹ 12-15). If the last DWORD must be used, then the two lower bits (byte15) must be always set to 00b. If these two bits are not zero, then the AHB/AXI master interface (when it forwards the message packet to the AHB/AXI fabric) will initiate a burst of 8-bit or 16-bit transactions.

Messages Without Payload Restriction on AHB

Messages without Payload (Msg) cannot be forwarded to the AHB bridge module master interface, as there is no concept of 'write strobes' in AHB to support null/empty write packets. Therefore it is only possible to access (parts of) the received Msg (message without payload) over the SII.

Format of Received Messages on the SII

Not all of the message TLP fields are sent to the SII. For some messages, only an indication that it has been received is signalled. For Vendor Defined messages (Msg or MsgD), the 3rd DWORD (bytes¹ 8-11) is sent to `radm_msg_payload[31:0]` but the fourth DWORD (bytes 12-15) is not presented at all. Furthermore, for Vendor Defined messages with payload (MsgD), the payload is not presented on SII.

Therefore, to access this missing information (if required), it is necessary to unmask the dropping² of Vendor Messages and have them sent to the application interface (AXI bridge master) in order to access the payload. This can be problematic for AHB as it is not possible to differentiate between 'Vendor Message without Payload (Msg)' and 'Vendor Message with Payload (MsgD)' for the masking (of the dropping) of Vendor messages. To avoid, this problem, program the remote link partner to not send Vendor Defined messages without payload (Msg), to an AHB connected end point.

46.3.7 Interrupts

Information found here describes the processing of interrupts through the core.

46.3.7.1 Interrupts Overview

The application logic in a PCI Express Endpoint may use one of three methods to signal an interrupt:

PCI legacy interrupt

PCI includes up to four virtual interrupt wires, referred to as INTA, INTB, INTC, and INTD. These wires are shared by all the PCI devices in the system. PCI Express emulates this capability by providing Assert_INTx and Deassert_INTx Message packets sent through the PCI Express serial Link.

MSI

A PCI Express Endpoint may signal an MSI by sending a standard PCI Express Posted Write packet towards the Root Port. The packet must contain a specific address and one of up to 32 data values. The varying data values, and the address value provide more detailed identification of interrupt events than legacy interrupts.

The PCI Express Cores support optional MSI per-vector masking (PVM).

MSI-X

An MSI-X interrupt is identical to an MSI, except that an Endpoint may use one of up to 2048 address and data pairs in the MSI-X Posted Write packet. Endpoints with MSI-X capability also include application logic to mask and hold pending interrupts, as well as a memory table for the address and data pairs. The large number of address values available to each Endpoint allows MSI-X Messages to be routed to different interrupt consumers in a system, as compared to the single address available to MSI packets.

Root Ports cannot send MSI-X packets. In complex systems, MSI-X packets could be routed to devices other than the RC, including other Endpoints, based on the multiple address/data pairs available.

Support of legacy interrupts and/or MSI/MSI-X may be required for backward compatibility. You may configure your core and application logic to support all three types of interrupts. However, you may only use one of these capabilities at a time. When host software clears the MSI Enable bit, you may only use legacy interrupts. When host software sets the MSI Enable bit, you may only use MSI. If host software enables MSI or MSI-X, legacy interrupts are automatically disabled. Functionality is undefined if both MSI and MSI-X are enabled.

46.3.7.1.1 PCI Legacy Interrupt

NOTE

Legacy Interrupt delivery are signalled using special Msg TLPs.
For more details see [Messages](#).

The PCI Express Endpoint Core provides an input pin (sys_int[NF-1:0]) per function, so that application logic can assert or deassert a legacy interrupt.

The Core automatically maps assertion/de-assertion edges on the input pin to PCI Express Assert or Deassert messages. Root Ports decode received Assert/Deassert messages into pulses. Refer to System Information Interface (SII) for additional information.

Multifunction Support

A single-function Endpoint always uses INTA. However in a multi-function Endpoint, you may choose which virtual interrupt is used for each function by setting the initial value of the Interrupt Pin configuration register. In a multi-function Endpoint, each function has its own interrupt input pin (sys_int[NF-1:0]). Each function's Interrupt Pin register determines which legacy interrupt Message the function uses (INTA, INTB, INTC, or INTD).

Ordering Considerations

You may wish to guarantee that a legacy interrupt Message is sent after a data packet. In that case, do not assert the interrupt input pin until after the data packet's header is accepted by the core's transmit client interface.

In a complex PCI Express system, which include Switches and/or multiple Virtual Channels, you cannot guarantee that the interrupt Message will arrive after a data packet, unless the data packet uses the same Traffic Class as the legacy interrupt packet (Traffic Class 0).

Deassertion of Interrupts

The application needs to deassert the virtual interrupt inputs if system software has disabled interrupts or if the PCI Express link has been placed in a low power state.

The Core does not automatically send a Deassert Interrupt Message when software disables interrupts. However, the application must eventually deassert the virtual interrupt before it can send a new interrupt because the Core requires a rising edge on the virtual interrupt signal to generate a new Assert Interrupt Message.

The Core does not automatically send a Deassert Interrupt Message when the power state changes.

46.3.7.1.2 MSI

Message Signalled Interrupts (MSI) are not messages (Msg/MsgD) but Memory Write (MWr) TLPs. They are indistinguishable from normal MWr's apart from the target address used in conjunction with the MSI Capability Structure. PVM (Per Vector Masking) is supported with MSI.

The PCI Express Core automatically builds an MSI packet for your application (if MSI is enabled) whenever requested by your application logic.

A simple handshake is required. The MSI interface is used only in the DM core in EP mode.

The Core informs the application logic whether MSI interrupts are enabled, and how many MSI data vectors have been allocated by system software.

Before performing the handshake, application logic must assert Traffic Class, and MSI vector information on the Core input pins. The Core inserts the Traffic Class into the MSI packet. It also merges the MSI vector number into the MSI packet data field.

Figure 46-19. MSI Message Passing

When an Endpoint sends an MSI Message, the Message packet is routed by address in the same way as any other PCIe Posted Write packet. In most systems, these packets will be routed to the Root Port and sent to Root Port application logic. The Root Port application logic recognizes the Posted Write packet by its MSI address and handles the interrupt in hardware or software. The data field is also available in the packet to further define the interrupt.

Multifunction Support

Each function in a multi-function device has its own configuration space, and therefore, its own MSI output controls. A multi-function core adds a function number to the MSI inputs shown in the following figure.

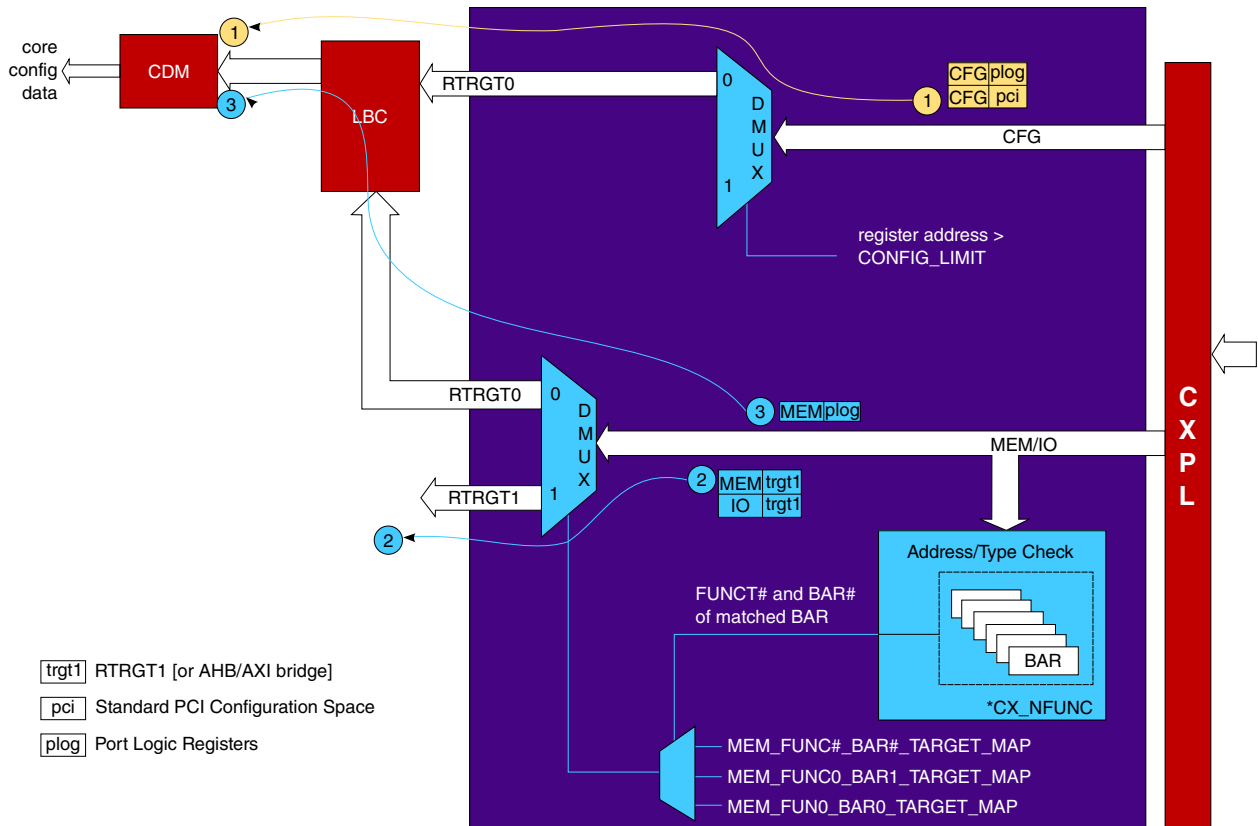

Figure 46-20. Typical use model

Ordering Considerations

You may wish to guarantee that an MSI is sent after a data packet. By setting the MSI packet's Traffic Class to the same value as an earlier data packet, you can guarantee that the MSI packet will always arrive at its destination after the data packet.

NOTE

The PCIe core sets the first byte enable (FBE) to 4'b1111 when it generates an MSI request, even though only the first two bytes of the payload are strictly valid/needed.

46.3.7.1.3 MSI-X

Message Signalled Interrupts (MSI-X) are not messages (Msg/MsgD) but Memory Write (MWr) TLPs. They are indistinguishable from normal MWr's apart from the target address used in conjunction with the MSI-X Capability Structure.

The PCI Express Core automatically builds an MSI packet for your application (if MSI-X is enabled) whenever requested by your application logic.

A simple handshake is required. The MSI-X interface is used only in the DM core in EP mode.

The following MSI interface signals are also used for MSI-X, depending on whether MSI or MSI-X is enabled: `ven_msi_req`, `ven_msi_func_num`, `ven_msi_tc`, and `ven_msi_grant`.

The address and data fields for MSI-X packets are defined in an MSI-X table located in the Endpoint's application logic, as shown in the figure below. Each entry in the table corresponds to an MSI-X packet that the application may send.

Each MSI-X table entry also includes a mask bit for that interrupt. An additional table, the pending bit array (PBA), includes a pending bit for each MSI-X table entry.

Host software sets and clears mask bits. If an interrupt's mask bit is set when the application wishes to send that MSI-X packet, the application must, instead, set the corresponding entry in the PBA.

Application logic monitors pending bits. If the corresponding mask bit is cleared, then the application sends the corresponding MSI-X packet, and clears the pending bit.

In addition, the MSI-X configuration registers in the Core include:

- Pointers to the function's MSI-X table and PBA
- Length of the function's MSI-X table
- An enable bit for MSI-X for that function
- A global mask for MSI-X

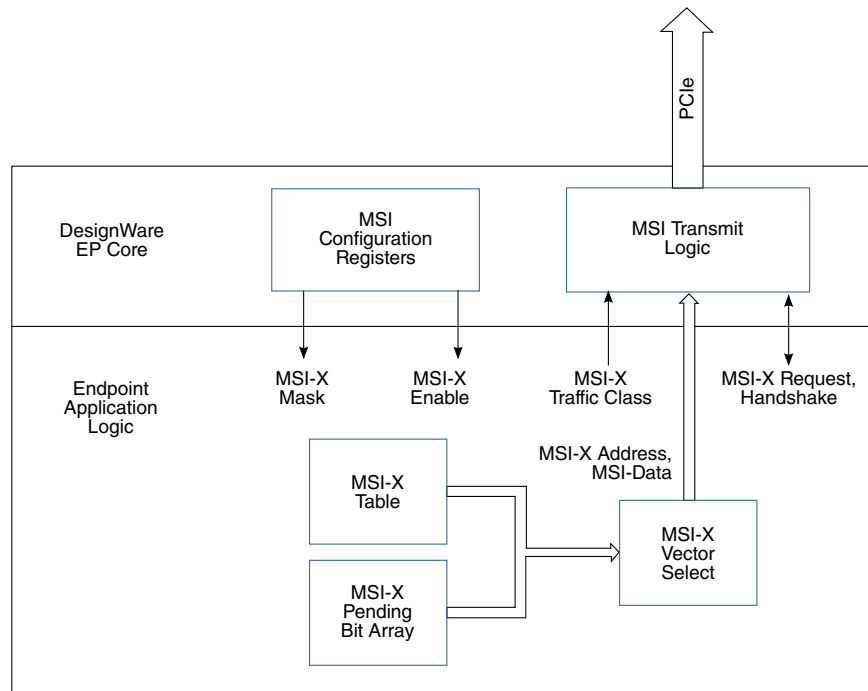

Figure 46-21. MSI-X Message Passing

Large MSI-X Tables

The MSI-X specification is written such that large MSI-X tables and PBAs may be implemented in compiled memories. However, if the host clears the function's global MSI-X mask, a search of the entire 2048 entry PBA might be necessary.

Also, in a large memory array like this, there would be no memory of the order in which the pending bits were set. This is not an MSI-X requirement, but might be required by some systems.

46.3.7.2 Interrupts (EP Mode)

In EP mode, the core supports the Legacy PCI INTx compatible interrupt emulation mechanism, the Message Signaled Interrupts (MSI).

A function can use the Legacy PCI INTx mechanism. Different functions of the same device can use different mechanisms. For example, function 0 can use INTA while function 1 uses MSI.

Legacy PCI INTx Support

The core generates two Messages, ASSERT_INTX and DEASSERT_INTX, in response to assertion and the deassertion of the sys_int input. The Interrupt Pin register for each function determines whether the function uses INTA, INTB, INTC, or INTD.

In a single-function configuration, the core uses only INTA. An input signal, sys_int, is provided for the application to notify the core that an interrupt message should be sent. The sys_int signal is level-sensitive on a per-function basis. The rising edge transition of this signal triggers an interrupt assert message. The falling edge transition of this signal triggers an interrupt deassert message.

Message Signaled Interrupt (MSI) Support

MSI support is required for PCI Express devices. MSI-capable devices deliver interrupts by performing Memory Write transactions. The MSI is requested by application logic through the MSI interface; the core then generates the corresponding Memory Write.

46.3.7.3 Interrupts (RC Mode)

In RC mode, the core accepts ASSERT_INTX and DEASSERT_INTX Messages from the downstream component and provides the decoded output signals on the SII (for example, radm_inta_asserted and radm_inta_deasserted).

For interrupts the downstream component transmits through the MSI-X mechanism, the core passes the received Memory Write to the application on the RTRGT1 interface.

PCI Express Hot-Plug Logic Interrupt and Wakeup

In RC mode, the Hot-Plug logic supports generation of Hot-Plug interrupts on the following Hot-Plug events:

- Power Fault Detected
- MRL Sensor Changed
- Presence Detect Changed
- Command Completed
- Attention Button Pressed
- Electromechanical Interlock Status Changed
- Data Link Layer State Changed

When MSI or MSI-X mode is enabled, the core notifies the RC application of Hot-Plug events using the hp_msi output. When INTx interrupt mode is enabled, the core notifies the application of Hot-Plug events using the hp_int output.

If PME is enabled, the The Hot-Plug logic generates a Hot-Plug wake-up signal on `hp_pme`, triggered by the above Hot-Plug events. The RC Core does not check if the PM state is D1, D2, OR D3_{HOT}. It is up to the application to check the value on `pm_dstate` to make sure the device is in D1, D2, OR D3_{HOT} upon receiving of `hp_pme` notification.

46.3.7.4 MSI Generation in the AXI Bridge

The standard AXI bridge simply sends MSI requests in the same manner as a memory write.

The method to send a MSI request is to have the AXI bridge send MSI requests in the same manner as a regular memory write. It is the application's responsibility to form the MSI request based on the native PCIe core's configuration. The native PCIe core CDM block contains the MSI address, enable, etc.

The application must obtain the MSI information (`cfg_msi_*`) from reading the MSI capability registers in the CDM through the DBI interface, and then form the MSI request to present onto the AXI bridge slave interface.

This method should be used by an application that wants to preserve the order of Posted transfers (MemWr) requested before an MSI request.

The AXI bridge simply sends MSI requests in the same manner as a memory write. To send an MSI to the PCIe link from the AXI bridge, the application presents the MSI address and data onto the AXI slave write channel.

46.3.7.5 MSI Reception in the AHB/AXI Bridge

The standard AHB/AXI bridge receives MSI requests in the same manner as a memory write.

It cannot and does not distinguish between MSI and memory requests. The termination of an MSI request (in RC mode) must be done by the application or by using the optional MSI Controller described next.

46.3.7.5.1 AHB/AXI MSI Controller (Optional in RC mode)

The bridge provides an optional programmable MSI controller to detect and terminate inbound MSI requests in the bridge for RC and DM (RC mode) products. It is enabled by setting the `CX_MSI_CTRL_ENABLE`) configuration parameter.

Rather than propagating MSI MWr TLPs onto the AHB/AXI bus via the Master interface; the MSI packets are captured and terminated in the AHB/AXI Bridge and an interrupt is signaled.

The MSI Controller is programmed with an address that will be used as the system MSI address. If an inbound (received) MWr request is passed to the AHB/AXI Bridge and matches the specified MSI address as well as the conditions specified for an MSI Memory Write request, then an MSI interrupt is detected. When this Memory Write Request is about to be driven onto the AHB/AXI bridge Master Interface - it is quashed and never appears on the AHB/AXI bus.

The MSI Controller decodes the MSI MWr data payload to determine which End Point device (EP) sent the MSI and which interrupt vector it corresponds to. When a valid interrupt has been decoded, the `msi_ctrl_int` output is asserted. This output remains asserted when any MSI interrupt is pending. It is only deasserted when there is no MSI interrupt pending.

Features:

- MSI Interrupt Controller only enabled in RC core and DM core in RC mode based on the
- `device_type` input to DM. It is inactive in EP mode.
- The MSI Interrupt controller will provide support for up to eight EPs. Each supported EP will have a set of Interrupt Enable, Interrupt Mask and Interrupt Status registers.
- A maximum of 32 interrupts are supported per EP.

MSI Request Detection Criteria:

An MSI Interrupt Request is defined to occur when a Memory Write TLP that satisfies the following conditions is received by the core:

- Header Attributes bits are zero. No Snoop (NS) and Relaxed Ordering (RO) must be zero.
- Length field is 0x01 to indicate payload of one DWORD.
- First Byte Enable must be such that it is enabling the first 2 bytes (16-bits) of the payload.
- Last Byte Enable is 4'b0000.
- TLP address corresponds to system's chosen MSI Address as programmed in the MSI Controller Address Register. This register is not the MSI Lower 32 Bits Address Register which is part of the PCI Express MSI Capability Register structure.

In addition to the conditions outlined above, the Memory Write Request must also pass the receive filtering rules as outlined in Receive Filtering to be recognized as a valid MSI Interrupt Request. For example, Poisoned Bit not set in TLP header, ECRC check passed.

46.3.7.5.2 Programming and Usage Model

- The host CPU configures MSI capabilities of all Endpoints (EP) via the local DBI bus (or¹ via Config requests from the remote link partner).
- The MSI data register (MSI Data Register which is part of the PCI Express MSI Capability Register structure) of each EP is programmed as follows to allow the MSI Interrupt Controller to decode the interrupt source.

Table 46-19. MSI Data Register Programming for Use with AHB/AXI MSI Interrupt Controller

15:8	7:5	4:0
Not Used	EP Number <ul style="list-style-type: none"> •Allows each EP to be identified within the system, •For example, EP#5 is programmed with 3'b101. 	Interrupt Vector Number <ul style="list-style-type: none"> •Identifies the interrupt source within each EP. •Programmed to 5'b00000. •Set by MSI generation logic to identify each interrupt source in real time. •Supports up to 32 Vectors.

- The MSI address register (MSI Lower 32 Bits Address Register which is part of the PCI Express MSI Capability Register structure) of each EP is programmed with the same message address.
- The host CPU configures the MSI Interrupt Controller via the local DBI bus (or via Config requests from the remote link partner).
- The common MSI Address that was used for the EPs is programmed into MSI Controller Address Register in the Interrupt Controller (MSI Controller Address Register).
- The Host CPU reads the MSI capabilities of each EP to determine the number of vectors enabled in each EP and uses this information to program the Interrupt Enable registers in the MSI Interrupt Controller. The Interrupt Enable register allows up to 32 MSI Interrupt Vectors to be enabled within the MSI Interrupt Controller for a given EP. It is the responsibility of the host CPU to read the contents of the "Multiple Message Enable" field in an EP's MSI capability structure and program that EP's Interrupt Enable register in the Interrupt Controller appropriately. For example, if Multiple Message Enable is 3'b100 for Endpoint N, which corresponds to 16 enabled Interrupt Vectors, then Interrupt Enable Register N in the Interrupt Controller should be programmed with 0x0000FFFF by the host CPU.

The MSI Interrupt Controller in your core is active and terminates all received MSI MemWr unless you deactivate it.

NOTE

The MSI Interrupt Controller is deactivated when:

- The core is not in RC mode (applies to DM product only). That is, device_type[3:0] is not 4'b0100.
- All of the eight Interrupt Enable Registers have a value of 0x0.

PROCESSING OF DETECTED INTERRUPTS

The MSI Controller decodes the MSI MWr data payload to determine which End Point device (EP) sent the MSI and which interrupt vector it corresponds to.

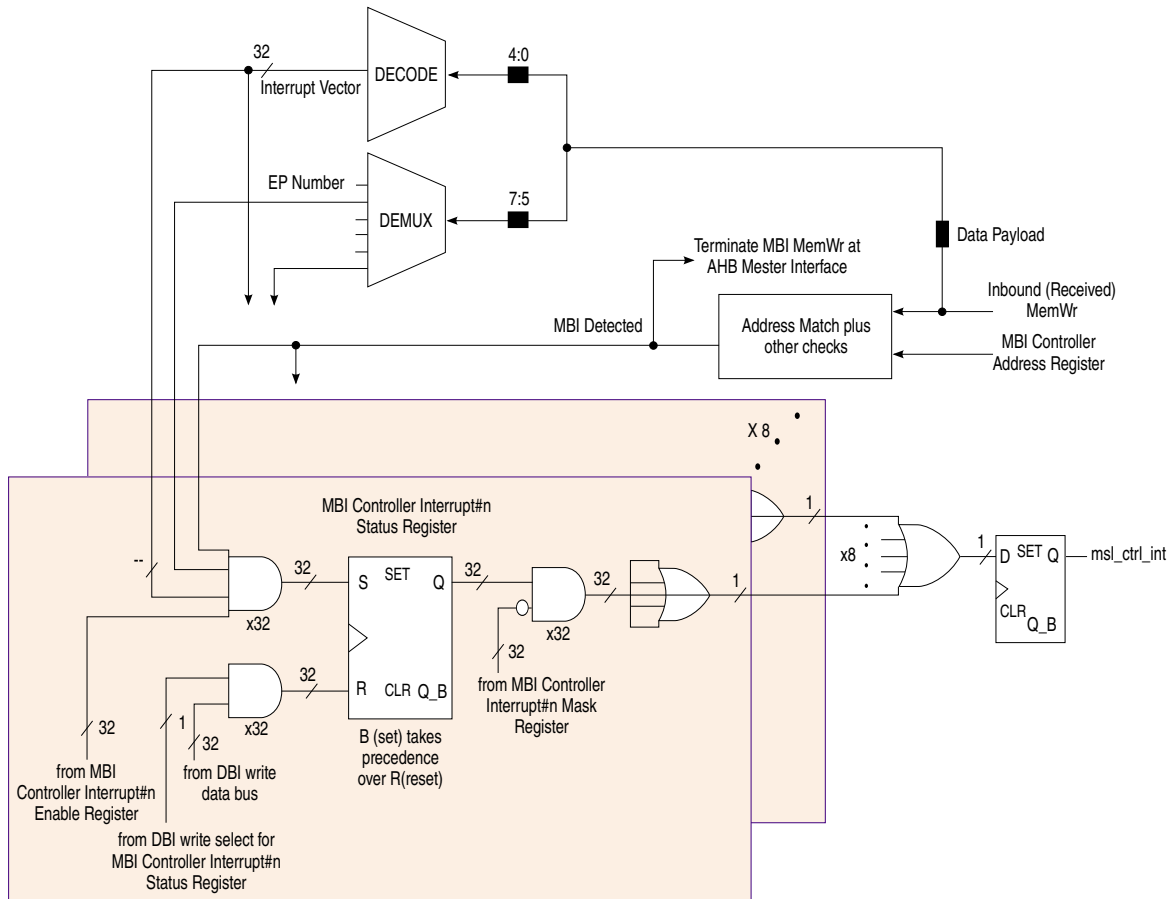

Figure 46-22. Architectural Representation of how the MSI Controller processes detected interrupts.

If the decoded Interrupt Vector is enabled and not masked then the corresponding bit is set in the Interrupt Status register (MSI Controller Interrupt#0 Status Register) and the top-level core output msl_ctrl_int is asserted. This signal remains asserted until the host CPU clears the status bit by writing a 1'b1 to the status bit. (Writing a 1'b0 has no effect). If any status bit remains set then msl_ctrl_int remains asserted. The Interrupt Status register provides a status bit for up to 32 Interrupt Vectors per Endpoint.

If the decoded Interrupt Vector is enabled but is masked then the corresponding bit is set in Interrupt Status register but the top-level core output `msi_ctrl_int` is not asserted.

If an MSI Interrupt Vector is received from an Endpoint but that Vector has not been enabled in the corresponding Interrupt Enable register (MSI Controller Interrupt#0 Enable Register) then no bit will get set in the Interrupt Status Register and `msi_ctrl_int` will not be asserted.

In addition, if no interrupts have been enabled in any of the eight Interrupt Enable Registers, then all MSI detection logic is disabled and valid MSI MWr request TLPs are not terminated in the bridge and are passed by the AHB/AXI master interface to the AHB/AXI bus.

The Interrupt Mask register (MSI Controller Interrupt#0 Mask Register) allows the Host to mask a given MSI Interrupt Vector. If a MSI Interrupt Vector is received for a masked Interrupt Vector, the corresponding bit in the Interrupt Status register will get set but `msi_ctr_intl` will not be asserted as the Interrupt Vector is masked. Note: This masking is local to the MSI Interrupt Controller and is not part of Per Vector Masking (PVM) in any of the downstream Endpoints.

The contents of the Interrupt Mask and Interrupt Status registers are used to drive the `msi_ctrl_int` output. If any status bit is set and the interrupt vector is not masked, then `msi_ctrl_int` is asserted HIGH. As long as any Interrupt Status bit is set and not masked, `msi_ctrl_int` will remain asserted.

ALTERNATIVE DATA REGISTER PROGRAMMING

The programming of the data register (MSI Data Register which is part of the PCI Express MSI Capability Register structure) assumes each Endpoint enables 32 Vectors. If one or more Endpoints only support 16 or less Interrupt Vectors then it is possible to share a single set of Interrupt Enable, Interrupt Mask and Interrupt Status registers among those Endpoints.

For example, assume that Endpoint #1 enables 16 Interrupt Vectors and Endpoint #2 also enables 16 Interrupt Vectors. If the MSI Data register for Endpoint #1 is programmed to 0x20 and the MSI Data Register for Endpoint#2 is programmed to 0x30, then both Endpoint's Interrupt Status will be contained in Interrupt Status Register#1 with Endpoint#1's Vectors in the lower 16 bits and Endpoint#2's Vectors in the upper 16 bits. Manipulating the MSI Data Register format in this manner allows the Interrupt Controller to support more than 8 Endpoints using the 8 Interrupt Status registers provided.

	15							8	7		5	4	3	2	1	0
Data Register Format									Reg N		EP #	Interrupt Vector Number				
Endpoint 1									0	0	1	0	0	0	0	0
Endpoint 2									0	0	1	1	0	0	0	0

Figure 46-23. Alternative MSI Data Register Format

46.3.8 Flow Control

PCI Express implements a differentiated, credit-based Flow Control system to prevent overflows at the receiver.

In contrast to the simple XON/XOFF type flow control of the Ethernet protocol, the PCI Express Flow Control system requires that the consumer of data advertise the available buffer space for each type and priority of traffic. The Flow Control mechanism is divided into two phases: the initialization phase and the update phase. The core automatically performs both of these phases with minimal support required from the application.

The Flow Control for VC0 must be initialized following Link initialization, but prior to sending normal traffic. This initialization is performed by the Flow Control Initialization state machine. The initialization process involves exchanging information with the Link partner about the size of the receiver's buffers for each type of packet data: Posted, Non-Posted, and Completion. Header and payload buffers for each of these types are tracked and reported independently. Flow Control must be initialized for Virtual Channel 0 (VC0) before the Data Link Layer's link state moves into the DL_ACTIVE state, and normal traffic can begin flowing. Additional VCs (if any) are initialized following this, intermingled with the regular traffic already flowing on VC0. Initialization of other VCs begins when the VCs are enabled. The VC0 traffic has priority over non-VC0 flow control initialization.

The core provides a configurable solution to choose the number of credits to advertise per type and per VC. It can be configured to support multiple VCs as well as infinite credits. The core performs all required Flow Control protocol handshakes. The core currently provides a solution in which the application does not have to deal with Flow Control

updates and checks. By default, the RADM is responsible for returning Flow Control credits as data is read out of the RADM queuing structure. Additionally, the core provides optional signals to enable the application to handle Flow Control returns in an application-specific manner

The core does not return Flow Control credits for packets that have Data Link Layer errors.

46.3.9 Address Translation

This is a local address translation implementation and is not related to the PCI-SIG ATS specification support.

If address translation support is enabled for the core, it can use an address translation unit (ATU) to replace the TLP address and TLP header fields in the current TLP request header.

Core Operations

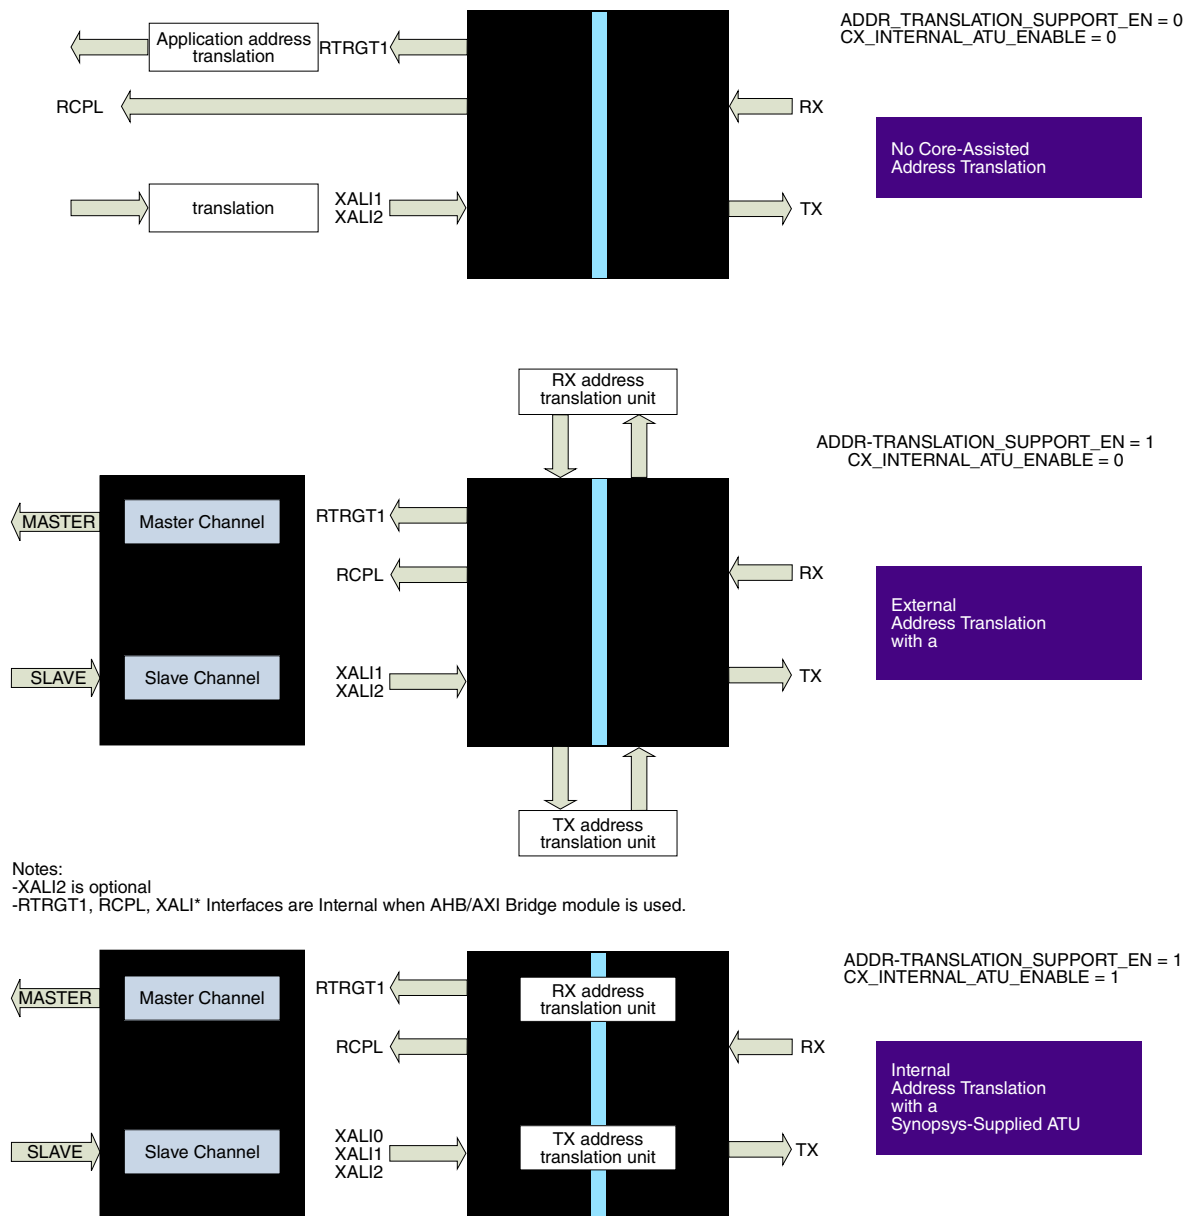

Figure 46-24. Address Translation options

Address translation is used for mapping different address ranges to different memory spaces supported by the application. A typical example will map the AMBA memory space to PCI memory space when the application has the PCIe-to-AMBA bridge in place. TYPE translation is also supported.

Without address translation, the application address is passed to/from the PCIe TLPs directly through AXI bridge interfaces.

The PCIe core supports address translation.

1. Internal Address Translation (iATU) instantiates an internal ATU (iATU) inside the PCIe core. It can be configured (by software) to implement a customer-defined address translation scheme without the need for additional hardware from the customer. To enable this option:

Table 46-20. Configuration Parameters Relevant to Address Translation

Parameter Name	Parameter Label	Value Range	
CX_ATU_NUM_OUTBOUND_REGIONS	Number of Outbound Address Translation Regions	4,	
CX_ATU_NUM_INBOUND_REGIONS	Number of Inbound Address Translation Regions	4,1	
CX_ATU_MIN_REGION_SIZE	Minimum Size of Address Translation Region	64 kB	

NOTE

The easiest and recommended method of implementing address translation is to use the Internal Address Translation Unit (iATU).

46.3.9.1 Internal Address Translation (iATU)

An internal ATU (iATU) is instantiated inside the PCIe core.

It can be configured (by software) to implement a customer-defined address (and TYPE/FORMAT) translation scheme without the need for additional external hardware.

46.3.9.1.1 Outbound (TX) Features

- Address Match Mode operation for MEM/IO/CFG/MSG TLPs. No address translation for CPL.
- Supports TYPE translation via TLP TYPE header field replacement for MEM¹ types to MSG/CFG types.
- This includes translation from Posted to Non-Posted (for example, MWr to CfgWr0).
- No TYPE translation from CPL TLPs.
- Programmable TLP header per region for the following fields for TLP field *replacement*.
 - TYPE / TD / TC / AT / ATTR / MSG Code
 - Function Number (Physical and Virtual).
 - 4 Address Regions based on programmable registers for location and size.
 - Programmable enable/disable per region.

- Automatic format (FMT) field translation between 3 DW and 4 DW for 64-bit addresses.
- Invert Address Matching Mode to translate accesses outside of a successful address match.
- ECAM Configuration Shift Mode to allow a 256 MB CFG1 space to be located anywhere in the 64-bit address space.
- Can be used to replace usage of misc sideband AXI slave bus signals.
- Supports regions from 64kB to 4 GB in size.
-

46.3.9.1.2 Inbound (RX) Features

- Address Match Mode operation for MEM/IO/CFG/MSG TLPs. No address translation for CPL. Selectable BAR Match Mode operation for IO/MEM TLPs.
- TLPs destined for RTRGT0 (internal CDM or ELBI) will not be translated.
- TLPs that are not error-free (ECRC, malformed and so on) will not be translated.
- Programmable TLP header per region for the following fields for *matching*.
- TYPE / TD / TC / AT / ATTR / MSG Code
- Function Number (Physical and Virtual).
- Up to 4 Address Regions based on programmable registers for location and size.
- Programmable enable/disable per region.
- Automatic format (FMT) field translation between 3 DW and 4 DW for 64-bit addresses.
- Invert Address Matching Mode to translate accesses outside of a successful address match.
- Configuration Shift Mode. Optimizes the memory footprint of CFG accesses destined for the AXI bridge interface in multi-function devices.
- Supports cores with and without the AHB/AXI Bridge module.
- Response Code defines the CPL completion status to return for accesses matching a region.
- Supports regions from 64 kB to 4 GB in size.

46.3.9.1.3 Programming (iATU)

The iATU registers are in the PCIe cores' port logic register space (See [PCIe CTRL Port Logic Memory Map/Register Definition](#)). This may be accessed locally via the DBI interface or via PCIe Configuration accesses.

The following registers are used for programming the iATU.

Table 46-21. iATU Register Map

Byte Offset	Description
-------------	-------------

Table continues on the next page...

Table 46-21. iATU Register Map (continued)

+0x200	iATU Viewport Register
+0x204	iATU Region Control 1 Register
+0x208	iATU Region Control 2 Register
+0x20C	iATU Region Lower Base Address Register
+0x210	iATU Region Upper Base Address Register
+0x214	iATU Region Limit Address Register
+0x218	iATU Region Lower Target Address Register
+0x21C	iATU Region Upper Target Address Register

Full descriptions of each register are available at [PCIe CTRL Port Logic Memory Map/ Register Definition](#).

46.3.9.2 Outbound iATU Operation

Information found here describes the processing of outbound requests by the iATU.

The topics for this section are:

- RID BDF Number Replacement
- iATU Outbound MSG Handling
- CFG Handling
- CFG Shift Feature
- FMT Translation
- Invert Feature
- No Address Match Result
- Writing to a MRdLk Region
- Programming Example

OVERVIEW (ADDRESS MATCH MODE)

The address field of each request MEM/IO TLP is checked to see if it falls into any of the enabled¹ address regions defined by the 'Start' and 'End' addresses. If an address match is found, then the TLP address field is modified as follows:

Address = Address - Base Address + Target Address

and the TYPE, TD, TC, AT and ATTR TLP header fields are replaced with the corresponding fields in iATU Control 1 Register.

If the application (AXI) address field matches more than one of the `CX_ATU_NUM_OUTBOUND_REGIONS` address regions, then the first (lowest of the numbers from 0 to `CX_ATU_NUM_OUTBOUND_REGIONS-1`) enabled region to be matched is used.

If there is no address match, then the address is untranslated. In the outbound direction (only), the TLP header information (for fields that are programmable) will come from the relevant fields on the AXI Slave Interface sideband busses (all fields will be 0). Since all `misc_info` are tied to 0, this is not recommended.

This operational mode (called Address Match Mode) is always used for outbound translation.

1. If the 'Region Enable' bit of the 'Region Control 2 Register' is '0', then that region is not used for address matching.

When the PCIe core is operating with 32-bit addresses, the operation is defined as in the following figure.

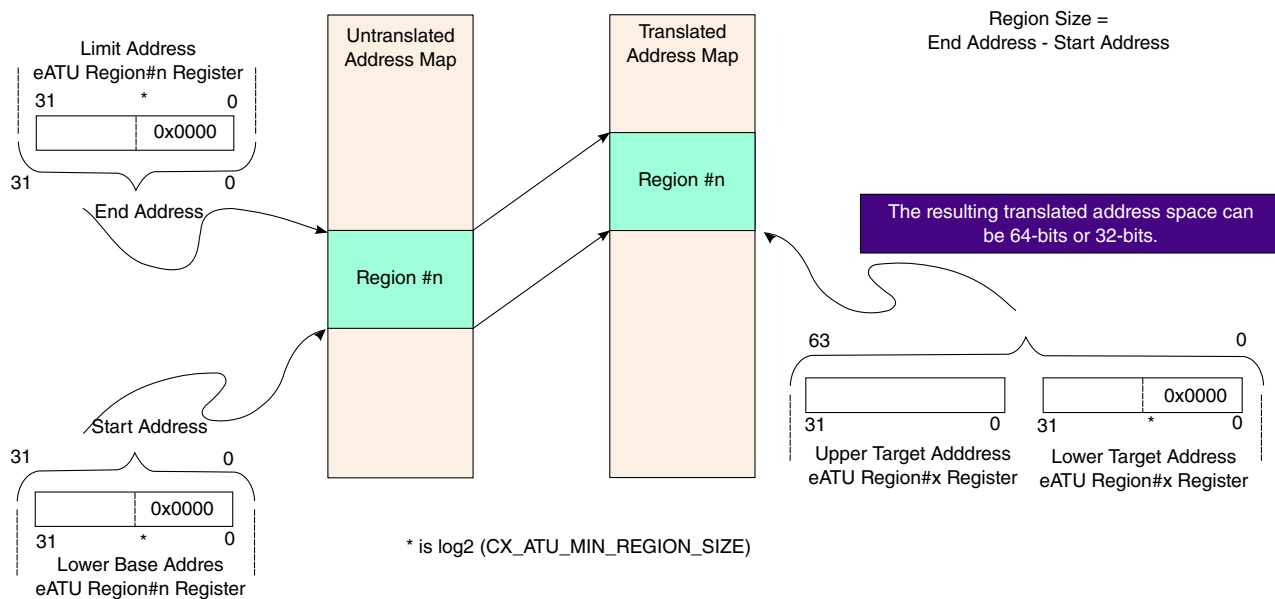

Figure 46-25. iATU Address Region Mapping: Outbound and Inbound (Address Match mode): 32-bit Address

The upper 32 bits of the Target Address Register will always form the upper 32 bits of the translated address because:

- The maximum region size is 4 GB.
- A region may not cross a 4 GB boundary.

The `CX_ATU_MIN_REGION_SIZE` (64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{CX_ATU_MIN_REGION_SIZE})$ bits are zero.

RID BDF NUMBER REPLACEMENT

When there is a successful address match on an outbound TLP, then the function number used in generating the 'Function' part of the Requester ID (RID¹) field of the TLP is taken from the 3-bit 'Function Number' field of the iATU Control 1 Register. The value in this field must be 0x0 unless MultiFunction operation in the core is enabled (`CX_NFUNC > 1`).

iATU OUTBOUND MSG HANDLING

The iATU supports TYPE translation/conversion of MEM⁴ TLP's to Msg/MsgD TLPs. This supports applications that are unable to generate Msg/MsgD type TLPs natively.

When there is a successful address match on an outbound MEM TLP, and the translated TLP TYPE field is 'Message' (that is, 'TYPE' field of the iATU Control 1 Register is 10xxx); then the Message Code field of the TLP is set to the value in the 'Message Code' field of the iATU Control 2 Register.

A MWr with an 'effective length of 0' (see ⁵) is converted to Msg and all other MWr TLPs are converted to MsgD.

NOTE

For more information on generating Messages, see [Message Generation](#).

For a proper understanding of Messages, you should be familiar with the PCI Express Base Specification.

MSG translation is possible with the iATU. For MSG transactions created directly by the application (as opposed to, by the iATU) you must ensure that the 3rd and 4th DWORD (In the PCI Express Base Specification) does not match any programmed iATU address region or else unintentional translation (TYPE) could occur.

RID uses the 8-bit.5-bit.3-bit PCI Bus.Device.Function (BDF) format.

The maximum size of this field is 8 bits, but the actual size depends on the number of Virtual functions (VFs) used as denoted by $2^{\text{NVF_WD}}$ Or IO.

For AXI, this takes the First and Last byte enables into account. For AXI this is through `slv_wstrb`. If you are just translating the address of MSG TLPs, then `client0_tlp_byte_en` is used to provide the Message Code.

CFG HANDLING

Outbound CFG transactions (formed by translation of IO/MEM TLPs from the application) can exist anywhere in address space -because the Routing ID or BDF, is created by the iATU from bits [31:16] of the untranslated address - and this BDF changes according on the PCIe bus topology.

In the normal untranslated transmission of CFG transactions, the PCIe core derives the CFG Bus.Device.Function (BDF) information from the address on the AXI Slave Interface address) as follows.

Table 46-22. Normal PCIe Core Outbound Derivation of BDF from XALI* or AHB/AXI Slave Interfaces

XAXI Slave Interface Bits	PCIe CFG Header Field
31:24	Bus Number
23:19	Device Number
18:16	Function Number
11:8	Extended Register Number
7:2	Register Number

The iATU supports translation (of address or type) of IO/MEM TLP's to CFG TLPs. This supports applications that are unable to generate CFG type TLPs natively.

The 16-bit Bus.Device.Function (BDF) is derived from bits [31:16] of the iATU Lower Target Address Register.

CFG translation is possible with the iATU. For CFG transactions created directly by the application (as opposed to, by the iATU) you must ensure that the Bus.Device.Function field does not match any programmed iATU address region or else unintentional translation (TYPE) could occur.

CFG SHIFT FEATURE

A expander feature (CFG Shift Feature) can be enabled by setting the 'CFG Shift' bit of the iATU Control 2 Register.

This shifts/maps the BDF - bits [27:12] of the Target Address up to bits [31:16] of the translated address. This allows all outgoing IO/MEM TLPs (that have been translated to CFG) to be mapped into any 256 MB region of the PCIe address space.

This scheme also supports the Enhanced Configuration Address Mapping (ECAM) mechanism from the *PCI Express, Revision 3.0 Base Specification*. ECAM supports the mapping (via MEM to CFG TYPE translation) from memory address space to PCI Express Configuration Space address. ECAM maps bits [27:12] of the untranslated MEM TLP to become the BDF of the resulting CFG TLP.

Table 46-23. ECAM Scheme from PCIe Specification using an 8-bit BDF Bus Number

Memory Address Bits	PCIe Configuration Space
27:20	Bus Number
19:15	Device Number
14:12	Function Number
11:8	Extended Register Number
7:2	Register Number

FMT TRANSLATION

The iATU automatically sets the TLP format (FMT) field for 3DW when it detects all zeroes in the upper 32- bits of the *translated* address. Otherwise, it sets it to 4DW when it detects a 64-bit address (that is, when there is a '1' in the upper 32-bits of the translated address). If the original address and the translated address are of different format, the iATU ensures that the TLP header size matches the translated address format.

INVERT FEATURE

Normally, an address match on an outbound TLP occurs, occurs when the untranslated address is in the region bounded by the Base Address and Limit Address.

When the Invert feature is activated, an address match occurs when the untranslated address is NOT in the region bounded by the Base Address and Limit Address.

This feature is activated by setting the 'Invert' field of the iATU Control 2 Register.

NO ADDRESS MATCH RESULT

When there is no address match, then the address is untranslated but

the TLP header information will come from the relevant fields on the AHB/AXI Slave Interface sideband busses (all fields will be 0).

WRITING TO A MRDLK REGION

When there is a successful address match for an outbound WRITE, and the TYPE header field - as replaced with the TPYE field in iATU Control 1 Register - is MRdLk, then the TYPE header field will be set to MEM (that is 00000b).

PROGRAMMING EXAMPLE

See [#d11725e4a1310](#) for details on the programming registers.

NOTE

Define Outbound Region 1 as:

NOTE

IO region from 0x80000000_d000000 - 0x80000000_d000ffff
(64k)

NOTE

mapped to 0x00010000 in PCIe IO space.

1. Setup the Viewport Register

Write 0x00000001 to Address { 0x700 + 0x200 } to set outbound region 1 as the current region

2. Setup the Region Base and Limit Address Registers

Write 0xd0000000 to Address {0x700 + 0x20C} to set the Lower Base Address. Write 0x80000000 to Address {0x700 + 0x210} to set the Upper Base Address. Write 0xd000ffff to Address {0x700 + 0x214} to set the Limit Address

3. Setup the Target Address Registers

Write 0x00010000 to Address {0x700 + 0x218} to set the Lower Target Address

Write 0x00000000 to Address {0x700 + 0x21C} to set the Upper Target Address

4. Configure the region via the Region Control 1 Register

Write 0x00000002 to Address {0x700 + 0x204} to define the type of the region to be IO.

5. Enable the region

Write 0x80000000 to Address {0x700 + 0x208} to enable the region.

46.3.9.2.1 Inbound iATU Operation

This section describe the processing of inbound requests by the iATU. The topics for this section are:

- Overview
- IO/MEM Match Modes
- CFG Handling
- Optional Matching Fields
- Response Code Feature
- iATU Inbound MSG Handling
- Fuzzy Type Match Mode
- FMT Translation
- Invert Feature
- Programming Examples

46.3.9.3 Overview (iATU)

The main difference between Inbound and Outbound iATU operation is that the TLP TYPE is never changed in the Inbound direction.

Instead, the TYPE field is used for more precise matching. Other fields may also be optionally used to further refine the matching process.

Another difference is that for MEM/IO TLPs, you can select between Address matching (as used in Outbound Operation) or BAR matching. Normally an End Point (EP) will use BAR match mode and a Root Complex (RC) will use Address mode as an RC normally has no BAR's implemented.

Lastly, for CFG0 TLPs, you can select between Routing ID matching or Accept mode.

If there is no match then the address is untranslated. In addition,

- TLPs destined for RTRGT0 (internal CDM or ELBI) will not be translated.
- TLPs that are not error-free (ECRC, malformed and so on) will not be translated.
- Address translation of all TLP types (MEM/IO/CFG/MSG) except CPL is supported in Address Match mode. In BAR Match mode only translation of IO/MEM is supported.

IO/MEM MATCH MODES

Inbound Address translation for IO/MEM TLPs will operate in one of two matching modes as determined by the 'Inbound Match Mode' field in the iATU Region Control 2 Register.

1. Address Match Mode

The operation is similar to Outbound iATU Operation.

The address field of each request TLP is checked to see if it falls into any of the enabled¹ address regions defined by the 'Start' and 'End' addresses. If an address match is found, then the TLP address field is modified as follows:

$$\text{Address} = \text{Address} - \text{Base Address} + \text{Target Address}$$

If the TLP address field matches more than one of the CX_ATU_NUM_INBOUND_REGIONS address regions, then the first (lowest of the numbers from 0 to CX_ATU_NUM_INBOUND_REGIONS-1) enabled region to be matched is used.

2. BAR Match Mode

Looking for an address match is a two-step process.

1. The address field of MEM/IO (*only*) request TLPs is checked by the standard internal *PCI Express BAR Matching Mechanism* to see if it falls into any address region defined by the enabled BAR Addresses and Masks.
2. If a matched BAR was found, then that matched BAR ID is compared by the iATU to the 'BAR Number' field in the iATU Region Control 2 Register for all enabled regions.

BAR Match Mode can only be used for MEM/IO transactions.

Address Match Mode should always be used to match MSG transactions as these will never generate a match against a BAR.

1. If the 'Region Enable' bit of the 'Region Control 2 Register' is '0', then that region is not used for address matching.

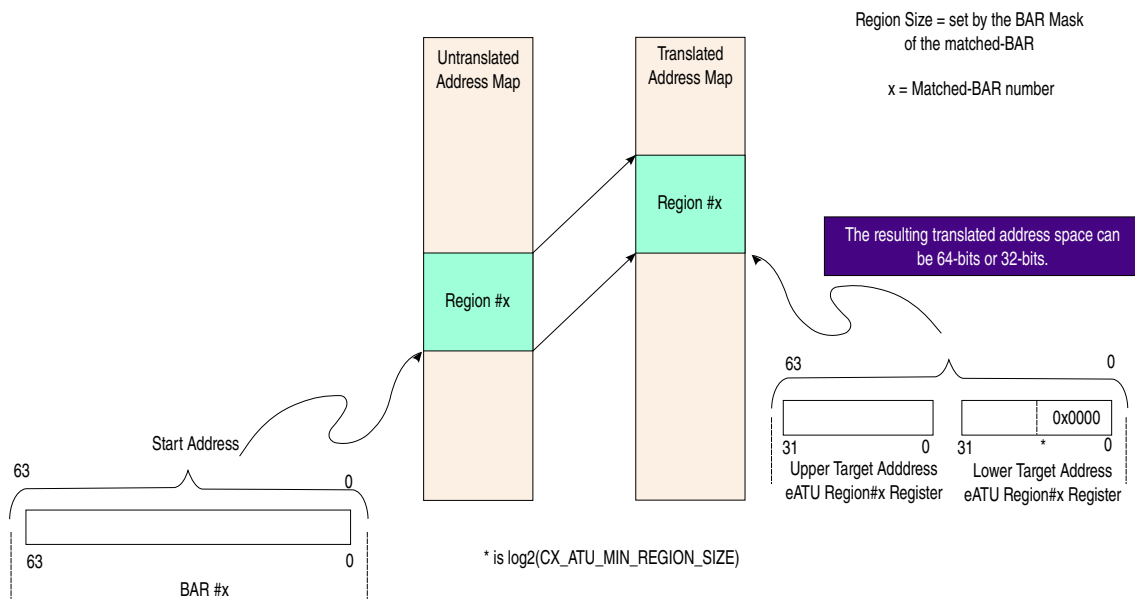

Figure 46-26. iATU Address Region Mapping: Inbound (BAR Match mode): 64-bit BAR

Normally an EP will use BAR match mode and an RC will use Address Match mode -as an RC normally has no BAR's implemented or at least must handle requests which do not match any of its BARs.

However, the user has the freedom to implement any mode in their device. For example, an EP device may use Address Match mode, but should be aware that if the address range does not match one of its BAR ranges in an EP, the device will reject the request with Unsupported Request (UR) completion status and no translation will occur.

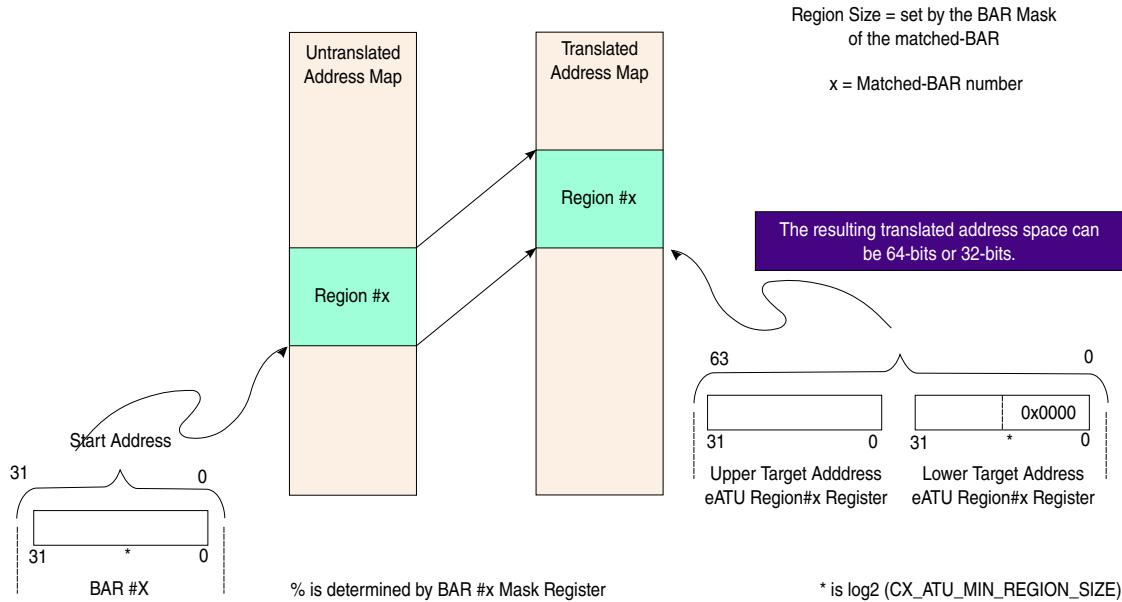

Figure 46-27. iATU Address Region Mapping: Inbound (BAR Match mode): 32-bit BAR

dress space

CFG HANDLING

CFG TLPs are normally routed to internal CDM. These will not be translated. Only CFG0 TLPs routed to AXI Bridge Master interface will be translated.

Inbound Address translation for CFG0 TLPs will operate in one of two matching modes as determined by the 'Inbound CFG0 Match Mode' field of the iATU Region Control 2 Register.

1. Routing ID Match Mode:

The operation is similar to outbound iATU operation. The Routing ID of the inbound CFG0 TLP must fall within the Base and Limit of the defined iATU region for matching to proceed. The iATU interprets the Routing ID (Bytes¹ 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM/IO transactions.

2. Accept Mode:

CFG0 TLPs should always be accepted and processed even if the bus number does not match the current Bus number of the device. This mode follows that behavior. The Routing ID of received CFG0 TLPs will be ignored when determining a match.

CFG1 TRANSACTIONS

For CfgRd1/CfgWr1 transactions the Base and Limit Address could enclose the entire 32-bit 4G memory space with Routing ID forming the upper 16 bits. The Target Address maps these CFG transactions to anywhere in application address space.

CFG SHIFT FEATURE

Inbound CFG transactions (routed for AXI Bridge Master) can exist anywhere in address space -because the Routing ID or BDF, is processed by the PCIe core RADM filter (see [Receive Application-Dependent Module \(RADM\)](#)) as bits [31:16] of an address - and this BDF changes according on the PCIe bus topology.

A compressor feature (CFG Shift Feature) can be enabled by setting the CFG Shift bit of the iATU Region Control 2 Register. Bits [15:12] of the 3rd DWORD¹ of CFG TLPs are reserved. The compressor feature uses this to reduce the memory requirement.

This shifts/maps the BDF - bits [31:16] of 3rd header DWORD which would be matched against the Base and Limit Addresses - of the incoming CfgRd0/CfgWr0 down to bits [27:12] of the translated address.

OPTIONAL MATCHING FIELDS

In Address or BAR Match mode, a successful address/BAR match can be optionally gated by successful matching of the following programmable TLP header fields (per region):

- TYPE / TD / TC / AT / ATTR
- MSG Code (MSG TLP's only)
- Function Number (MEM, IO or CFG TLPs only)
- Virtual Function Number (MEM or IO TLPs only)

For each of the above fields in the iATU Region Control 1 Register (ATU Region Control 2 Register for MSG) there is an associated 'Match Enable' bit in the iATU Region Control 2 Register. Address translation will only proceed if all enabled field-matches are successful.

If SR-IOV is enabled (CX_SRIOV_ENABLE=1), and the Virtual Function Match Enable field of the iATU Region Control 2 Register is set, then the 'Function' is no longer the 3-bit 'Function' but the combined 8-bit 'Device' 'Function' parts. When SR-IOV is enabled, the Alternate RID Interpretation (ARI) RID scheme is used. This uses a 8-bit.0-bit.8-bit BDF format. where the device number is assumed to be zero.

RESPONSE CODE FEATURE

When the 'Response Code' field of the inbound iATU Region Control 2 Register is set to a value other than 00b, it will determine the Completion Status of the CPL TLP sent in response to a successfully matched Non Posted TLP. This can be set to Unsupported Request (UR) or Completer Abort (CA). When the error response field is set to 00b, then the normal RADM (see [Receive Application-Dependent Module \(RADM\)](#)) filter response for this TLP will be used.

IATU INBOUND MSG HANDLING

Inbound Message (Msg/MsgD) transactions can use one of two matching modes:

Address Match Mode: The 3rd and 4th header DWORDs are treated as an address and matched against the iATU Region Base and Limit Address registers. Furthermore, for Vendor Defined messages, this allows specific vendor defined messages to be filtered into memory at the Target Address. The Upper Base Address should be set to Bus.Device.Function (BDF) and Vendor ID. The Lower Base Address can be used as a filter for specific messages.

Vendor ID Match Mode: This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the 3rd DWORD of the TLP header¹, but matches against the Vendor ID in bits [15:0] of the 3rd DWORD of the TLP header (bytes¹ 10 and 11). This allows Vendor defined messages to be filtered against specific Vendor IDs without needing to know the BDF number which may vary depending on the PCI topology.

Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID as follows:

- Region Upper Base[15:8] = byte 10
- Region Upper Base[7:0] = byte 11

The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the 4th DWORD of the TLP header.

NOTE

For more information on generating Messages, see [Message Generation](#). For a proper understanding of Messages you should be familiar with Message Request Rules of the PCI Express Base Specification.

FUZZY TYPE MATCH MODE

When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that

- CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1.
- MRd and MRdLk TLPs are seen as identical
- The Routing field of MsgD TLPs is ignored

For example, CFG0 in the TYPE field in the iATU Control 1 Register will match against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP.

To enable this feature, then set the 'Fuzzy Type Match Mode' bit of the iATU Region Control 2 Register.

FMT TRANSLATION

The iATU automatically sets the TLP format (FMT) field for 3DW when it detects all zeroes in the upper 32- bits of the *translated* address. Otherwise, it sets it to 4DW when it detects a 64-bit address (that is, when there is a '1' in the upper 32-bits of the translated address). If the original address and the translated address are of different format, the iATU ensures that the TLP header size matches the translated address format.

INVERT FEATURE

Normally, an address match on an outbound TLP occurs, occurs when the untranslated address is in the region bounded by the Base Address and Limit Address.

When the Invert feature is activated, an address match occurs when the untranslated address is NOT in the region bounded by the Base Address and Limit Address.

This feature is activated by setting the 'Invert' field of the iATU Region Control 2 Register.

PROGRAMMING EXAMPLES

Define Inbound Region 2 as: MEM region matching BAR4 (BAR Match mode) mapping to 0x800000020000000 in the application memory space

1. Setup the Viewport Register
 - Write 0x80000002 to Address { 0x700 + 0x200 } to set inbound region 2as the current region
2. Setup the Target Address Registers
 - Write 0x20000000 to Address {0x700 + 0x218} to set the Lower Target Address
 - Write 0x80000000 to Address {0x700 + 0x21C} to set the Upper Target Address
3. Configure the region via the Region Control 1 Register
 - Write 0x00000000 to Address {0x700 + 0x204} to define the type of the region to be MEM.
4. Enable the region for BAR Match Mode
 - Write 0xC0000400 to Address {0x700 + 0x208} to enable the region for BAR match mode for BAR#4.

Define Inbound Region 0 as: MEM region matching TLPs with addresses in the range 0x00010000 - 0x0005ffff mapped to 0x1000000020000000 - 0x100000002004ffff in the application memory space

1. Setup the Viewport Register
 - Write 0x80000000 to Address { 0x700 + 0x200 } to set inbound region 0 as the current region
2. Setup the Region Base and Limit Address Registers

- Write 0x00010000 to Address {0x700 + 0x20C} to set the Lower Base Address.
Write 0x00000000 to Address {0x700 + 0x210} to set the Upper Base Address.
Write 0x0005ffff to Address {0x700 + 0x214} to set the Limit Address
3. Setup the Target Address Registers
 - Write 0x20000000 to Address {0x700 + 0x218} to set the Lower Target Address
 - Write 0x10000000 to Address {0x700 + 0x21C} to set the Upper Target Address
 4. Configure the region via the Region Control 1 Register
 - Write 0x00000000 to Address {0x700 + 0x204} to define the type of the region to be MEM.
 5. Enable the region
 - Write 0x80000000 to Address {0x700 + 0x208} to enable the region in address match mode.
 - EP: Defined MEM or IO regions must be inside an enabled BAR range.
 - RC: Defined MEM or IO regions must either match a BAR or be outside of the base and limit ranges defined for the port in the Type 1 configuration header.

46.3.10 Gen2 5.0 GT/s Operation

The PCIe Express core supports all of the non-optional Gen2 5.0 GT/s features defined in the *PCI Express 3.0 Specification*.

46.3.10.1 Overview (Gen2 5.0 GT/s)

The DWC PCIe cores support achieves the PCI Express 2.0 rate, by DYNAMIC FREQUENCY

1. When supporting Gen2 DYNAMIC FREQUENCY, the core operates at either 125 MHz at the Gen1 rate. When operating at the Gen2 rate, the core's clock frequency is changed to 250 MHz

Software configuration of Gen2 5.0 GT/s operation is available through the Gen2 Control Register.

46.3.10.2 Speed Changing

If bit 17 *Directed Speed Change* of the Gen2 Control Register is set to '1', then the LTSSM will initiate a speed change after the link is initialized. The default value of this register is the '1'.

A PIPE signal, `mac_phy_rate`, is used to negotiate the Link data rate. The core drives `mac_phy_rate` to indicate the negotiated Link data rate. For `mac_phy_rate`, a value of zero indicates 2.5 Gbps, and a value of one indicates 5.0 Gbps. The PCIe core changes the rate signal and waits for a pulse on the `phy_mac_phystatus` signal to confirm that the PHY has accepted the requested rate.

The PCIe core uses `core_clk` to sample the `phy_mac_phystatus` signal during speed changes. The PHY generates `phy_mac_phystatus` based on `pipe_clk`. Therefore, the following restrictions are placed on DWC_pcie external logic when the PHY is Gen2 Dynamic Frequency and the PCIe core is Gen2 Dynamic Width (i.e. when `core_clk` is not equivalent to `pipe_clk`).

1. ensure that `core_clk` is toggling when the PHY returns `phy_mac_phystatus` for a speed change

OR

2. the external logic must hold `phy_mac_phystatus` (for the speed change) until `core_clk` toggles again

For other configurations, the `core_clk` is equivalent to the `pipe_clk`, and this restriction is not needed.

46.3.11 Power Management

An architectural overview of the Power Management Controller is given in "Power Management Controller (PMC)".

There are two types of power management operations:

- Software controlled PCI power management operations
- Active state power management operation (ASPM) for PCIe device only

The following figure shows the capable link state and its control conditions.

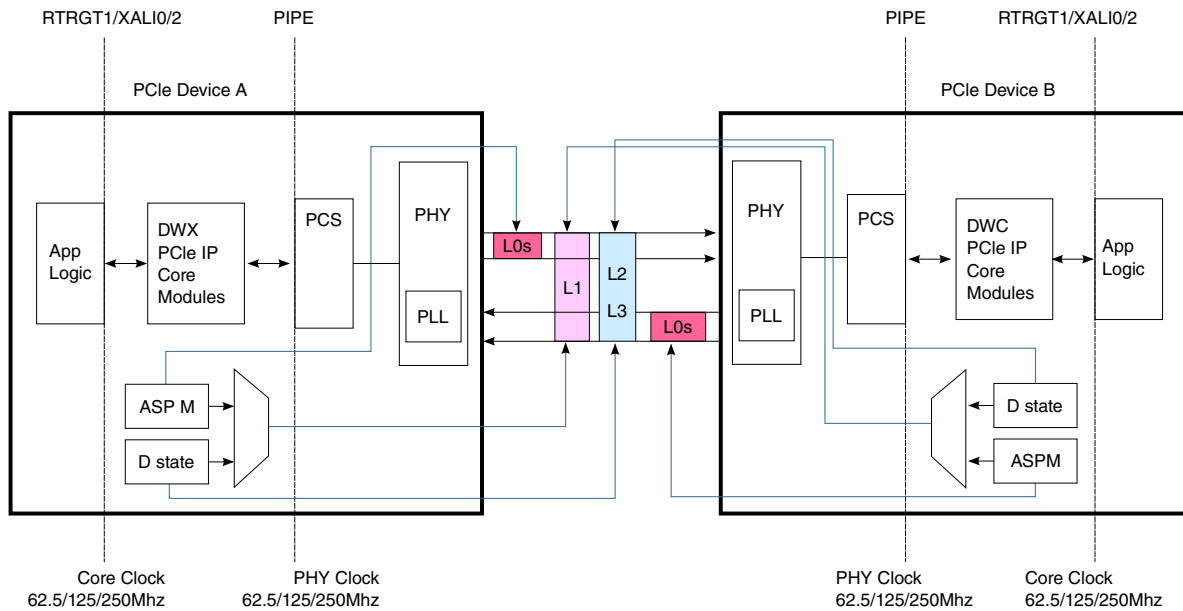

Figure 46-28. Power Management - Capable Link State and Control Conditions

The L0s link state is controlled by the ASPM L0s enter condition met state. The L1 link state is controlled either by the ASPM L1 enter condition met state, or by the D-state (D1, D2, or D3) of the PCIe device. The D-state of the PCIe device is programmable by software. The L2/L3 ready state is controlled by D-state and power turn-off event.

The power saving of links in lower power states is greater as the link state numbers get larger. The following figure shows the links states of PCIe devices and the relationships of power down states between link partners.

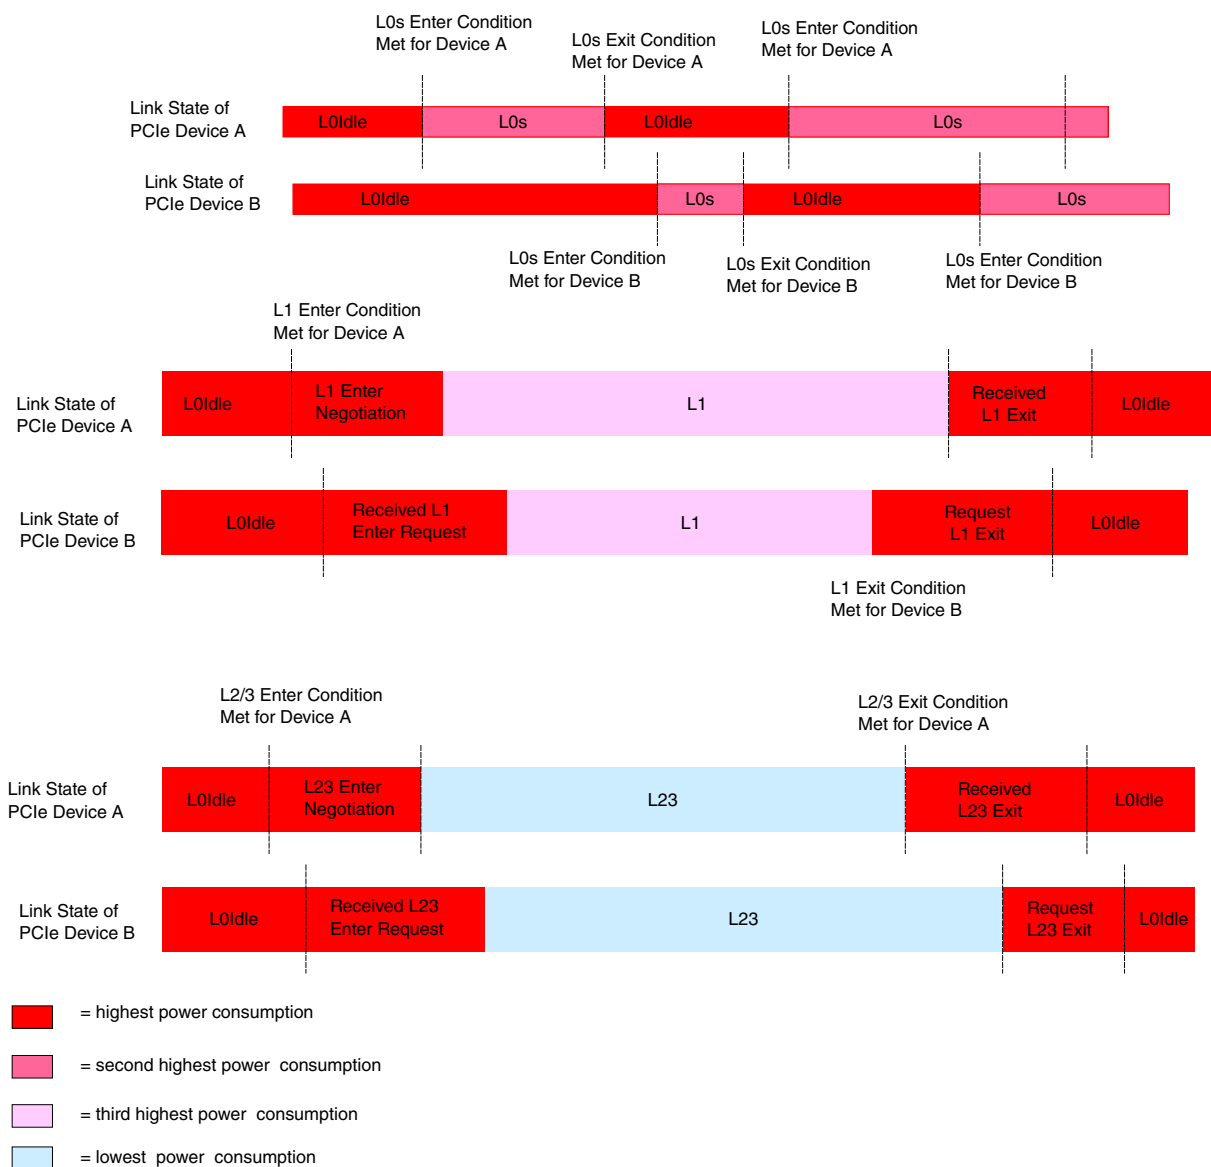

Figure 46-29. Relationships of Power Down States between Link Partners

46.3.11.1 L0s Power Down

L0s is a low power state enabled by Active State Power Management (ASPM). ASPM enabled devices can only control L0s entrance of the transmitter. The receiver L0s is controlled by the remote devices.

L0S ENTER CONDITIONS (ALL CONDITIONS MET)

- ASPM L0s is enabled.
- L0s enter conditions defined by *PCI Express Specification* for a duration of time and there is no higher stage of power down requested.
- The timeout value is controlled by the DEFAULT_L0S_ENTR_LATENCY parameter.

L0S EXIT CONDITIONS (ANY CONDITION MET)

- Any DLLP or TLP pending to be sent.
- L1 enter condition met.
- PCIe link partner request to enter into link recovery.

46.3.11.2 L1 Power Down

L1 is a power down state enabled either by ASPM or by the software controlled D1, D2 or D3 state (which is programmed by the system power management unit). L1 state is a bi-directional link power down state. Both link partners must negotiate to go to L1 state.

L1 ENTER CONDITIONS DUE TO ASPM (ALL CONDITIONS MET)

There are three scenarios that result in the L1 state:

- Scenario 1: L1 Idle Timeout From L0s

ASPM L1 and L0s are enabled.

Link state is in L0s for both transmitter and receiver of the link, and bit 30 of the [Ack Frequency and L0-L1 ASPM Control Register](#) is set to 0 (default setting) OR Link state is in L0s of transmitter and bit 30 of the [Ack Frequency and L0-L1 ASPM Control Register](#) is set to 1.

L1 enter conditions defined by PCIe spec for a duration of time and there is no higher stage of power down requested.

The timeout value is controlled by the DEFAULT_L1_ENTR_LATENCY parameter.

- Scenario 2: L1 Idle Timeout from L0

ASPM L1 is enabled and L0s is not enabled.

Link state is in L0.

L1 enter conditions defined by PCIe spec for duration of time, and there is no higher stage of power down requested.

The timeout value is controlled by the DEFAULT_L1_ENTR_LATENCY parameter.

- Scenario 3: Application Controlled

ASPM L1 is enabled.

Application request to enter L1 by asserting signal `app_req_entr_11`

L1 enter conditions defined by PCIe spec is met.

NOTE

The `app_req_entr_11` is a pulse. The core latches the command and makes sure that L1 has been entered.

L1 ENTER CONDITIONS DUE TO D1/D2/D3 STATES (ALL CONDITIONS MET)

- All functions that are programmed to D1, D2 or D3 states.
- Always enter L1 when L2/L3 PM turn-off negotiation has not yet been done.

L1 EXIT CONDITIONS (ANY CONDITION MET)

- Software requests a higher stage of power down.
- Any DLLP or TLP pending to be sent.
- Application requesting exit of L1 by asserting signal `app_req_exit_11`.
- Link partner requesting exit of L1.

Once L1 has exited, another L1 entry will not be initiated for 10us if the enter L1 condition is due to ASPM. If the enter L1 condition is due to lower power D-state, the core will enter L1 again after a wait time of `cfg_cpl_sent_count` cycles defined in PL register. This wait time to ensures the exit conditions have been served.

3.14.3 L2/L3 Power Down

The core has control over the L2 or L3 ready link state. After the L2/L3 ready is entered, the downstream device will begin preparation for the power and clock removal. After main power has been removed, the link will transition to L2 if `Vaux` is provided, or it will transition to L3 if no `Vaux` is provided. L2/L3 ready is a bi-directional link power down state.

L2/L3 ENTER CONDITIONS (ALL CONDITIONS MET)

- `PME_Turn_Off/Pme_To_Ack` handshake has been completed at any of D0,D1,D2,D3 states.
- Application is ready to be turned off by asserting signal `app_ready_entr_123`.

L2/L3 EXIT CONDITIONS (ANY CONDITION MET)

- Device is programmed with capability to support PME and application requests wakeup by asserting the apps_pm_xmt_pme signal or by triggering a native hot-plug event when D-state is in D1, D2 or D3.
- Link partner requesting exit of L2/L3.

The core supports beacon signaling by asserting signal pm_phy_beacongen or wake when a wake-up event is initiated by a PCIe device.

46.3.12 Completion Timeout Ranges

Timeout ranges are supported as defined in the *PCI Express 3.0 Specification*.

The Device Capabilities 2 Register (Offset 24h) shows support for all ranges. The Device Control 2 Register (Offset 28h) will have a reset value equal to the default value in the spec: "0000b Default range: 50 us to 50 ms". If the default value is used then the timeout will be in "Range B: 0101b: 16ms to 55ms." This range was chosen for the default because the *PCI Express 3.0 Specification* states "It is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms." The following table illustrates the specification values versus the PCI Express core values for the ranges.

NOTE

As per the PCIe 2.1 spec, "This mechanism is intended to be activated only when there is no reasonable expectation that the Completion will be returned, and should never occur under normal operating conditions."

Table 46-24. PCIe Core Completion Timeout Ranges versus PCI Express Specification

Range	Encoding	Spec Minimum	Spec Maximum	PCIe Core Minimum	PCIe Core Maximum
Default	0000b	50µs	50ms	28ms	44ms
A	0001b	50µs	100µs	65µs	99µs
A	0010b	1ms	10ms	4.1ms	6.2ms
B	0101b	16ms	55ms	28ms	44ms
B	0110b	65ms	210ms	86ms	131ms
C	1001b	260ms	900ms	260ms	390ms
C	1010b	1s	3.5s	1.8s	2.8s
D	1101b	4s	13s	5.4s	8.2s
D	1110b	17s	64s	38s	58s

46.4 AXI Bridge Module

46.4.1 Product Overview

46.4.1.1 Overview

The PCIe Core provides an AXI Bridging capability for directly adding a PCI Express link to an AXI system fabric. This significantly reduces the time to design PCI Express into an AXI-based SOC.

The AXI Bridge Module acts as a bridge between the standard AXI interfaces and the PCIe Core native interfaces. The bridge interconnects the AXI interfaces within an AMBA-embedded system with a remote PCIe link, as either a root complex port or as an endpoint port. The bridge supports up to two AXI interfaces, one for an AXI master, and one AXI bus shared for AXI Slave and DBI bus access to the native PCIe core.

The AXI master interface enables a remote PCIe device to read and write to an AXI slave connected to the AXI bridge. The AXI slave interface enables an AXI master to read and write through the AXI bridge to a remote PCIe device. The slave DBI (see [DBI Access](#)) enables an AXI master to read and write to registers inside the native PCIe core, It is shared with the AXI slave interface.

Throughout this chapter, the terms inbound and outbound are defined with respect to the AXI fabric. That is, inbound transactions are defined as the transactions presented by the native PCIe core's AXI master interface. Outbound transactions are defined as the transactions generated by an AXI master that targets a remote PCIe device.

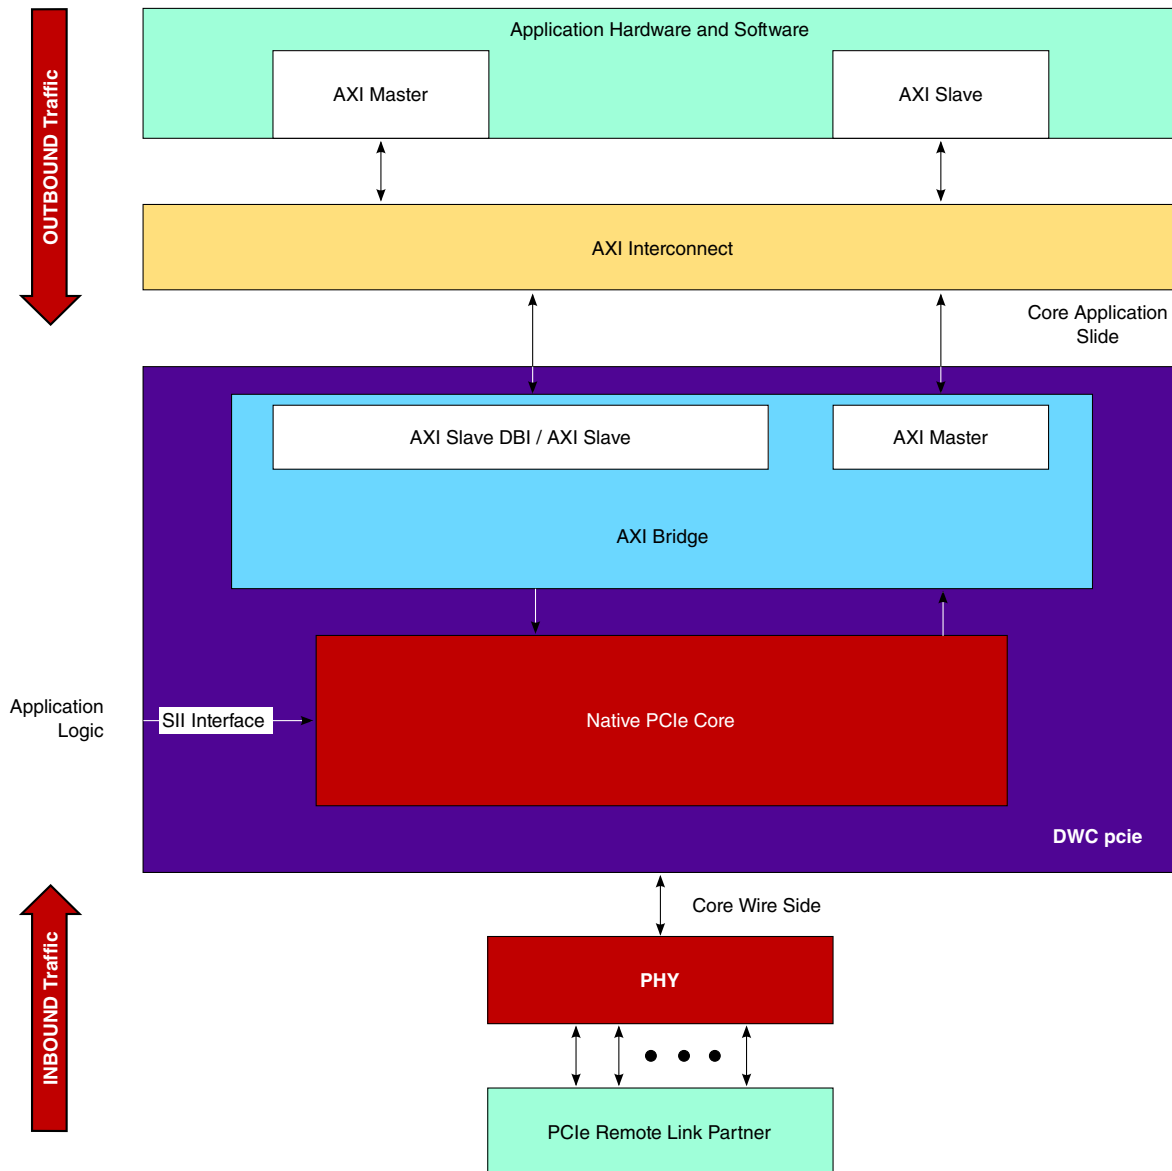

Figure 46-30. System-Level View of the DWC PCIe AXI Core

46.4.1.2 Interfaces

The figure below shows the DWC PCIe AXI core top-level interfaces.

Figure 46-31. DWC PCIe AXI Core Top-Level Interfaces

For definitions of acronyms used for block and interface names, see [Terms and Abbreviations](#).

46.4.1.3 Features List

The AXI Bridge Module supports the following features.

- AXI Master and Slave interfaces for inbound and outbound PCI Express requests.
- Multi-function support (up to 8 functions) [EP mode only].
- All types of PCI Express transactions supported through the AXI Bridge.
- A shared AXI Slave interface to access native core's CDM registers
- Programmable buffer sizes for AXI master and slave requests.

- Independent programmable user-defined clock rates for the PCI Express core, AXI master bus, AXI slave bus,.
- Programmable maximum number of outstanding inbound and outbound read requests for AXI.
- All burst-sizes supported for both AXI master and slave interfaces.
- Programmable and extended AXI burst lengths to support up to 4K read/write burst lengths over AXI master and slave interfaces.
- Little-endian operation.
- Independent maximum read request and transfer sizes between AXI and PCI Express (transfers can be split into multiple transfers).
- Response to AXI slave request combined gathering from split PCI Express completions that are received in-order.
- Response to AXI master request combined gathering from multiple AXI responses.
- PCIe legacy interrupt or MSI support.
- User-defined error mapping between PCI Express errors (UR, CA, CRS, poisoned, and ECRC error) and AXI slave response errors (SLVERR and DECERR).
- User-defined error mapping between PCI Express errors (UR, CA, CRS, poisoned, and ECRC error) and AXI master response error (DECERR_W and DECERR_R).
- Programmable byte parity check for the address and data buses throughout the bridge.
- Non-contiguous byte enables supported for inbound read/write and outbound write TLPs.
- Programmable MSI Interrupt controller to detect and terminate inbound MSI TLP's in the bridge for RC and DM (RC mode) products.

46.4.1.4 Limitations

The table below identifies the limitations encountered when using the AXI bridge with the DWC PCIe native core.

Table 46-25. AXI Bridge Limitations

AXI Bridge Limitation	Note
PCIe completions of a decomposed outbound AXI read request must be returned in-order.	<p>Decomposition of outbound reads will not occur if your application master always generates read requests of size less than Max_Read_Request_Size.</p> <p>If decomposition occurs, and the remote device (or switch) is reordering completions, then corruption will occur at the Slave Response Composer in the AXI bridge. The Slave Response Composer only performs only in-order reassembly.</p> <p>In this case, you can set the AMBA Multiple Outbound Decomposed NP Sub-Requests Control Register to '0' to avoid corruption, at the expense of some performance.</p>

Table continues on the next page...

Table 46-25. AXI Bridge Limitations (continued)

	See Outbound Ordering Limitation #1 for more details.
Posted and non-posted AXI writes targeting the bridge slave should use different AXI tags in order to allow the relevant B-channel responses to be received in order	See Outbound Ordering Limitation #2 for more details.
The AXI bridge only supports the CPL queue in <code>Store</code> and <code>Forward</code> mode, when a <code>Segmented Queue</code> architecture is used. Otherwise, the CPL queue operates in <code>Bypass</code> mode, as it does for the <code>Single</code> and <code>Multiple</code> queue architectures.	Set completions (CPL) to <code>Bypass</code> mode if you have not configured the core to use a segmented buffer queue architecture. See Queue to Port Mapping .
Vendor Messages must not be decomposed.	See AHB/AXI Message Address and Size Limitations for more details.
Big-endian operation is not supported	-
PCIe Advanced Error Reporting (AER) is not supported in the AXI bridge.	AER is only supported with respect to the native PCIe core. Errors detected by the bridge are not reported as part of AER.

46.4.2 Bridge Architecture

46.4.2.1 Bridge Architecture Overview

This module contains AXI master and slave protocol handlers, internal slave and master control for generic request and response interfaces, a packet composer, and a packet decomposer for response formation.

The slave and master protocol handlers support the AXI protocol conversion between an AXI transfer and a generic transfer within the bridge. The slave and master generic interface (GIF) supports the conversion of an AXI transfer to a PCIe transaction. The packet decomposer and composer support the segmentation and reassembly of a PCIe transaction.

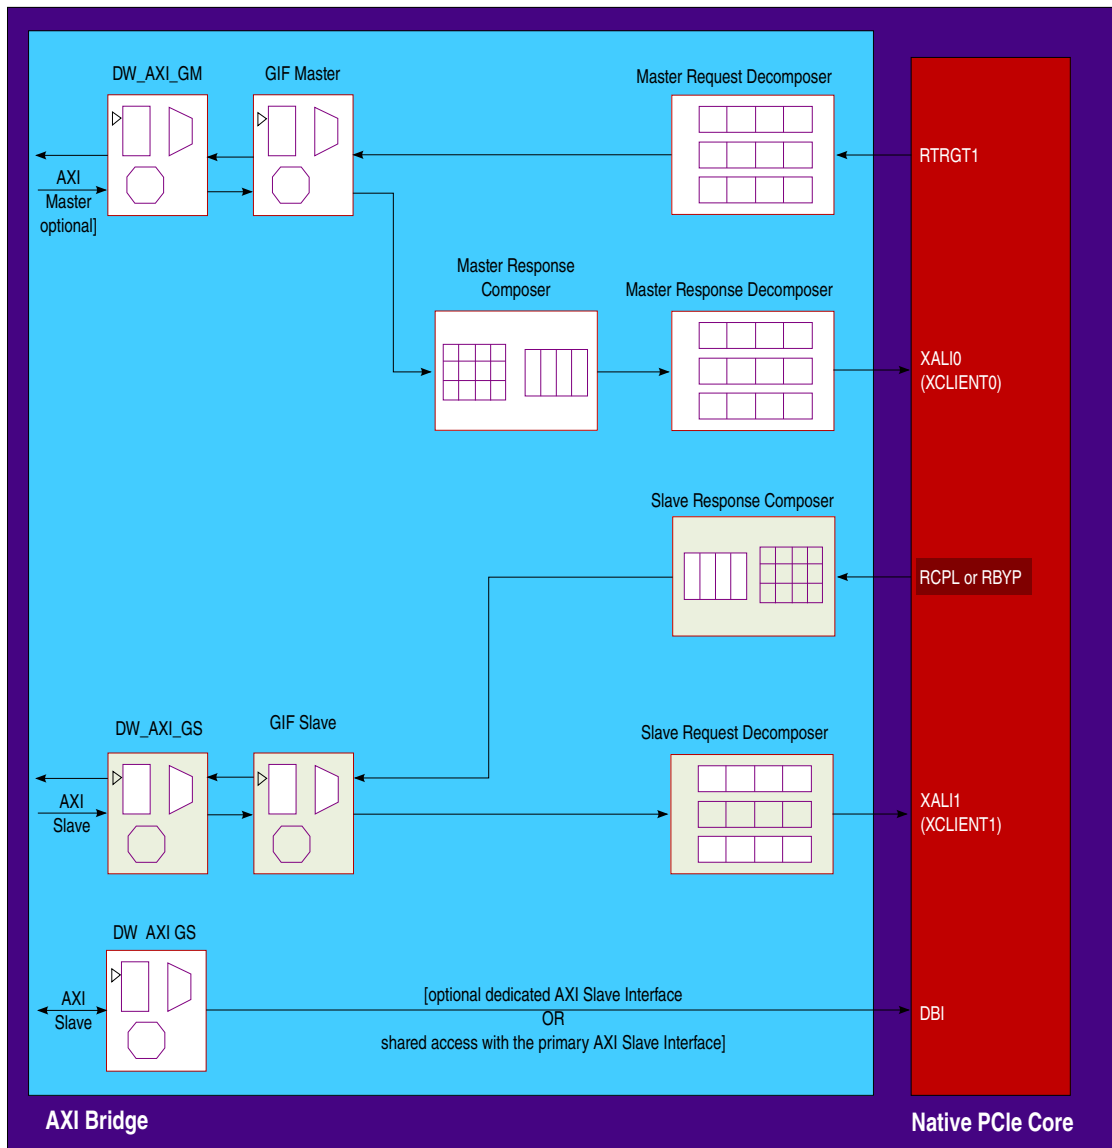

Figure 46-32. AXI Bridge Module, Block Diagram

The bridge module provides flexible buffering ([Bridge Buffering](#)) and tag management ([Outbound Bridge Tag Management](#)) to facilitate seamless bridging between the PCI Express native core and your application modules.

It has an optional master interface and a second optional slave (DBI) for accessing local registers in the native core CDM. Note also that DBI access is without the second slave (DBI). In this mode (shared DBI) the single slave is used to access both the DBI and the PCIe link.

46.4.2.1.1 Inbound Processing Module Chain

The following table lists the bridge modules involved in processing inbound requests.

Table 46-26. Bridge Modules Involved in Processing an Inbound (PCIe -> AXI) Requests

Module	Processing Step	Function
Master Request Decomposer	Request	Performs packet segmentation to satisfy the AXI fabric's "Max Burst Size" and "4KB Address Boundary" rules. These rules are discussed in Bridge Buffering .
Generic InterFace (GIF) Master	Request	The internal bridge circuitry is based on a generic protocol (GIF) and is not explicitly aware of whether it is interfacing to AXI or AHB.
Master Interface (DWC_axi_gm)	Request	This is the AXI protocol handler.
Master Response Composer	Response (Completion)	Performs packet reassembly caused by the bridge-initiated packet segmentation on the inbound request in the Master Request Decomposer.
Master Response Decomposer	Response (Completion)	Performs packet segmentation to satisfy PCI Express "Max Payload Size" and "Max Read Request Size" rules. These rules are discussed in Bridge Buffering .

46.4.2.1.2 Outbound Processing Module Chain

The following table lists the bridge modules involved in processing outbound requests.

Table 46-27. Bridge Modules Involved in Processing an Outbound (AXI -> PCIe) Requests

Module	Processing Step	Function
Slave Interface (DWC_axi_gs)	Request	This is the AXI protocol handler
Generic InterFace (GIF) Slave	Request	The internal bridge circuitry is based on a generic protocol (GIF) and is not explicitly aware of whether it is interfacing to AXI or AHB.
Slave Request Decomposer	Request	Performs packet segmentation to satisfy PCI Express "Max Payload Size" and "Max Read Request Size" rules. These rules are discussed in Bridge Buffering .
Slave Response Composer	Response (Completion)	Performs packet reassembly caused by the following sources of segmentation: <ul style="list-style-type: none"> •Bridge initiated packet segmentation on the outbound request in the Slave Request Decomposer. •Packet segmentation caused by the remote completer.

The application master request (at the AXI Slave Interface) will not - AXI protocol demands it - request more than 128 bytes and will not issue a request that involves crossing a 4K page boundary. Therefore the AXI response (completion) - composed from one or more completions that arrive in off the PCIe wire -is AXI compliant and does not need to be processed in a decomposer to enforce AXI page boundary and maximum packet size rules. Therefore there is no Slave Response Decomposer in the bridge module. In contrast, there is a Master Response Decomposer.

NOTE**CC_SLV_MTU**

Also known as **CC_SLV_RD_REQ_SIZE**

This value is used to set memory sizes in the bridge (Slave Request Decomposer Data FIFO and Slave Response Composer).

Calculated as $CC_SLV_BURST_LEN * (SLAVE_BUS_DATA_WIDTH / 8) = 16 * 64 / 8 = 128$

CC_SLV_BURST_LEN is the maximum burst in beats that the application will ever issue to the bridge slave interface.

46.4.2.2 Decomposition

The bridge manages the different transfer sizes between PCIe and AXI.

The maximum payload is configured independently between the AXI and PCIe systems. Each system's transfer size will sometimes need to be converted causing a split of a request and composition of a response.

Automatic segmentation and reassembly of outbound (application to PCIe wire) packets is performed to satisfy PCI Express *Max_Read_Request_Size* and *Max_Payload_Size* rules. When a decomposition rule is triggered, the outbound TLP is broken up into two or more smaller TLPs. If the TLP type is Non Posted then additional PCIe TAGs are used from the TAG pool. Additional entries in the outbound header buffer are also used.

In a similar manner, automatic segmentation and reassembly of inbound packets is performed. The same AXI ID is used for all decomposed Non-Posted (but not for Posted; see [Inbound Bridge Tag Management](#)) packets.

The host software can program the PCIe device to support certain maximum write transfer sizes and maximum read request sizes. The native PCIe core's configuration module contains the device's *Max_Payload_Size* and *Max_Read_Request* size information, which are defined by the application software. The AXI bridge supports mismatches that occur when the AXI maximum transfer length is different than the *Max_Payload_Size* and *Max_Read_Request* size. For example, an inbound read transfer has an associated response buffer that is dependent on the remote PCIe device's *Max_Read_Request* size. An inbound write transfer has a master write buffer that is dependent on the remote PCIe device's *Max_Payload_Size*.

More detailed information on decomposition rules and effects is available at the end of the AXI bridge section at [AXI Decomposition Rules](#).

46.4.2.3 Bridge Buffering

The bridge has additional buffering in addition to buffering already present in the native core.

The following table identifies all of the RAMs that are used in the AXI bridge for buffering purposes.

Table 46-28. Lists of Buffering Related RAMS

RAM Name	Alternative Name
Slave Request Decomposer Header and Data Queues : buffering of Outbound AXI Request	XADMX1 Decomposer Header and Data RAMs
Slave Response Composer : buffering of Inbound Responses to Outbound AXI Request	RADMX Composition RAM
Slave Response Asynchronous Clock Crossing FIFO : synchronization of Inbound Responses to Outbound AXI Request	RADMX Asynchronous RAM
Master Request Decomposer Header and Data Queues : buffering of Inbound PCIe Request	RADMX Decomposer Header and Data RAMs
Master Response Composer : buffering of Outbound Responses to Inbound PCIe Request	GM Composition RAM
Master Response Decomposer Header and Data Queues : buffering of Outbound Responses to Inbound PCIe Request	XADMX0 Decomposer Header and Data RAMs

More detailed information on buffering is available at the end of the AXI bridge section at [Outbound Bridge Tag Management](#) .

Figure 46-33. Overview of Bridge Buffering

46.4.2.4 Outbound Bridge Tag Management

The bridge transfers IDs/TAGs between PCIe and AXI.

Transactions on PCIe and AXI bus have separate IDs/TAGs and as the bridge transfers the data, it maps and keeps track of the IDs/TAGs on each side.

The diagram found here gives an overview of the outbound tag management system for Non Posted requests.

Figure 46-34. Outbound Tag Management Architecture (Non Posted requests only) - request path is shown but completion path is omitted.

When an AXI outbound Non Posted request at the slave interface is converted to a PCIe request TLP, it is necessary to:

- Select a PCIe tag from the 'free' pool of currently available PCIe tags. This is performed using a Tag Manager (see Module 'b' in figure above). When the pool is exhausted, no more PCIe request TLPs can be transmitted until the pool is replenished by tags from inbound PCIe completion TLPs. See steps 2 and 3 in figure above.
- Store the mapping from AXI request to PCIe TAG, so that when the corresponding PCIe completion TLP arrives back in the future, it can be correctly associated with

the originating request. This is achieved using a Tag Look Up Table (LUT) - see Module 'd' in figure above.

The process of mapping AXI requests IDs to PCIe tags is a two-step process - Application Tag mapping and PCIe Tag mapping (as described above).

Application Tag mapping -which is internal to the bridge -is an intermediate step which has to occur first. See steps 1 and 2 in figure above.

In the AXI protocol, it is possible to have several AXI requests with the same AXI ID. Therefore it is necessary for the bridge to differentiate between individual AXI requests to enable it to track them and their completions throughout the system.

This is necessary to aid in reassembling or recomposing (but not necessarily re-ordering, see [Outbound Ordering Limitation #1](#) for more details) the multiple inbound completions that are returning for an original single AXI outbound request.

Multiple completions can occur due to decomposition (see [Decomposition](#)) of the original outbound request or due to the remote link partner choosing to complete a request using multiple completions.

Application tag mapping occurs via the following process:

- The bridge maps the AXI ID to an internal application tag (see Module 'a' in figure above). This application tag identifies the reserved space in the Slave Response Composer for the expected returning completions.
- The bridge store the mapping from the AXI ID to the internal application tag, so that when the corresponding PCIe completion TLP arrives back in the future, it can be correctly associated with the originating request. This is achieved using a Tag Look Up Table (LUT) - see Module 'c' in figure above.
- If decomposition occurs, each PCIe TLP is assigned a unique PCIe tag from the pool of CX_MAX_TAG (31) tags (see Module 'b' in figure above). Each of these PCIe tags is associated with the same internal application tag and this information is stored in a LUT (see Module 'c' in figure above).

If at any time, all PCIe TAGs or internal application tags are consumed, then the AXI Bridge Slave interface will not accept any new transactions and will apply back-pressure to the AXI fabric.

46.4.2.5 Inbound Bridge Tag Management

The bridge transfers IDs/TAGs between PCIe and AXI.

Transactions on PCIe and AXI bus have separate IDs/TAGs and as the bridge transfers the data, it maps and keeps track of the IDs/TAGs on each side. When an inbound PCIe request TLP is converted to an AXI request at the master interface, it is necessary to:

- Select an AXI ID from the 'free' pool of currently available AXI IDs.
 - For Non Posted requests, this is done using an ID Manager - see Module 'b' in the figure below.
 - Posted (P) requests always use ID '0'.
- When the pool is exhausted, no more requests can be launched onto the AXI fabric until the pool is replenished by IDs. An ID is released to the pool when the completion has arrived back from the application AXI master. In the case where the inbound PCIe TLP request was decomposed, then the ID is released when all the individual completions have arrived back into the master response composer.
- Store the mapping from PCIe TAG to AXI request ID to, so that when the corresponding AXI response arrives back in the future, it can be correctly associated with the originating request. This is achieved using an ID Look Up Table (LUT) - see Module 'a' in the figure below.

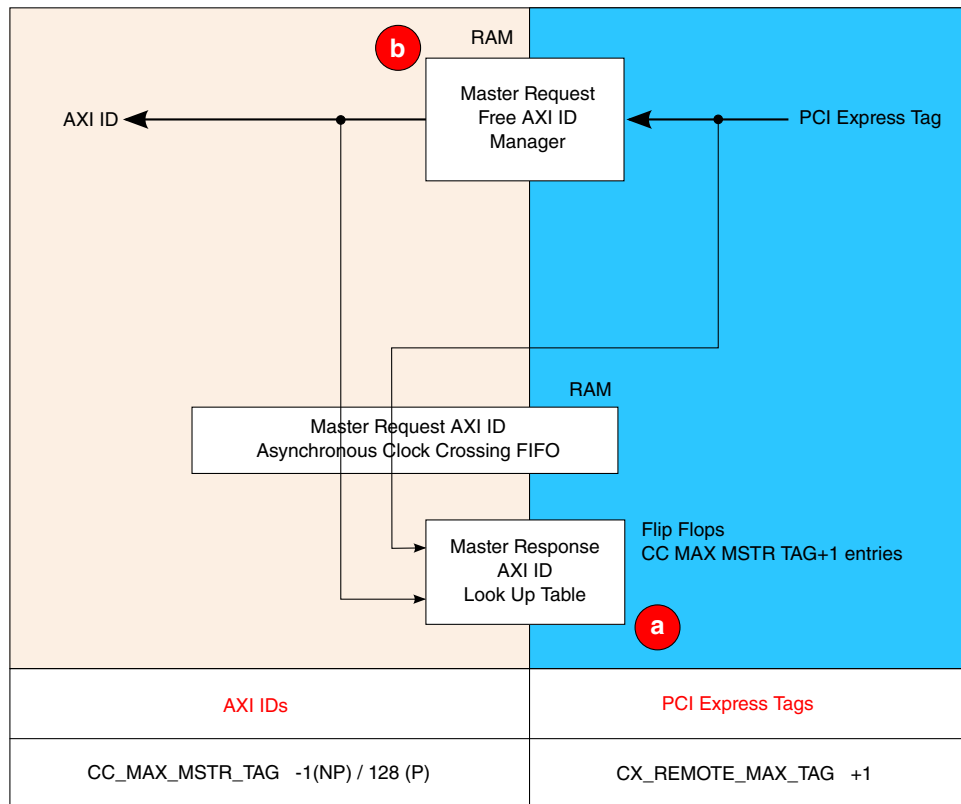

Figure 46-35. Inbound Tag Management Architecture - request path is shown but completion path is omitted.

Decomposition ([Decomposition](#)) does not affect AXI ID usage. If decomposition is occurring, then the same ID is used for each AXI request that is generated by decomposition. Each response is identified by the AXI bridge using its response ID.

Since the PCIe Posted transfer expects no response (completion) for a Posted request, the AXI bridge drops the write responses.

The AXI bridge master interface issues all Posted requests with an ID of '0'. The AXI bridge master interface issues Non Posted requests with an ID from the range 1 to $CC_MAX_MSTR_TAG - 1$ ($4 - 1 = 3$).

It is possible to have $CC_MAX_MSTR_TAG - 1$ ($4 - 1 = 3$). outstanding Non Posted requests and 128 Posted requests at the same time since Posted requests are always writes and use a different AXI ID signal (`mstr_awid`). The following memory devices are connected with inbound tag management in the bridge.

46.4.2.6 Inbound Order Enforcement for AXI Bridge

The DWC PCIe AXI bridge has the inbound buffers shown in the figure found [here](#).

- a single FIFO queue structure (Master Request Decomposer Data and Header Queues) for inbound read/write requests
- a segmented buffer queue structure (Slave Response Composer) for inbound completions in response to outbound read requests.

There is no reordering after an inbound request has left the native core's receive queue. The request FIFO is blocking and will not allow read or write requests pass each other. This default design architecture is designed to serve inbound traffic as a FIFO (first-come, first-served) i.e. in-order service.

Figure 46-36. DWC PCIe AXI Bridge Inbound Traffic Queue Architectures

The native core (before the bridge) has flexible buffering (see [Queue to Port Mapping](#) and PCIe order rule enforcement is performed within the native core. See [PCIe Core Inbound Order Enforcement](#).

46.4.2.6.1 Ordering Enforcement Hardware Lock Feature

Once a completion has been taken out of the receive queues of the DWC PCIe core, it can pass a posted request.

To enforce the PCIe Ordering rule completions should not pass posted if relaxed ordering is not set for applications that require it, the DWC PCIe AXI bridge employs a hardware lock mechanism feature.

This feature will prevent completions from passing posted requests by requiring that posted transactions all complete through the bridge to an AXI interface before a completion can be taken out of the receive queue. This ensures that previous posted transactions are never passed by a completion. This feature is turned on when the DWC PCIe core is configured to have a receive queue in the segmented buffer mode and completion is in store-forward mode.

The feature employs packet halt signals generated by the bridge and used by the core when deciding how to unload the segmented buffer queue of the core. There is an individual halt signal for posted, non posted and completion transactions. Completion transactions are halted when there are any posted transactions in the bridge FIFO.

The limitation of the above feature is that it gives the posted transactions priority such that it can always pass through the bridge when it is available, while the completions are blocked.

Figure 46-37. DWC PCIe AXI Bridge Inbound Traffic Order Enforcement

46.4.2.6.2 Re-Ordering Effects of AXI Fabric

The ordering rules, in typical AXI bridge configurations, apply only to the PCIe native core inbound queue and not after the inbound or outbound traffic has reached the AXI bridge. This means, for example, if a posted request followed by a completion reaches the AXI bridge, then it is possible that the completion will reach the AXI slave response channel before the posted reaches the AXI master request channel. This depends on the readiness of AXI master request channel (if wait states are asserted by the AXI bus).

The AXI bridge has independent AXI channels for outbound and inbound transfers. Therefore, a read response can be presented on the read outbound AXI channel while a write request is being presented onto the write inbound AXI channel. Since the response of an outbound read and inbound write request can be presented onto the application logic of AXI simultaneously, then the PCIe traffic order rules do not get completely enforced by most AXI bridge applications.

The AXI bridge master will generate a unique ID for each Non-Posted request (If decomposition is occurring, then the same ID is used for each AXI Non Posted request. For more details see [Decomposition](#) and [Inbound Bridge Tag Management](#)). Each response is identified by the AXI bridge using its response ID.

The AXI bridge master interface issues a Posted request (write) with a unique ID that is independent from master reads. Since the PCIe Posted transfer expects no response, the AXI bridge drops the write responses. If decomposition is occurring, then a unique ID is used for each AXI write request. For more details see [Inbound Bridge Tag Management](#).

46.4.2.6.2.1 Inbound Ordering Limitation

Sometimes a Non-Posted transaction can pass a Posted transaction on the AXI fabric and this is a violation of the ordering rules. The AXI master interface does not wait for a write response - when it issues write transactions on the AW channel - before issuing a read transaction issued on the AR channel. As a result, a read transaction issued on the AR channel (after a write transaction on the AW channel) could complete first. This could happen if the AXI fabric delays completion of a write request (for example, due to latency in a write buffer) and a read request from the same address follows the write.

NOTE

For information on AXI ID generation see [Inbound Bridge Tag Management](#).

46.4.2.6.3 Additional Information (ordering)

- Order enforcement through the native core is discussed in [App Note: Order Enforcement Using the PCIe Core](#).
- Outbound Order Enforcement for AXI Bridge

The DWC PCIe AXI bridge has the following outbound buffers (see the figure below):

- a single FIFO queue structure (Slave Request Decomposer Data and Header Queues) for outbound read/write requests
- a segmented buffer queue structure (Master Response Composer) for outbound completions in response to inbound read requests.

These two queues are independently structured. Therefore, there is no order maintained (between completions and requests) once outbound requests or outbound responses have entered the bridge.

The FIFO is blocking and will not allow read or write requests pass each other. This default design architecture is designed to serve outbound traffic as a FIFO (first-come, first -served) i.e. in-order service. Outbound requests are served onto the PCIe wire in the order that they are received from an AXI master.

Figure 46-38. AXI Bridge Outbound Traffic Queuing Architecture

The native core (after the bridge) has no transmit buffering and requests and completions are transmitted onto the wire directly. Completions use a different interface (XALI0) to requests (XALI1) and may or may not pass the outbound requests depending on client arbitration.

46.4.2.6.4 PCIe Completion Reordering

If the returning completions (for all Non Posted outbound requests with the same AXI ID) from the remote device are returned out-of-order, the bridge Slave Response Composer will re-order them according to AXI IDs.

Only completions corresponding to outbound requests with the same AXI ID are re-ordered, while all others ones will be returned following the chronological order in which they are received from the remote device.

46.4.2.6.5 Outbound Ordering Limitation #1

An outbound AXI request at the slave interface may be decomposed into multiple PCIe TLP requests.

See [Decomposition](#) for more information. There is a PCI Express protocol ordering rule that states that the completions associated with the different TLPs may pass each other. The current bridge Slave Response Composer design cannot handle this scenario and will not re-order the completions, resulting in data corruption. To avoid data corruption, one of the following workarounds is required.

- Prevent outbound decomposition by ensuring that your application master does not generate bursts of size greater than `Max_Read_Request_Size`. Otherwise, you must program or design your PCI Express system with a larger value of `Max_Read_Request_Size`. See [Decomposition Side-Effects](#).
- Set AMBA Multiple Outbound Decomposed NP Sub-Requests Control Register to '0' which will disable the possibility of having multiple outstanding non-posted requests that were derived from decomposition of an AMBA request. This should only be done when decomposition is guaranteed to occur and completions are coming back out of order from the wire, as it restricts the PCIe transmit link performance by only having one outstanding non-posted request TLP (from a request that is being decomposed) on the PCIe link at any one time.

It is also a PCI Express ordering rule that a remote device which completes a single request using multiple completions (CplID) must return them in-order. The bridge can accept an interleaved stream of multiple completions (in response to multiple requests it originally transmitted), provided that all the completions for any one original request are in-order.

46.4.2.6.6 Outbound Ordering Limitation #2

Posted and non-posted AXI *writes* targeting the bridge slave must use different AXI tags in order to allow the relevant B-channel responses to be received in-order.

If this restriction is not observed, it can happen that a B-channel response to a posted (P) write (MWr/Msg) arrives before the B-channel response associated to a non posted (NP) write (for example, IOWr), even if the NP request send first.

The B-channel response to a P write is issued by the AXI bridge slave immediately after the request is accepted by the bridge slave. The B-channel response to an NP write is issued by the AXI bridge slave when the completion (CplID) arrives back from the remote link partner.

46.4.2.6.7 Additional Information (AXI bridge bandwidth)

Order enforcement through the native core is discussed in [App Note: Order Enforcement Using the PCIe Core](#).

46.4.3 PCIe AXI Core Operations

46.4.3.1 AXI Sideband (Misc. Bus) Signals

An AXI sub-system can only convey data, address and read/write information. It has no way to propagate PCIe concepts such as TLP type, Posted/Non Posted, Function Number, TLP attributes and so on. Therefore, some method is required to map these PCIe concepts between AXI and PCIe. This is done through the Software option.

Use the Internal Address Translation (iATU) to map outbound AXI transactions from different AXI address regions to particular PCIe address regions and TLP types. For example, map all AXI transactions in the region 0x0010FD00 - 0x00FFFFFF to CFG TLPs in the PCIe address region 0xD010FD00 - 0xD0FFFFFF.

46.4.3.2 Supported AXI Transfer Type

The AXI Bridge Module is compliant with the AMBA 3.0 AXI specification.

46.4.3.3 Supported AXI Burst Operations

- For outbound transfers (accessing bridge SLAVE):
 - The AXI bridge slave supports the incremental burst type (INCR) which is used in conjunction with ARLEN and AWLEN to define any length of burst.
 - The AXI bridge slave does not support the WRAP and FIXED burst types. If your application issues these burst types to the AXI bridge slave, a SLVERR or DECERR response is not returned by the bridge slave. In this scenario, the PCIe core exhibits undefined behavior.
- For inbound transfers (using bridge MASTER):
 - The AXI bridge master used the incremental burst type (INCR) which is used in conjunction with ARLEN and WLEN to define any length of burst.
 - The parameter CC_MSTR_BURST_LEN controls the maximum length burst that will be generated by the master interface.
 - The AXI bridge master does not use the WRAP and FIXED burst types.

46.4.3.4 I/O and CFG Transaction Handling over AXI Bridge

I/O and CFG-type inbound and outbound transfers are fully supported by the AXI bridge. I/O and CFG transactions always have the following characteristics:

Table 46-29. IO and CFG Characteristics

A payload of length equal to one DWORD (four bytes, 32 bits).
First byte enable (FBE) can be any value including '0000'.

Table continues on the next page...

Table 46-29. IO and CFG Characteristics (continued)

A payload of length equal to one DWORD (four bytes, 32 bits).
Last byte enable (LBE) is always '0000'.

46.4.3.4.1 Outbound I/O and CFG Transaction Handling

The following conditions must be satisfied for all outbound CFG and I/O requests presented by the application to the bridge slave interface:

- The outbound IO/CFG transactions should be DWORD aligned. Therefore, $slv_a*addr[1:0]=00b$ and $slv_a*size=2$.
- The outbound AXI -> PCIe transfer must complete in a single AXI transfer without the need for a bus burst or a series of bus transfers.
- The maximum burst length for outbound IO and CFG transfers is one, corresponding to one DWORD.

There is one methods that can be used to signal to the PCIe core that the application wants to send an IO or CFG transfer.

46.4.3.4.1.1 Method I: Address Translation Method of Sending an Outbound IO or CFG Transfer

The optional internal address translation unit (iATU) in the native core can change the TYPE of an outbound request from MEM to IO or CFG by matching the address of that request to a configured address range as set by the application. See [Internal Address Translation \(iATU\)](#).

NOTE

You should use the Internal Address Translation (iATU) instead of the Slave Request Sideband Bus (slv_a*misc) - to transmit CFG or IO requests.

It is also possible to do the same (for READs only) using a customer defined external address translation unit.

46.4.3.4.2 Inbound I/O and CFG Transaction Handling

The inbound PCIe -> AXI transfer completes in a single transfer without the need for a burst or a series of transfers except during:

- NCBE transfer. e.g. FBE = 1011 | 0101 | 1001 | 1101.
- Unaligned¹ transfer. e.g. FBE = 1110 | 1100 | 1000
- Narrow transfer. e.g. FBE = 1110 | 1100 | 1000 | 0111 | 0011 | 0001

1. For an unaligned (i.e. non-DWORD aligned) inbound PCIe -> AXI transfer ($FBE = 1110 \mid 1100 \mid 1000$), the AXI transfer still completes in one bus beat since $LBE = 0000$.

46.4.4 Additional AXI Reference Material

46.4.4.1 AXI Decomposition Rules

The host software can program the PCIe device to support certain maximum write transfer sizes and maximum read request sizes.

The native PCIe core's configuration module contains the device's *Max_Payload_Size* and *Max_Read_Request* size information, which are defined by the application software. The AXI bridge supports mismatches that occur when the AXI maximum transfer length is different than the *Max_Payload_Size* and *Max_Read_Request* size. For example, an inbound read transfer has an associated response buffer that is dependent on the remote PCIe device's *Max_Read_Request* size. An inbound write transfer has a master write buffer that is dependent on the remote PCIe device's *Max_Payload_Size*.

46.4.4.1.1 Outbound Decomposition

Automatic segmentation and reassembly of outbound (application to PCIe wire) packets is performed to satisfy PCI Express *Max_Read_Request_Size* and *Max_Payload_Size* rules. When a decomposition rule is triggered, the outbound TLP is broken up into two or more smaller TLPs. If the TLP type is Non Posted then additional PCIe TAGs are used from the TAG pool. Additional entries in the outbound header buffer are also used.

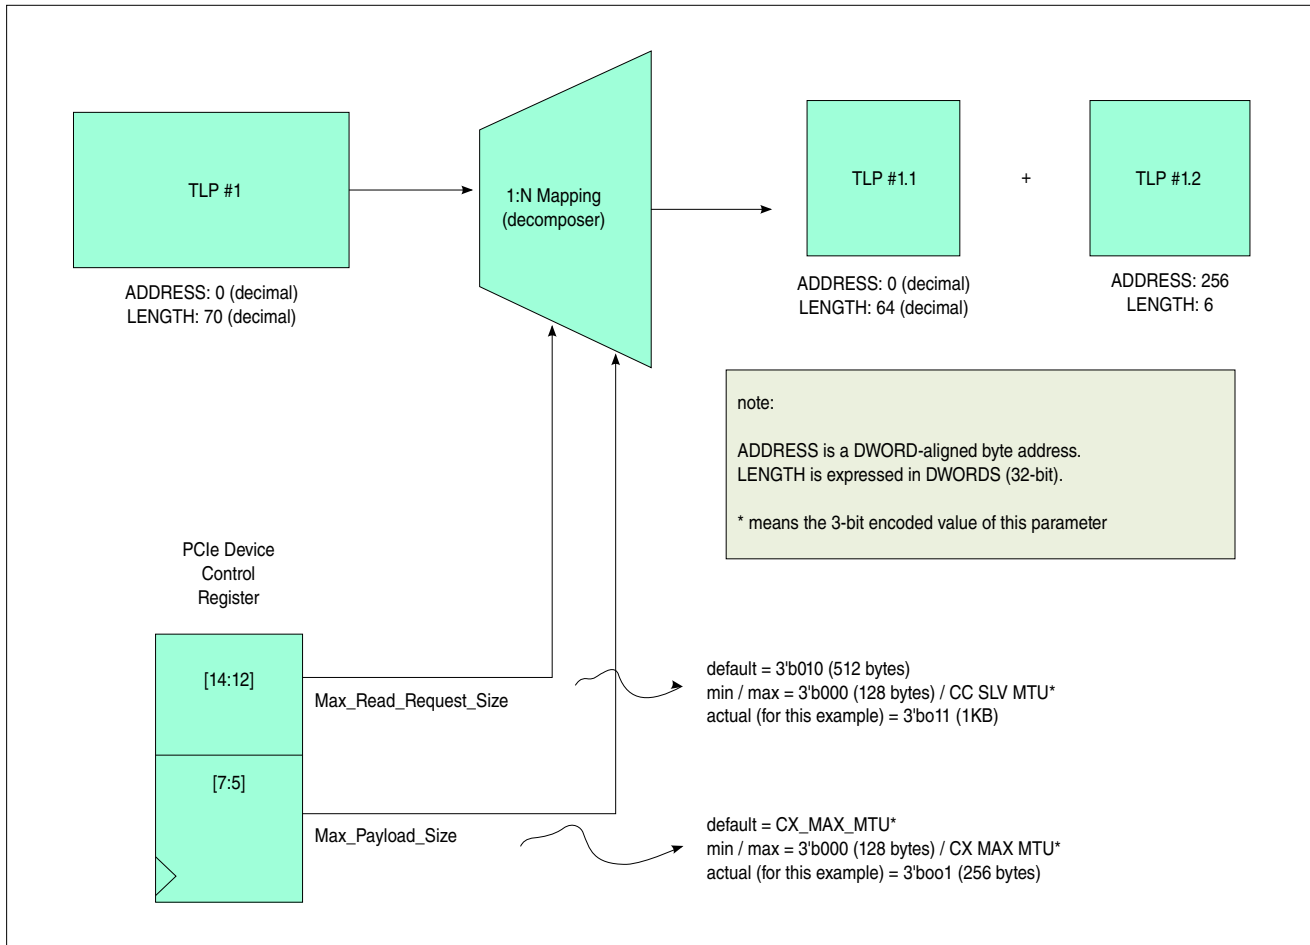

Figure 46-39. Outbound Decomposition Example of MemWr with Max Payload Size set to 256 bytes (64 DWORDs)

The Slave Request Decomposer module uses the following rules to determine when decomposing takes place.

Table 46-30. Outbound Decomposition Rules

TLP Request Type	Decompose ¹ When
Read	TLP length >= PCIe Max_Read_Request_Size
Write	TLP length >= PCIe Max_Payload_Size

1. To avoid possible decomposition when the address is not DWORD aligned, you must ensure that TLP length is not only > Max_Read_Request_Size but also >= Max_Read_Request_Size.

The AXI page boundary is 4K, and so the application master request (at the AXI Slave Interface) will not issue a request that involves crossing a 4K PCIe page boundary - AXI protocol demands it.

NOTE

`CX_MAX_MTU` - 128

The largest packet payload (Maximum Transfer Unit) that the device will support. Specified in bytes and not DWORDS.

This is distinct from the maximum operating payload (`Max_Payload_Size`) which may be set by software.

46.4.4.1.1 Decomposition Side-Effects

Decomposition degrades the PCIe link performance as because it increases the amount of TLP header overhead and uses up extra PCIe TAGS.

Decomposition uses up extra header FIFO locations which will reduce the bridges bus-offloading ability in some cases.

46.4.4.1.2 Reducing Outbound Decomposition

To reduce decomposition on the outbound path, observe the following guidelines.

For Write Requests:

- Ensure that your application master does not generate bursts of size greater than or equal to Max Payload Size. In this context 'burst size' refers to the total number of bytes requested, or
- Program your PCI Express system with a larger value of `Max_Payload_Size` without exceeding `CX_MAX_MTU` (128).

For Read Requests:

- Ensure that your application master does not generate bursts of size greater than or equal to `Max_Read_Request Size` or,
- Program your PCI Express system with a larger value of `Max_Read_Request` without exceeding `CC_SLV_MTU` (128).

46.4.4.1.2 Inbound Decomposition

In a similar manner, automatic segmentation and reassembly of inbound packets is performed. The same AXI ID is used for all decomposed packets. The figure below illustrates the rules that are used in the Master Request Decomposer module to determine when decomposing takes place.

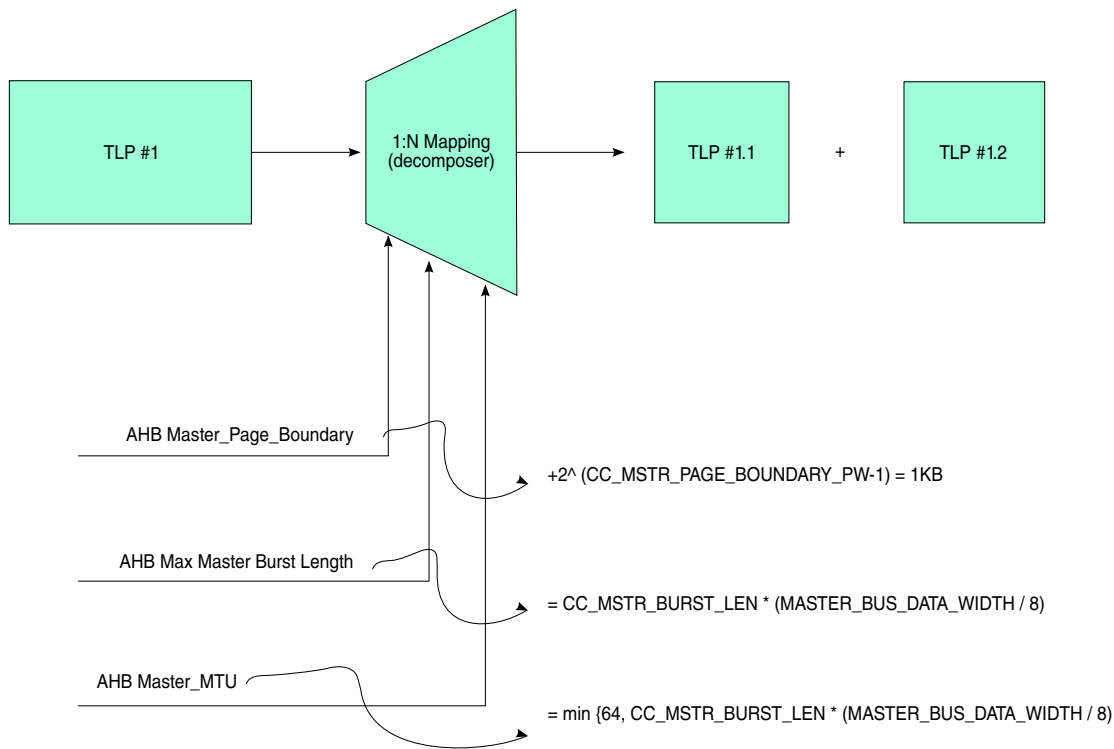

Figure 46-40. Inbound Decomposition

CC_MSTR_BURST_LEN (16) is the maximum burst in bus beats that the bridge will ever issue at the bridge master interface. It is set by the user.

The following rules are used in the Master Request Decomposer module to determine when decomposing takes place.

Table 46-31. Inbound Decomposition Rules

TLP Request Type	Decompose When
Read	TLP length (bytes) > AXI Master_Max_Read_Request_Size (see Figure 46-40)
Write	TLP length (bytes) > AXI Master_MTU (see Figure 46-40)
Read or Write	TLP address + TLP length crosses an AXI Master_Page_Boundary (see Figure 46-40)

The AXI *Master_Page_Boundary* specifies an address page boundary of 4K. The AXI bridge will ensure that the inbound request will not cross the selected page boundary when driven onto AXI master interface. .

46.4.4.1.2.1 Reducing Inbound Decomposition

To reduce decomposition on the inbound path, observe the following guidelines. For Read Requests:

- Ensure that the remote link partner does not issue a read request TLP with a requested length greater than the *AXI Master_Max_Read_Request_Size* (see [Figure 46-40](#)).

or

- Design your application (and configure the bridge) to handle longer AXI bursts. That is, increase the value of the configuration parameter *CC_MSTR_BURST_LEN* or increase the AXI master data bus width.

For Write Requests:

- Ensure that the remote link partner does not issue a write request TLP with a payload greater than the *AXI Master_MTU* (see [Figure 46-40](#)).

or

- Design your application (and configure the bridge) to handle longer AXI bursts. That is, increase the value of the configuration parameter *CC_MSTR_BURST_LEN* or increase the AXI master data bus width.

For All Requests:

- Program or design your PCI Express system so that a TLP address plus the TLP length does not cross the *AXI Master_Page_Boundary* (see [Figure 46-40](#)).

46.5 App Note: Order Enforcement Using the PCIe Core

46.5.1 PCIe Ordering Rule Overview

This application note is written for applications that require certain ordering rules within PCIe traffic. There are many ordering rules according to the PCIe specification. The following is a general description from the PCIe 2.1. base spec.

PCIe 2.1 base specification defines the ordering requirements for PCI Express transactions. The ordering rules defined in the spec apply within a single traffic class (TC). There is no ordering requirement among transactions with different TC levels.

Root Complexes that support peer-to-peer operation and Switches must enforce these transaction ordering rules for all forwarded traffic. These forwarding devices should not forward traffic from one virtual channel to another.

Basic ordering rules are summarized as follows:

- Posted is permitted to pass posted transaction only if the relaxed order bit is set.
- Non-posted is permitted to pass or to be blocked by non-posted.
- Completion with different ID is permitted to pass or be blocked by other completions.
- Posted must be allowed to pass non-posted to avoid deadlock.
- Posted is permitted to be blocked by completions.
- Non-posted can never pass posted.
- Non-posted is permitted to pass or be blocked by completions.
- Completions can pass posted only if the relaxed order bit is set.
- Completions must be allowed to pass non-posted to avoid deadlock.

In general, ordering rules are used based on a specific device's functionality. Root Complexes with peer-to-peer support and switch devices must enforce the above rules. For endpoint devices, it is device-specific. For example, it is possible that an endpoint device is allowed to have completions passing posted and non-posted requests. Because most of the above rules are considered as "permitted or blocked", it is legal to have "permitted" or "blocked" be determined by the architecture of the PCIe core and AXI bridge. The DWC PCIe core and AXI bridge IP is designed such that the order rules may be enforced strictly or less strictly, based on the requirements of the application.

46.5.2 PCIe Core Inbound Order Enforcement

There are three receive queue architectures within the DWC PCIe core. These queue structures will determine different order enforcement based on different receive queue architectures.

If the core is configured with all transactions in bypass mode, then order enforcement should be performed by the application logic. The core will not be responsible for implementing PCIe order enforcement. Since it is an all bypass configuration, all transactions are presented onto the application interface in the order that they arrived.

Below are descriptions for different queueing architectures that are implemented in the PCIe IP core. Three different queue modes are configurable and are designed to suit different applications.

46.5.2.1 Single queue

In Single queue mode, a single header and data queue are populated in the DWC PCIe core for all transactions received. Completions can be bypassed if desired, based on the application. Single queue mode implements strong ordering (in order delivery). All transactions of the same or different traffic class are enqueued and dequeued in the order the transactions were received. For example, if a non-posted transaction is followed by a posted transaction, then the application interface (the DWC PCIe core's target1 interface) will have a non-posted transaction being presented, followed by a posted transaction. Even if the non-posted transaction is blocked by the application (halt), the posted transaction will not be allowed to bypass.

This queue mode has followed all ordering rules above except for rule #4 and rule #9 if completion is not in bypass. What this queuing mode implements is that posted transactions will be blocked by another posted, non-posted will be blocked by another non-posted, etc. That is, we have selected `block` as the default of the above ordering rules. According to the spec., these are permitted except for rule #4, and possibly rule #9, if the completion is not in bypass. Rule #4 and rule #9 exist to avoid deadlocks caused by credit starvation and are applicable only when the TLP will be forwarded to another PCI/PCIe link. Because of these violations, this queue mode is not appropriate for a Root Complex (with peer-to-peer support) or for switch designs. This is designed for endpoint devices that have no order rule requirement at the transaction forwarding between the DWC PCIe core receive queue and the core application interface. The advantage of this queue mode is that it is simple, resulting in an area and power advantage.

46.5.2.2 Multiple queue

In Multiple queue mode, a header and data queue per type of transaction are populated in the DWC PCIe core. All transactions are enqueued in-order. All posted are enqueued into posted header/data queue. All non-posted are enqueued into a header/data non-posted queue and all completions are enqueued into a header/data completion queue. In multiple VC cases, each VC will have its own set of queues.

This queue mode has the same ordering as for single-queue mode. The user has further flexibility in setting which TLPs are bypassed and which TLPs are added to the ordering queue, but these additional modes offer little practical value in the normal case. Since it shares the same limitations as single-queue mode, this queue mode is not likely appropriate for a Root Complex with peer-to-peer support or for switch designs. This queue has some gate count advantage over the full order support provided by the segmented buffer; however, this advantage is generally minor, especially for multi-VC systems.

46.5.2.3 Segmented buffer queue

A single header/data queue are populated in the DWC PCIe core for this queue mode. Transactions of different types are queued into a segmented buffer; each TLP type into a separate segment in the buffer. The transaction's order information is also queued into the segmented buffer. All posted requests are enqueued into the posted segment, all non-posted requests are queued into the non-posted segment and all completions are enqueued into the completion segment. Each traffic class also has its own dedicated per-type segments.

All PCIe order enforcement rules are strictly followed. All transactions are normally served in the order of reception, if the application has no blocking (halt) of the transactions received. If the application does have blocking conditions, then the order rules are enforced for transactions being read out of the queue. For example, if a non-posted request is received followed by a posted request, and the application could not take any more non-posted requests, then the posted will be allowed to pass the non-posted request and the posted transaction will be presented onto the application interface. In a second example, a posted request is received followed by a non-posted request, and the application can not take any more posted requests, then the non-posted transaction will be blocked even if the application can take the next non-posted transaction. Only when there are no previously received posted requests will the non-posted transaction be presented onto the application interface.

Since the order information is stored along with each transaction, full PCIe order enforcement can be accomplished through this mode of operation. This is the difference from the single and multiple queue architectures.

Segmented buffer queue mode is designed for Switches and Root Complexes with peer-to-peer support. The primary advantage of this mode is the full support of PCIe ordering rules. In addition, this mode offers a reduced RAM requirement when compared with multi-queue mode, especially for multi-VC designs.

The figure below represents the various queue architectures of the DWC PCIe IP core inbound receiving traffic. There are three different queue modes. As described above, the ordering rules are implemented differently, based on different queue architecture.

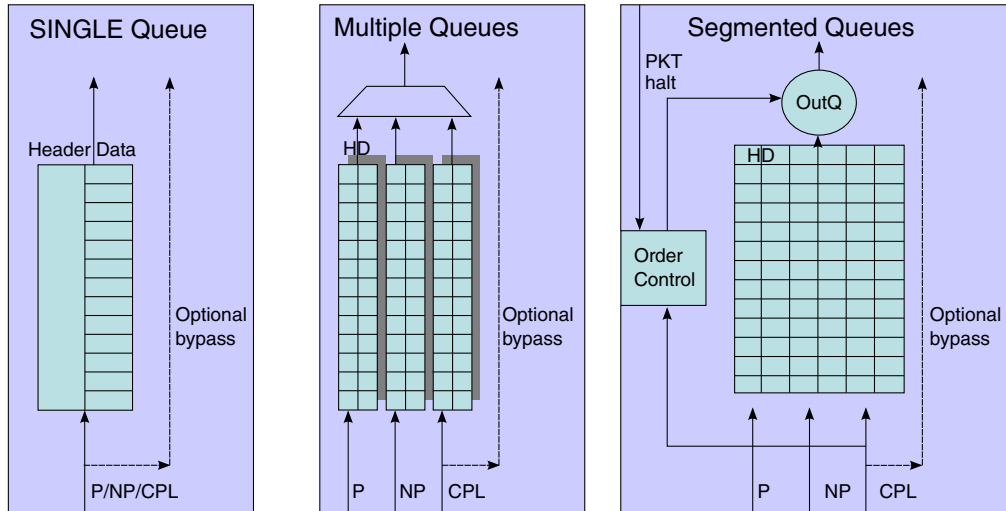

Figure 46-41. DWC PCIe Core Inbound Traffic Queue Architectures

46.5.3 PCIe Core Outbound Order Enforcement

The PCIe Core has a basic transmit architecture such that all transactions are presented outbound onto the PCIe wire based on the order the application presents them onto the PCIe core transmit interfaces.

There are up to three application outbound transmit interfaces (client0, client1 and optionally, client2). All client interfaces are served default as round robin arbitration if credit is available, regardless of the type of transaction. For example, if a posted transaction is presented onto client1 followed by a completion transaction, and if credits permit, then the posted transaction will be transmitted onto the wire before the completion. If the credit is not available, then the completion can pass the posted and be sent onto the wire.

It is the responsibility of the application to make appropriate use of the three client interfaces. An application that has three independent threads of traffic can use the three client interfaces such that the PCIe core will do the arbitration for the outbound transmission. For example, if the application has one source of outbound read transactions and one source of outbound write transactions, and they are independent sources, then client0 and client1 interfaces of the PCIe core should be used to perform the outbound transmission of the transactions. If the read and write are related, then one single interface client0 should be used and it is up to the application to maintain the desired order.

Most applications have independent threads of inbound reads such that its completion is not related to the outbound reads and writes. With these, an independent application interface such as client2 should be used for outbound completions.

In general, there is no transmit queuing in the PCIe core. Therefore, there is no order enforcement among outbound transactions within the transmit queue. The PCIe core has a cut-through transmit architecture where all outbound transaction order rules are enforced by the application. The PCIe core transmits TLPs in the order they are accepted by the core.

Endpoint devices can use two or three client interfaces for posted, non-posted and completion outbound traffic. The two or three client interfaces are determined by whether there is a dependency between the posted and non-posted traffic.

Root Complex and Switch devices will likely use one client interface where the order enforcement is performed by the application logic, where the outbound transfer queue is near to the transmit interface. The credit information is an output of the PCIe core, where it can be used as an input for taking outbound transactions out of the application's queue.

The figure below shows the outbound traffic queue architecture of the PCIe core. As shown in the figure, there is no transmit queue implemented in the core. There is just a retry buffer for replaying PCIe traffic as required by the PCIe base specification. Therefore, outbound TLPs will pass directly from the client interface through the core and to the wire in the same order they were accepted from the application.

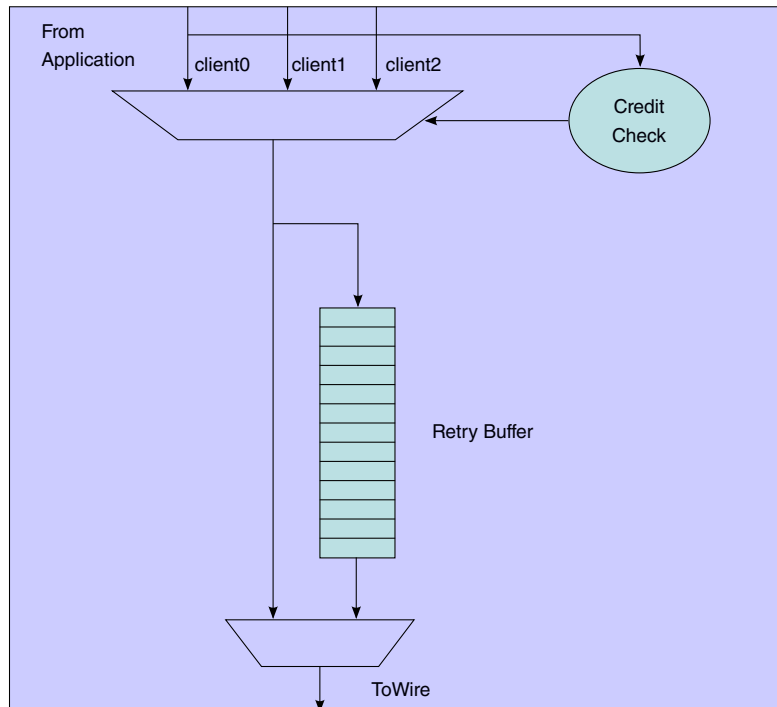

Figure 46-42. PCIe Core Outbound Traffic Queue Architectures

46.5.4 PCIe AHB/AXI Bridge Order Enforcement

Order enforcement through the AXI/AHB bridges is discussed in the following sections:

- [Inbound Order Enforcement for AXI Bridge](#)
- [Additional Information \(ordering\)](#)

46.5.5 Additional Information

Additional information is available at:

- [Queuing Architecture.](#)
- [Queue Modes.](#)
- [Order Enforcement.](#)

46.6 App Note: Calculating Gen1 PCI Express and AXI Bridge Throughput

This application note defines the throughput calculation (primarily) with respect to the PCI Express core in Gen1 2.5 GT/s mode.

NOTE

The max transfer size is 128bits

46.6.1 PCI Express Throughput

PCI Express bandwidth is 2.5 Gb/s (gigabits per second), per lane, when operating at the Gen 1 data rate. Because data is encoded using 8b10b encoding, the effective maximum throughput is 250 MB/s (megabytes per second), per lane (and overall throughput since we have 1 lane) , calculated as follows:

$$2.5 \text{ Gb} * 8\text{b}/10\text{b} = 2 \text{ Gb} * 1\text{B}/8\text{b} = 250 \text{ MB/sec per lane}$$

46.6.2 Effective Throughput

The effective throughput is the payload throughput once all PCIe protocol's overheads have been factored out. The key protocol features are:

- 8b10b encoding at the physical layer. This takes away 20% of the raw bandwidth.
- Acknowledge and flow control update packets at the data link layer (DLLPs). This takes away 1% to 5% of the remaining bandwidth.
- Packet overhead at the transaction layer. Your design choices have a great effect here:
 - Small packets may take away 75% of the bandwidth!
 - Large packets may take away as little as 1%.

46.6.2.1 Effective Throughput Calculation

The table below identifies the TLP package.

Table 46-32. TLP Packet (with associated Data Link Layer overhead bytes)

STP 1 Byte	SEQ 2 Bytes	TLP Header 12/16 Bytes	Data Payload	ECRC 4 Bytes	LCRC 4 Bytes	END 1 Byte
---------------	-------------	---------------------------	--------------	--------------	--------------	---------------

46.6.2.1.1 Packet Level: (Start and End, Link CRC, Header)

The table below summarizes throughput calculations based on a payload size from 16 to 4K bytes.

Table 46-33. Effective Throughput

	Payload Bytes	Header Bytes	ECRC Bytes	PHY and Data Link Layer Bytes	Calculation	Percent Throughput	Note
Worst Packet	16	16	4	8	16/44	36%	Has ECRC.
Typical Packet	128	16	0	8	128/152	84%	No ECRC.
Typical Packet	256	16	0	8	256/280	91%	No ECRC.
Typical Packet	512	16	0	8	512/536	96%	No ECRC.
Best Packet	4096	12	0	8	4096/4116	99%	No ECRC.

NOTE

A 128-byte payload size yields about 67% of the net throughput. Increasing the payload size to 512 bytes increases the net throughput to 92%. Increasing the payload size from 512 bytes to 4096 bytes only contributes an increase of 8% in the net throughput, and the storage requirements are more than doubled. In addition, a large payload size may have an impact on performance due to re-transmission of TLPs. Therefore, 256-byte and 512-byte payload sizes are the most popular choices. Most chipsets support 128 -byte or 256-byte payload sizes, with 512 bytes gaining in popularity.

46.6.2.1.2 Link Layer: (Flow Control and ACK/NAK DLLPs)

DLLPs should be sent as often as required to avoid a negative impact on the TLP throughput. The core sends a pending DLLP if there is no competing TLP traffic.

Sending ACK/NAK and Update FC is controlled by timers. The core provides flexibility to fine-tune these as required. The default setup is minimal flow control (one per time-out) and minimal ACK/NAK device latencies. The link partners retry buffer (payload) size may require a change in the ACK/NAK/Update FC time-out to obtain optimal system latencies.

The core provides a feature to accumulate up to 255 ACKs before issuing an ACK. This feature offers fine tuning of ACK frequency impact. The core transmits ACKs at fixed intervals, by default.

The following table identifies the DLLP package.

Table 46-34. DLLP Package

STP 1 Byte	Type 1 Byte	Data 4 Bytes	16b CRC 2 Bytes	END 1 Byte
---------------	----------------	-----------------	--------------------	---------------

The following table summarizes the throughput calculations.

Table 46-35. Effective Throughput

	Bytes	Result	Percent Throughput
Worst Packet	One ACK plus one FC per 128 (8 packets of 16) bytes of data => 2 DLLPs per 8 data packets	$(8 \times 44) / (8 \times 44 + 2 \times 8)$	95%
Typical Packet	One ACK plus one FC per 1.4 (256 byte payload) bytes of data => 2 DLLPs per 1.4 packets	$1.4 \times 280 / (1.4 \times 280 + 2 \times 8)$	96%
Best Packet	One ACK plus one FC per 4096 bytes of data => 2 DLLP per data packet	$4116 / (4116 + 2 \times 8)$	99%

46.6.2.2 Other Factors Impacting Throughput

Replay buffer and receiver queue sizing should be optimal to avoid a harmful impact of larger ACK/NAK or Update FC latencies by the link partner. The core does a very effective autosizing of the buffers taking into consideration the impact of these parameters.

Effective Throughput (ET) = Raw Throughput * (NL x 2.5 Gb)

Consideration of lane width and payload size results in the following:

Table 46-36. Consideration of lane width and payload size

Factor	Throughput
8b10b	*(80%)
Link Packet	*(95% to 99%)
Data Payload	*(36% to 99%)

The table below identifies lane width and payload vs. throughput.

Table 46-37. Lane Width and Payload vs. Throughput

	Real Throughput Gb/s vs. Data Payload			
Lane Width	16	128	256	4096
x1	0.5	1.7	1.7	2.0

46.7 PCIe Registers (EP mode)

Information found here describes the core implementation of the PCI Express configuration space in the core in EP mode.

46.7.1 Register Space Layout (EP mode)

The core has 4096 bytes of PCI Express configuration space per function.

For each function, the PCI Express configuration space is divided into:

- 256 bytes of PCI Configuration Space, containing:
 - 64 bytes of PCI 3.0 Compatible Configuration Space Header (type 0 in EP mode)
 - PCI Standard Capabilities Structures linked list, which can start anywhere after offset 0x40
- 3840 bytes of PCI Express Extended Configuration Space (which starts at offset 0x100), containing:
 - PCI Express Extended Capabilities Structures linked list, which starts at offset 0x100
 - Port Logic registers (vendor-specific registers), which start at offset 0x700. The Port Logic registers have specific pre-defined usages, mostly for test purposes, and can optionally be removed from the core hardware configuration. The usage of the Port Logic registers is the same in both EP mode and RC mode. See [PCIe Registers: Port Logic](#) for details.

The figure below shows the EP mode layout of the core configuration space.

PCIe Registers (EP mode)

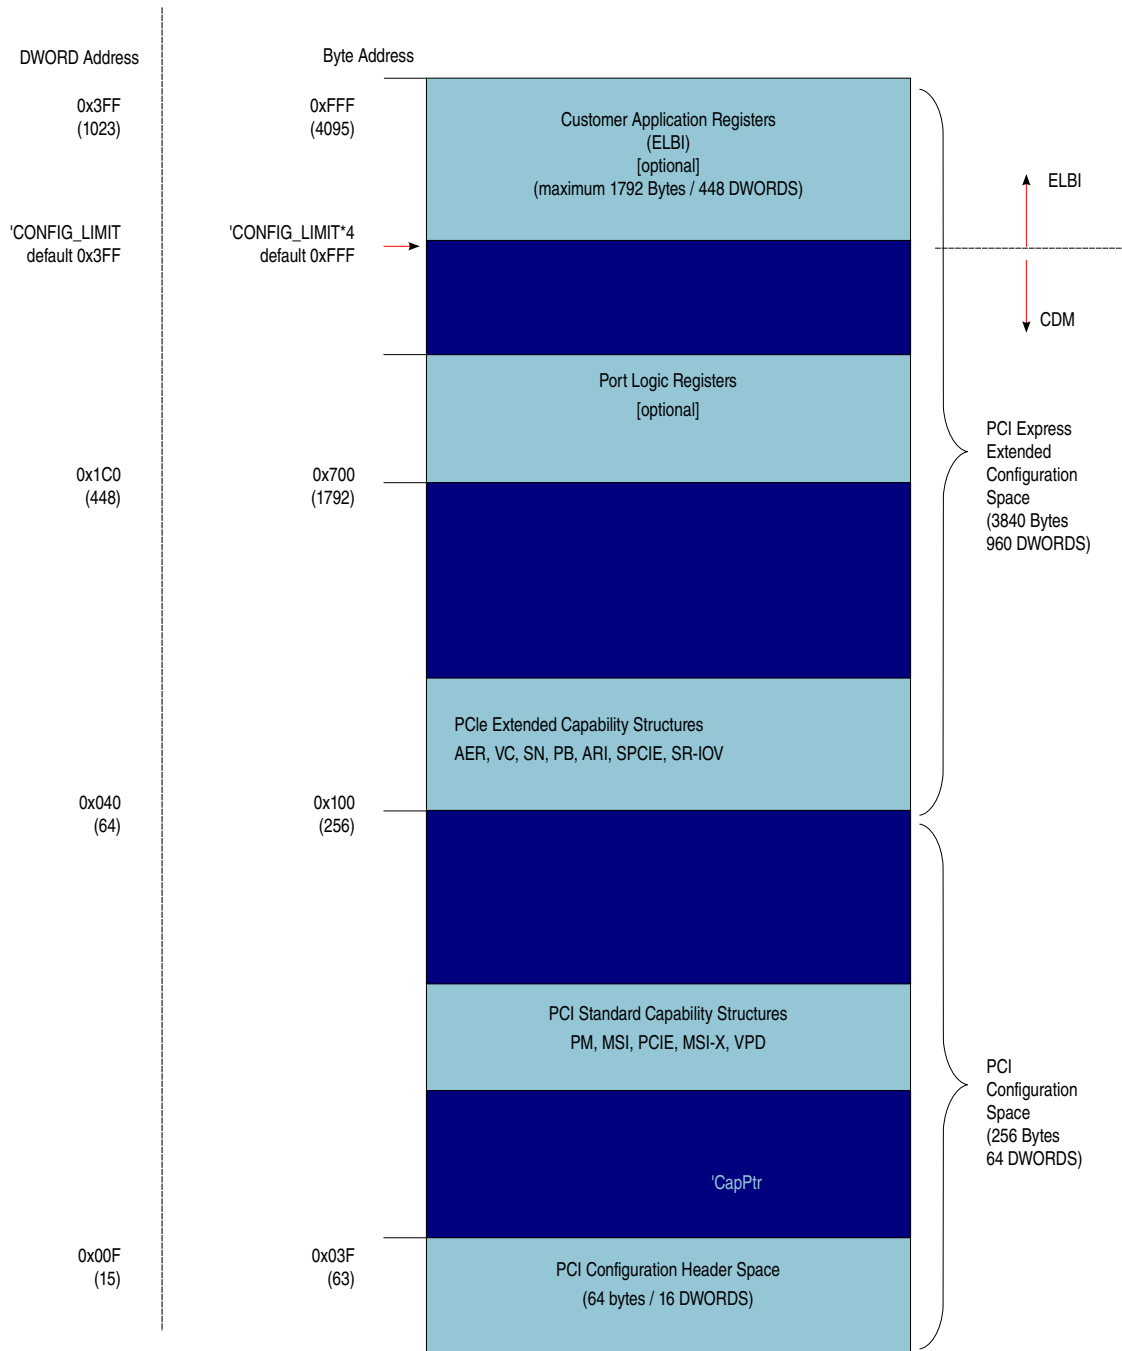

Figure 46-43. Core Configuration Space Layout (EP Mode)

46.7.2 PF Register Maps

Capability configuration registers are in structures (groups) identified by a Capability ID.

Groups are linked together as in PCI. Register locations within a group are specified, but the starting location of each group must be found by traversing the linked list. There are two linked lists of register groups: PCI Compatible Capability registers and PCI Express Extended Capability registers. PCI Compatible Capability register groups begin at the configuration address stored in the capability pointer register at 0x34. PCI Express Extended Capability register groups begin at address 0x100.

46.7.2.1 PF PCI Configuration Space Header - Type 0

The table below shows the layout of the Type 0 Configuration Space Header. Most PCI-compatible register fields have the same software interpretation in PCI 3.0 and PCI Express.

Table 46-38. PF PCI Configuration Space Header - Type 0

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x00	Device ID		Vendor ID	
0x04	Status Register		Command Register	
0x08	Class Code			Revision ID
0x0C	BIST(0x00)	Header Type	Latency Timer	Cache Line Size
0x10	Base Address Register 0			
0x14	Base Address Register 1			
0x18	Base Address Register 2			
0x1C	Base Address Register 3			
0x20	Base Address Register 4			
0x24	Base Address Register 5			
0x28	CardBus CIS Pointer			
0x2C	Subsystem ID		Subsystem Vendor ID	
0x30	Expansion ROM Base Address			
0x34	Reserved			CapPtr
0x38	Reserved			
0x3C	Max_Latency ¹	Min_Grant ¹	Interrupt Pin	Interrupt Line

1. The Max_Latency and Min_Grant registers do not apply to PCI Express and are read-only registers with values hardwired to 0x00.

46.7.2.2 PF PCI Standard Capability Structures Register Maps

The Capability Pointer register in the PCI-compatible header register points to the next item in the linked list of capabilities, which, by default, is the PCI Power Management capabilities register space.

NOTE

Even though there is an unique standard capabilities linked lists provided per function, specific capabilities cannot be enabled/ disabled on a per-function basis; for example, MSI-X capability is enabled/disabled for all functions (PF) at the same time through the coreConsultant GUI.

NOTE

Each function (PF) may have a different configuration of that capability structure once it is enabled, although some features/ settings are common across all functions.

The following tables list the capabilities supported by the core and their respective default address offsets and next capability pointers and provides the default values of the default address offsets.

Table 46-39. PF Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 0)	
0x40	PCI Power Management	
0x50	Message Signaled Interrupt (MSI)	
0x70	PCI Express Capabilities	

Table 46-40. PF Default Values of Parameters that Define Starting Addresses

Parameter	Default Value
CFG_PM_CAP	8'h40
CFG_MSI_CAP	8'h50
CFG_PCIE_CAP	8'h70

The following tables show the PCI Standard Capability Structures.

Table 46-41. PF Power Management Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x40	Power Management Capabilities (PMC)		Next Capability Pointer (PM_NEXT_PTR)	Capability ID (0x01)
+0x4	Data	PMCSR_BSE Bridge Extensions	Power Management Control Status Register (PMCSR)	

Table 46-42. PF MSI Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x50	Message Control Register		Next Capability Pointer (MSI_NEXT_PTR)	Capability ID (0x05)
+0x4	MSI Lower 32-bit Address Register			
+0x8	MSI Upper 32-bit Address Register			
+0xC	Reserved		MSI Data	
+0x10	Mask Bits Register			
+0x14	Pending Bits Register			

Table 46-43. PF PCI Express Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x70	PCI Express Capabilities Register		Next Capability Pointer (PCIE_NEXT_PTR)	Capability ID (0x10)
+0x4	Device Capabilities			
+0x8	Device Status		Device Control	
+0xC	Link Capabilities			
+0x10	Link Status		Link Control	
+0x24	Device Capabilities 2			
+0x28			Device Control 2	
+0x2C	Link Capabilities 2			
+0x30	Link Status 2		Link Control 2	

46.7.2.3 PF PCI Express Extended Capability Register Maps

The PCI Express Extended Capabilities registers are located in device configuration space at offsets 0x100 or higher. As with PCI Standard Capability Structures, the PCI Express Extended Capability structures are allocated using a linked list with a similar method and format to those of PCI.

NOTE

Even though there is a unique extended capabilities linked list provided per function, specific capabilities cannot be enabled/disabled on a per function basis.

NOTE

Each function (PF) may have a different configuration of that capability structure once it is enabled, although some features/settings are common across all functions.

The Advanced Error Reporting (AER) Capability and Virtual Channel (VC) Capability are optional extended capabilities that may be implemented by PCI Express devices supporting advanced error control and reporting and multiple VCs, respectively. The Advanced Error Reporting Capability is required when the device supports ECRC generation/checking. The Virtual Channel Capability is required for any device that supports multiple VCs and/or multiple Traffic Classes (TCs).

The Next Capability Pointer register in the PCI Express Extended Capability Structures Register Maps points to the next item in the linked list of capabilities, which, by default, is the Advanced Error Reporting (AER) Capability register space.

The table below lists the extended capabilities supported by the core and their respective default address offsets and next capability pointers.

Table 46-44. PF Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 0)	
0x100	Advanced Error Reporting	
0x140	Virtual Channel	

The following tables outline the PCI Express Extended Capabilities structures.

Table 46-45. PF Advanced Error Reporting (AER) Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x100	AER Extended Capability Header			
+0x4	Uncorrectable Error Status Register			
+0x8	Uncorrectable Error Mask Register			
+0xC	Uncorrectable Error Severity Register			
+0x10	Correctable Error Status Register			
+0x14	Correctable Error Mask Register			
+0x18	Advanced Error Capabilities and Control Register			
+0x1C through +0x28	Header Log Registers			

Table 46-46. PF Virtual Channel Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x140	Virtual Channel Extended Capability Header			
+0x4	Port VC Capability Register 1			
+0x8	Port Capability Register 2			
+0xC	Port VC Status Register		Port VC Control Register	

Table continues on the next page...

Table 46-46. PF Virtual Channel Capability Structure (continued)

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
+0x10	VC Resource Capability Register (0)			
+0x14	VC Resource Control Register (0)			
+0x18	VC Resource Status Register (0)		RsvdP	
0x10+(N*0x0C)	VC Resource Capability Register (N) ¹			
0x14+(N*0x0C)	VC Resource Control Register (N)			
0x18+(N*0x0C)	VC Resource Status Register (N)		RsvdP	

1. There is one VC Resource Capability/Control/Status Register N set for each configured VC (in addition to VC0).

1. Depends on the number of VCs

46.7.3 VF Register Maps

Similar to PFs, VFs also have Type 0 Configuration Space Header, a linked list of PCI Compatible Capabilities and a linked list of PCI Express Extended Capabilities.

The following PCI Compatible Capabilities are supported for VFs: P.

46.7.3.1 VF PCI Configuration Space Header - Type 0

The table below shows the layout of the Type 0 Configuration Space Header for Virtual Functions.

Table 46-47. VF PCI Configuration Space Header - Type 0

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x00	Device ID		Vendor ID	
0x04	Status Register		Command Register	
0x08	Class Code			Revision ID
0x0C	BIST(0x00)	Header Type	Latency Timer	Cache Line Size
0x10	Base Address Register 0			
0x14	Base Address Register 1			
0x18	Base Address Register 2			
0x1C	Base Address Register 3			
0x20	Base Address Register 4			
0x24	Base Address Register 5			
0x28	CardBus CIS Pointer			

Table continues on the next page...

Table 46-47. VF PCI Configuration Space Header - Type 0 (continued)

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0

0x30	Expansion ROM Base Address			
0x34	Reserved			CapPtr
0x38	Reserved			
0x3C	Max_Latency ¹	Min_Grant ¹	Interrupt Pin	Interrupt Line

1. The Max_Latency and Min_Grant registers do not apply to PCI Express and are read-only registers with values hardwired to 0x00.

46.7.3.2 VF PCI Standard Capability Structures Register Maps

NOTE

All VFs have the same linked list of capabilities.

The Capability Pointer register in the Type 0 Header points to the next item in the linked list of capabilities, which, by default, is the PCI Express Capability.

The tables below list the VF standard capabilities supported by the core and their respective default address offsets and next capability pointers and provides the default values of the default address offsets.

Table 46-48. VF Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 0)	0x70
0x70	PCI Express Capability	0x00

Table 46-49. VF Default Values of Parameters that Define Starting Addresses

Parameter	Default Value
CFG_PCIE_CAP	8'h70

The table below shows the VF PCI Express Capability Structure.

Table 46-50. VF PCI Express Capability Structure

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x70	PCI Express Capabilities Register		Next Capability Pointer 0x0	Capability ID (0x10)

+0x24	Device Capabilities 2			
+0x28			Device Control 2	
+0x30	Link Status 2		Link Control 2	

46.7.4 Accessing Configuration Registers

The application can access the configuration space through the DBI. Bits [11:0] of the DBI address bus select the target register.

Host software accesses the configuration registers through PCI Express Configuration Requests.

The Attribute (Attr) column in each register description indicates the read/write access for the register or bit. The table below defines the read/write attribute abbreviations that are used in the register and bit descriptions throughout this chapter.

Table 46-51. Configuration Register Bit-Field Types

Attribute	Description
HwInit	Hardware Initialized HwInit bits are controlled by core hardware and are read-only (RO) by host system software. These bits can only be reset with cold reset. They are not modified by an FLR, or by a warm or hot reset.
RO	Read-Only Register bits are read-only and cannot be altered by software. Register bits are permitted to be initialized by core hardware.
RW	Read-Write Register bits are read-write and may be read and written normally by the host and the application. Writing from the application side (if any) requires careful synchronization with the host software.
RW1C	Read-Only Status/Write-1-to-Clear Status Register bits indicate status when read. A set bit indicates a status event may be cleared by writing a 1. Writing 0 to RW1C bits has no effect. Writing from the application side (if any) requires careful synchronization with host software.

Table continues on the next page...

Table 46-51. Configuration Register Bit-Field Types (continued)

Attribute	Description
ROS	<p>Sticky Read-Only</p> <p>Register bits are read-only and cannot be altered by host or application software, except as noted.</p> <p>Registers are not initialized or modified by a hot reset or FLR.</p> <p>A few bits designated as very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.</p>
RWS	<p>Sticky Read-Write</p> <p>Register bits are read-write and are set or cleared by host or application software to the desired state.</p> <p>Bits are not initialized or modified by a hot reset or FLR.</p> <p>A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.</p>
RW1CS	<p>Sticky Read-Only Status/Write-1-to-Clear Status</p> <p>Register bits indicate status when read. A set bit indicates a status event which is cleared by writing a 1, except as noted.</p> <p>Writing 0 to RW1CS bits has no effect.</p> <p>Bits are not initialized or modified by a hot reset or FLR.</p> <p>A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.</p>
RsvdP	<p>Reserved and Preserved</p> <p>Reserved for future RW implementations.</p> <p>Registers are read-only and return zero when read.</p> <p>Software must preserve the value read when writing to other bits in the same register.</p>
RsvdZ	<p>Reserved and Zero</p> <p>Reserved for future RW1C implementations. Registers are read-only and return zero when read.</p> <p>Software must write 0 to these bits when writing to other bits in the same register.</p>
PF	<p>Physical Function</p> <p>Indicates that this Virtual Function (VF) register bit inherits it's value from the corresponding parent Physical Function.</p>

Most of the these registers are in the non-sticky reset domain. Non-sticky registers should be reset after a cold, warm or hot reset. .

46.8 PCIe Registers (RC mode)

Information found here describes the core implementation of the PCI Express configuration space when in RC mode.

Register definition applies to all cases unless otherwise specified.

46.8.1 Register Space Layout

The core has 4096 bytes of PCI Express configuration space per function.

For each function, the PCI Express configuration space is divided into:

- 256 bytes of PCI Configuration Space, containing:
 - 64 bytes of PCI 3.0 Compatible Configuration Space Header (type 1)
 - PCI Standard Capabilities Structures linked list, which can start anywhere after offset 0x40
- 3840 bytes of PCI Express Extended Configuration Space (which starts at offset 0x100), containing:
 - PCI Express Extended Capabilities Structures linked list, which starts at offset 0x100
 - Port Logic registers (vendor-specific registers), which start at offset 0x700. The Port Logic registers have specific pre-defined usages, mostly for test purposes, and can optionally be removed from the core hardware configuration. The usage of the Port Logic registers is the same in both EP mode and RC mode. See [PCIe Registers: Port Logic](#) for details.

The figure below shows the layout of the core configuration space.

PCIe Registers (RC mode)

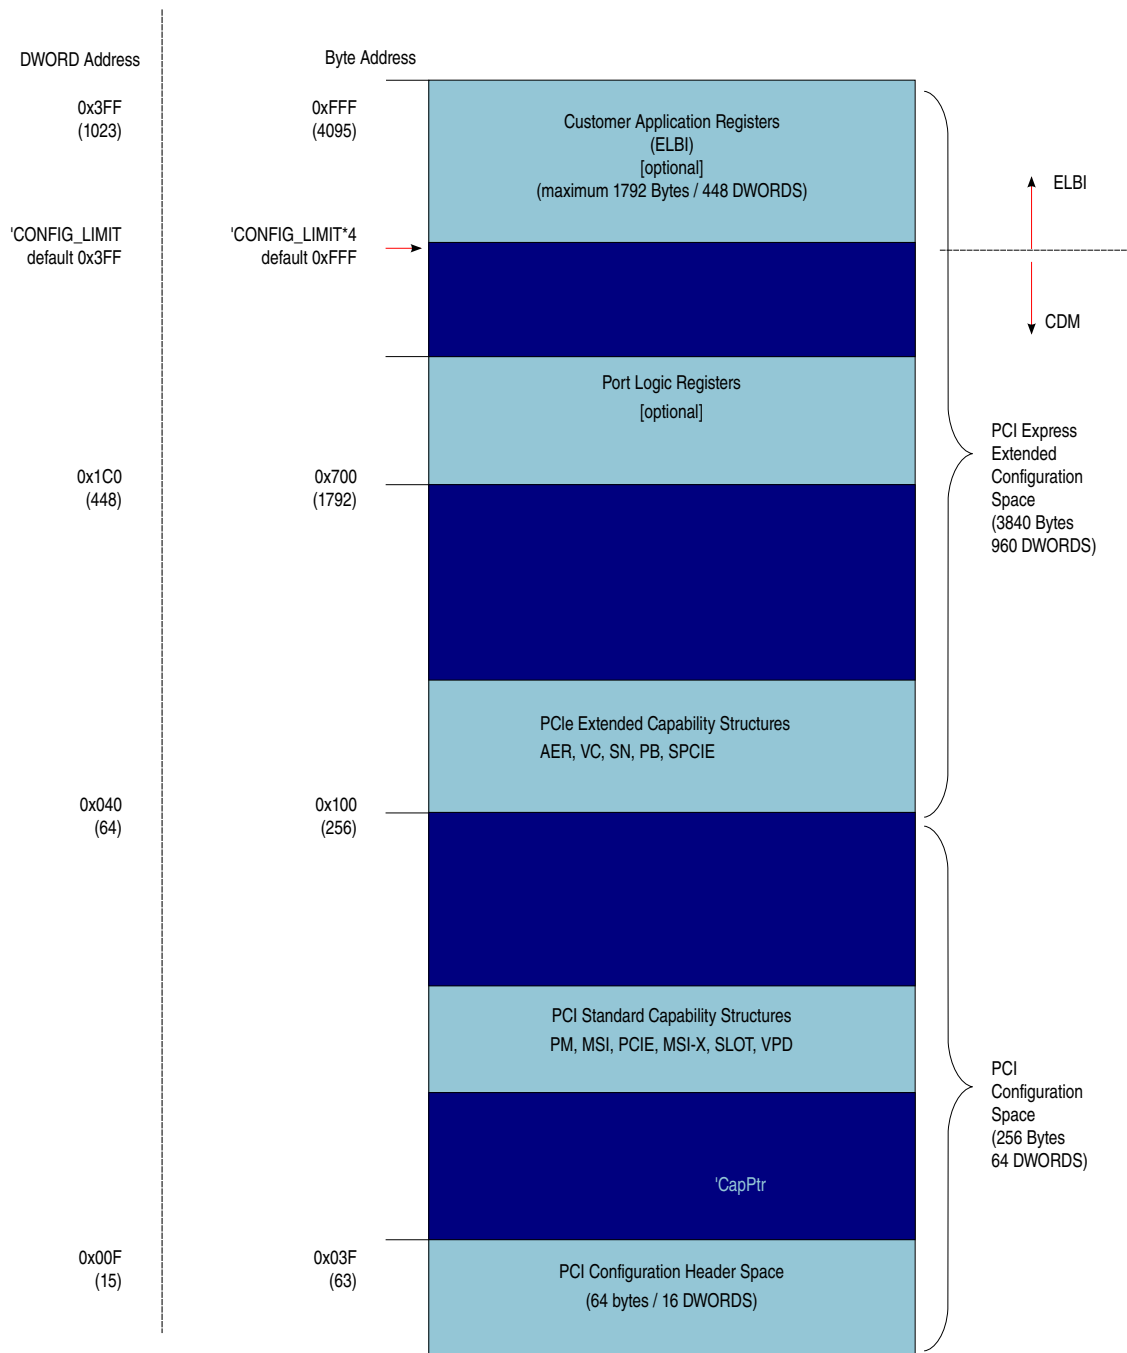

Figure 46-44. Core Configuration Space Layout: (RC Mode)

46.8.2 Register Maps

Configuration registers are in structures (groups) identified by a Capability ID. Groups are linked together as in PCI.

Register locations within a group are specified, but the starting location of each group must be found by traversing the linked list. There are two linked lists of register groups: PCI-compatible base registers and PCI Express Extended Capability registers. PCI-compatible base register groups begin at configuration address stored in capability pointer register at 0x34. PCI Express Extended Capability register groups begin at address 0x100.

Table below shows the configuration field register definitions for PCI Express Type 1 Configuration Space header. Most PCI-compatible register fields have the same software interpretation in PCI 3.0 and PCI Express.

Table 46-52. PCI Configuration Space Header - Type 1

Byte Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x00	Device ID		Vendor ID	
0x04	Status Register		Command Register	
0x08	Class Code			Revision ID
0x0C	BIST(0x00)	Header Type	Latency Timer	Cache Line Size
0x10	Base Address Register 0			
0x14	Base Address Register 1			
0x18	Secondary Latency Timer	Subordinate Bus Number	Secondary Bus Number	Primary Bus Number
0x1C	Secondary Status		I/O Limit	I/O Base
0x20	Memory Limit		Memory Base	
0x24	Prefetchable Memory Limit		Prefetchable Memory Base	
0x28	Prefetchable Base Upper 32 Bits			
0x2C	Prefetchable Limit 32 Upper Bits			
0x30	I/O Limit Upper 16 Bits		I/O Base Upper 16 Bits	
0x34	Reserved			CapPtr
0x38	Expansion ROM Base Address			
0x3C	Bridge Control		Interrupt Pin	Interrupt Line

46.8.2.1 PCI Standard Capability Structures Register Maps

The Capability Pointer register in the PCI-compatible header register points to the next item in the linked list of capabilities, which, by default, is the PCI Power Management capabilities register space.

PCIe Registers (RC mode)

Even though there is a unique standard capabilities linked lists provided per function, specific capabilities cannot be enabled/disabled on a per-function basis; for example, MSI-X capability is enabled/disabled for all functions at the same time through the coreConsultant GUI.

Each function may have a different configuration of that capability structure once it is enabled, although some features/settings are common across all functions.

Table below lists the capabilities supported by the core and their respective default address offsets and next capability pointers. [Table 46-54](#) provides the default values of the default address offsets.

Table 46-53. Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 1)	
0x40	PCI Power Management	
0x50	Message Signaled Interrupt (MSI)	
0x70	PCI Express Capabilities

+0x34	Slot Capabilities 2			
+0x38	Slot Status 2		Slot Control 2	
1. Slot Capabilities apply only to downstream ports; for example, RC.				

46.8.2.2 PCI Express Extended Capability Register Maps

The PCI Express Extended Capabilities registers are located in device configuration space at offsets 0x100 or higher. As with PCI Capabilities, the PCI Express Extended Capability structures are allocated using a linked list with a similar method and format to those of PCI.

Even though there is a unique extended capabilities linked list provided per function, specific capabilities cannot be enabled/disabled on a per function basis.

Each function may have a different configuration of that capability structure once it is enabled, although some features/settings are common across all functions.

The Advanced Error Reporting Capability and Virtual Channel Capability are optional extended capabilities that may be implemented by PCI Express devices supporting advanced error control and reporting and multiple VCs, respectively. The Advanced

Error Reporting Capability is required when the device supports ECRC generation/checking. The Virtual Channel Capability is required for any device that supports multiple VCs and/or multiple Traffic Classes (TCs).

The Next Capability Pointer register in the PCI Express Extended Capability Structures Register Maps points to the next item in the linked list of capabilities, which, by default, is the Advanced Error Reporting (AER) Capability register space.

Table below lists the capabilities supported by the core and their respective default address offsets and next capability pointers.

Table 46-58. Configuration Structure: Starting Addresses and Next Capability Pointers

Start Address Offset	Item	Next Pointer
0x00	PCI-Compatible Header (Type 1)	0x100
0x100	Advanced Error Reporting	
0x140	Virtual Channel	

The following tables outline the PCI Express Extended Capabilities structures.

Table 46-59. Advanced Error Reporting Capability Structure

0x10+(N*0x0C)	VC Resource Capability Register (N)1	
0x14+(N*0x0C)	VC Resource Control Register (N)	
0x18+(N*0x0C)	VC Resource Status Register (N)	RsvdP

1. There is one VC Resource Capability/Control/Status Register N set for each configured VC (in addition to VC0).

46.8.3 Accessing Configuration Registers (Configuration)

>The application can access the configuration space through the DBI. Bits [11:0] of the DBI address bus select the target register.

The Attribute column in each register description indicates the read/write access for the register or bit. Table below defines the read/write attribute abbreviations that are used in the register and bit descriptions throughout this chapter. The definitions match the PCI Express 3.0 Specification; in the case of a Root Port, all accesses are through the DBI so the host-access information does not apply.

Table 46-61. Configuration Register Bit-Field Types

Attribute	Description
HwInit	<p>Hardware Initialized</p> <p>HwInit bits are controlled by core hardware and are read-only (RO) by host system software.</p> <p>Some HwInit bits are writable from the application through the DBI (if <code>^CX_DBI_RO_WR_EN = 1</code>), as indicated in the register descriptions. If <code>^CX_DBI_RO_WR_EN = 0</code>, none of the HwInit bits are writable through the DBI. These bits can only be reset with cold reset.</p> <p>They are not modified by an FLR, or by a warm or hot reset.</p>
RO	<p>Read-Only</p> <p>Register bits are read-only and cannot be altered by software. Register bits are permitted to be initialized by core hardware.</p> <p>Some RO bits are writable from the application through the DBI (if <code>^CX_DBI_RO_WR_EN = 1</code>), as indicated in the register descriptions. If <code>^CX_DBI_RO_WR_EN = 0</code>, none of the RO bits are writable through the DBI.</p>
RW	<p>Read-Write</p> <p>Register bits are read-write and may be read and written normally by the host and the application.</p> <p>Writing from the application side (if any) requires careful synchronization with the host software.</p>

Table continues on the next page...

RW1CS	<p>Sticky Read-Only Status/Write-1-to-Clear Status</p> <p>Register bits indicate status when read. A set bit indicates a status event which is cleared by writing a 1, except as noted.</p> <p>Writing 0 to RW1CS bits has no effect.</p> <p>Bits are not initialized or modified by a hot reset or FLR.</p> <p>A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.</p>
RsvdP	<p>Reserved and Preserved</p> <p>Reserved for future RW implementations.</p> <p>Registers are read-only and return zero when read.</p> <p>Software must preserve the value read when writing to other bits in the same register.</p>
RsvdZ	<p>Reserved and Zero</p> <p>Reserved for future RW1C implementations. Registers are read-only and return zero when read.</p> <p>Software must write 0 to these bits when writing to other bits in the same register.</p>
PF	<p>Physical Function</p> <p>Indicates that this Virtual Function (VF) register bit inherits it's value from the corresponding parent Physical Function.</p>

Some RO bits are writable from the application through the DBI

Most of the these registers are in the non-sticky reset domain. Non-sticky registers should be reset after a cold, warm or hot reset.

46.9 PCIe Registers: Port Logic

Information found here describes the Port Logic register map and the usage of each Port Logic register.

46.9.1 Overview (Port Logic)

The Port Logic (PL) registers are vendor-specific registers and are used mainly for configuration of PCIe core implementation features, status reporting and testing.

The usage of the Port Logic registers is the same in both EP and RC modes and in the Switch. The Port Logic registers reside in the application register section of the configuration space starting at address 0x700.

46.9.2 Non-Standard Addressing of the iATU Port Logic Registers

See [PCIe CTRL Port Logic Memory Map/Register Definition](#) iATU Registers are programmed through an index (Viewport) register to reduce the memory footprint in the PCI Express Extended Configuration Space.

46.9.3 Accessing Configuration Registers (Port Logic Registers)

The application can access the port logic configuration space through the DBI. Bits [11:0] of the DBI address bus select the target register. Host software accesses the configuration registers through PCI Express Configuration Requests.

The Attribute (Attr) column in each register description indicates the read/write access for the register or bit. The table below defines the read/write attribute abbreviations that are used in the register and bit descriptions throughout this chapter.

Table 46-62. Configuration Register Bit-Field Types

Attribute	Description
HwInit	Hardware Initialized HwInit bits are controlled by core hardware and are read-only (RO) by host system software. None of the HwInit bits are writable through the DBI. These bits can only be reset with cold reset. They are not modified by an FLR, or by a warm or hot reset.
RO	Read-Only

Table continues on the next page...

Table 46-62. Configuration Register Bit-Field Types (continued)

Attribute	Description
	<p>Register bits are read-only and cannot be altered by software. Register bits are permitted to be initialized by core hardware.</p> <p>None of the RO bits are writable through the DBI.</p>
RW	<p>Read-Write</p> <p>Register bits are read-write and may be read and written normally by the host and the application. Writing from the application side (if any) requires careful synchronization with the host software.</p>
RW1C	<p>Read-Only Status/Write-1-to-Clear Status</p> <p>Register bits indicate status when read. A set bit indicates a status event may is cleared by writing a 1. Writing 0 to RW1C bits has no effect.</p> <p>Writing from the application side (if any) requires careful synchronization with host software.</p>
ROS	<p>Sticky Read-Only</p> <p>Register bits are read-only and cannot be altered by host or application software, except as noted. Registers are not initialized or modified by a hot reset or FLR.</p> <p>A few bits designated as very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.</p>
RWS	<p>Sticky Read-Write</p> <p>Register bits are read-write and are set or cleared by host or application software to the desired state. Bits are not initialized or modified by a hot reset or FLR.</p> <p>A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.</p>
RW1CS	<p>Sticky Read-Only Status/Write-1-to-Clear Status</p> <p>Register bits indicate status when read. A set bit indicates a status event which is cleared by writing a 1, except as noted.</p> <p>Writing 0 to RW1CS bits has no effect.</p> <p>Bits are not initialized or modified by a hot reset or FLR.</p> <p>A few bits designated very sticky are not cleared by any type of core reset when auxiliary power is supplied and enabled.</p>
RsvdP	<p>Reserved and Preserved</p> <p>Reserved for future RW implementations.</p> <p>Registers are read-only and return zero when read.</p> <p>Software must preserve the value read when writing to other bits in the same register.</p>
RsvdZ	<p>Reserved and Zero</p> <p>Reserved for future RW1C implementations. Registers are read-only and return zero when read.</p> <p>Software must write 0 to these bits when writing to other bits in the same register.</p>
PF	<p>Physical Function</p> <p>Indicates that this Virtual Function (VF) register bit inherits it's value from the corresponding parent Physical Function.</p>

Some of the Port Logic registers are in the sticky reset domain. Sticky registers should not be reset after a warm or hot reset.

PCIE_EP_BIST field descriptions

Field	Description
31–24 Not_supported_by__core	The BIST register functions are not supported by the core. All 8 bits of the BIST register are hardwired to 0.
23 Multi_Function_Device	Multi Function Device The default value is 0 for a single function device ('CX_NFUNC = 1) or 1 for a multi-function device ('CX_NFUNC != 1). The Multi Function Device bit is writable through the DBI.
22–16 Configuration_Header_Format	Configuration Header Format Hardwired to 0 for type 0.

Table continues on the next page...

PCIE_EP_BIST field descriptions (continued)

Field	Description
15–8 Master_Latency_Timer	Master Latency Timer Not applicable for PCI Express, hardwired to 0.
Cache_Line_Size	Cache Line Size The Cache Line Size register is RW for legacy compatibility purposes and is not applicable to PCI Express device functionality. Writing to the Cache Line Size register does not impact functionality of the core.

46.10.4 Base Address 0 (PCIE_EP_BAR0)

Offset: 0x10-0x24

The core provides three pairs of 32-bit BARs for each implemented function. Each pair (BARs 0 and 1, BARs 2 and 3, BARs 4 and 5) can be configured as follows:

- One 64-bit BAR: For example, BARs 0 and 1 are combined to form a single 64-bit BAR.
- Two 32-bit BARs: For example, BARs 0 and 1 are two independent 32-bit BARs.
- One 32-bit BAR: For example, BAR 0 is a 32-bit BAR and BAR 1 is either disabled or removed from the core altogether to reduce gate count.

In addition, you can configure each BAR to have its incoming Requests routed to either:

- RTRGT1
-

The following sections describe how to set up the BAR types and sizes by programming values into the base address registers. For more information about routing Requests to either RTRGT1 on a BAR-by- BAR basis, see [Receive Filtering](#).

The contents of the six BARs determine the BAR configuration. The reset values of the BARs are determined by hardware configuration options.

At runtime, application software can overwrite the BAR contents to reconfigure the BARs (unless the affected BAR is removed during hardware configuration). Application software must observe the rules listed below when writing to the BARs.

The rules for BAR configuration are the same for all three pairs. Using BARs 0 and 1 as the example pair, the rules for BAR configuration are:

- Any pair (for example, BARs 0 and 1) can be configured as one 64-bit BAR, two 32-bit BARs, or one 32-bit BAR.

- BAR pairs cannot overlap to form a 64-bit BAR. For example, you cannot combine BARs 1 and 2 to form a 64-bit BAR.
-
- An I/O BAR must be a 32-bit BAR and cannot be prefetchable.
- If the device is configured as a PCI Express Endpoint (not a Legacy Endpoint), then any memory that is configured as prefetchable must be a 64-bit memory BAR.
- If BAR 0 is configured as a 64-bit BAR:
 - BAR 1 is the upper 32 bits of the combined 64-bit BAR formed by BARs 0 and 1. Therefore, BAR 1 must be disabled and cannot be configured independently.
 - BAR 0 must be a memory BAR and can be either prefetchable or non-prefetchable.
 - The contents of the BAR 0 Mask register determine the number of writable bits in the 64-bit BAR, subject to the restrictions described in BAR Mask Registers . The BAR 1 Mask register contains the upper 32 bits of the BAR 0 Mask value.
 - BAR 0 can be disabled by writing 0 to bit 0 of the BAR 0 Mask register
- If BAR 0 is configured as a 32-bit BAR:
 - You can configure BAR 1 as an independent 32-bit BAR
 - BAR 0 can be configured as a memory BAR or an I/O BAR.
 - The contents of the BAR 0 Mask register determine the number of writable bits in the 32-bit BAR 0, subject to the restrictions described in BAR Mask Registers.
 - BAR 0 can be disabled by writing 0 to bit 0 of the BAR 0 Mask register
- When BAR 0 is configured as a 32-bit BAR, BAR 1 is available as an independent 32-bit BAR according to the following rules:
 - BAR 1 can be configured as a memory BAR or an I/O BAR.
 - The contents of the BAR 1 Mask register determine the number of writable bits in the 32-bit BAR 1, subject to the restrictions described in BAR Mask Registers.
 -
 -

The same rules apply for pairs 2/3 and 4/5.

Offset: 0x10 (if included in the core hardware configuration)

PCIe CTRL EP Mode Memory Map/Register Definition

Address: 0h base + 10h offset = 10h

PCIe_EP_BAR0 field descriptions

Field	Description
31–4 ADDRESS	BAR 0 base address bits (for a 64-bit BAR, the remaining upper address bits are in BAR 1). The BAR 0 Mask value determines which address bits are masked.
3 PREF	If BAR 0 is an I/O BAR, bit 3 is the second least significant bit of the base address. Bits [3:0] are writable through the DBI. If BAR 0 is a memory BAR, bit 3 indicates if the memory region is prefetchable: 0 = Non-prefetchable 1 = Prefetchable
2–1 TYPE	If BAR 0 is an I/O BAR, bit 2 the least significant bit of the base address and bit 1 is 0. Bits [3:0] are writable through the DBI. If BAR 0 is a memory BAR, bits [2:1] determine the BAR type: 00 = 32-bit BAR 10 = 64-bit BAR
0 Mem_I_O	Bits [3:0] are writable through the DBI. 0 = BAR 0 is a memory BAR 1 = BAR 0 is an I/O BAR

46.10.5 BAR 0 Mask Register (PCIE_EP_MASK0)

The BAR masks are used for indicating the amount of memory each BAR requests from host software. The application logic can overwrite the default values via the DBI.

The BAR Mask registers determine which bits in each BAR are non-writable by host software, which determines the size of the address space claimed by each BAR.

The BAR Mask values indicate the range of low-order bits in each implemented BAR not to use for address matching. The BAR Mask value also indicates the range of low-order bits in the BAR that cannot be written from the host. The application can write to all BAR bits to allow setting of memory, I/O, and other standard BAR options.

To disable any BAR, the application can write a 0 to bit 0 of the corresponding BAR Mask register. To change the BAR Mask value for a disabled BAR, the application must first enable the BAR by writing 1 to bit 0. After enabling the BAR, the application can then write a new value to the BAR Mask register.

The BAR Mask registers are accessible through the same address as the corresponding BAR registers, but requires dbi_cs2 assertions instead i.e. bit address 12 must be set. The BAR Mask registers are writable only, not readable.

If the BAR Mask value for a BAR is less than that required for the BAR type, the core automatically uses the minimum value for the BAR type:

BAR bits [11:0] are always masked for a memory BAR. The core requires each memory BAR to claim at least 4 KB.

The PCI Express Base Specification states that the minimum memory address range requested by a BAR is 128 bytes. In the PCI Local Bus Specification, Rev 3.0 it is recommended that devices that need less than 4 KB of Address Space should still consume 4 KB of address space in order to minimize the number of bits in the address decoder. A Memory BAR size of 256 bytes can be achieved by using a DBI2 write to BAR Mask.

BAR bits [7:0] are always masked for an I/O BAR. The core requires each I/O BAR to claim at least 256 bytes.

The PCI Local Bus Specification, Rev 3.0 allows I/O BARs to consume between 4 bytes and 256 bytes of address space. The core only permits I/O BARs to consume 256 bytes of address space. This restriction is used in order to minimize the number of bits in the address decoder.

The aperture of the BAR is actually the larger of the written size or the system page size (set by the operating system). In the case where the system page size is larger than the requested bar size, the BAR is actually sized to the system page size. This means that when the OS writes all 1s then reads back to determine the size of the BAR, the OS will see the BAR size to be the system page size. The application logic, most likely, will only have the original requested amount of physical memory. A transaction will receive a UR if the transaction is from the RC and it targets an address that is within the range of the allocated system page size but above the implemented application memory.

The figure below shows an example configuration of the six BARs and their corresponding BAR Mask registers. The example configuration includes:

- One 64-bit memory BAR (non-prefetchable)
- One 32-bit memory BAR (non-prefetchable)
- One 32-bit I/O BAR

Figure 46-50. Example Base Address Register Configuration

46.10.12 Expansion ROM BAR Mask Register (PCIE_EP_EROMMASK)

Offset: 0x30 (same as the Expansion ROM BAR, but requires dbi_cs2 for write access)

Address: 0h base + 30h offset = 30h

PCIE_EP_EROMMASK field descriptions

Field	Description
31–1 ROM_MASK_N	<p>Indicates which Expansion ROM BAR bits to mask (make non-writable) from host software, which, in turn, determines the size of the BAR. For example, writing 0xFFFF to the Expansion ROM BAR Mask register claims a 4096-byte BAR by masking bits 11:0 of the BAR from writing by host software.</p> <p>The maximum value is 0xFFFFFFF because the maximum space that can be claimed by an Expansion ROM BAR is 16 MB.</p> <p>The Expansion ROM BAR Mask register is invisible to host software and not readable from the application. Application access depends on the value of</p> <ul style="list-style-type: none"> the Expansion ROM BAR Mask register is writable through the DBI.
0 ROM_BAR_ENABLED_N	<p>Expansion ROM BAR Enable</p> <p>0 Expansion ROM BAR is disabled</p> <p>1 Expansion ROM BAR is enabled</p>

46.10.13 Capability Pointer Register (PCIE_EP_CAPPR)

Offset: 0x34

Byte: 0

Address: 0h base + 34h offset = 34h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PCIE_EP_ILR field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 INT_PIN_MAPPING_N	Interrupt Pin Identifies the legacy interrupt Message that the device (or device function) uses. In a single-function configuration, the core only uses INTA. The Interrupt Pin register is writable through the DBI. Valid values are: 0x00 The device (or function) does not use legacy interrupt

Table continues on the next page...

PCIE_EP_ILR field descriptions (continued)

Field	Description
	0x01 The device (or function) uses INTA 0x02 The device (or function) uses INTB 0x03 The device (or function) uses INTC 0x04 The device (or function) uses INTD
INTERRUPT_LINE	Interrupt Line Value in this register is system architecture specific. POST software will write the routing information into this register as it initializes and configures the system.

46.10.15 AER Capability Header (PCIE_EP_AER)

The core implements the following PCI Express Extended Capabilities registers:

? Advanced Error Reporting Capability register set

? Virtual Channel Capability register set -

Address: 0x100

Address: 0h base + 100h offset = 100h

PCIE_EP_AER field descriptions

Field	Description
31–20 Next_Capability_Offset	Next Capability Offset
19–16 Capability_Version	Capability Version
PCI_Express_Extended_Capability_ID	PCI Express Extended Capability ID Value is 0x1 for Advanced Error Reporting.

46.10.16 Uncorrectable Error Status Register (PCIE_EP_UESR)

Offset: 0x04

Address: 0h base + 104h offset = 104h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PCIe CTRL RC Mode Memory Map/Register Definition

PCIE_RC_BIST field descriptions

Field	Description
31–24 Not_supported_by_core	The BIST register functions are not supported by the core. All 8 bits of the BIST register are hardwired to 0.
23 Multi_Function_Device	Multi Function Device The default value is 0 for a single function device ('CX_NFUNC = 1) or 1 for a multi-function device ('CX_NFUNC != 1). The Multi Function Device bit is writable through the DBI.
22–16 Configuration_Header_Format	Configuration Header Format Hardwired to 0 for type 0.
15–8 Master_Latency_Timer	Master Latency Timer Not applicable for PCI Express, hardwired to 0.
Cache_Line_Size	Cache Line Size The Cache Line Size register is RW for legacy compatibility purposes and is not applicable to PCI Express device functionality. Writing to the Cache Line Size register does not impact functionality of the core.

46.11.5 Base Address 0 (PCIE_RC_BAR0)

Offset: 0x10-0x24

The core provides three pairs of 32-bit BARs for each implemented function. Each pair (BARs 0 and 1, BARs 2 and 3, BARs 4 and 5) can be configured as follows:

- One 64-bit BAR: For example, BARs 0 and 1 are combined to form a single 64-bit BAR.
- Two 32-bit BARs: For example, BARs 0 and 1 are two independent 32-bit BARs.
- One 32-bit BAR: For example, BAR 0 is a 32-bit BAR and BAR 1 is either disabled or removed from the core altogether to reduce gate count.

In addition, you can configure each BAR to have its incoming Requests routed to either:

- RTRGT1
-

The following sections describe how to set up the BAR types and sizes by programming values into the base address registers. For more information about routing Requests to either RTRGT1 on a BAR-by- BAR basis, see Receive Filtering.

The contents of the six BARs determine the BAR configuration. The reset values of the BARs are determined by hardware configuration options.

At runtime, application software can overwrite the BAR contents to reconfigure the BARs (unless the affected BAR is removed during hardware configuration). Application software must observe the rules listed below when writing to the BARs.

The rules for BAR configuration are the same for all three pairs. Using BARs 0 and 1 as the example pair, the rules for BAR configuration are:

- Any pair (for example, BARs 0 and 1) can be configured as one 64-bit BAR, two 32-bit BARs, or one 32-bit BAR.
- BAR pairs cannot overlap to form a 64-bit BAR. For example, you cannot combine BARs 1 and 2 to form a 64-bit BAR.
-
- An I/O BAR must be a 32-bit BAR and cannot be prefetchable.
- If the device is configured as a PCI Express Endpoint (not a Legacy Endpoint), then any memory that is configured as prefetchable must be a 64-bit memory BAR.
- If BAR 0 is configured as a 64-bit BAR:
 - BAR 1 is the upper 32 bits of the combined 64-bit BAR formed by BARs 0 and 1. Therefore, BAR 1 must be disabled and cannot be configured independently.
 - BAR 0 must be a memory BAR and can be either prefetchable or non-prefetchable.
 - The contents of the BAR 0 Mask register determine the number of writable bits in the 64-bit BAR, subject to the restrictions described in BAR Mask Register. The BAR 1 Mask register contains the upper 32 bits of the BAR 0 Mask value.
 - BAR 0 can be disabled by writing 0 to bit 0 of the BAR 0 Mask register
- If BAR 0 is configured as a 32-bit BAR:
 - You can configure BAR 1 as an independent 32-bit BAR
 - BAR 0 can be configured as a memory BAR or an I/O BAR.
 - The contents of the BAR 0 Mask register determine the number of writable bits in the 32-bit BAR 0, subject to the restrictions described in BAR Mask Registers.
 - BAR 0 can be disabled by writing 0 to bit 0 of the BAR 0 Mask register
- When BAR 0 is configured as a 32-bit BAR, BAR 1 is available as an independent 32-bit BAR according to the following rules:
 - BAR 1 can be configured as a memory BAR or an I/O BAR.

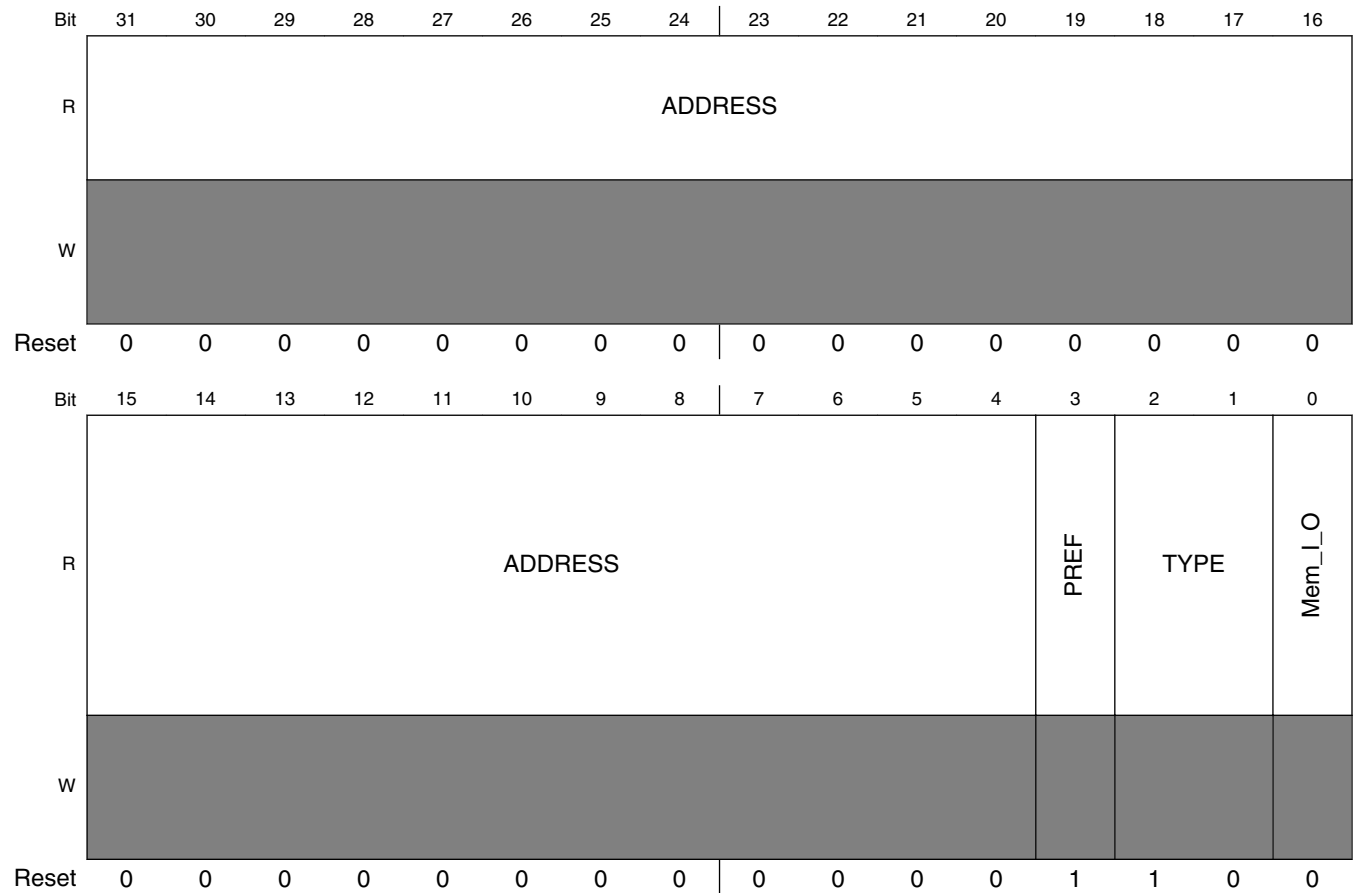

PCIe CTRL RC Mode Memory Map/Register Definition

- The contents of the BAR 1 Mask register determine the number of writable bits in the 32-bit BAR 1, subject to the restrictions described in BAR Mask Registers.
-
-

The same rules apply for pairs 2/3 and 4/5.

Offset: 0x10 (if included in the core hardware configuration)

Address: 0h base + 10h offset = 10h

PCIE_RC_BAR0 field descriptions

Field	Description
31-4 ADDRESS	BAR 0 base address bits (for a 64-bit BAR, the remaining upper address bits are in BAR 1). The BAR 0 Mask value determines which address bits are masked.
3 PREF	If BAR 0 is an I/O BAR, bit 3 is the second least significant bit of the base address. Bits [3:0] are writable through the DBI. If BAR 0 is a memory BAR, bit 3 indicates if the memory region is prefetchable: 0 = Non-prefetchable 1 = Prefetchable

Table continues on the next page...

46.11.17 Power Management Capability Register (PCIE_RC_PMCR)

The core implements power management capabilities. The Capability Pointer field in the configuration header points to the PCI Power Management registers as the first extended capability by default.

The extent of the power management implementation in the core includes:

- Power Management register space
- Link state information (provided to both the application logic and PHY interfaces)
- Power management-ready clock and reset implementation

The following sections describe the PCI Power Management registers implemented in the core. See the *PCI Power Management specification* and the *PCI Express 3.0 Specification* for more details.

Offset: `CFG_PM_CAP

Address: 0h base + 40h offset = 40h

PCIE_RC_PMCR field descriptions

Field	Description
31-22 -	This field is reserved. Reserved
21 Transaction_Pending	Transaction Pending Hard-wired to 0.
20 Aux_Power_Detected	Aux Power Detected From sys_aux_pwr_det input port.
19 Unsupported_Request_Detected	Unsupported Request Detected Errors are logged in this register regardless of whether error reporting is enabled in the Device Control register.
18 Fatal_Error_Detected	Fatal Error Detected Errors are logged in this register regardless of whether error reporting is enabled in the Device Control register.

Table continues on the next page...

PCIE_RC_DConR field descriptions (continued)

Field	Description
17 Non_Fatal_Error_detected	Non-Fatal Error detected Errors are logged in this register regardless of whether error reporting is enabled in the Device Control register.
16 Correctable_Error_Detected	Correctable Error Detected Errors are logged in this register regardless of whether error reporting is enabled in the Device Control register.
15 -	This field is reserved. Reserved
14–12 Max_Read_Request_Size	Max_Read_Request_Size
11 Enable_No_Snoop	Enable No Snoop
10 AUX_Power_PM_Enable	AUX Power PM Enable
9 Phantom_Function_Enable	Phantom Function Enable
8 Extended_Tag_Field_Enable	Extended Tag Field Enable 1 when CX_MAX_TAG > 32, else 0
7–5 Max_Payload_Size	Max_Payload_Size
4 Enable_Relaxed_Ordering	Enable Relaxed Ordering This bit is not used by the core.
3 Unsupported_Request_Reporting_Enable	Unsupported Request Reporting Enable
2 Fatal_Error_Reporting_Enable	Fatal Error Reporting Enable
1 Non_Fatal_Error_Reporting_Enable	Non-Fatal Error Reporting Enable
0 Correctable_Error_Reporting_Enable	Correctable Error Reporting Enable

46.11.22 Link Capabilities Register (PCIE_RC_LCR)

Offset: `CFG_PCIE_CAP + 0x0C

Address: 0h base + 7Ch offset = 7Ch

PCIe CTRL RC Mode Memory Map/Register Definition

PCIE_RC_LCR field descriptions

Field	Description
31–24 Port_Number	Port Number
23–22 -	This field is reserved. Reserved
21 Link_Bandwidth_Notification_Capability	Link Bandwidth Notification Capability Hardwired to 1 for Downstream Ports and 0 for Upstream Ports.
20 Data_Link_Layer_Active_Reporting_Capable	Data Link Layer Active Reporting Capable Hardwired to 1 for Downstream Ports and 0 for Upstream Ports.
19 Surprise_Down_Error_Reporting_Capable	Surprise Down Error Reporting Capable Not supported, hardwired to 0x0.

Table continues on the next page...

PCIE_RC_LCR field descriptions (continued)

Field	Description
18 Clock_Power_ Management	Clock Power Management Component can tolerate the removal of refclk via CLKREQ# (if supported). Hardwired to 0 for downstream ports. Writable through the DBI.
17–15 L1_Exit_Latency	L1 Exit Latency Writable through the DBI.
14–12 L0s_Exit_Latency	L0s Exit Latency Writable through the DBI.
11–10 Active_State_ Link_PM_ Support	Active State Link PM Support The default value is the value you specify during core configuration, writable through the DBI.
9–4 Maximum_Link_ Width	Maximum Link Width Writable through the DBI.
Max_Link_ Speeds	Max Link Speeds Indicates the supported maximum Link speeds of the associated Port. The encoding is the binary value of the bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the maximum Link speed. This field is writable through the DBI. 0001 Gen1 2.5 GT/s 0010 Gen2 5.0 GT/s 0100 Reserved

46.11.23 Link Control and Status Register (PCIE_RC_LCSR)

Offset: `CFG_PCIE_CAP + 0x10

Address: 0h base + 80h offset = 80h

PCIE_RC_LCSR field descriptions

Field	Description
31 Link_Autonomous_Bandwidth_Status	<p>Link Autonomous Bandwidth Status</p> <p>This bit is set by hardware to indicate that hardware has autonomously changed Link speed or width, without the Port transitioning through DL_Down status, for reasons other than to attempt to correct unreliable Link operation. This bit must be set if the Physical Layer reports a speed or a width change was initiated by the Downstream component that was indicated as an autonomous change.</p> <p>NOTE: This bit is not applicable and is reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges.</p>
30 Link_Bandwidth_Management_Status	<p>Link Bandwidth Management Status</p> <p>This bit is set by hardware to indicate that either of the following has occurred without the Port transitioning through DL_Down status:</p> <ul style="list-style-type: none"> •A Link retraining has completed following a write of 1b to the Retrain Link bit.

Table continues on the next page...

PCIE_RC_LCSR field descriptions (continued)

Field	Description
	<p>•Hardware has changed Link speed or width to attempt to correct unreliable Link operation, either through an LTSSM timeout or a higher level process. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was not indicated as an autonomous change.</p> <p>NOTE: : This bit is set following any write of 1b to the Retrain Link bit, including when the Link is in the process of retraining for some other reason.</p> <p>NOTE: This bit is not applicable and is reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges.</p>
29 Data_Link_Layer_Active	<p>Data Link Layer Active</p> <p>This bit must be implemented if the corresponding Data Link Layer Link Active Reporting capability bit is implemented. Otherwise, this bit must be hardwired to 0b.</p>
28 Slot_Clock_Configuration	<p>Slot Clock Configuration</p> <p>Indicates that the component uses the same physical reference clock that the platform provides on the connector. The default value is the value you select during hardware configuration, writable through the DBI.</p>
27 Link_Training	<p>Link Training</p> <p>This bit is not applicable and is reserved for Endpoints, PCI Express to PCI/PCI-X bridges.</p>
26 -	<p>This field is reserved.</p> <p>Reserved</p> <p>Undefined for PCI Express 1.1</p> <p>(Was Training Error for PCI Express 1.0a)</p>
25–20 Negotiated_Link_Width	<p>Negotiated Link Width</p> <p>Set automatically by hardware after Link initialization. The value is undefined when link is not up.</p>
19–16 Link_Speed	<p>Link Speed</p> <p>Indicates the negotiated Link speed.</p> <p>The encoding is the binary value of the bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the current Link speed.</p> <p>Possible values are:</p> <p>0001 Gen1 2.5 GT/s</p> <p>0010 Gen2 5.0 GT/s</p>
15–12 -	<p>This field is reserved.</p> <p>Reserved</p>
11 Link_Autonomous_Bandwidth_Interrupt_Enable	<p>Link Autonomous Bandwidth Interrupt Enable When set, this bit enables the generation of an interrupt to indicate that the Link Autonomous Bandwidth Status bit has been set.</p> <p>NOTE: This bit is not applicable and is reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges.</p>
10 Link_Bandwidth_Management_Interrupt_Enable	<p>Link Bandwidth Management Interrupt Enable When set, this bit enables the generation of an interrupt to indicate that the Link Bandwidth Management Status bit has been set.</p> <p>NOTE: This bit is not applicable and is reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges.</p>

Table continues on the next page...

PCIE_RC_LCSR field descriptions (continued)

Field	Description
9 Hardware_Autonomous_Width_Disable	Hardware Autonomous Width Disable Not supported, hardwired to 0.
8 Enable_Clock_Power_Management	Enable Clock Power Management Hardwired to 0 if Clock Power Management is disabled in the Link Capabilities register.
7 Extended_Synch	Extended Synch
6 Common_Clock_Configuration	Common Clock Configuration
5 Retrain_Link	Retrain Link This bit is reserved for PCI Express-to-PCI/PCI-X bridges.
4 Link_Disable	Link Disable This bit is reserved for PCI Express-to-PCI/PCI-X bridges.
3 RCB	Read Completion Boundary (RCB) RC: Writable through DBI
2 -	This field is reserved. Reserved
Active_State_Link_PM_Control	Active State Link PM Control

46.11.24 Slot Capabilities Register (PCIE_RC_SCR)

31-22 -	This field is reserved. Reserved
21 Link_Equalization_Request	Link Equalization Request
20 Equalization_Phase_3_Successful	Equalization Phase 3 Successful
19 Equalization_Phase_2_Successful	Equalization Phase 2 Successful

Table continues on the next page...

PCIE_RC_LCSR2 field descriptions (continued)

Field	Description
18 Equalization_ Phase_1_ Successful	Equalization Phase 1 Successful
17 Equalization_ Complete	Equalization Complete
16 Current_ Deemphasis_ Level	Current De-emphasis Level
15–12 Compliance_ Pre_set_ Deemphasis	Compliance Pre-set/ De-emphasis
11 Compliance_ SOS	Compliance SOS When set to 1b, the LTSSM is required to send SKP Ordered Sets periodically in between the (modified) compliance patterns. GT/s speed are permitted to hardwire this bit to 0b. NOTE: When the Link is operating at 2.5 GT/s, the setting of this bit has no effect. Components that support only 2.5
10 Enter_Modified_ Compliance	Enter Modified Compliance When this bit is set to 1b, the device transmits modified compliance pattern if the LTSSM enters Polling. Compliance state.
9–7 Transmit_Margin	Transmit Margin This field is reset to 000b on entry to the LTSSM Polling. Compliance substate. Components that support only the 2.5 GT/s speed are permitted to hard-wire this bit to 0b. When operating in 5.0 GT/s mode with full swing, the de-emphasis ratio must be maintained within +/- 1 dB from the specification-defined operational value (either -3.5 or -6 dB). This field controls the value of the non-de-emphasized voltage level at the Transmitter pins: 000 800-1200 mV for full swing 400-600 mV for half- swing 001-010 values must be monotonic with a non-zero slope 011 200-400 mV for full-swing and 100-200 mV for halfswing 100-111 reserved
6 Selectable_ Deemphasis	Selectable De-emphasis When the Link is operating at 2.5 GT/s speed, the setting of this bit has no effect. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b. Default value is implementation-specific, unless a specific value is required for a selected form factor or platform. When the Link is operating at 5.0 GT/s speed, selects the level of de-emphasis: 1 -3.5 dB 0 -6 dB

Table continues on the next page...

PCIE_RC_LCSR2 field descriptions (continued)

Field	Description
5 Hardware_Autonomous_Speed_Disable	<p>Hardware Autonomous Speed Disable</p> <p>When cfg_hw_auto_sp_dis signal is asserted, the application must disable hardware from changing the Link speed for device-specific reasons other than attempting to correct unreliable Link operation by reducing Link speed. Initial transition to the highest supported common link speed is not blocked by this signal.</p>
4 Enter_Compliance	<p>Enter Compliance</p> <p>Software is permitted to force a link to enter Compliance mode at the speed indicated in the Target Link Speed field by setting this bit to 1b in both components on a link and then initiating a hot reset on the link.</p> <p>The default value of this field following Fundamental Reset is 0b.</p>
Target_Link_Speed	<p>Target Link Speed</p> <p>For Downstream ports, this field sets an upper limit on link operational speed by restricting the values advertised by the upstream component in its training sequences:</p> <p>The encoding is the binary value of the bit in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the desired target Link speed.</p> <p>NOTE: If a value is written to this field that does not correspond to a speed included in the Supported Link Speeds field, the result is undefined.</p> <p>NOTE: The default value of this field is the highest link speed supported by the component (as reported in the Max Link Speed field of the Link Capabilities Register) unless the corresponding platform / form factor requires a different default value.</p> <p>NOTE: Components that support only the 2.5 GT/s speed are permitted to hardwire this field to 0000b. All other encodings are reserved.</p> <p>0000001 Gen1 2.5 GT/s 0000010 Gen2 5.0 GT/s</p>

46.11.32 AER Capability Header (PCIE_RC_AER)

The core implements the following PCI Express Extended Capabilities registers:

- Advanced Error Reporting Capability register set
- Virtual Channel Capability register set
- Secondary PCI Express Capability register set (Gen3)
- TLP Processing Hints (TPH) Capability register set
- Address Translation Services (ATS) Capability register set
- Resizable BAR (RBAR) Extended Capability register set

Address: 0x100

Address: 0h base + 100h offset = 100h

PCIE_RC_AER field descriptions

Field	Description
31–20 Next_Capability_Offset	Next Capability Offset
19–16 Capability_Version	Capability Version
PCI_Express_Extended_Capability_ID	PCI Express Extended Capability ID Value is 0x1 for Advanced Error Reporting.

46.11.33 Uncorrectable Error Status Register (PCIE_RC_UESR)

Offset: 0x04

Address: 0h base + 104h offset = 104h

PCIE_RC_UESR field descriptions

Field	Description
32–25 -	This field is reserved. Reserved
24 AOP_EGRESS_BLOCK_STAT	AtomicOp Egress Blocked Status

PCIE_PL_VSDR field descriptions

Field	Description
Vendor_Specific_DLLP	Vendor Specific DLLP Register Used to send a specific PCI Express DLLP. The application writes the 8-bit DLLP Type and 24-bits of Payload data into this register, then sets bit 0 of Port Link Control Register (PCIE_PL_PLCR) to send the DLLP.

46.12.3 Port Force Link Register (PCIE_PL_PFLR)

Offset: 0x700 + 0x8

Address: 0h base + 708h offset = 708h

PCIE_PL_PFLR field descriptions

Field	Description
31–24 Low_Power_Entrance_Count	Low Power Entrance Count The Power Management state will wait for this many clock cycles for the associated completion of a CfgWr to D-state register to go low-power. This register is intended for applications that do not let the core handle a completion for configuration request to the PMCSCR register. Note: Only used in the DM core (in EP mode), EP core, and the upstream port of a Switch.
23–22 -	This field is reserved. Reserved
21–16 Link_State	Link State The Link state that the core will be forced to when bit 15 (Force Link) is set. State encoding is defined in xmlh_ltssm.v.
15 Force_Link	Force Link Forces the Link to the state specified by the Link State field. The Force Link pulse will trigger Link re-negotiation.

Table continues on the next page...

PCIE_PL_PFLR field descriptions (continued)

Field	Description
	* Reading from this self-clearing register field always returns a 0.
14–8 -	This field is reserved. Reserved
Link_Number	Link Number Not used for Endpoint

46.12.4 Ack Frequency and L0-L1 ASPM Control Register (PCIE_PL_AFLACR)

Offset: 0x700 + 0xC

Address: 0h base + 70Ch offset = 70Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	1	0	1	1	0	0	0	0	0	0	0	0	0	0

PCIE_PL_AFLACR field descriptions

Field	Description
31 -	This field is reserved. Reserved
30 Enter_ASPM_L1	Enter ASPM L1 without receive in L0s. Allow core to enter ASPM L1 even when link partner did not go to L0s (receive is not in L0s).

Table continues on the next page...

PCIE_PL_AFLACR field descriptions (continued)

Field	Description
	When not set, core goes to ASPM L1 only after idle period during which both receive and transmit are in L0s.
29–27 L1_Entrance_ Latency	L1 Entrance Latency Values correspond to: 000 1 is 001 2 is 010 4 is 011 8 is 100 16 is 101 32 is 110 64 is 111 64 is
26–24 L0s_Entrance_ Latency	L0s Entrance Latency Values correspond to: 000 1 is 001 2 is 010 3 is 011 4 is 100 5 is 101 6 is 110 7 is 111 7 is
23–16 Common_Clock_ N_FTS	Common Clock N_FTS This is the N_FTS when common clock is used. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. This field is writable only if the parameters are selected as follows during configuration of the core; CX_NFTS != CX_COMM_NFTS DEFAULT_L0S_EXIT_LATENCY != DEFAULT_COMM_L0S_EXIT_LATENCY DEFAULT_L1_EXIT_LATENCY != DEFAULT_COMM_L1_EXIT_LATENCY otherwise, it will be hard coded to the value of the CX_COMM_NFTS configuration parameter. Note: The core does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s.
15–8 N_FTS	N_FTS The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. Note: The core does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s.
Ack_Frequency	Ack Frequency The core accumulates the number of pending Ack's specified here (up to 255) before sending an Ack DLLP see Link Layer: (Flow Control and ACK/NAK DLLPs) for more details.

46.12.5 Port Link Control Register (PCIE_PL_PLCR)

Offset: 0x700 + 0x10

Address: 0h base + 710h offset = 710h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	

PCIE_PL_PLCR field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23 Crosslink_Active	Crosslink Active. Indicates a change from upstream to downstream or downstream to upstream. Same as the xmlh_crosslink_active output.
22 Crosslink_Enable	Crosslink Enable
21–16 Link_Mode_Enable	Link Mode Enable The default value is the number of Lanes supported in the version of the core you are using. 000001 x1 000011 x2 000111 x4 001111 x8

Table continues on the next page...

PCIE_PL_PLCR field descriptions (continued)

Field	Description
	011111 x16 111111 x32 (not supported)
15–8 -	This field is reserved. Reserved
7 Fast_Link_Mode	Fast Link Mode Sets all internal timers to Fast Mode for speeding up simulation. Forces the LTSSM training (link initialization) to use shorter time-outs and to link up faster. The scaling factor is 1024 for all internal timers. Note: Fast Link Mode can also be activated by setting the diag_ctrl_bus[2] pin to '1'.
6 -	This field is reserved. Reserved
5 DLL_Link_Enable	DLL Link Enable Enables Link initialization. If DLL Link Enable = 0, the core does not transmit InitFC DLLPs and does not establish a Link.
4 -	This field is reserved. Reserved
3 Reset_Assert	Reset Assert Triggers a recovery and forces the LTSSM to the Hot Reset state (downstream port only).
2 Loopback_Enabled	Loopback Enable Turns on loopback.
1 Scramble_Disable	Scramble Disable Turns off data scrambling.
0 Vendor_Specific_DLLP_Request	Vendor Specific DLLP Request When software writes a '1' to this bit, the core transmits the DLLP contained in the Vendor Specific DLLP Register (PCIE_PL_VSDR) . * Reading from this self-clearing register field always returns a 0.

46.12.6 Lane Skew Register (PCIE_PL_LSR)

Offset: 0x700 + 0x14

Address: 0h base + 714h offset = 714h

PCIE_PL_LSR field descriptions

Field	Description
31 Disable_Lane_to_Lane_Deskew	Disable Lane-to-Lane Deskew Causes the core to disable the internal Lane-to-Lane deskew logic.
30–26 -	This field is reserved. Reserved
25 Ack_Nak_Disable	Ack/Nak Disable Prevents the core from sending Ack and Nak DLLPs.
24 Flow_Control_Disable	Flow Control Disable Prevents the core from sending FC DLLPs.
Insert_Lane_Skew_for_Transmit	Insert Lane Skew for Transmit (not supported for x16) Optional feature that causes the core to insert skew between Lanes for test purposes. There are three bits per Lane. The value is in units of one symbol time. For example, the value 010b for a Lane forces a skew of two symbol times for that Lane. The maximum skew value for any Lane is 5 symbol times.

46.12.7 Symbol Number Register (PCIE_PL_SNR)

Offset: 0x700 + 0x18

Address: 0h base + 718h offset = 718h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	1	0	0	0	0	0	1	1	0	0	0	0	1	0	1	0

PCIE_PL_SNR field descriptions

Field	Description
31–29 Configuration_Requests	Configuration Requests targeted at function numbers above this value will be returned with UR (unsupported request).
28–24 Timer_Modifier_for_Flow_Control_Watchdog_Timer	Timer Modifier for Flow Control Watchdog Timer Increases the timer value for the Flow Control watchdog timer, in increments of 16 clock cycles.
23–19 Timer_Modifier_for_Ack_Nak_Latency_Timer	Timer Modifier for Ack/Nak Latency Timer Increases the timer value for the Ack/Nak latency timer, in increments of 64 clock cycles.
18–14 Timer_Modifier_for_Replay_Timer	Timer Modifier for Replay Timer Increases the timer value for the replay timer, in increments of 64 clock cycles.
13–8 -	This field is reserved. Reserved
MAX_FUNC_NUM_REQ	Maximum Function Number that can be used in a Request.

46.12.8 Symbol Timer Register and Filter Mask Register 1 (PCIE_PL_STRFM1)

Offset: 0x700 + 0x1C

Table 46-152. Filter Mask 1: Mask RADM Filtering and Error Handling Rules

Bits	Name	Name
31	CX_FLT_MASK_RC_CFG_DISCARD	CX_FLT_MASK_RC_CFG_DISCARD 0 For RADM RC filter to not allow CFG transaction being received 1 For RADM RC filter to allow CFG transaction being received
30	CX_FLT_MASK_RC_IO_DISCARD	CX_FLT_MASK_RC_IO_DISCARD 0 For RADM RC filter to not allow IO transaction being received 1 For RADM RC filter to allow IO transaction being received
29	CX_FLT_MASK_MSG_DROP	CX_FLT_MASK_MSG_DROP 0 Drop MSG TLP (except for Vendor MSG) 1 Do not Drop MSG (except for Vendor MSG)
28	CX_FLT_MASK_CPL_ECRC_DISCARD	CX_FLT_MASK_CPL_ECRC_DISCARD 0 Discard TLPs with ECRC errors for CPL type 1 Allow TLPs with ECRC errors to be passed up for CPL type
27	CX_FLT_MASK_ECRC_DISCARD	CX_FLT_MASK_ECRC_DISCARD 0 Discard TLPs with ECRC errors 1 Allow TLPs with ECRC errors to be passed up
26	CX_FLT_MASK_CPL_LEN_MATCH	CX_FLT_MASK_CPL_LEN_MATCH 0 Enforce length match for received CPL TLPs; a violation results in cpl_abort, and possibly AER of unexp_cpl_err 1 MASK length match for received CPL TLPs

PCIE_PL_STRFM1 field descriptions

Field	Description
31-16 Mask_RADM_Filtering_and_Error_Handling_Rules	Mask RADM Filtering and Error Handling Rules: Mask 1 There are several mask bits to turn off the filtering and error handling rules In each case, 0 applies the associated filtering rule and 1 masks the associated filtering rule. A more detailed description for these bits is provided in Table 5-348. [31]: Mask filtering of received Configuration Requests (RC mode only)

Table continues on the next page...

PCIE_PL_STRFM1 field descriptions (continued)

Field	Description
	<p>[30]: Mask filtering of received I/O Requests (RC mode only)</p> <p>[29]: Send Message TLPs to the application on RTRGT1 and send decoded Message on the SII (1) or send decoded Message on the SII, then drop the Message TLPs (0). The default value for this bit is the inverse of `FLT_DROP_MSG. That is, if `FLT_DROP_MSG = 1, then the default value of this bit is 0 (drop Message TLPs). Note that this bit only controls message TLPs other than Vendor MSGs. Vendor MSGs are controlled by Filter Mask Register 2 (PCIE_PL_STRFM2), bits [1:0].</p> <p>[28]: Mask ECRC error filtering for Completions</p> <p>[27]: Mask ECRC error filtering</p> <p>[26]: Mask Length mismatch error for received Completions</p> <p>[25]: Mask Attributes mismatch error for received Completions</p> <p>[24]: Mask Traffic Class mismatch error for received Completions</p> <p>[23]: Mask function mismatch error for received Completions</p> <p>[23]: Mask Requester ID mismatch error for received Completions</p> <p>[21]: Mask Tag error rules for received Completions</p> <p>[20]: Mask Locked Request filtering</p> <p>[19]: Mask Type 1 Configuration Request filtering</p> <p>[18]: Mask BAR match filtering</p> <p>[17]: Mask poisoned TLP filtering</p> <p>[16]: Mask function mismatch filtering for incoming Requests</p>
<p>15 Disable_FC_ Watchdog_Timer</p>	<p>Disable FC Watchdog Timer</p>
<p>14–11 -</p>	<p>This field is reserved. Reserved</p>
<p>SKP_Interval_ Value</p>	<p>SKP Interval Value</p> <p>The number of symbol times to wait between transmitting SKP ordered sets. Note that the core actually waits the number of symbol times in this register plus 1 between transmitting SKP ordered sets. The application must program this register accordingly. For example, if 1536 we're programmed into this register (in a 250MHz core), then the core will actually transmit Skp ordered sets once every 1537 symbol times.</p> <p>Also, the value programmed to this register is actually clock ticks and not symbol times. In a 125MHz core, programming the value programmed to this register should be scaled down by a factor of 2 (since 1 clock tick=2 symbol times in this case).</p>

Field	Description
1 Transmit_Retry_ Buffer_Not_Empty	Transmit Retry Buffer Not Empty Indicates that there is data in the transmit retry buffer.
0 Received_TLP_FC_Credits_Not_Returned	Received TLP FC Credits Not Returned Indicates that the core has sent a TLP but has not yet received an UpdateFC DLLP indicating that the credits for that TLP have been restored by the receiver at the other end of the Link. Note: This bit is for simulation only and will always be synthesized as 0.

46.12.17 VC Transmit Arbitration Register 1 (PCIE_PL_VCTAR1)

Offset: 0x700 + 0x40

VC Transmit Arbitration Registers 1 and 2 specify the weights assigned to VC0-VC7 to be used for WRR transmit arbitration for VCs in the LPVC group. The following rules and restrictions apply regarding the values programmed in VC Transmit Arbitration Registers 1 and 2:

- There are 8 bits allocated for each weight value.
- No weight value for a VC in the LPVC group can be less than 1.
- No weight value can be greater than the number of phases in the selected arbitration scheme.
- The sum of the weights assigned to all VCs in the LPVC group must equal the number of phases in the selected arbitration scheme. For example, if 64-phase WRR arbitration is selected, the total of all WRR Weight values for all VCs in the LPVC group must equal 64.

Each of the VC numbers listed in the bit field table is a VC ID, not the VC structure number. VC Transmit Arbitration Registers 1 and 2 are hardwired to the default values set by the configuration parameters listed in the Default columns of the bit field table.

31–21 -	This field is reserved. Reserved
20 De_emphasis_level	Used to set the de-emphasis level for upstream ports.
19 Config_Tx_Compliance_Receive_Bit	Config Tx Compliance Receive Bit When set to 1, signals LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to 1).
18 Config_PHY_Tx_Swing	Config PHY Tx Swing Indicates the voltage level the PHY should drive. When set to 1, indicates Full Swing. When set to 0, indicates Low Swing
17 Directed_Speed_Change	Directed Speed Change Indicates to the LTSSM whether or not to initiate a speed change to Gen2
16–8 Predetermined_Number_of_Lanes	Predetermined Number of Lanes Used to limit the effective link width to ignore "broken" lanes that detect a receiver. Indicates the number of lanes to check for exit from Electrical Idle in POLLING.ACTIVE and L2.IDLE. It is possible that the LTSSM may detect a Receiver on a 'bad' or 'broken' lane during the Detect Sub-state. However, it is also possible that such a lane may also fail to exit Electrical Idle and therefore prevent a valid link from being configured. Encoding is as follows: 0x01 = 1 lane

Table continues on the next page...

PCIE_PL_G2CR field descriptions (continued)

Field	Description
N_FTS	Sets the Number of Fast Training Sequences (N_FTS) that the core advertises as its N_FTS during Gen2 Link training. This value is used to inform the Link partner about the PHY's ability to recover synchronization after a low power state. The number should be provided by the PHY vendor. NOTE: Note: Do not set N_FTS to zero; doing so can cause the LTSSM to go into the recovery state when exiting from L0s.

PCIE_PL_MRCCR0 field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 Remote_Max_Bridge_Tag	Remote Max Bridge Tag Specifies the maximum number (-1) of Non-Posted AMBA requests outstanding at one time issued from the bridge master. Excludes any internally created TLP's as a result of decomposition. The core will automatically derive this when bits[2:0] (Remote Read Request Size) are written to. It is saturated in core at CX_REMOTE_MAX_TAG since the TRGT_CPL_LUT has only this many entries. Therefore it is important that the core is initially sized (at configuration time pre-silicon) with the true maximum value of CX_REMOTE_MAX_TAG to take advantage of the ability to dynamically increase remote_max_bridge_tag from CX_REMOTE_MAX_BRIDGE_TAG to any new value up to a maximum of CX_REMOTE_MAX_TAG NOTE: You must not change the value of the CC_MAX_MSTR_TAG configuration parameter to be less than CX_REMOTE_MAX_TAG+1, or there will not be enough AXI Master IDs available to simultaneously launch all of the NP requests.
7–3 -	This field is reserved. Reserved
Remote_Read_Request_Size	Remote Read Request Size Specifies the largest amount of data (bytes) that will ever be requested (via an inbound MemRd TLP) by a remote device. Must never be programmed with a value that exceeds the value represented by the configuration parameter CX_REMOTE_RD_REQ_SIZE as the Master Response Composer RAM in the AXI bridge is sized using CX_REMOTE_RD_REQ_SIZE. Must only be programmed with the values 3'b000 to 3'b101. Any other value has the same effect as writing a value of 3'b000. NOTE: You must not use a value that exceeds the default value.

PIPE Loopback

Address: 0h base + 8B8h offset = 8B8h

PCIE_PL_PIPE_LOOPBACK_CTRL field descriptions

Field	Description
31 PIPE_ LOOPBACK_EN	PIPE Loopback Enable
-	This field is reserved. Reserved

46.12.43 iATU Viewport Register (PCIE_PL_iATUVR)

See [Internal Address Translation \(iATU\)](#) for more information on iATU operation.

The iATU registers are programmed through an index (Viewport) register to reduce the footprint in the PCI Express Extended Configuration Space. The size of the required port logic space does not depend on the number of regions defined as the Viewport register is used to select which memory region is being accessed. There are 28 bytes of register space implemented *per address region* per direction. The number of address regions that are remapped by the iATU is 4 for inbound and 4 for outbound. However, only 32 bytes of the PCIe Extended Configuration Space Address Map is used.

Offset: 0x700 + 0x200

The viewport register has a "Region Direction" bit to determine whether an inbound or outbound region is being accessed and a "Region Index" field to determine which region to program/read when accessing the other address translation registers in the iATU Register Map below..

As an example, to access the Control, Base, Limit and Target registers for Outbound region number 4:

- Write 0x00000004 to Address {0x700 + 0x200} to index the Outbound Address Region #4
- Then proceed to write to any of the other registers in the iATU Register Map below.

Table 46-254. iATU Register Map

Byte Offset	Description
+0x200	iATU Viewport Register
+0x204	iATU Region Control 1 Register
+0x208	iATU Region Control 2 Register
+0x20C	iATU Region Lower Base Address Register
+0x210	iATU Region Upper Base Address Register
+0x214	iATU Region Limit Address Register

Table continues on the next page...

Table 46-254. iATU Register Map (continued)

Byte Offset	Description
+0x218	iATU Region Lower Target Address Register
+0x21C	iATU Region Upper Target Address Register
+0x220	iATU Region Control 3 Register

NOTE

Since AXI core is async to the core_clk, the iATU registers may not be updated while operations are in progress on the AXI Bridge Slave interface.

Address: 0h base + 900h offset = 900h

PCIE_PL_iATUVR field descriptions

Field	Description
31 Region_Direction	Region Direction Defines the region being accessed as either 0 Outbound 1 Inbound
30-4 -	This field is reserved. Reserved
Region_Index	Region Index Defines which region is being accessed when writing to the control, base, limit and target registers. Must not be set to a number greater than CX_ATU_NUM_OUTBOUND_REGIONS - 1 when an outbound region is being accessed. Must not be set to a value greater than 3 since there are 4 regions for both inbound or outbound (4 each).

46.12.44 iATU Region Control 1 Register (PCIE_PL_iATURC1)

Offset: 0x700 + 0x204

footnote 1 - If all other enabled field-matches are successful

Address: 0h base + 904h offset = 904h

PCIE_PL_iATURC2 field descriptions

Field	Description
31 Region_Enable	Region Enable Outbound / Inbound: This bit must be set to '1' for address translation to take place.
30 Match_Mode	Match Mode Outbound: Not used. Inbound MEM/IO: Determines Inbound matching mode for MEM/IO TLPs. <ul style="list-style-type: none"> 0: Address Mode. The iATU operates using addresses as in the Outbound direction. The Region Base and Limit Registers must be setup. 1: BAR Mode. BAR matching is used. The 'BAR Number' field is relevant. Inbound CFG0: Determines Inbound matching mode for CFG0 TLPs.

Table continues on the next page...

PCIE_PL_iATURC2 field descriptions (continued)

Field	Description
	<ul style="list-style-type: none"> 0: Routing ID match mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM/IO transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. <p>Inbound MSG/MSGD: Determines Inbound matching mode for MSG/MSGD TLPs.</p> <ul style="list-style-type: none"> 0: Address Mode. The iATU treats the 3rd DWORD and 4th DWORD of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. 1: Vendor ID match mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the 3rd DWORD of the TLP header, but matches against the Vendor ID in bits [15:0] of the 3rd DWORD of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the 4th DWORD of the TLP header.
29 Invert_Mode	<p>Invert Mode</p> <p>Outbound / Inbound: When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address).</p>
28 CFG_Shift_Mode	<p>CFG Shift Mode</p> <p>This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of the application memory space using a 28-bit effective address.</p> <p>Outbound: Shifts bits [27:12] of the untranslated address to form bits [31:16] of the translated address.</p> <p>Inbound: Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address.</p>
27 Fuzzy_Type_Match_Mode	<p>Fuzzy Type Match Mode</p> <p>Outbound: Not used.</p> <p>Inbound: When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that</p> <ul style="list-style-type: none"> CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. MRd and MRdLk TLPs are seen as identical The Routing field of Msg/MsgD TLPs is ignored <p>For example, CFG0 in the TYPE field in the iATU Region Control 1 Register (PCIE_PL_iATURC1) will match against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP.</p>
26 -	<p>This field is reserved. Reserved</p>
25-24 Response_Code	<p>Response Code</p> <p>Outbound: Not used.</p> <p>Inbound: Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response.</p> <p>00 - Normal RADM filter response is used. 01 - Unsupported Request (UR) 10 - Completer Abort (CA) 11 - Not used / undefined / reserved.</p>

Field	Description
	<p>Inbound: When the BAR number of an inbound MEM or IO TLP - that is matched by the normal internal BAR address matching mechanism - is the same as this field, address translation will proceed¹. This check is only performed if the iMatch Mode bit of the iATU Region Control 2 Register (PCIE_PL_iATURC2) is set.</p> <p>IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR.</p> <p>000b - BAR#0 001b - BAR#1 010b - BAR#2 011b - BAR#3 100b - BAR#4 101b - BAR#5 110b - ROM 111b - reserved</p>
Message_Code	<p>Message Code</p> <p>Outbound: When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the Message field of the TLP is changed to the value in this register.</p> <p>Inbound: When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation will proceed¹. This check is only performed if the iFunction Message Code Match Enable bit of the iATU Region Control 2 Register (PCIE_PL_iATURC2) is set.</p>

46.12.46 iATU Region Lower Base Address Register (PCIE_PL_iATURLBA)

The CX_ATU_MIN_REGION_SIZE configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log₂(CX_ATU_MIN_REGION_SIZE) bits are zero.

Offset: 0x700 + 0x20C

Address: 0h base + 90Ch offset = 90Ch

PCIE_PL_iATURLBA field descriptions

Field	Description
31-16 Address_upper	Forms bits [31:16] of the start address of the address region to be translated.

Table continues on the next page...

PCIE_PL_iATURLBA field descriptions (continued)

Field	Description
Address_lower	Forms bits [15:0] of the start address of the address region to be translated. The start address must be aligned to a CX_ATU_MIN_REGION_SIZE kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe core.

46.12.47 iATU Region Upper Base Address Register (PCIE_PL_iATURUBA)

Chapter 47

PCI Express PHY (PCIe_PHY)

47.1 Overview

PCIe 2.0 PHY is a complete mixed-signal semiconductor intellectual property (IP) solution, designed for single-chip integration into computer applications.

The PCIe 2.0 PHY supports both the 5 Gbp/s data rate of the PCI Express Gen 2.0 specifications as well as being backwards compatible to the 2.5Gb/s Gen 1.1 specification.

This chapter provides an introduction to the PCIe 2.0 PHY and its features.

47.2 Applications

>

Designed for low power, the PCIe 2.0 PHY allows designers to introduce competitive products using the latest generation of the PCI Express standard.

47.3 PCIe2 PHY Features

47.3.1 Standards Compliance

The PCIe2 PHY is fully compliant with all of the required features of the following standards:

- PCI Express Base Specification, Revision 2.0 (including legacy 2.5-Gbps support)
- 5.0 Gbps data rate

- PCI Express Base Specification, Revision 1.1
- 2.5Gbps data rate

47.3.2 PHY Features

- 5 Gbps data transmission rate
- Integrated PHY includes transmitter, receiver, PLL, digital core, and ESD.
- Programmable RX equalization
- Designed for excellent performance margin and receiver sensitivity
- Robust PHY architecture tolerates wide process, voltage and temperature variations
- Low-jitter PLL technology with excellent supply isolation
- IEEE 1149.6 (JTAG) boundary scan
- Built-in Self-Test (BIST) features for production, at-speed, testing on any digital tester
- 5Gb/s PCIe Gen 2 and 2.5Gb/s PCIe Gen 1.1 test modes supported
- Advanced built-in diagnostics including on-chip sampling scope for easy debug
- Visibility & controllability of hard macro functionality thru programmable registers in the design
- Over-rides on all ASIC side inputs for easy debug
- Access register space thru simple 16 bit parallel interface
- Access register space thru JTAG

47.4 External Signals

The following table describes the external signals of PCIe:

Table 47-1. PCIe External Signals

Signal	Description	Pad	Mode	Direction
PCIE_RX_N	PCIe negative receive signal	PCIE_RX_N	No muxing	I
PCIE_RX_P	PCIe positive receive signal	PCIE_RX_P	No muxing	I
PCIE_TX_N	PCIe negative transmit signal	PCIE_TX_N	No muxing	O
PCIE_TX_P	PCIe positive transmit signal	PCIE_TX_P	No muxing	O

47.5 Functional Description

This section provides a complete functional description of the block.

47.5.1 Clocks and Resets

47.5.1.1 Reference Clock Enables

To enable to lowest possible power state, there is an enable on the reference clock input buffer. When totally powered down and prior to removing the reference clock, can be de-asserted to completely shut down the PHY.

- To enable the reference clock buffer in the PCIe2 PHY, the signal `phy_ref_ssp_en` must be asserted after the reference clock is up and stable and prior to de-asserting `phy_reset`.

47.5.1.2 Reference Clock Frequency Selection

The MPLL in the PCIe2 PHY has the ability to multiply the reference clock by integer and non-integer values, allowing for a wide range input reference clock frequencies.

Based on the incoming reference clock frequency, the MPLL controls must be set as shown in the table below to get proper 5Gb/s operation. With these MPLL settings, the reference clock output `phy_ref_output_clk` will provide the frequencies shown in the right-most column the table below.

NOTE

Reference clock jitter is greater than the specification requirement when the clock source is the internal ENET PLL.

Table 47-2. Reference Clock Frequency Selection

Reference Clock (MHz)	Required Multiplication	ref_clkdiv2	mpll_multiplier[6:0]	phy_ref_output_clk
100	25	0	0011001	100 MHz
125	40	1	0101000	62.5 MHz
200	25	1	0011001	100 MHz

47.5.1.3 Spread Spectrum Clocking

The PCIe2 PHY uses the PCIe reference clock which may or may not be spread. Since the PCIe specification does not allow independently spread clocks, the ability of the PHY to add a spread to a fixed frequency reference clock must be disabled.

47.5.2 Termination Resistance Tuning

The PHY uses an external resistor to calibrate the termination impedances of the high speed inputs and outputs of the PHY.

47.5.3 Control Register Access

The CR port is a simple 16bit data/16bit address parallel port that is provided for on-chip access to the control registers inside the PCIe2 PHY.

While access to these registers is NOT required for normal operation of the PHY, this interface is included for users that want to access some of the diagnostic features of the PHY during normal operation or over-ride some of the basic PHY control signals.

This interface is completely asynchronous using a hand shake between phy_cr_cap_addr, phy_cr_data, and phy_cr_ack input commands with phy_cr_ack acknowledgements and phy_cr_data_out outputs from the PHY. The CR port access is broken down into Address, Read, and Write transactions.

The details of the Control Registers themselves is detailed [Control Registers](#).

Figure 47-1. CR Bus Address Capture Transaction

Figure 47-2. CR Bus Read Transaction

Figure 47-3. CR Bus Write Transaction

NOTE

In all cases, phy_cr_ack will de-assert when the command (phy_cr_cap_addr, phy_cr_cap_data, phy_cr_read, cr_write) is removed.

If the Control Register port is not going to be used, tie the input signals as follows,

- phy_cr_cap_addr = 1'b0
- phy_cr_cap_data = 1'b0
- phy_cr_data_in = 16'b0
- phy_cr_read = 1'b0
- phy_cr_write = 1'b0
- No connect (leave floating) the following:
 - phy_cr_data_out[15:0]
 - phy_cr_ack.

47.6 Control Memory Map/Register Definition

NOTE

PCIe PHY registers are only accessible by the corresponding controller (PCIE_PHY_CTRL_R and PCIE_PHY_STS_R) or in debug through the JTAG port. PCIe PHY is not memory mapped to processor address space, so the absolute addresses shown is the relative address and is not valid.

PCIE_PHY memory map

47.6.1 Register ID Low 16 bits (PCIE_PHY_IDCODE_LO)

Address: 0h base + 0h offset = 0h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	IDCODE_LO															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_IDCODE_LO field descriptions

Field	Description
IDCODE_LO	Data

47.6.2 Register ID High 16 bits (PCIE_PHY_IDCODE_HI)

Address: 0h base + 1h offset = 1h

PCIE_PHY_IDCODE_HI field descriptions

Field	Description
IDCODE_HI	Data

47.6.3 Debug Register (PCIE_PHY_DEBUG)

Address: 0h base + 2h offset = 2h

PCIE_PHY_DEBUG field descriptions

Field	Description
15–6 -	This field is reserved. Reserved
6–5 DTB_SEL	Description: The lane DTB's are ORed together with the support DTB signals selected with the following encodings. 00 None 01 reset_ctl DTB output 10 Scope DTB output 11 rtune DTB output
TX_VREF_SEL	-

47.6.4 Debug Register (PCIE_PHY_RTUNE_DEBUG)

Address: 0h base + 3h offset = 3h

Bit	15	14	13	12	11	10	9	8
Read	Reserved		VALUE					
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	VALUE			TYPE		SET_VAL	MAN_TUNE	FLIP_COMP
Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RTUNE_DEBUG field descriptions

Field	Description
15 -	This field is reserved. Reserved
14–5 VALUE	Value to use when triggering SET_VAL field. Only the 6 LSB's are used when setting Rx cal or Tx cal values.
4–3 TYPE	Type of manual tuning or register read/write to execute. 00 ADC, or read/write rt_value 01 Rx tune, or read/write rx_cal_val (only 6 bits) 10 Tx tune, or read/write tx_cal_val (only 6 bits) 11 Resref detect (no affect when triggering SET_VAL fi
2 SET_VAL	Sets value. Write a 1 to manually write the register specified by the TYPE field to the value in the VALUE field.
1 MAN_TUNE	Write a 1 to perform a manual tuning specified by the TYPE field. Starting a manual tune while a tune is currently running can cause unpredictable results. For use only when you know what the part is doing (with respect to resistor tuning). NOTE: Write a 1 to perform an operation. Subsequent writes with the bit set will trigger the operation. No need to clear (0) the bit between writes.
0 FLIP_COMP	Inverts Analog Comparator Output.

47.6.5 PCIE_PHY_RTUNE_STAT

Address: 0h base + 4h offset = 4h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved							STAT								
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_RTUNE_STAT field descriptions

Field	Description
15-10 -	This field is reserved. Reserved
STAT	Current value of the register specified by the RTUNE_DEBUG[TYPE] field.

47.6.6 PCIE_PHY_SS_PHASE

Address: 0h base + 5h offset = 5h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved							DTHR								
Write	Reserved							DTHR								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_SS_PHASE field descriptions

Field	Description
15-10 -	This field is reserved. Reserved
DTHR	Current value of the register specified by the RTUNE_DEBUG[TYPE] field.

47.6.7 PCIE_PHY_SS_FREQ

Address: 0h base + 6h offset = 6h

Bit	15	14	13	12	11	10	9	8
Read	Reserved		FREQ_OVRD		FREQ_PK			
Write	Reserved		FREQ_OVRD		FREQ_PK			
Reset	0	0	1	1	0	0	1	1
Bit	7	6	5	4	3	2	1	0
Read	FREQ_PK		FREQ_CNT_INIT					
Write	FREQ_PK		FREQ_CNT_INIT					
Reset	0	0	1	0	0	1	1	1

PCIE_PHY_SS_FREQ field descriptions

Field	Description
15 -	This field is reserved. Reserved
14 FREQ_OVRD	Frequency register override. Spread spectrum clocking must be enabled to read from or write to this register. NOTE: Must be set for PHASE writes to stick.
13-7 FREQ_PK	Peak frequency value (for changing direction). Spread spectrum clocking must be enabled to read from or write to this register.

Table continues on the next page...

PCIE_PHY_SS_FREQ field descriptions (continued)

Field	Description
FREQ_CNT_INIT	Initial frequency counter value. Spread spectrum clocking must be enabled to read from or write to this register.

47.6.8 PCIE_PHY_ATEOVRD

Address: 0h base + 10h offset = 10h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write	Reserved							
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	Reserved				ateovrd_en	ref_usb2_en	ref_clkdiv2	Reserved
Write	Reserved				ateovrd_en	ref_usb2_en	ref_clkdiv2	Reserved
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_ATEOVRD field descriptions

Field	Description
15–4 -	This field is reserved. Reserved
3 ateovrd_en	Override enable for ATE signals.
2 ref_usb2_en	Override value for HSPHY ref_clk enable.
1 ref_clkdiv2	Override value for SSP ref_clk prescaler.
0 -	This field is reserved. Reserved

47.6.9 PCIE_PHY_MPLL_OVRD_IN_LO

Address: 0h base + 11h offset = 11h

Bit	15	14	13	12	11	10	9	8
Read	RES_ACK_	RES_ACK_	RES_REQ_	RES_REQ_	RTUNE_	RTUNE_	MPLL_	MPLL_
Write	IN_OVRD	IN	IN_OVRD	IN	REQ_OVRD	REQ	MULTIPLIE	MULTIPLIE
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	MPLL_MULTIPLIER						MPLL_EN_	MPLL_EN
Write	MPLL_MULTIPLIER						OVRD	
Reset	0	1	0	0	1	1	0	0

PCIE_PHY_MPLL_OVRD_IN_LO field descriptions

Field	Description
15 RES_ACK_IN_OVRD	Override enable for res_ack_in.
14 RES_ACK_IN	Override value for res_ack_in.
13 RES_REQ_IN_OVRD	Override enable for res_req_in.
12 RES_REQ_IN	Override value for res_req_in.
11 RTUNE_REQ_OVRD	Override enable for rtune_req.
10 RTUNE_REQ	Override value for rtune_req.
9 MPLL_MULTIPLIER_OVRD	Override enable for mpll_multiplier.
8-2 MPLL_MULTIPLIER	Override value for mpll_multiplier.
1 MPLL_EN_OVRD	Override enable for mpll_en.
0 MPLL_EN	Override value for mpll_en.

47.6.10 PCIE_PHY_MPLL_OVRD_IN_HI

Address: 0h base + 11h offset = 11h

Bit	15	14	13	12	11	10	9	8
Read	Reserved					MPLL_RST	FSEL_OVR	FSEL
Write	Reserved					MPLL_RST	FSEL_OVR	FSEL
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	FSEL		MPLL_WORD_CLK_EN_OVRD	MPLL_WORD_CLK_EN	MPLL_DWORD_CLK_EN_OVRD	MPLL_DWORD_CLK_EN	MPLL_QWORD_CLK_EN_OVRD	MPLL_QWORD_CLK_EN
Write	FSEL		MPLL_WORD_CLK_EN_OVRD	MPLL_WORD_CLK_EN	MPLL_DWORD_CLK_EN_OVRD	MPLL_DWORD_CLK_EN	MPLL_QWORD_CLK_EN_OVRD	MPLL_QWORD_CLK_EN
Reset	0	1	0	0	1	1	0	0

PCIE_PHY_MPLL_OVRD_IN_HI field descriptions

Field	Description
15–11 -	This field is reserved. Reserved.
10 MPLL_RST	Resets the MPLL state machine. Writing the register with this bit set will reset the MPLL power-up/down FSM, regardless of the current state of the register bit.
9 FSEL_OVR	Override enable for fsel[2:0].
8–6 FSEL	: Override value for fsel[2:0].
5 MPLL_WORD_CLK_EN_OVRD	Override enable for mpll_word_clk_en.
4 MPLL_WORD_CLK_EN	Override value for mpll_word_clk_en.
3 MPLL_DWORD_CLK_EN_OVRD	Override enable for mpll_dword_clk_en.
2 MPLL_DWORD_CLK_EN	Override value for mpll_dword_clk_en.
1 MPLL_QWORD_CLK_EN_OVRD	Override enable for mpll_qword_clk_en.
0 MPLL_QWORD_CLK_EN	Override value for mpll_qword_clk_en.

47.6.11 PCIE_PHY_SSC_OVRD_IN

Address: 0h base + 13h offset = 13h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved				SSC_OVRD_IN_EN	SSC_EN	SSC_RANGE		SSC_REF_CLK_SEL							
Write	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_SSC_OVRD_IN field descriptions

Field	Description
15–12 -	This field is reserved. Reserved

Table continues on the next page...

PCIE_PHY_SSC_OVRD_IN field descriptions (continued)

Field	Description
11 SSC_OVRD_IN_EN	Override enable for Spread Spectrum generator.
10 SSC_EN	Override value for SSC enable.
9–8 SSC_RANGE	Override value for SSC modulation range.
SSC_REF_CLK_SEL	Override value for reference clock scaling.

47.6.12 PCIE_PHY_BS_OVRD_IN

Address: 0h base + 14h offset = 14h

Bit	15	14	13	12	11	10	9	8
Read	Reserved				EN	INVERT	INIT	HIGHZ
Write	Reserved

15–10 -	This field is reserved. Reserved.
9–5 ACJT_LEVEL	Value from ASIC for acjt_level.
LOS_LEVEL	Value from ASIC for los_level.

47.6.18 PCIE_PHY_SSC_ASIC_IN

Address: 0h base + 1Ah offset = 1Ah

Bit	15	14	13	12	11	10	9	8
Read	Reserved		SS_EN	SSC_RANGE		SSC_REF_CLK_SEL		
Write	Reserved							
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	SSC_REF_CLK_SEL					FSEL		
Write	Reserved							
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_SSC_ASIC_IN field descriptions

Field	Description
15–14 -	This field is reserved. Reserved.
13 SS_EN	Value from ASIC for ssc_en.
12–11 SSC_RANGE	Value from ASIC for ssc_range.
10–3 SSC_REF_CLK_SEL	Value from ASIC for ssc_ref_clk_sel
FSEL	Value from ASIC for fsel.

47.6.19 PCIE_PHY_SUP_ASIC_OUT

Address: 0h base + 1Bh offset = 1Bh

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write	Reserved							
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	Reserved			MPLL_STATE	BS_OUT	RTUNE_ACK	RES_REQ_OUT	RES_ACK_OUT
Write	Reserved							
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_SUP_ASIC_OUT field descriptions

Field	Description
15-5 -	This field is reserved. Reserved.
4 MPLL_STATE	Value from PHY for mpll_state output.
3 BS_OUT	Value from PHY for bs_out output.
2 RTUNE_ACK	Value from PHY for rtune_ack output.
1 RES_REQ_OUT	Value from PHY for res_req_out output.
0 RES_ACK_OUT	Value from PHY for res_ack_out output.

47.6.20 PCIE_PHY_ATEOVRD_STATUS

Address: 0h base + 1Ch offset = 1Ch

PCIE_PHY_ATEOVRD_STATUS field descriptions

Field	Description
15–9 -	This field is reserved. Reserved.
8 REF_SSP_EN	Value from ASIC for ref_ssp_en.
7 REF_USE_PAD	Value from ASIC for ref_use_pad
6 PHY_RESET_IN	Value from ASIC for phy_reset
5 REF_CLKDIV2_IN	Value from ASIC for ref_clkdiv2.
4 REF_USB2_EN_IN	Value from ASIC for ref_usb2_en.
3 ATEOVRD_EN	When set, values from ATEOVRD register are sent to PHY.
2 PHY_RESET_OUT	Value from ATEOVRD for phy_reset.
1 REF_CLKDIV2_OUT	Value from ATEOVRD for ref_clkdiv2.
0 REF_USB2_EN_OUT	Value from ATEOVRD for ref_usb2_en.

47.6.21 PCIE_PHY_SCOPE_ENABLES

Address: 0h base + 20h offset = 20h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved													MAS K_		
Write	Reserved													SATU RATI ON_	MAS	XOR_
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_SCOPE_ENABLES field descriptions

Field	Description
15–3 -	This field is reserved. Reserved.

Table continues on the next page...

PCIE_PHY_SCOPE_ENABLES field descriptions (continued)

Field	Description
2 MASK_ SATURATION_ MODE	Method of mask saturation. 1 Saturates when the first mask_counter reaches sample_limit. 0 Saturates when all mask_counters have reached sample_limit.
1 MASK_EN	Enables scope_mask input for tracking count values. Clears registers when deasserted.
0 XOR_EN	Uses scope_xor input for count values.

47.6.22 PCIE_PHY_SCOPE_SAMPLES

Address: 0h base + 21h offset = 21h

Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
Read	SAMPLES																
Write																	
Reset	0	0	0	0	0	0	0	1		0	0	0	0	0	0	0	0

PCIE_PHY_SCOPE_SAMPLES field descriptions

Field	Description
SAMPLES	Number of samples to count.

47.6.23 PCIE_PHY_SCOPE_COUNT

Address: 0h base + 22h offset = 22h

Bit	15	14	13	12	11	10	9	8		7	6	5	4	3	2	1	0
Read	COUNT																
Write																	
Reset	1	1	1	1	1	1	1	1		1	1	1	1	1	1	1	1

PCIE_PHY_SCOPE_COUNT field descriptions

Field	Description
COUNT	A write to this register starts the counting process. The value of FFFF indicates counting still in progress. If in MASK mode, asserting MASK_EN also starts the counting

47.6.24 PCIE_PHY_SCOPE_CTL

Address: 0h base + 23h offset = 23h

Bit	15	14	13	12	11	10	9	8	
Read	Reserved								
Write									
Reset	0	0	0	0	0	0	0	0	
Bit	7	6	5	4	3	2	1	0	
Read	Reserved						COUNT	MASK_	SATURATI
Write									
Reset	0	0	0	0	0	0	0	0	

PCIE_PHY_SCOPE_CTL field descriptions

Field	Description
15–2 -	This field is reserved. Reserved.
1 COUNT	A write to this register starts the counting process. The value of FFFF indicates counting still in progress. If in MASK mode, asserting MASK_EN also starts the counting
0 MASK_	When asserted, mask registers have saturated.
SATURATION	

47.6.25 PCIE_PHY_SCOPE_MASK_n

Address: 0h base + 24h offset + (1d × i), where i=0d to 7d

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	MASK_VAL_n															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_SCOPE_MASK_n field descriptions

Field	Description
MASK_VAL_n	Starting count value of mask register. Scope must be enabled to read from or write to this register.

47.6.26 PCIE_PHY_MPLL_LOOP_CTL

Address: 0h base + 30h offset = 30h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	PROP_CNTRL				INT_CNTRL		VBF_SF	VMB
Write								
Reset	1	1	0	0	0	0	0	0

PCIE_PHY_MPLL_LOOP_CTL field descriptions

Field	Description
15–8 -	This field is reserved. Reserved.
7–4 PROP_CNTRL	Charge pump proportional current setting.
3–2 INT_CNTRL	Charge pump integrating current setting.
1 VBF_SF	Measures MPLL VBF_SF (RC filtered gate voltage for VPSF source follower).
0 VMB	Measures MPLL master bias voltage.

47.6.27 PCIE_PHY_MPLL_ATB_MEAS2

Address: 0h base + 32h offset = 32h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved								IVCO	VCNT	VCNT	ATB_	MEA	FRC_	EN_	EN_
Write									_FILT	RL_M	RL_P	SENS	S_	PMIX	MPMI	EN_
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_MPLL_ATB_MEAS2 field descriptions

Field	Description
15–8 -	This field is reserved. Reserved.
7 IVCO_FILT	Puts filtered version of ivco on atb_s_p

Table continues on the next page...

PCIE_PHY_MPLL_ATB_MEAS2 field descriptions (continued)

Field	Description
6 VCNTRL_M	Puts dcc output vcntrl_p on atb_s_m
5 VCNTRL_P	Puts dcc output vcntrl_m on atb_s_p
4 ATB_SENSE_SEL	connects internal atb sense bus to external bus
3 MEAS_TEMP	Instructs POR block to measure the temperature.
2 FRC_PMIK_VPMIX	Forces mpll_pmix_vreg to use atb_s_m as its input instead of vbg.
1 EN_MPMIX_VPMIX	Puts vreg_pmix on atb_s_p.
0 EN_MPMIX_TST	Enables XOR gate to test linearity of MPLL phase mixer.

47.6.28 PCIE_PHY_MPLL_OVR

Address: 0h base + 33h offset = 33h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	PWRON_LCL	EN_PWRON_LCL	GS_LCL	EN_GS_LCL	RST_LCL	EN_RST_LCL	PMIX_CLK_SEL_LCL	EN_PMIK_CLK_SEL_LCL
Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_MPLL_OVR field descriptions

Field	Description
15–8 -	This field is reserved. Reserved.

Table continues on the next page...

PCIE_PHY_MPLL_OVR field descriptions (continued)

Field	Description
7 PWRON_LCL	local power_on value
6 EN_PWRON_LCL	Enables local control of power_on
5 GS_LCL	local gear_shift value
4 EN_GS_LCL	Enables local control of gear_shift
3 RST_LCL	local Reset value
2 EN_RST_LCL	enable local control of reset
1 PMIX_CLK_SEL_LCL	local pmix_clk_sel value
0 EN_PMIX_CLK_SEL_LCL	enable local control of pmix_clk_sel

47.6.29 PCIE_PHY_RTUNE_RTUNE_CTRL

Address: 0h base + 34h offset = 34h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write	Reserved							
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0

RX_RATE	Value from ASIC for rx_rate

47.6.42 PCIE_PHY_RX_ASIC_OUT

Address: 0h base + 100Dh offset = 100Dh

PCIE_PHY_RX_ASIC_OUT field descriptions

Field	Description
15–3 -	This field is reserved. Reserved.
2 LOS	Value from PHY for rx_los
1 PLL_STATE	Value from PHY for rx_pll_state
0 VALID	Value from PHY for rx_valid

47.6.43 PCIE_PHY_TX_VMD_FSM_TX_VCM_0

Address: 0h base + 1011h offset = 1011h

Bit	15	14	13	12	11	10	9	8
Read	Reserved	DONE	N_USE					
Write	Reserved							
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	N_USE	N_TRISTATE						
Write	Reserved							
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_TX_VMD_FSM_TX_VCM_0 field descriptions

Field	Description
15 -	This field is reserved. Reserved.
14 DONE	Configuration is done
13-7 N_USE	Value from VMD for legs to use
N_TRISTATE	Value from VMD for number of tristate legs.

47.6.44 PCIE_PHY_TX_VMD_FSM_TX_VCM_1

Address: 0h base + 1012h offset = 1012h

Bit	15	14	13	12	11	10	9	8
Read	FIXED_DONE	TRA_DONE	N_FIXED					
Write	Reserved							
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	N_FIXED	N_TRAILER						
Write	Reserved							
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_TX_VMD_FSM_TX_VCM_1 field descriptions

Field	Description
15 FIXED_DONE	N_FIXED Multiplication has completed.
14 TRA_DONE	N_TRAILER Multiplication has completed.
13–7 N_FIXED	Value from VMD for number of fixed driver legs.
N_TRAILER	Value from VMD for number of trailer legs.

47.6.45 PCIE_PHY_TX_VMD_FSM_TX_VCM_DEBUG_IN

Address: 0h base + 1013h offset = 1013h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	Reserved				CONFIG_	CONFIG_	CONFIG_	CONFIG_
Write					OVRD	LOAD	CLK	DATA
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_TX_VMD_FSM_TX_VCM_DEBUG_IN field descriptions

Field	Description
15–4 -	This field is reserved. Reserved
3 CONFIG_OVRD	Override the Voltage Mode Driver Configuration FSM and access the shift chain directly.
2 CONFIG_LOAD	Override value for the Voltage Mode Driver Configuration FSM's config load.
1 CONFIG_CLK	Override value for the Voltage Mode Driver Configuration FSM's config clk.
0 CONFIG_DATA	Override value for the Voltage Mode Driver Configuration FSM's config data.

47.6.46 PCIE_PHY_TX_VMD_FSM_TX_VCM_DEBUG_OUT

Address: 0h base + 1014h offset = 1014h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write	Reserved							
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	Reserved							SHIFT_OUT
Write	Reserved							
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_TX_VMD_FSM_TX_VCM_DEBUG_OUT field descriptions

Field	Description
15–1 -	This field is reserved. Reserved
0 SHIFT_OUT	Current value from TX_ANAs configuration shift register.

47.6.47 PCIE_PHY_TX_LBERT_CTL

Address: 0h base + 1015h offset = 1015h

Bit	15	14	13	12	11	10	9	8
Read	Reserved			PAT0				
Write	Reserved			PAT0				
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	PAT0				TRIGGER_	MODE		
Write	PAT0				ERR	MODE		
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_TX_LBERT_CTL field descriptions

Field	Description
15–14 -	This field is reserved. Reserved
13–4 PAT0	Pattern for modes 3-5
3 TRIGGER_ERR	Insert a single error into a lsb Any write of a 1 to this bit will insert an error
MODE	Pattern to generate When changing modes, you must first change to disabled.

Table continues on the next page...

PCIE_PHY_TX_LBERT_CTL field descriptions (continued)

Field	Description
6	DC-balanced word (PAT0)
5	Fixed word (PAT0)
4	lfsr7. $X^7 + X^6 + 1$
3	lfsr15. $X^{15} + X^{14} + 1$
2	lfsr23. $X^{23} + X^{18} + 1$
1	lfsr31. $X^{31} + X^{28} + 1$
0	Disabled

47.6.48 PCIE_PHY_RX_LBERT_CTL

Address: 0h base + 1016h offset = 1016h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	Reserved				SYNC	MODE		
Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_LBERT_CTL field descriptions

Field	Description
15–4 -	This field is reserved. Reserved
3 SYNC	Synchronize pattern matcher LFSR with incoming data A write of a one to this bit will reset the error counter and start a synchronization of the PM. There is no need to write this back to zero to run normally.
MODE	Pattern to match When changing modes, you must first change to disabled. 7 $d[n] =$ 6 $d[n] = !d[n-10]$ 5 $d[n] = d[n-10]$ 4 lfsr7 : $X^7 + X^6 + 1$ 3 lfsr15: $X^{15} + X^{14} + 1$ 2 lfsr23. $X^{23} + X^{18} + 1$ 1 lfsr31. $X^{31} + X^{28} + 1$ 0 Disabled

47.6.49 PCIE_PHY_RX_LBERT_ERR

Address: 0h base + 1017h offset = 1017h

Bit	15	14	13	12	11	10	9	8
Read	OV14		COUNT					
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	COUNT							
Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_LBERT_ERR field descriptions

Field	Description
15 OV14	If active, multiply COUNT by 128. If OV14=1 and COUNT=2 ¹⁵ -1, signals overflow of counter
COUNT	A read of this register, or a sync of the PM resets the error count. Current error count If OV14 field is active, then multiply count by 128

47.6.50 PCIE_PHY_RX_SCOPE_CTL

Address: 0h base + 1018h offset = 1018h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved													MODE		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_RX_SCOPE_CTL field descriptions

Field	Description
15–3 -	This field is reserved. Reserved
MODE	<p>Sampling mode of counters.</p> <p>NOTE: WORD is 20 bits.</p> <p>0 Off</p> <p>1 Sample data every WORD *(1 + DELAY) bits</p> <p>2 Sample data every WORD *(1 + DELAY) + 1 bits</p> <p>3 Sample data every WORD *(1 + DELAY) + 2 bits</p> <p>4 Sample data every clk and assert XOR and MASK increment</p>

47.6.51 PCIE_PHY_RX_SCOPE_PHASE

Address: 0h base + 1019h offset = 1019h

Bit	15	14	13	12	11	10	9	8
Read	Reserved		BASE				SCOPE_DELAY	
Write	Reserved		BASE				SCOPE_DELAY	
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	SCOPE_SEL	UPDATE	SAMPLE_PHASE					
Write	SCOPE_SEL	UPDATE	SAMPLE_PHASE					
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_SCOPE_PHASE field descriptions

Field	Description
15 -	This field is reserved. Reserved
14–10 BASE	which bit to sample when MODE = 1 or 4
9–8 SCOPE_DELAY	How many clocks to delay the analog scope_data.
7 SCOPE_SEL	Select sampling mode. 0 Before AFE sampling 1 After AFE sampling
6 UPDATE	Update Sampling phase. Write a 1.
SAMPLE_PHASE	Sampling Phase

47.6.52 PCIE_PHY_RX_DPLL_FREQ

Address: 0h base + 101Ah offset = 101Ah

Bit	15	14	13	12	11	10	9	8
Read	Reserved				VAL			
Write	Reserved				VAL			
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	VAL							DTHR
Write	VAL							DTHR
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_DPLL_FREQ field descriptions

Field	Description
15–13 -	This field is reserved. Reserved
12–1 VAL	Freq is $1.526 \times \text{VAL}$ ppm from the reference When <code>mpll_slow</code> is set, the ppm is half the eqn above
0 DTHR	Bits below the useful resolution

47.6.53 PCIE_PHY_RX_CDR_CTL

Address: 0h base + 101Bh offset = 101Bh

Bit	15	14	13	12	11	10	9	8
Read	DTB_SEL				ALWAYS_ REALIGN	FAST_ START	FRUG_VALUE	
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	PHUG_VALUE		OVRD_ DPLL_ GAIN	PHDET_ POL	PHDET_EDGE		PHDET_EN	
Write								
Reset	0	0	0	0	1	1	1	1

PCIE_PHY_RX_CDR_CTL field descriptions

Field	Description
15–12 DTB_SEL	Select to drive various signals onto the DTB. 0 disabled 1 <code>pll_ana_rst,pll_count</code> from <code>rx_pwr_ctl</code> 2 <code>com_good_high/low</code> from aligner 3 <code>com_bad_high/low</code> from aligner 4 <code>shift_in_prog,ana_odd_data</code> from aligner 5 Low bits of XAUI align FSM state
11 ALWAYS_ REALIGN	realign on any misaligned comma
10 FAST_ START	decrease startup steps by 50%
9–8 FRUG_VALUE	override value for FRUG
7–6 PHUG_VALUE	override value for PHUG
5 OVRD_ DPLL_ GAIN	Override PHUG and FRUG values
4 PHDET_ POL	Reverse polarity of phase error

Table continues on the next page...

PCIE_PHY_RX_CDR_CTL field descriptions (continued)

Field	Description
3-2 PHDET_EDGE	Edges to use for phase detection. 11 Use both edges 10 Use rising edges only 01 Use falling edges only 00 Ignore all edges
PHDET_EN	Enables phase detector. top bit is odd slicers, bottom is even

47.6.54 PCIE_PHY_RX_CDR_CDR_FSM_DEBUG

Address: 0h base + 101Ch offset = 101Ch

Bit	15	14	13	12	11	10	9	8
Read	adap_rx_eq			rx_eq_ctr			rx_ana_eq	
Write	[Greyed out]			[Greyed out]			[Greyed out]	
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	rx_ana_eq	adap_rx_valid	cdr_en_adap	cdr_en_eq	aligned	cdr_rx_valid	cdr_timeout	cdr_en
Write	[Greyed out]							
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_CDR_CDR_FSM_DEBUG field descriptions

Field	Description
15-13 adap_rx_eq	Equalization setting from adaptation FSM.
12-10 rx_eq_ctr	Initial centre point from equalization FSM.
9-7 rx_ana_eq	Equalization setting to Analog.
6 adap_rx_valid	Adaptation has completed and locked
5 cdr_en_adap	Adapatation loop is enabling the CDR.
4 cdr_en_eq	Equalization loop is enabling the CDR.
3 aligned	Datapath is bit-aligned.
2 cdr_rx_valid	CDR has locked to incoming data stream.

Table continues on the next page...

PCIE_PHY_RX_CDR_CDR_FSM_DEBUG field descriptions (continued)

Field	Description
1 cdr_timeout	CDR has not locked to datastream and has timed-out.
0 cdr_en	CDR has been enabled.

47.6.55 PCIE_PHY_RX_CDR_LOCK_VEC_OVRD

Address: 0h base + 101Dh offset = 101Dh

Bit	15	14	13	12	11	10	9	8
Read	adap_ctr_level					adap_polarity	lock_vector_ovrd	lock_vector_en
Write								
Reset	1	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	lock_vector							
Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_CDR_LOCK_VEC_OVRD field descriptions

Field	Description
15–11 adap_ctr_level	Amount of earlies that increment the adaptation counter (times 16).
10 adap_polarity	If asserted invert default adaptation adjustment for equalization. IF early decrease equalization. Normal mode is to decrease.
9 lock_vector_ovrd	Override enable for the rx_eq outputs.
8 lock_vector_en	Override value for the locked_vector output completion.
lock_vector	Override value for the locked_vector.

47.6.56 PCIE_PHY_RX_CDR_LOCK_VEC

Address: 0h base + 101Eh offset = 101Eh

Bit	15	14	13	12	11	10	9	8
Read	Reserved				eq_rx_eq			eq_locked_vector_en
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	eq_locked_vector							
Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_CDR_LOCK_VEC field descriptions

Field	Description
15–12 -	This field is reserved. Reserved
11–9 eq_rx_eq	Equalization setting from the Equalization Loop.
8 eq_locked_vector_en	Equalization locked vector has been filled.
eq_locked_vector	Results of equalization loop.

47.6.57 PCIE_PHY_RX_CDR_ADAP_FSM

Address: 0h base + 101Fh offset = 101Fh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	mstr_ctr				loop_ctr				adap_ctr				adap_state			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_RX_CDR_ADAP_FSM field descriptions

Field	Description
15–11 mstr_ctr	Master count register.
10–7 loop_ctr	Loop count register.
6–3 adap_ctr	Adaptation count register.

Table continues on the next page...

PCIE_PHY_RX_CDR_ADAP_FSM field descriptions (continued)

Field	Description
adap_state	Adaptation State. 000 ADAP_RESET 001 ADAP_LOCK 010 ADAP_SUFF 011 ADAP_LOOP 100 ADAP_MSTR 101 ADAP_DONE

47.6.58 PCIE_PHY_RX_ATB0

Address: 0h base + 1020h offset = 1020h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Read	Reserved								EN_ATB	EN_ATB	EN_MARG	EN_ATB_RM_F	EN_ATB_RM_S	EN_ATB_RP_F	EN_ATB_RP_S	EN_ATB_VOFF	
Write																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

PCIE_PHY_RX_ATB0 field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 EN_ATB	Enables ATB sensing and forcing on internal Rx nodes.
6 EN_ATB	Enables margining mode in receiver; requires atb_f_m to be high-Z!
5 EN_MARG	Enables atb_force_p on negative-side termination resistor.
4 EN_ATB_RM_F	Enables atb_sense_m on negative-side termination resistor.
3 EN_ATB_RM_S	Enables atb_force_p on positive-side termination resistor.
2 EN_ATB_RP_F	Enables atb_sense_p on positive-side termination resistor.
1 EN_ATB_RP_S	Puts rxafe outputs vo_p on atb_s_p and vo_m on atb_s_m.
0 EN_ATB_VOFF	Puts rxafe voff_p on atb_s_p and voff_m on atb_s_m.

47.6.59 PCIE_PHY_RX_ATB1

Address: 0h base + 1021h offset = 1021h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	VLOS_MAX	VLOS_MIN	EN_ATB_VLOS	EN_ATB_VRF	MEAS_GD	MEAS_VP	EN_VLOS_USB3	NC0
Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_ATB1 field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 VLOS_MAX	Sets LOS reference voltage. (VLOS_MAX, VLOS_MIN): (1,1): None (1,0): Maximum (0,1): Minimum (0,0): Nominal
6 VLOS_MIN	Sets LOS reference voltage. (VLOS_MAX, VLOS_MIN): (1,1): None (1,0): Maximum (0,1): Minimum (0,0): Nominal
5 EN_ATB_VLOS	Enables sensing of LOS reference voltage on atb_sense_p.
4 EN_ATB_VRF	Enables sensing of vref_rx on atb_sense_p.
3 MEAS_GD	Enables sensing of local gd in Rx; ties gd to atb_sense_m.
2 MEAS_VP	Enables sensing of local vp in Rx; ties vp to atb_sense_p.
1 EN_VLOS_USB3	Enables LOS levels to be those for USB3; otherwise, PCI Express levels.
0 NC0	Enables/disables Rx termination resistor.

47.6.60 PCIE_PHY_RX_ENPWR0

Address: 0h base + 1022h offset = 1022h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0

Write								
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_RX_ENPWR0 field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 CTL_RXPWRON	Enables override of Rx block power.
6 LCL_RXPWRON	Enables/disables Rx slicers.
5 CTL_EN_LOS	Enables override of LOS block state.
4 LCL_EN_LOS	Enables/disables LOS block.
3 CTL_RXCK	Enables override of Rx clock circuit state.
2 LCL_RXCK	Enables/disables en_rx_clock (Rx clock enable).
1 CTL_ACJT	Enables override of ACJTAG block state.
0 LCL_ACJT	Enables/disables ACJTAG block.

47.6.61 PCIE_PHY_RX_PMI_X_PHASE

Address: 0h base + 1023h offset = 1023h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved								PHASE							
Write	Reserved								PHASE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PCIE_PHY_RX_PMI_X_PHASE field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
PHASE	Write to bits 8-1 of the Phase Select register in the phase mixer.

47.6.62 PCIE_PHY_RX_ENPWR1

Address: 0h base + 1024h offset = 1024h

Bit	15	14	13	12	11	10	9	8
Read	Reserved							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0

PCIe_PHY_RX_ENPWR2 field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 EN_RXPMIX_ TST	Enables XOR gate to test linearity of Rx phase mixer using atb_s_p and atb_s_m.
6 EN_RXPMIX_ VPMIX	Puts vreg_pmix on atb_s_p.
5 EN_RXPMIX_ VRX	Puts vreg_rx on atb_s_p.
4 EN_RXPMIX_ VOSC	Puts vreg_vosc on atb_s_p.
3 EN_RXPMIX_ FRC_ VPMIX	Instructs rx_pmix_vreg_pmix to use atb_s_m as a reference instead of vbg.
2 RX_SCOPE_ ATB_2	Puts XOR of Rx scope PMIX input and output on atb_s_p.
1 RX_SCOPE_ ATB_1	Puts Rx scope regulated VP on atb_s_p.
0 RX_SCOPE_ ATB_0	Instructs Rx scope regulated VP to use atb_f_p as reference instead of VP.

47.6.64 PCIE_PHY_RX_SCOPE

Address: 0h base + 1026h offset = 1026h

Write						Reserved	Reserved	Reserved
Reset	0	0	0	0	0	0	0	0

PCIE_PHY_TX_TXDRV_CNTRL field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 PULL_DN_REG	Register bit that causes the calibrated Tx bits to pull down in common mode fashion. If pull_dn_reg and tx_pull_up are both high, then pull_dn_reg wins (takes precedence").
6 PULL_UP_REG	Register override for tx_pull_up; selected when ovrd_pull_up is high; causes calibrated TX bits to pull up in common mode fashion, unless pull_dn_reg is high.
5 OVRD_PULL_UP	Selects loval value of pull_up_reg instead of tx_pull_up.
4 VCM_HOLD_REG	Register override for tx_vcm_hold; selected when ovrd_vcm_hold is high; controls the TX common mode hold circuitry.
3 OVRD_VCM_HOLD	Selects local value of vcm_hold_reg instead of tx_vcm_hold to control state of TX common mode hold circuitry.
2 NOCONN_8	This field is reserved. Reserved
1 NOCONN_7	This field is reserved. Reserved
0 NOCONN_6	This field is reserved. Reserved

47.6.66 PCIE_PHY_TX_POWER_CTL

Address: 0h base + 102Ch offset = 102Ch

PCIE_PHY_TX_POWER_CTL field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 OVRD_EN	Enables local overrides for all signals in this register.
6 SERIAL_EN_REG	Value for tx_serial_en when OVRD_EN is 1.
5 CLK_EN_REG	Value for tx_clk_en when OVRD_EN is 1.
4 DATA_EN_REG	Value for tx_data_en when OVRD_EN is 1.
3 REFGEN_EN_REG	Register override value for tx_refgen_en; turns on the pmos_bias refgen block and the rxdetect comparators.
2 TX_DIV_CLK_EN	Enables the div clock that is output from the Tx to the undersampler, more appropriately called tx_sampler_clk_en; this clock is output after the optional divide-by-2/ 4; tx_clk_en must be high to output a clock.
1 REFGEN_PDN_REG	Value for refgen_pwdn when OVRD_EN is 1.
0 NOCONN_5	This field is reserved. Reserved

47.6.67 PCIE_PHY_TX_ALT_BLOCK

7 ATB_PBIAS	Connects real pmos_bias voltage for Tx PMOS driver pull-up path to atb_s_p and local ground at the pmos_bias block to atb_s_m.
6 ATB_VCM_REP	Connects common mode replica voltage in pmos_bias block to atb_s_p and local ground to atb_s_m.
5 ATB_RXDETRF	Connects Rx detect block reference voltage to atb_s_p and local ground to atb_s_m.
4 ATB_TXFP	Connects tx_p to atb_f_p.
3 ATB_TXFM	Connects tx_m to atb_f_m.
2 ATB_TXSP	Connects tx_p to atb_s_p.
1 ATB_TXSM	Connects tx_m to atb_s_m.
0 ATB_VCM	Connects tx_p/tx_m common mode voltage onto atb_s_p and local ground onto atb_s_m.

Chapter 48

Power Management Unit (PMU)

48.1 Overview

The power management unit (PMU) is designed to simplify the external power interface. The power system can be split into the input power sources and their characteristics, the integrated power transforming and controlling elements, and the final load interconnection and requirements.

A typical power system utilizing the PMU is depicted below.

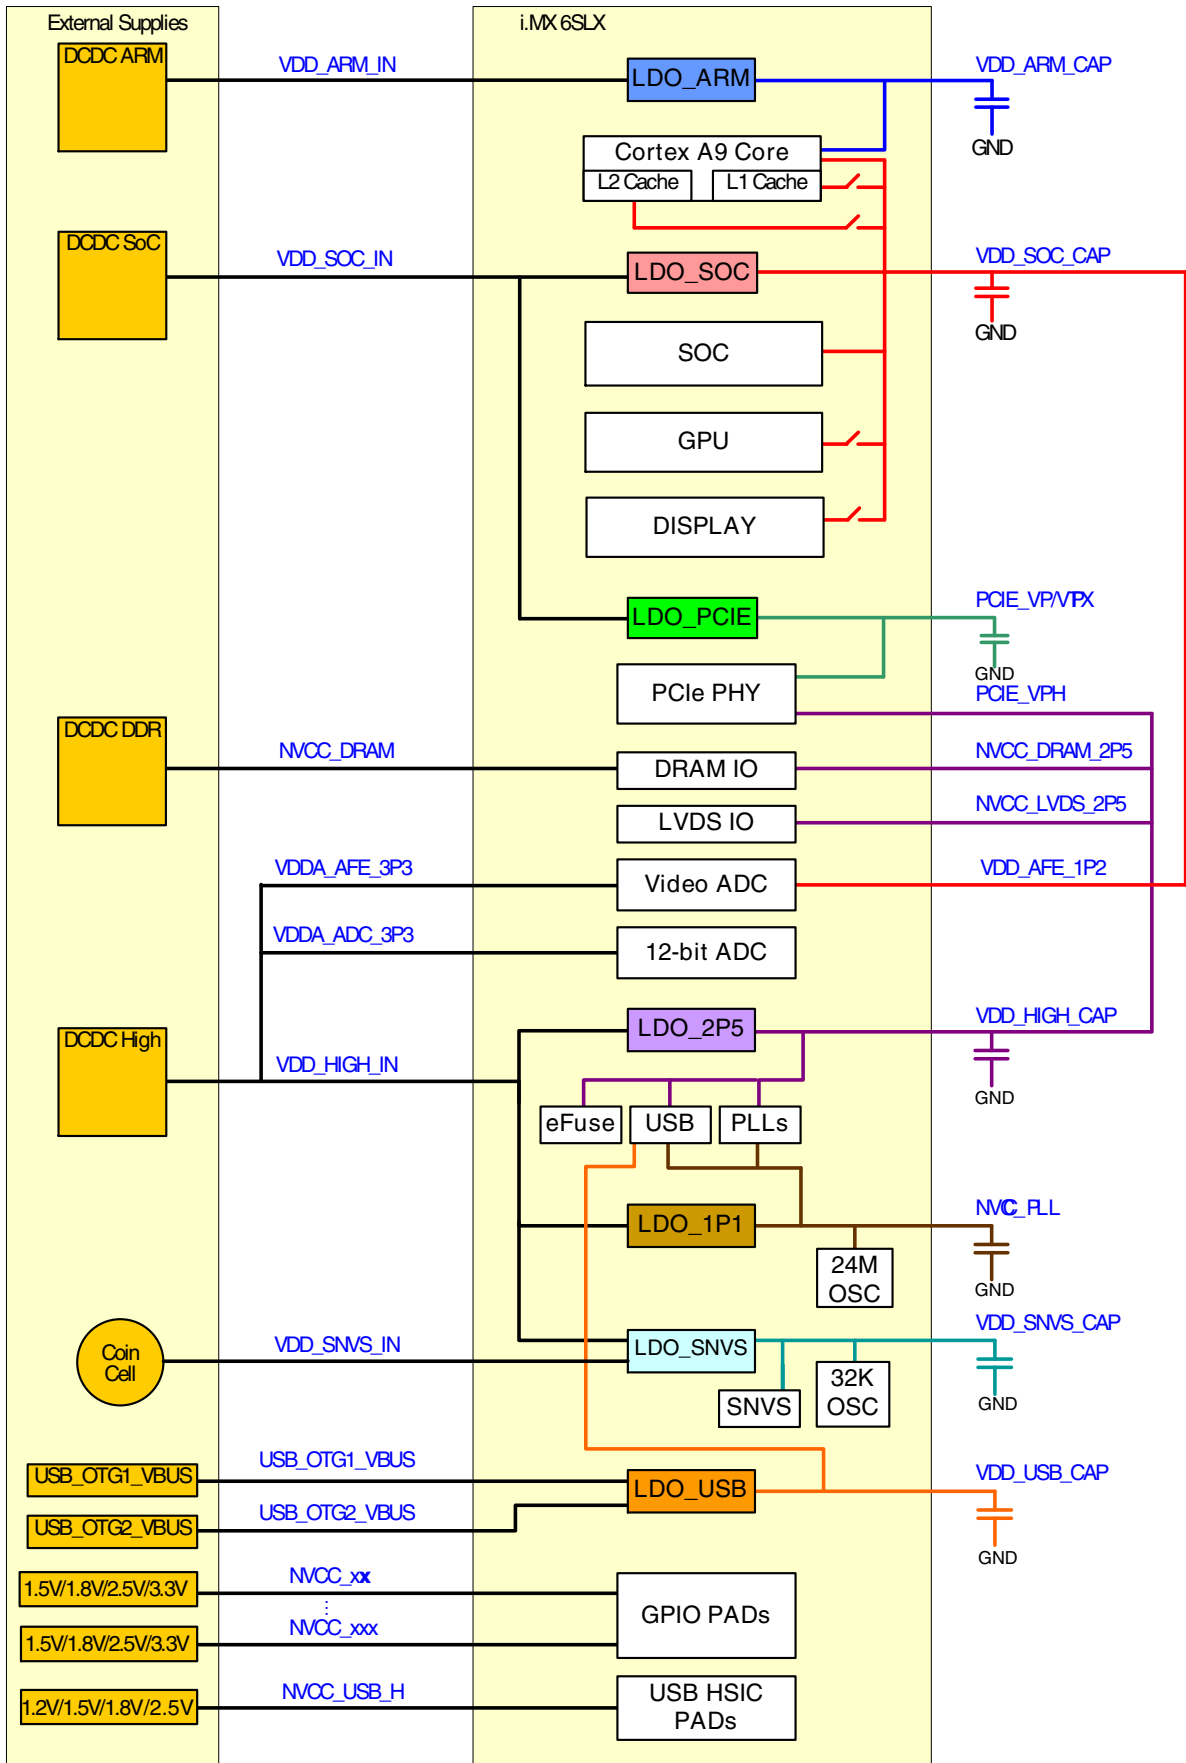

Figure 48-1 Power system overview
 i.MX 6SoloX Applications Processor Reference Manual, Rev. 0, 2/2015

Utilizing seven LDO regulators, the number of external supplies is greatly reduced. Not counting the backup coin and USB inputs, the number of external supplies is reduced to two. Missing from this external supply total is the number of necessary external supplies to power the desired memory interface; that number varies depending on the type of external memory selected. Other supplies may also be necessary to supply the voltage to the different I/O power segments if their I/O voltages have to be different from what is provided above.

48.2 Digital LDO Regulators

The PMU has three digital LDO regulators. They are referred to as "digital" because of the logic loads they drive, not because of their construction. These regulators have three basic modes that are unique to the digital regulators.

- **Internal Bypass**—The regulation FET is switched fully on passing the external input voltage to the load unaltered. The analog part of the regulator is powered down in this state, removing any loss other than the IR drop through the power grid and the FET. (TARG = 0x1F)
- **Power Gate**—The regulation FET is switched off fully, limiting the current draw from the supply. The analog part of the regulator is powered down, limiting the power consumption. The output voltage falls to a level at which the residual leakage of the power FET balances with the leakage of the load. (TARG = 0x00)
- **Analog regulation mode**—The regulation FET is controlled such that the output voltage of the regulator equals the programmed target voltage. The target voltage is fully programmable in 25-mV steps.

These modes allow the regulators to implement voltage scaling and power gating and allow bypass. With the bypass feature, all of the accuracy and control requirements can be shifted to the external supply source if capable and desired.

These digital regulators also feature brownout detection which is helpful when supplies are starting to collapse. The voltage value where brownout is signaled is programmable as an offset from the programmed target voltage. The controls are located in the PMU_MISC2 register. The core is interrupted on a brownout.

The three digital regulators are known as LDO_ARM, LDO_PCIE, and LDO_SOC. As shown in the power system overview figure, the ARM regulator powers the ARM cores. The LDO_SOC powers the SOC (Cortex-M4, CCM, Analog IP, etc), GPU, and display portions of the chip. The LDO_PCIE regulator powers the PCIe PHY. All regulators support generous programming ranges in 25-mV steps. It is possible to program voltages

above the process limit for the chip, thus causing permanent damage. Likewise, it is possible to program the voltage so low that the chip cannot continue to operate or even retain state without clocks. Care should be taken with these settings.

Care must be taken when raising the output voltage of the regulator rapidly. This can cause large currents to flow into the output cap of the regulator up to the limits of the input supply. When the input supply capability is exceeded, this can cause an input supply dip that may affect other regulators on the same supply. Therefore, the rate of voltage change on the output of the regulator should be limited. When powering up the regulator, the integrated current limiter controls the ramp rate. This limiter is only effective when transitioning from the off state of the regulator (bypassed or power gated).

However, in a DVFS situation, the same high rate of change can occur if the target voltage is raised rapidly by software. To limit the rate of change, the hardware controlling the regulator effects a piecewise linear ramp by stepping the output voltage in 25-mV steps until the desired output voltage is reached. The slope of the ramp is controlled by the time spent at each 25-mV step and is controlled by the step time field in the PMU_MISC2 register. The same situation is not a problem when the output voltage is dropped as the load pulls down the output cap. As a result, any reduction in the programmed regulator target voltage is immediately effective with the actual supply voltage falling at a rate controlled by the load on the regulator.

48.3 Analog LDO Regulators

There are two analog regulators described here.

48.3.1 LDO 1P1

The LDO_1P1 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8 V–3.3 V) to produce a nominal 1.1-V output voltage.

The output of the regulator can be programmed in 25-mV steps from 0.8 V to 1.4 V. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitance, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken.

Current limiting can be enabled by setting the PMU_REG_1P1[ENABLE_ILIMIT] bit to allow for in-rush current requirements during startup if needed. Active pulldown can also be enabled by setting the PMU_REG_1P1[ENABLE_PULLDOWN] bit for systems requiring this feature.

48.3.2 LDO 2P5

The LDO_2P5 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8V-3.3V) to produce a nominal 2.5V output voltage.

The output of the regulator can be programmed in 25mV steps from 2.0V to 2.75V. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitance, though the actual capacitance required should be determined by the application. A programmable brown-out detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded to take the necessary steps.

Current-limiting can be enabled by setting the REG_PMU_2P5[ENABLE_ILIMIT] bit to allow for in-rush current requirements during start-up if needed. Active-pulldown can also be enabled by setting the REG_PMU_2P5[ENABLE_PULLDOWN] bit for systems requiring this feature.

48.3.3 Low Power Operation

The 1.1 V and 2.5 V LDO includes an alternate, self-biased, low-precision, weak regulator which can be enabled for applications needing to keep the 1.1 V and 2.5-V output voltage alive during low-power modes where the main regulator and its associated global bandgap reference module are disabled.

The output of this weak regulator is not programmable and is a function of its input power supply as well as load current. The low-power mode is enabled by setting high the PMU_REG_1P1[ENABLE_WEAK_LINREG] and PMU_REG_2P5[ENABLE_WEAK_LINREG] bit of the regulator. It is recommended that the following sequence be followed to enable this mode:

1. Throttle down the 1.1 V / 2.5 V attached load to its low-power maintain state.
2. Disable the main 1.1 V / 2.5 V regulator driver by clearing the PMU_REG_1P1[ENABLE_LINREG] / PMU_REG_2P5[ENABLE_LINREG] bit.
3. Enable the weak 1.1 V / 2.5 V regulator by setting the PMU_REG_1P1[ENABLE_WEAK_LINREG] / PMU_REG_2P5[ENABLE_WEAK_LINREG] bit.

To go back to full-power operation, reverse the steps outlined above. Note that the external decoupling cap is supporting the power supply between steps 2 and 3. Therefore step 3 should happen appropriately in time relative to the discharge of the supporting capacitor.

48.4 USB LDO Regulator

The USB_LDO module on the chip implements a programmable linear-regulator function from the USB VBUS voltages (typically 5 V) to produce a nominal 3.0-V output voltage.

The output of the regulator can be programmed in 25-mV steps, from 2.625V to 3.4 V . The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitor of 4.7 μ F, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken. This regulator has a built-in power mux which allows the user to choose to run the regulator from either VBUS supply when both are present. If only one of the VBUS voltages is present, then the regulator automatically selects this supply. Current limit is also included to help the system meet in-rush current targets.

Upon attachment of VBUS, this regulator starts up in a low-power, self-preservation mode to prevent over-voltage conditions on the chip. It is expected that the user transition to full regulation by enabling the regulator and disabling the in-rush current limits via its control registers. Upon VBUS removal, it is further expected that the regulator controls are returned to their reset state.

48.5 SNVS Regulator

The SNVS regulator takes the SNVS_IN supply and generates the SNVS_CAP supply, which powers the real time clock and SNVS blocks.

If VDDHIGH_IN is present, then the SNVS_IN supply is internally shorted to the VDDHIGH_IN supply to allow coin cell recharging if necessary. The output voltage is roughly one third of SNVS_IN.

48.6 PMU Memory Map/Register Definition

The register definitions that affect the behavior of the digital LDO regulators follow.

NOTE

Some of the registers are collections of bits that affect multiple components on the chip. Those that are not pertinent to this chapter have comments in the related register bitfields.

If a full description is desired, please consult the full register programming reference in the related block.

48.6.1 Regulator 1P1 Register (PMU_REG_1P1)

This register defines the control and status bits for the 1.1V regulator. This regulator is designed to power the digital portions of the analog cells.

Address: 20C_8000h base + 110h offset = 20C_8110h

PMU_REG_1P1 field descriptions

Field	Description
31–20 -	This field is reserved.
19 SELREF_ WEAK_LINREG	Selects the source for the reference voltage of the weak 1p1 regulator. 0 Weak-linreg output tracks low-power-bandgap voltage 1 Weak-linreg output tracks VDD_SOC_CAP voltage
18 ENABLE_ WEAK_LINREG	Enables the weak 1p1 regulator. This regulator can be used when the main 1p1 regulator is disabled, under low-power conditions.
17 OK_VDD1P1	Status bit that signals when the regulator output is ok. 1 = regulator output > brownout target
16 BO_VDD1P1	Status bit that signals when a brownout is detected on the regulator output.
15–13 -	This field is reserved.
12–8 OUTPUT_TRG	Control bits to adjust the regulator output voltage. Each LSB is worth 25mV. Programming examples are detailed below. Other output target voltages may be interpolated from these examples. Choices must be in this range: 0x1b >= output_trg >= 0x04 NOTE: There may be reduced chip functionality or reliability at the extremes of the programming range. 0x04 0.8V 0x10 1.1V 0x1b 1.375V
7 -	This field is reserved.

Table continues on the next page...

PMU_REG_1P1 field descriptions (continued)

Field	Description
6-4 BO_OFFSET	Control bits to adjust the regulator brownout offset voltage in 25mV steps. The reset brown-offset is 175mV below the programmed target code. Brownout target = OUTPUT_TRG - BO_OFFSET. Some steps may be irrelevant because of input supply limitations or load operation.
3 ENABLE_PULLDOWN	Control bit to enable the pull-down circuitry in the regulator
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator.
1 ENABLE_BO	Control bit to enable the brownout circuitry in the regulator.
0 ENABLE_LINREG	Control bit to enable the regulator output.

48.6.2 Regulator 3P0 Register (PMU_REG_3P0)

This register defines the control and status bits for the 3.0V regulator powered by the host USB VBUS pin.

Address: 20C_8000h base + 120h offset = 20C_8120h

PMU_REG_3P0 field descriptions

Field	Description
31-18 -	This field is reserved.

Table continues on the next page...

PMU_REG_3P0 field descriptions (continued)

Field	Description
17 OK_VDD3P0	Status bit that signals when the regulator output is ok. 1 = regulator output > brownout target
16 BO_VDD3P0	Status bit that signals when a brownout is detected on the regulator output.
15–13 -	This field is reserved.
12–8 OUTPUT_TRG	Control bits to adjust the regulator output voltage. Each LSB is worth 25mV. Programming examples are detailed below. Other output target voltages may be interpolated from these examples. NOTE: There may be reduced chip functionality or reliability at the extremes of the programming range. 0x00 2.625V 0x0f 3.000V 0x1f 3.400V
7 VBUS_SEL	Select input voltage source for LDO_3P0 from either USB_OTG1_VBUS or USB_OTG2_VBUS. If only one of the two VBUS voltages is present, it is automatically selected. 0 USB_OTG1_VBUS — Utilize VBUS OTG1 for power 1 USB_OTG2_VBUS — Utilize VBUS OTG2 power
6–4 BO_OFFSET	Control bits to adjust the regulator brownout offset voltage in 25mV steps. The reset brown-offset is 175mV below the programmed target code. Brownout target = OUTPUT_TRG - BO_OFFSET. Some steps may not be relevant because of input supply limitations or load operation.
3 -	Reserved
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator.
1 ENABLE_BO	Control bit to enable the brownout circuitry in the regulator.
0 ENABLE_LINREG	Control bit to enable the regulator output to be set by the programmed target voltage setting and internal bandgap reference.

48.6.3 Regulator 2P5 Register (PMU_REG_2P5)

This register defines the control and status bits for the 2.5V regulator.

Address: 20C_8000h base + 130h offset = 20C_8130h

PMU Memory Map/Register Definition

PMU_REG_2P5 field descriptions

Field	Description
31–19 -	This field is reserved.
18 ENABLE_WEAK_LINREG	Enables the weak 2p5 regulator. This low power regulator is used when the main 2p5 regulator is disabled to keep the 2.5V output roughly at 2.5V. Scales directly with the value of VDDHIGH_IN.
17 OK_VDD2P5	Status bit that signals when the regulator output is ok. 1 = regulator output > brownout target
16 BO_VDD2P5	Status bit that signals when a brownout is detected on the regulator output.
15–13 -	This field is reserved.
12–8 OUTPUT_TRG	Control bits to adjust the regulator output voltage. Each LSB is worth 25mV. Programming examples are detailed below. Other output target voltages may be interpolated from these examples. NOTE: There may be reduced chip functionality or reliability at the extremes of the programming range. 0x00 2.10V 0x10 2.50V 0x1f 2.875V
7 -	This field is reserved.
6–4 BO_OFFSET	Control bits to adjust the regulator brownout offset voltage in 25mV steps. The reset brown-offset is 175mV below the programmed target code. Brownout target = OUTPUT_TRG - BO_OFFSET. Some steps may be irrelevant because of input supply limitations or load operation.
3 ENABLE_PULLDOWN	Control bit to enable the pull-down circuitry in the regulator

48.6.5 Miscellaneous Register 0 (PMU_MISC0)

This register defines the control and status bits for miscellaneous analog blocks.

Address: 20C_8000h base + 150h offset = 20C_8150h

PMU_MISC0 field descriptions

Field	Description
31 VID_PLL_ PREDIV	Predivider for the source clock of the PLL's. 0 Divide by 1 1 Divide by 2
30 XTAL_24M_PWD	This field powers down the 24M crystal oscillator if set true.
29 RTC_XTAL_ SOURCE	This field indicates which chip source is being used for the rtc clock. 0 Internal ring oscillator 1 RTC_XTAL
28–26 CLKGATE_ DELAY	This field specifies the delay between powering up the XTAL 24MHz clock and releasing the clock to the digital logic inside the analog block. NOTE: Do not change the field during a low power event. This is not a field that the user would normally need to modify. NOTE: Not related to PMU. 000 0.5ms 001 1.0ms 010 2.0ms 011 3.0ms 100 4.0ms 101 5.0ms 110 6.0ms 111 7.0ms
25 CLKGATE_CTRL	This bit allows disabling the clock gate (always ungated) for the xtal 24MHz clock that clocks the digital logic in the analog block. NOTE: Do not change the field during a low power event. This is not a field that the user would normally need to modify. NOTE: Not related to PMU. 0 ALLOW_AUTO_GATE — Allow the logic to automatically gate the clock when the XTAL is powered down. 1 NO_AUTO_GATE — Prevent the logic from ever gating off the clock.
24–17 -	This field is reserved. Always set to zero.
16 OSC_XTALOK_ EN	This bit enables the detector that signals when the 24MHz crystal oscillator is stable. NOTE: Not related to PMU, Clocking content
15 OSC_XTALOK	Status bit that signals that the output of the 24-MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency. NOTE: Not related to PMU, clocking content.
14–13 OSC_I	This field determines the bias current in the 24MHz oscillator. The aim is to start up with the highest bias current, which can be decreased after startup if it is determined to be acceptable.

Table continues on the next page...

PMU_MISC0 field descriptions (continued)

Field	Description
	<p>NOTE: Not related to PMU.</p> <p>00 NOMINAL — Nominal 01 MINUS_12_5_PERCENT — Decrease current by 12.5% 10 MINUS_25_PERCENT — Decrease current by 25.0% 11 MINUS_37_5_PERCENT — Decrease current by 37.5%</p>
12 RTC_RINGOSC_ EN	Enables the internal ring oscillator that can be used in lieu of an external 32k crystal. The accuracy is relatively poor ~(10-40KHz) over process and environmental conditions. The crystal oscillator is automatically chosen to source the rtc clock if present. The choice is made based on the output of the clock monitor block.
11-10 STOP_MODE_ CONFIG	Configure the analog behavior in stop mode. 00 SUSPEND (DSM) — All analog except rtc powered down on stop mode assertion. 01 STANDBY — Analog regulators are ON. 10 STOP (lower power) — Analog regulators are ON. 11 STOP (very lower power) — Analog regulators are OFF.
9-8 -	This field is reserved. Reserved
7 REFTOP_ VBGUP	Status bit that signals the analog bandgap voltage is up and stable. 1 - Stable.
6-4 REFTOP_ VBGADJ	000 Nominal VBG 001 VBG+0.78% 010 VBG+1.56% 011 VBG+2.34% 100 VBG-0.78% 101 VBG-1.56% 110 VBG-2.34% 111 VBG-3.12%
3 REFTOP_ SELFBIAOFF	Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This bit should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap. <p>NOTE: Value should be returned to zero before removing vddhigh_in or asserting bit 0 of this register (REFTOP_PWD) to assure proper restart of the circuit.</p> 0 Uses coarse bias currents for startup 1 Uses bandgap-based bias currents for best performance.
2-1 -	This field is reserved.
0 REFTOP_PWD	Control bit to power-down the analog bandgap reference circuitry. <p>NOTE: A note of caution, the bandgap is necessary for correct operation of most of the LDO, pll, and other analog functions on the die.</p>

48.6.6 Miscellaneous Register 1 (PMU_MISC1n)

This register defines the control and status bits for miscellaneous analog blocks. The LVDS1 and LVDS2 controls below control the behavior of the anaclk1/1b

Address: 20C_8000h base + 160h offset + (4d × i), where i=0d to 3d

Chapter 49

Pulse Width Modulation (PWM)

49.1 Overview

The Pulse Width Modulation (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4 x 16 data FIFO.

This section presents an overview of the PWM. A block diagram of the PWM module is shown in the figure below.

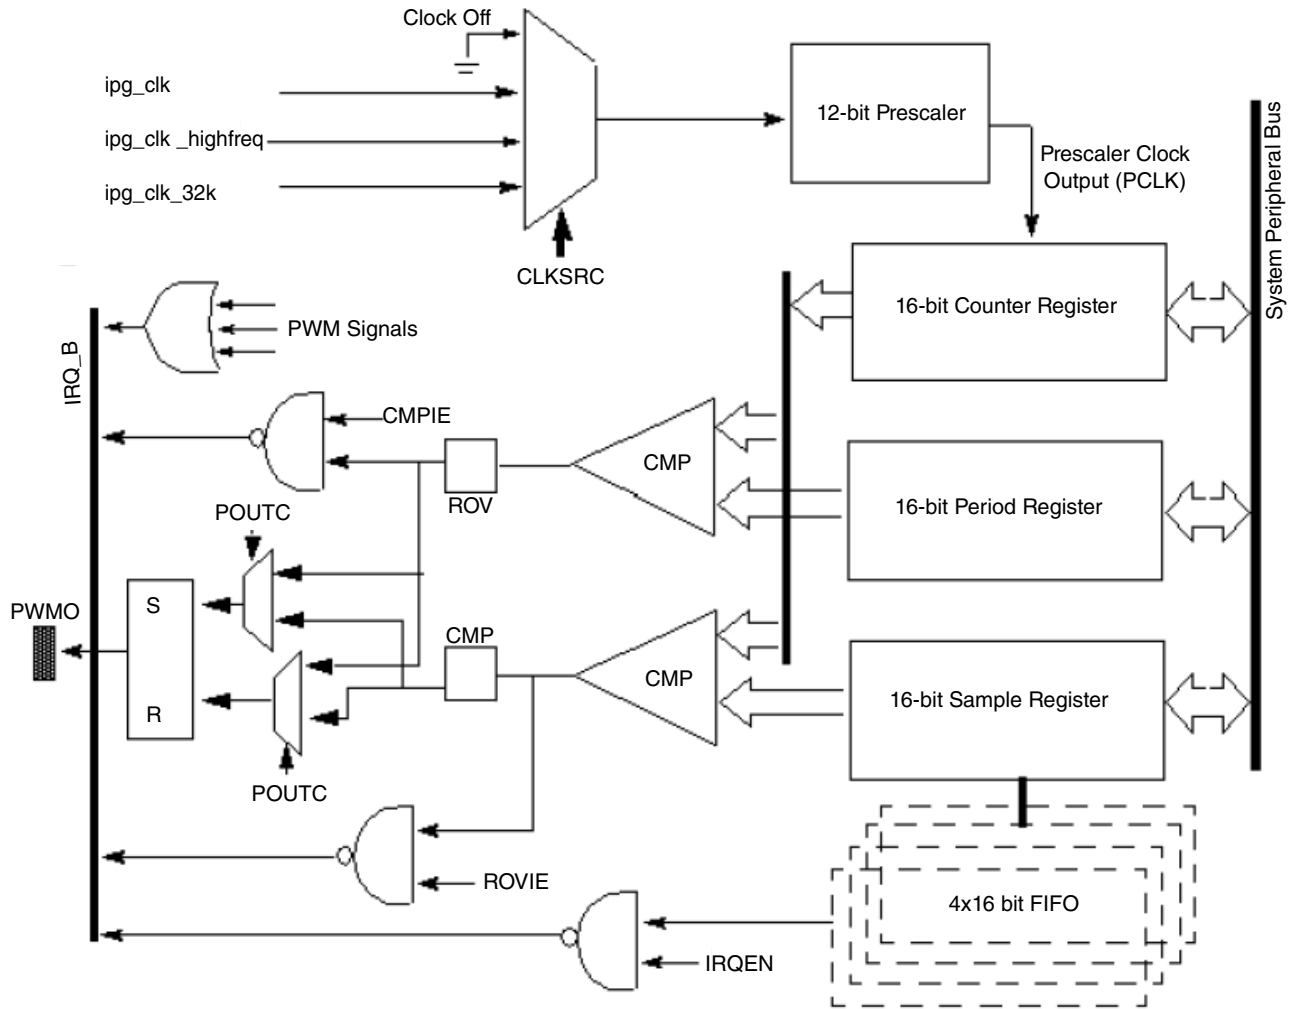

Figure 49-1. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4 x 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power mode
- Can be programmed to be active in debug mode
- Interrupts at compare and rollover

49.2 External Signals

The PWM follows IP Bus protocol when interfacing with the processor core. PWM does not have any interface signals with any other block inside the chip except for clock and reset inputs from the Clock Control Module (CCM), System Reset Controller (SRC), and interrupt signals to the processor interrupt handler. There is a single output signal.

The following table outlines the external signals.

Table 49-1. PWM External Signals

Signal	Description	Pad	Mode	Direction
PWM1_OUT	This is the PWM1 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%. This is the PWM4 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	GPIO1_IO10	ALT2	O

49.3 Clocks

The table found here describes the clock sources for PWM.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 49-2. PWM Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_32k	ckil_sync_clk_root	low-frequency reference clock (32kHz)
ipg_clk_highfreq	perclk_clk_root	high-frequency reference clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

The clock that feeds the prescaler can be selected from:

- High-frequency reference clock (ipg_clk_highfreq) pat_ref or CKIH

This is a high frequency clock, provided by the Clock Control Module (CCM). This clock should be on in the low power mode when the ipg_clk is turned off. Thus, the PWM can be run on this clock in the low power mode.

- Low-frequency reference clock (ipg_clk_32k, CKIL)

This is the 32 KHz low reference clock which is provided by the CCM. This clock should be on in the low power mode when `ipg_clk` is turned off. Thus, PWM can be run on this clock in the low power mode.

- Peripheral clock (`ipg_clk`)

This clock should be on in normal operations. In low power mode, it can be switched off.

- Peripheral access clock (`ipg_clk_s`)

This clock is used for register read/write.

The clock input source is determined by the PWM control register field `PWM_CR[CLKSRC]`. The `CLKSRC` value should only be changed when the PWM is disabled.

A change in the value of the `PRESCALER` field of the control register is immediately reflected on its output clock frequency.

49.4 Functional Description

The following sections detail the PWM operation and function.

49.4.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from `0x0000` until the counter value equals the `PWM_PR + 1`. After this match occurs the counter is reset to `0x0000`.

At the beginning of a count period cycle, the `PWMO` pin is set to one (default) and the counter begins counting up from `0x0000`. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the `PWMO` signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled, the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers being cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

49.4.1.1 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianness can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write to the PWM_SAR sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM_SR[FIFOAV] field shows how many data words are currently contained in the FIFO and whether or not it can be written into.

A read on the sample register yields the current FIFO value that is being used, or will be used, by the PWM for generation on the output signal. Therefore, a write and a subsequent read on the sample register may result in different values being obtained.

49.4.1.2 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PWM_PR[PERIOD] + 1 and resumes counting thereafter. This event is referred to as a rollover. For example, if PWM_PR[PERIOD] = 0x0000, the counter is reset when it equals 0x0001. When PWM_PR[PERIOD] = 0xFFFF or 0xFFFE, the counter is reset when it equals 0xFFFF. For more information, see the PWM Period Register (PWM_PR) description.

During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal, the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

49.4.1.3 Low Power Mode Behavior

In low power mode, if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced, depending on whether the control bit for that mode is set or not. In the absence of the clock itself, or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

49.4.1.4 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWM_PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

49.5 Enable Sequence for the PWM

The sequence found here should be used to enable the PWM.

1. Configure the desired settings for the PWM Control Register (PWM_x_PWMCR) while keeping the PWM disabled (PWM_x_PWMCR[0]=0).
2. Enable the desired interrupts in the PWM Interrupt Register (PWM_x_PWMIR).
3. One to three initial samples may be written to the PWM Sample Register (PWM_x_PWMSAR). The initial sample values will be loaded into the PWM FIFO even if the PWM is not yet enabled. Do not write a 4th sample because the FIFO will become full and trigger a FIFO Write Error (FWE). This error will prevent the PWM from starting once it is enabled.
4. Check the FIFO Write Error status bit (FWE), the Compare status bit (CMP) and the Roll-over status bit (ROV) in the PWM Status Register (PWM_x_PWMSR) to make sure they are all zero. Any non-zero status bits should be cleared by writing a 1 to them.
5. Write the desired period to the PWM Period Register (PWM_x_PWMPR).
6. Enable the PWM by writing a 1 to the PWM Enable bit, PWM_x_PWMCR[0], while maintaining the other register bits in their previously configured state.

49.6 Disable Sequence for the PWM

The PWM can be disabled at any time by clearing the PWM enable bit, PWM_x_PWMCR[0] to 0.

Any data remaining in the FIFO will not be produced at the PWM output after the PWM has been disabled and will remain in the FIFO until the PWM is enabled again. A software reset (setting PWM_x_PWMCR[3] to 1) or a hardware reset will clear the FIFO and any remaining data will be lost.

49.7 PWM Memory Map/Register Definition

The PWM includes six user-accessible 32-bit registers.

PWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
208_0000	PWM Control Register (PWM1_PWMCR)	32	R/W	0000_0000h	49.7.1/3254
208_0004	PWM Status Register (PWM1_PWMSR)	32	w1c	0000_0008h	49.7.2/3256
208_0008	PWM Interrupt Register (PWM1_PWMIR)	32	R/W	0000_0000h	49.7.3/3257
208_000C	PWM Sample Register (PWM1_PWMSAR)	32	R/W	0000_0000h	49.7.4/3258
208_0010	PWM Period Register (PWM1_PWMPR)	32	R/W	0000_FFFEh	49.7.5/3259
208_0014	PWM Counter Register (PWM1_PWMCNR)	32	R	0000_0000h	49.7.6/3260
208_4000	PWM Control Register (PWM2_PWMCR)	32	R/W	0000_0000h	49.7.1/3254
208_4004	PWM Status Register (PWM2_PWMSR)	32	w1c	0000_0008h	49.7.2/3256
208_4008	PWM Interrupt Register (PWM2_PWMIR)	32	R/W	0000_0000h	49.7.3/3257
208_400C	PWM Sample Register (PWM2_PWMSAR)	32	R/W	0000_0000h	49.7.4/3258

PWMx_PWMCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 FWM	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated 00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset.

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
	0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register. 0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32-bit IP Bus interface is written into the lower 16 bits of the sample register. 0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin. 00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15–4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter. 0x000 Divide by 1 0x001 Divide by 2 0xff Divide by 4096
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the block is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register. 0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used. 00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
0 EN	<p>PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins.</p> <p>To make the PWM work with softreset and disable/enable, users can do software reset by setting the SWR bit, wait software reset done, configure the registers, and then enable the PWM by setting this bit to "1"</p> <p>Users can also disable/enable the PWM if PWM would like to be stopped and resumed with same registers configurations .</p> <p>0 PWM disabled 1 PWM enabled</p>

49.7.2 PWM Status Register (PWMx_PWMSR)

The PWM status register (PWM_PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. The FE, ROV, and CMP bits are associated with FIFO-Empty, Roll-over, and Compare interrupts, respectively.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	[Shaded]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								FWE	CMP	ROV	FE	FIFOAV

PWMx_PWMSR field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FWE	<p>FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full.</p> <p>0 FIFO write error not occurred 1 FIFO write error occurred</p>
5 CMP	<p>Compare Status. This bit shows that a compare event has occurred.</p> <p>0 Compare event not occurred 1 Compare event occurred</p>

Table continues on the next page...

PWMx_PWMSR field descriptions (continued)

Field	Description
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred. 0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register. 0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated. 000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

49.7.3 PWM Interrupt Register (PWMx_PWMIR)

The PWM Interrupt register (PWM_PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0													CIE	RIE	FIE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMIR field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt.

Table continues on the next page...

PWMx_PWMIR field descriptions (continued)

Field	Description
	0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

49.7.4 PWM Sample Register (PWMx_PWMSAR)

The PWM sample register (PWM_PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the PWMO output signal always being low/high (POUTC = 00 it will be low and POUTC = 01 it will be high), and no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be set/reset depending on POUTC value.

Address: Base address + Ch offset

PWMx_PWMSAR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

49.7.5 PWM Period Register (PWMx_PWMPR)

The PWM period register (PWM_PWMPR) determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

$$\text{PWMO (Hz)} = \text{PCLK(Hz)} / (\text{period} + 2)$$

A value of zero in the PWM_PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWM_PWMPR results in the counter being reset to zero and the start of a new count period.

NOTE

Settings PWM_PWMPR to 0xFFFF when PWMx_PWMCR REPEAT bits are set to non-zero values is not allowed.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																PERIOD															
W	1																1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

PWMx_PWMPR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PERIOD	Period Value. These bits determine the Period of the count cycle. The counter counts up to [Period Value] +1 and is then reset to 0x0000.

49.7.6 PWM Counter Register (PWMx_PWMCNR)

The read-only pulse-width modulator counter register (PWM_PWMCNR) contains the current count value and can be read at any time without disturbing the counter.

Address: Base address + 14h offset

PWMx_PWMCNR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

Chapter 50

Pixel Pipeline (PXP)

50.1 Overview

This document describes the micro-architecture for the proposed Pixel Pipeline used to process graphics buffers or composite video and graphics data before sending to an LCD display or TV encoder.

The goal is to minimize the memory footprint required for the display pipeline and provide an area and performance optimized engine that can meet the needs of both SDRAM-less and SRAM-based systems.

The PXP targets the integration of several independent processing stages into a cohesive strategy to create a pixel pipeline that is flexible enough to handle the requirements of current and future chips.

The PXP combines scaling, color space conversion (or CSC), alpha-blending, secondary color space conversion (or CSC2), pixel conversion lookup memory table (or LUT) and rotation into a single processing engine, as shown in the diagram below. By integrating multiple blocks, intermediate buffer operations to external memory are removed, reducing external memory bandwidth, power, and software control complexity.

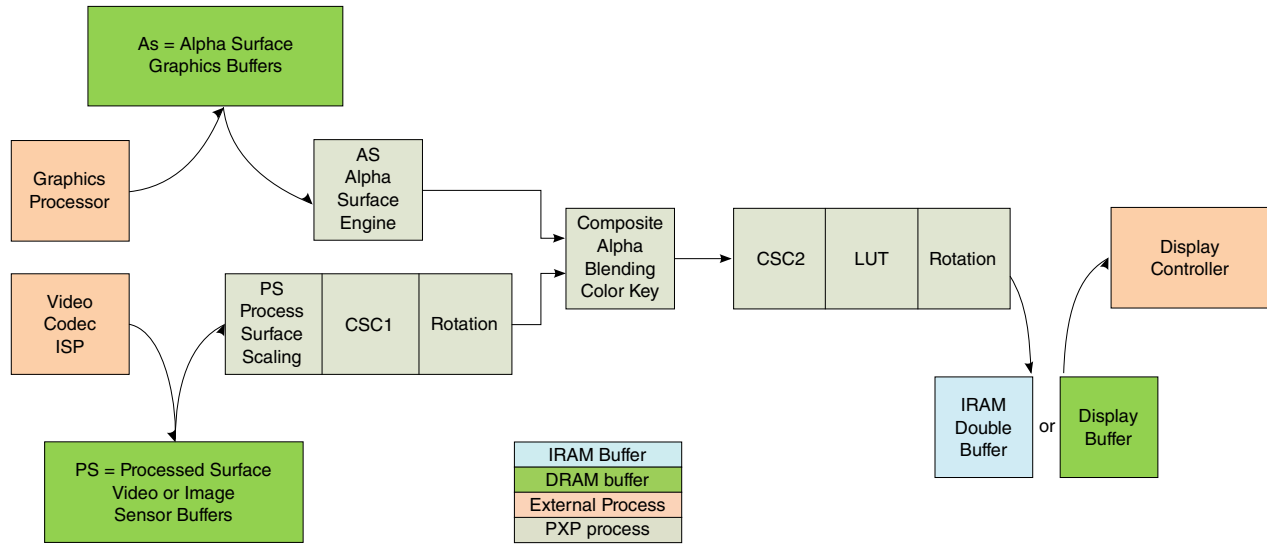

Figure 50-1. PXP Architecture

50.2 Clocks

The following table describes the clock sources for PXP. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 50-1. PXP Clocks

Clock name	Clock Root	Description
clk	pxp_axi_clk_root	PXP clock

50.3 Top-level architecture

The PXP will consist of several pipelined blocks that perform the video source frame scaling, color space conversion, alpha-blending/color key algorithm, secondary CSC, pixel correction, and input/output rotation.

The entire pipeline will operate within the requirements of the PXP architecture, and will thus perform operations on either 8x8 or 16x16 pixel blocks in the representative source buffers. The entire pipeline will operate within the context of two iteration counters that iterate through the appropriate grid of input blocks to produce the rotated output grid blocks in scan-line order.

Figure 50-1 above shows the high-level architecture of the scaling, color space conversion, blending, pixel correction and rotation engines. The Alpha Formatter fetches one RGB graphics plane alpha surface, or AS. The Scaling engine fetches a single processed surface, or PS, which can be blended with the AS surface. Although the PXP processes $N \times N$ pixel macro blocks, each of the AS or PS surfaces can have any pixel alignment within the output buffer. There are no restrictions and any pixel coordinates within the output buffer are valid. The upper left origin of the output buffer is defined as pixel 0,0. The upper left and lower right coordinates for each of the AS and PS surfaces are inclusive within the output buffer.

Figure 50-2 represents a sample output buffer configuration with both an AS and PS surfaces included. The alignment of each AS and PS surface within the output buffer can be at any arbitrary pixel locations. For example, the PS surface has an upper left coordinate (ULC) of 2,2 and a lower right coordinate (LRC) at pixel 13,13. The maximum value for the ULC and LRC for each of the AS and PS surfaces is bounded by the LRC of the output buffer, 15,15 for this example.

Figure 50-2. Sample output buffer configuration

The AS engine supports RGB pixel formats, and the PS engine supports RGB, YUV, and YCbCr pixel formats and variants of these pixel types. The CSC1 can be used to convert to RGB pixel formats so that the PS surface can be blended with the AS surfaces in the compositing engine in the RGB color space. There is a single rotation engine in the PXP with a programmable location within the PXP pipeline. Rotation can occur at the output stage after image composition occurs, or it can occur at the output of the PS engine. In the first scenario, all the data produced by the AS and PS engines will be rotated. When the rotation module is programmed to rotate only PS images, the AS is not rotated, and AS pixels are combined with rotated PS surfaces. The CSC2 unit can convert to any color space for final output. Pixels can be corrected using a programmable LUT resource to achieve any desired pixels effects.

The new PXP design also supports two parallel image processing paths. The legacy flow can operate in parallel with the input fetch engine or the dithering or waveform processing engines. Please refer to HW_PXP_CTRL and HW_PXP_CTRL2 for details on how to enable each of the individual data flows. In addition to this, the the CSC, Rotation 1 and LUT engines can be used as either part of the legacy flow or as a part of the second parallel data flow. These blocks can work in the scan line format or in block format. There are two separate blending engines for each flow.

50.3.1 Processing Details

The PXP architecture has been driven primarily by the requirement that the output buffer must be processed and rotated without intermediate frame buffer stored in external memory.

This reduces the use of external memory bandwidth requirements thus reducing overall system power consumed.

Since the output of the rotation block must be NxN pixel blocks in scan order, the entire pipeline will operate on NxN pixel blocks. In essence, the pipeline will be able to operate on blocks in a random access fashion, but the entire pipeline will operate within the context of two iteration counters that will iterate through the horizontal and vertical input blocks to generate the required output block.

Processing Pipeline

The control block will coordinate the processing of the pixel blocks within the source and destination image buffers. It begins by issuing a command to each stage of the pipeline requesting that operations be done for the block at offset x, y. When the block accepts the command, it asserts its acknowledge signal for a single cycle to indicate the acceptance and allow the control unit to move to the next block.

When the PS and AS fetch engines have received a command, they will fetch the required data and place it into their fetch buffers. If compositing the RGB AS surface with the PS surface, then the output of the PS engine needs to be converted to the RGB color space using CSC1, since all compositing occurs in the RGB color space. For YUV output pixel formats, the CSC1 unit can be enabled to convert pixels into the RGB space for subsequent compositing with AS pixels. Then, the CSC2 module can convert the resulting pixels back into the YUV output color space. If the final output color space is YUV and there is no compositing required (AS not present, for example), then both the CSC units can be bypassed and the pixel data path will pass the YUV pixels to the rotation engine. For YUV output formats, scaling operations, LUT, and rotation operations are still valid, but blending RGB AS surfaces with YUV PS surfaces is NOT supported. The two CSC units in the overall pixel data path must be used to achieve the desired source frame compositing and output pixel formatting.

The alpha blender/color key module will process a pixel any time that both inputs present valid data.

A handshake will be created between each stage and a pipeline controller to handle the advance of the pipeline and generation of the iteration counters. The pipeline controller will also maintain the interlocks with the LCD interface for the case where the LCD display and pixel pipeline use the SRAM to maintain the double buffer block intermediate buffer.

50.3.2 Scaling Operation

The scaling engine operates on YUV (or YCbCr) 422 or 420 and any RGB formatted pixels. Each color plane is sourced from color planes indicated by different base address registers.

The scaling source data can be stored as 3 individual planes for each Y, U, and V data, stored as two planes as a single Y and interleaved UV plane, or stored as a single plane with YUV/RGB interleaved on a per byte basis.

The scaled output image is presented to the CSC module as YUV444 or RGB888 pixels with a single byte for each color channel. The scaler can reduce an input image by a maximum factor of 16. In this case, the output image will be 1/16 the dimension of the input image in each of the X and Y axis. There are no limits, essentially, on increasing the source image size. The theoretical maximum increase is 4096 since a 12 bit fractional step function is used when scaling an input image. Scaling in either axis, X or Y is independent, so a source image can appear stretched in either direction.

All source images pass through the scale engine. The PXP alpha blend module and AS pixel streams are in the RGB888 format, so PS pixel buffers must be converted to the RGB888 format for alpha blending. The scaling engine works with the CSC1 module to translate YUV/YCbCr pixel formats to RGB888 for output frame buffer compositing using the alpha blender. The CSC2 module can be bypassed or enabled to convert pixels to any output color space. In the case of processing RGB pixels in the PS engine, the CSC1 unit can be bypassed so compositing can occur in the alpha engine.

The scaling operation is divided into two scaling steps. The first step is a decimation scaler, and the second step is a bilinear filter. The decimation filter provides a maximum down scaling factor of 8, and the subsequent bilinear filter provides a maximum scaling factor of 2. Combined, the maximum scaling factor can be up to 16. The decimation and bilinear scaling engines are independently programmable. There is also an initial offset that is programmable to allow more source data to be considered in the bilinear scaling engine.

50.3.3 Decimation Image Scaling

The first of two scaling engines is the decimation filter.

The intent of the decimation filter is to use as much source data as is possible to create the output image frame buffer. The decimation filter simply discards certain pixels from the source PS image depending on the reduction selected.

For RGB pixel formats, each color channel is treated equally since there is the same amount of pixel data within each color plane. For YUV422/420 formats, the chroma samples are already subsampled by 2. In these decimation scenarios, the chroma decimation factor is adjusted to account for the pre-decimation of the chroma samples. For example, since YUV422 is already sub-sampled by 2 horizontally, an X decimation factor of 2 does not apply to the YUV422 pixels in the X direction. All the chroma samples are passed on to the bilinear filter in this case. As another example, an X decimation factor of 4 will decimate the chroma samples by 2, since this factor combined with the pre-decimation factor of 2 in the pixel source buffers totals an overall decimation factor of 4.

The following example will show which pixels (in green) in a source RGB buffer that are passed to the bilinear filter for an X decimation factor of 2 and a Y decimation factor of 4. All pixels coincident with dashed lines are discarded.

Figure 50-3. RGB decimation X /2, Y /4

Using the same decimation factor as the above scenario for RGB pixels, but using YUV420 source buffers, it can be shown that the decimation factor for the Y and UV components of data are decimated differently. This is due to the pre-decimation of the chroma samples in the source frame buffers. Figure 4: YUV420 decimation X /2, Y /4 indicates that the U/V samples in the X direction are not decimated, but the Y samples in the X direction are decimated by the factor of 2.

Figure 50-4. YUV420 decimation X /2, Y /4

50.3.4 Bilinear Image Scaling Filter

The PXP implements a bilinear scaling filter to resize an input image to a different resolution for display output.

The bilinear filter is a weighted average of the four nearest pixels that can be sourced to approximate the pixel in the output frame buffer.

When scaling YUV data, the UV values are offset by 0x80 (top bit inverted) to shift the signed UV bits into an unsigned equivalent with a range of 0 to 255. YCbCr data does not have to be shifted since it is defined as an unsigned byte. The REG_CSC1_COEF0[YCBCR_MODE] bit controls whether this operation is applied to the input UV bytes.

After scaling, the offset is removed so that the range for UV data is signed from -128 to 127.

The reason for this adjustment is based on the implementation of an unsigned scaling engine, and therefore, is to ensure that the scaled values are handled properly. Consider the following table:

Format	pixel0	pixel1	average	Result
decimal	-2	+2	0	Correct
CbCr	0x7E	0x82	0x80	Correct (0x80 is 0 in CbCr)
UV	0xFE	0x02	0x80	Incorrect (0x80 is -128 in UV)
decimal	-32	+16	-8	Correct
CbCr	0x60	0x90	0x78	Correct (0x78 is -8 in CbCr)
UV	0xE0	0x10	0x78	Incorrect (0x78 is +120 in UV)

To compute the output pixel value at position as indicated by P, consider the diagram below.

Figure 50-5. Output Pixel Value

A step function is used to indicate the position of the pixel "P" in the output frame. This position may not coincide with a single pixel position in the input frame buffer. In this case, the four closest pixels in the input frame are used to approximate the value of the pixel in the output frame.

The PXP scaler first computes a linear filter in the X axis to create the two intermediate pixel values Px0 and Px1. The step function's X fractional component is used to provide the weighting factor for blending p00 with p10 to provide Px0. Likewise, Px1 is also derived from a linear filter using p01 and p11.

The equations for Px0 and Px1 are as follows:

$$Px0 = p00*(1-Rx) + p10*Rx$$

$$Px1 = p01*(1-Rx) + p11*Rx$$

The PXP scaler uses the intermediate X pixels Px0 and Px1 and implements a bilinear filter on these two pixel values to produce the final pixel value at position P. The remainder of the step function for the Y axis is used to compute the weighted average pixel result. The equation for final filtered pixel is:

$$P = Px0*(1-Ry) + Px1*Rx$$

50.3.5 YUV 4:2:2 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:2 formats. There are twice as many Y luma samples then U and V chroma samples horizontally.

Figure 50-6. YUV Sample Positioning, 4:2:2

Consider the scaled output pixel P_s (pixel scaled) which has an accumulated step function of $X=1.5$ and $Y=0.5$. The remainder for the step function is $R_x = 0.5$ and $R_y = 0.5$. Or, the sub pixel position of output pixel P_s is half way between line 0 and 1 and half way between column 1 and 2.

The Y output component of P_s is simply the bilinear function of the four nearest Y samples from the input image. Specifically, the Y values at [1,0], [2,0], [1,1], and [2,1] are used to compute the Y for P_s .

For the U and V components of P_s , there are no samples present in the column position 1. The bilinear filter uses chroma components located at [0,0], [2,0], [0,1] and [2,1]. Since the chroma components are not sub sampled vertically, the remainder used to combine pixels vertically is $R_y=0.5$ (the same as for Y). However, horizontally, the scaling engine shifts the remainder by a factor of 2. So an X axis step function value of $X=1.5$ has a remainder $R_x=0.75$. Source chroma values are not replicated, they are completely interpolated using the four nearest chroma samples to approximate U and V at P_s .

50.3.6 YUV 4:2:0 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:0 formats. Chroma is sub sampled both horizontally and vertically. In this format, the chroma frame buffers contain $\frac{1}{4}$ the data that the luma frame buffers store.

Figure 50-7. YUV Sample Positioning, 4:2:0

The Y output component for all scaled pixels in 4:2:0 formats are the same as for the 4:2:2 pixel formats.

The U and V output components have two considerations when computing the output pixel Ps.

1. All chroma samples from the input source image are shifted left and up by $\frac{1}{2}$ a sample position of the input pixel matrix.
2. Odd scan lines are replicated using the previous even chroma scan line values. So, output image chroma values that map between even to odd scan lines are replicated in the vertical axis. In contrast, output image chroma values between odd to even scan lines are interpolated vertically.

The chroma values are interpolated horizontally as in the 4:2:2 pixel format.

As an example, consider the interpolated pixel Ps in the 4:2:0 diagram above. For the Y component, the interpolated output luma is a function of the Y values in the source frame buffer at position [1,0], [2,0], [1,1], [2,1].

For the U and V interpolated samples, the chroma values on scan line position 0.5 are shifted so that they coincide with the even luma sample points. They are also replicated so that a single chroma scan line is used twice. The chroma scan line at 0.5 is replicated to represent the 4:2:2 sample points for scan line 0 and 1. The chroma scan line at 2.5 is replicated to represent the 4:2:2 sample points for scan line 2 and 3. This pattern of chroma replication occurs for the entire source frame buffer during the scaling operation.

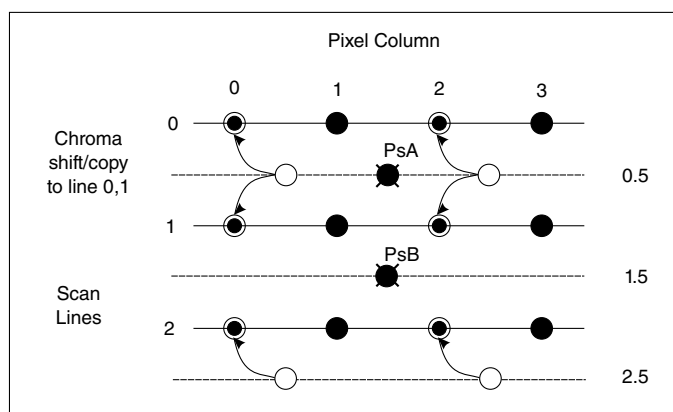

Figure 50-8. Scaled Chroma Computation Examples

The preceding diagram has two examples for the computation of the scaled chroma output pixel. For chroma at output position PsA (vertical position 0.5), interpolation occurs in the X axis using chroma values at column 0 and column 2. However, since line 0 and line 1 have equal chroma values due to chroma line replication, scaling in the Y axis results in replication of chroma values.

For chroma at output position PsB (vertical position 1.5), interpolation occurs in both the X and Y axis. The Y axis is an interpolation since the chroma values copied to scan line 1 and 2 and not the same.

In summary, any output image pixels that map to an odd scan line above and an even scan line below are interpolated vertically. Output image pixels that map to an even scan line above and an odd scan line below are replicated vertically.

50.3.7 RGB/YUV444 Image Scaling

For all RGB formats, the RGB pixels are converted up to RGB888 with 8 bits per each color component.

Then each color component is passed to the scaling engine and each component is treated in the same manner. The RGB scaling operation is the same as for the Y scaling operation described in the preceding sections. Also, YUV444 contains a byte for each color plane at each pixel location, so all three color components are scaled in the same manner.

50.3.8 Color Space Conversion (CSC)

There are two modules in the PXP to convert pixels between color spaces. They are referred to as CSC1 and CSC2 (for lack of a better naming convention).

CSC1 exists after the scaling unit and is dedicated to converting from YUV to RGB. CSC2 is a full duplex color space converter in that it can convert into either RGB or YUV (or YCbCr) color spaces depending on the desired output pixel format. All coefficients are programmed as two's complement numbers and both CSC units can be bypassed if CSC is not desired at either position of these CSC units in the pixel data path.

50.3.9 CSC1 Operation

The CSC1 module receives scaled YUV/YCbCr444 pixels from the scale engine and converts the pixels to the RGB888 color space only if CSC1 is enabled.

The CSC1 module will convert only to the RGB color space and it can be bypassed to allow YUV pixels through the data path. These pixels are loaded into the pixel FIFO for processing by subsequent modules in the pixel data path.

The following equations are used to perform YUV/YCbCr -> RGB conversion. The constants will be stored in the PXP control registers as two's complement values to allow flexibility in the implementation and to allow for differences in the video encode and decode operations. In addition, this provides a software mechanism to manipulate brightness or contrast.

$$R = C0(Y+Yoffset) + C1(V+UVoffset)$$

$$G = C0(Y+Yoffset) + C3(U+UVoffset) + C2(V+UVoffset)$$

$$B = C0(Y+Yoffset) + C4(U+UVoffset)$$

Note: In the equations above, U and V are synonymous with Cb and Cr in regards to the color space format of the source frame buffer.

Saturation of each color channel is checked and corrected for excursions outside the nominal YUV/YCbCr color spaces. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:

Coefficient	YUV	YCbCr
Yoffset	0x000	0x1F0 (-16)
UVoffset	0x000	0x180 (-128)
C0	0x100 (1.00)	0x12A (1.164)
C1	0x123 (1.140)	0x198 (1.596)
C2	0x76B (-0.581)	0x730 (-0.813)
C3	0x79B (-0.394)	0x79C (-0.392)
C4	0x208 (2.032)	0x204 (2.017)

50.3.10 YUV versus YCbCr Support

By default, the PXP color space coefficients are set to support the conversion of YUV data to RGB data.

If YCbCr input is present, software must change the coefficient registers appropriately (see the register definitions for values). Software must also set the YCBCR_MODE bit in the COEFF0 register to ensure proper conversion of YUV versus YCBCR data.

50.3.11 CSC2 operation

The CSC2 module receives pixels in any color space and can convert the pixels into any of RGB, YUV, or YCbCr color spaces.

All coefficients are programmable and in the two's complement notation. The output pixels are passed onto the LUT and rotation engine for further processing.

The following equations indicate the CSC2 modules ALU architecture.

Selecting RGB output in REG_CSC2_CTRL[CSC_MODE] configures the ALU in the following manor:

$$R = A1(Y-D1) + A2(U-D2) + A3(V-D3)$$

$$G = B1(Y-D1) + B2(U-D2) + B3(V-D3)$$

$$B = C1(Y-D1) + C2(U-D2) + C3(V-D3)$$

Selecting YUV output configures the ALU in the alternate manor:

$$Y = A1*R + A2*G + A3*B + D1$$

$$U = B1*R + B2*G + B3*B + D2$$

$$V = C1*R + C2*G + C3*B + D3$$

Saturation of each color channel is checked and corrected for excursions outside the nominal color space. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

50.3.12 Alpha Blending/Color Key

Regardless of pixel input format, the PS and AS pixels are normalized to 32-bits, organized as one alpha and three data bytes.

Alpha blending occurs in the RGB space, if blending is required, PS pixels should be converted to RGB space. If no alpha blending is required, then YUV pixels can bypass the alpha blending ALU without color space conversion.

All pixels are processed by the pixel ALU, but the ALU operations can be disabled to achieve pixel pass through for either PS or AS source pixels.

50.3.13 Alpha Blend

The alpha value for an individual pixel represents a mathematical weighting factor applied to the AS pixel.

An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an AS pixel is determined by the REG_AS_CTRL[ALPHA] and REG_AS_CTRL[ALPHA_CTRL] register fields. If REG_AS_CTRL[ALPHA_CTRL] = ALPHA_OVERRIDE, the alpha value for the pixel is taken from the REG_AS_CTRL[ALPHA]. This can be useful for applying a constant alpha to an entire image or for image formats that don't include an alpha value. If REG_AS_CTRL[ALPHA_CTRL] = ALPHA_MULTIPLY, the pixel's alpha value will be multiplied by the pixel's ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as RGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

$G\acute{a}$ = PIO programmed global alpha (8-bit value).

$E\acute{a}$ = Embedded alpha associated with AS pixel.

$$\acute{a} = G\acute{a} * E\acute{a} + 0x80$$

The result for the red channel as an example:

$$R[7:0] = (\acute{a} * PS.r) + ((1 - \acute{a}) * AS.r)$$

When \acute{a} is 0xff, the PS pixel will not be blended with the AS pixel, but PS will be passed as the output pixel and will not be blended with AS. In this case, AS will be discarded. Likewise, if \acute{a} is 0x00 for a given pixel, PS will be loaded as the output pixel.

REG_AS_CTRL[ALPHA_INVERT] provides the option to invert the final alpha value. This essentially inverts the effect the alpha value has on the AS and PS blending operation.

50.3.14 Color Key

The color key function is provided to create transparent effects on the output pixel.

Color keying is applied on the input pixels after they are converted to 8-bits for each red, green, and blue color channels (color keys are not applied directly to 16-bit pixel formats but to their corresponding 24-bit representation). A color key range is programmable for both PS and AS pixels. If the PS 24-bit pixel is within the PS color key range, then AS is passed through the pixel pipeline. In this case, alpha blending does NOT occur.

Conversely, if PS is within the AS color key range, then PS is passed via the PXP data pipeline. If both PS and AS color key tests pass, then the back ground color register is passed onto following PXP processing components in the pipeline.

The condition for color keying to be satisfied is:

$$CK0.r.low \leq PS.r \leq CK0.r.high$$

$$CK0.g.low \leq PS.g \leq CK0.g.high$$

$$CK0.b.low \leq PS.b \leq CK0.b.high$$

For example, if the "red" 8-bit value for the PS pixel (or PS.r) is between the color key low and high values (CK0.r.l and CK0.r.h), the condition is true for the red color plane. When ALL three color planes meet this condition, then only the PS pixel is loaded into the output register.

To disable color keying, program the low color key register value to 0xff and the high value to 0x00. This will guarantee that the color key range test will never be true.

50.3.15 LUT

The lookup table (LUT) is used to modify pixels in a manner that is not linear and that cannot be achieved by the color space conversion modules.

Nonlinear response to the input pixels can be achieved based on how the lookup table is programmed.

Programming of the direct access LUT table can be facilitated by single PIO register writes or DMA access. For efficient loading of the LUT, DMA access should be used.

50.3.16 Lookup Modes

The LUT has four lookup modes. The lookup modes determine how the `src_pixel` is used to address the LUT memory.

The four lookup modes are:

1. `DIRECT_Y8`
2. `DIRECT_RGB444`
3. `DIRECT_RGB454`
4. `CACHE_RGB565`

The `DIRECT` modes access the LUT memory as a monolithic SRAM. The `CACHE_RGB565` will access the memory as a 2-way set associative cache.

50.3.17 `DIRECT_Y8`

`DIRECT_Y8` is used for a 256-byte lookup. In `DIRECT_Y8`, the most significant byte of the pixel is used to address the LUT entry.

This byte reflects the Y/R channel of the pixel data path. Luma, or monochrome, transformations are possible with this lookup mode. The address is generated as: `src_pixel[23:16]`. In `DIRECT_Y8` operation, the memory is byte addressable.

50.3.18 `DIRECT_RGB444`

`DIRECT_RGB444` is used for a 8KB (4K pixel) RGB444 to RGB565 lookup.

Pixel formats that are in the YUV color space at the position of the LUT in the PXP data path can also be converted. To take advantage of the full 16KB memory, the `REG_LUT_CTRL[SEL_8KB]` bit can be used to select the upper or lower 8KB memory, thus facilitating the use of 2 separate 444 LUT tables. In `DIRECT_RGB444`, the `src_pixel` is RGB/YUV[23:0] data is used to generate the lookup address. The address is generated as: `{R/Y[23:20],G/U[15:12],B/V[7:4]}`. In `DIRECT_RGB444`, the memory is pixel (2 byte) addressable.

50.3.19 `DIRECT_RGB454`

`DIRECT_RGB454` is used for a 16KB (8K pixel) RGB454 to RGB565 lookup.

Pixel formats that are in the YUV color space at the position of the LUT in the PXP data path can also be converted. In DIRECT_RGB454, the src_pixel is RGB/YUV[23:0] data is used to generate the lookup address. The address is generated as: {R/Y[23:20],G/U[15:11],B/V[7:4]}. In DIRECT_RGB454, the memory is pixel (2 byte) addressable.

50.3.20 CACHE_RGB565

The CACHE_RGB565 lookup is used for a 128KB (65K pixel) RGB/YUV565 to RGB/YUV565 lookup.

The 128KB memory requirement is too costly from an area perspective to implement a complete lookup table in the LUT's on chip memory. For this reason, a LRU (least recently used) 16KB 2-way set associative cache has been implemented to reference the full 128KB lookup table stored in external memory.

The 2-way set associative cache is organized in the following way:

- 16KB total data storage
- 512 entries split between 256 ways
- 6 pixels/entry cache line

Cache efficiency is very critical. For a cache miss, the PXP will be stalled until the cache line can be filled. For a 32 bit DDR memory interface, the latency can be calculated as follows:

cycles latency for read command through DDR controller + CAS Latency + # burst cycles for read data to be returned + # cycles latency for data through DDR controller to LUT + 1 cycle for cache access of new data

The src_pixel is RGB[23:0] data used to generate the lookup address. To improve the cache efficiency the RGB/YUV565 address and the lookup table must be formatted in the following way:

Address: $A[15:0] = R_7G_7G_6B_7 R_6G_5B_6 R_5G_4B_5 R_4G_3B_4 R_3G_2B_3$

The address is organized as follows:

- A[15:12] tag address, used to compare a hit between cache ways
- A[11:4] index address, used to select cache set (i.e. row of memory)
- A[3:0] block address, used to select Pixel in the cache line

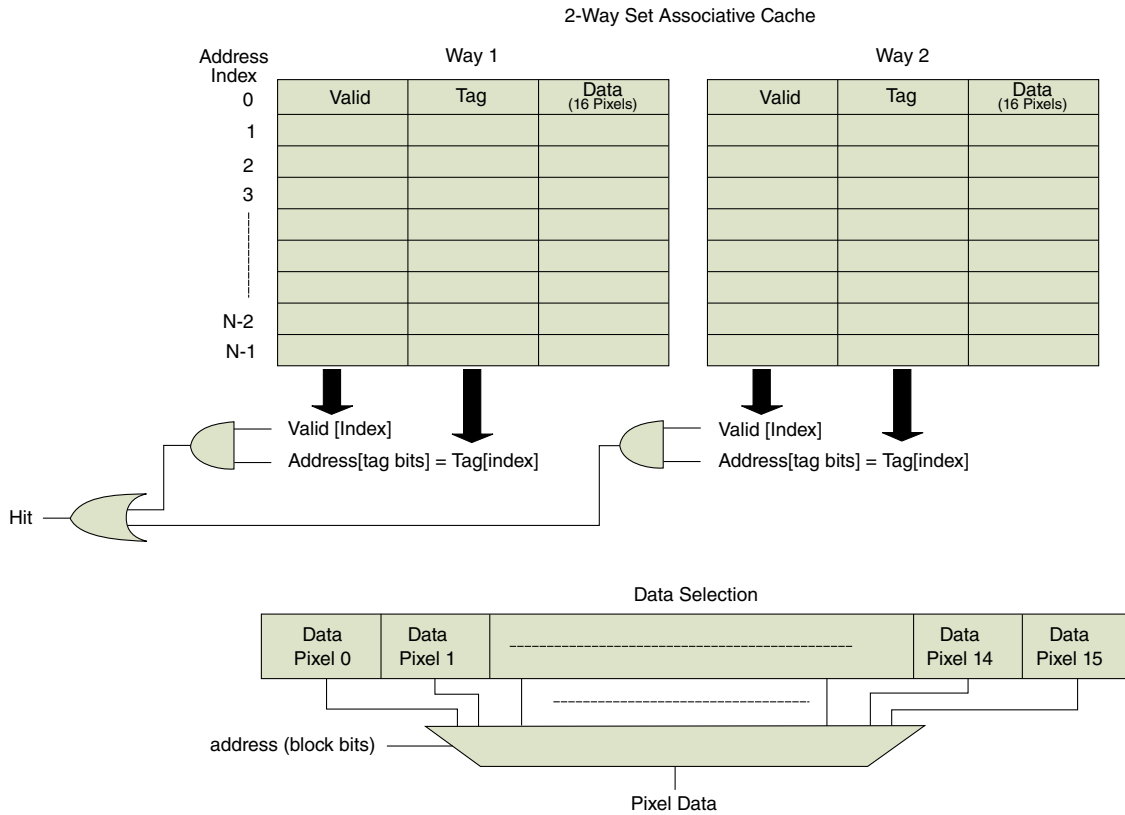

Figure 50-9. 2-Way Set Associative Cache and Data Selection

50.3.21 Output Modes

The LUT has three output modes for color space conversion.

1. Y8
2. RGBW4444CFA
3. RGB888

50.3.22 Y8

With `out_mode` set to Y8, in conjunction with DIRECT_Y8 lookup mode, the intended operation is Gama Correction.

Only the third byte is processed by the lookup table. The third byte is represented by the Y value or the R value in the data path since pixel data is either YUV[23:0] or RGB[23:0] where the Y or R byte encompass bits [23:16] respectfully. So, bits 15:0 are

always bypassed and left unchanged. Currently, the LUT is intended to process Y data when any YUV, Y8, or Y4 output pixel formats are selected. However, this resource can be enabled and used for any conceivable purpose.

Note: When the DIRECT_RGB444, DIRECT_RGB454 or CACHE_RGB565 lookup mode is selected in conjunction with the Y8 output mode the low order byte of the two bytes read from the LUT memory will be used as the Gama Correction value.

50.3.23 RGBW4444CFA

With REG_LUT_CTRL[OUT_MODE] set to RGBW4444CFA, the REG_CFA[DATA] is used to select one nibble from the LUT 16 bit output value.

The LUT memory lookup will contain a RGBW4444 value. The REG_CFA[DATA] will select the R,G,B or W nibble as the pixel value to present to the PXP data path based on the matrix defined by the REG_CFA[DATA] register. The 4 bit value is presented in the Y, or third byte lane, of the PXP data path. The final pixel transferred to the next PXP stage is {CFA[3:0],CFA[3:0],LUT[15:0]}

50.3.23.1 CFA Correction

The 32-bit REG__CFA[DATA] register is used to encode 16 CFA correction values.

The CFA correction values are encoded as follows:

- 00 selects R
- 01 selects G
- 10 selects B
- 11 selects W

The CFA correction uses 4x4 block processing. Figure 5; CFA mapping translation shows how CFA 4x4 blocks will iterate over the PXP's 8x8 or 16x16 pixel block being processed:

Figure 50-10. CFA mapping translation

50.3.24 RGB888

With `out_mode` set to RGB888, the memory output data is interpolated from RGB565 to RGB888.

The RGB[23:0] data is formatted as follows: R[7:3]R[7:5],G[7:2]G[7:6],B[7:3]B[7:5].

50.3.25 Rotation

There is a single rotation resource integrated into the PXP. The location of this resource within the PXP data path is programmable. Rotation can occur after compositing the AS and PS buffers in the output stage.

As an alternative configuration, the PS buffer can be rotated and later composited with the AS surface that is not rotated. There is a single configuration bit that provides the configuration of where rotation is implemented within the PXP.

To rotate graphics, the hardware must read pixels in one direction across a frame buffer and write them in a alternate orientation. For the 90 and 270 degree cases, this means that lines of pixels must either be read or written vertically in a frame buffer.

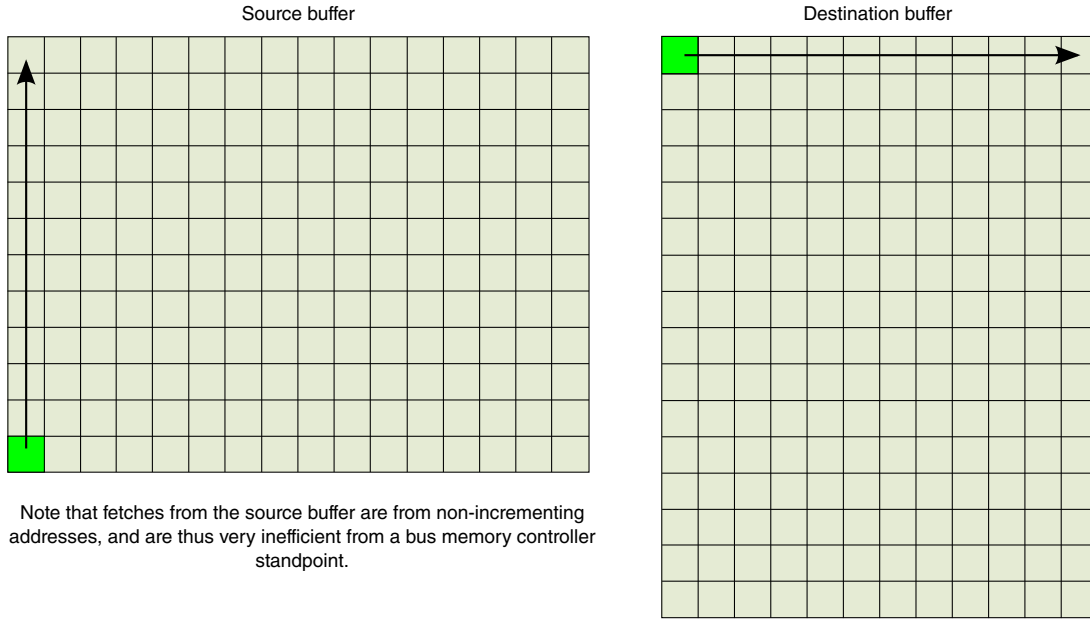

Figure 50-11. Rotation Read and Write

In order to rotate efficiently, multiple columns must be rotated to enable the engine to both fetch and store bursts of pixels, thus improving memory performance. The simplest method of doing this is to operate on square blocks of pixels. To rotate the image, each sub-block of pixels must be rotated by the required rotation angle.

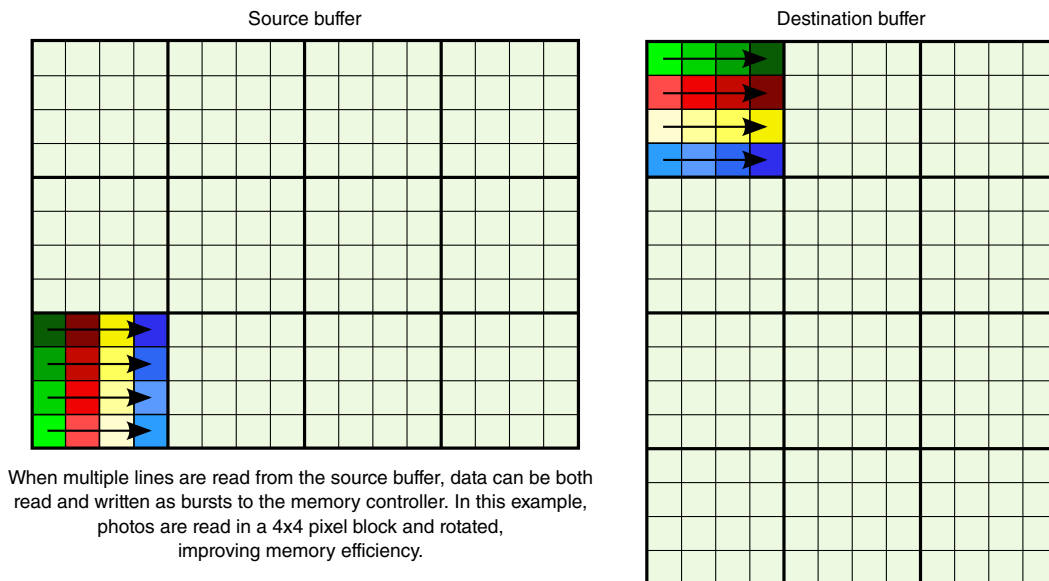

Figure 50-12. Rotated Sub-blocks

To manage the rotation process, the source image can be broken into a grid of sub-blocks that have coordinates as shown in the diagram below. In addition to rotating the sub-block, each block must be translated to a new coordinate location. For each of the rotation angles (0, 90, 180, 270), it is possible to define a simple algorithm for computing the new translated grid address. The hardware must then simply compute the memory address from the base grid address for both load and store operations.

Figure 50-13. Grid of Sub-Blocks with Coordinates

In order to balance the requirements of reasonable burst sizes to the memory controller as well as keep the hardware storage requirements to a minimum, the blending/rotation engine will operate on either 8x8 or 16x16 pixel blocks. When using the Rotate engine with the input fetch engine, you need to program the input fetch engine to work in 8x8 block mode.

IMPORTANT NOTE: An important artifact of the PXP is when rotating a source image and the output is NOT divisible by the block size selected. The output engine essentially truncates any output pixels after the desired number of pixels has been written. Since the output buffer is written as a horizontal row of blocks, the incorrect pixels could be truncated and the final output image can look shifted. In the case where the block size is programmed to 8x8, and the output size that is programmed is 12x12, then there is a remainder of 4 pixels that will be truncated in either the X and/or Y axis when the PXP operation is complete. The output will be shifted by 4 pixels in this example. To compensate for this, the source base address needs to be adjusted so the correct pixels get

truncated and the image does not look shifted. In this example, with 90 degrees of rotation, the PS base address should be adjusted by 4 times the actual PS base address - (4*pitch).

50.3.26 Output Buffer

The output buffer engine accepts data from the PXP pixel pipeline and issues requests to transfer the output pixels to external DRAM or the internal SRAM double buffer row of blocks. It can also connect to the dither engine using the handshake mode. This works for the output engine programmed in the scan line mode as well as block mode. For more details, please refer to the Dither fetch engine.

50.3.27 Address calculator

Each of the blocks will manage its own fetch address using a common address calculator block that computes real addresses from a base address and relative block offset from the base.

Each block will then perform the multiple line fetches (or stores) required to perform the operation. This hides all the address buffer computations from the processing blocks and allows each block to simply track the coordinate of the block it is working on.

50.3.28 Block size selection

The PXP can be configured to process blocks that are either 8x8 pixels or 16x16 pixels with the REG_CTRL[BLOCK_SIZE] control bit.

When selecting a 16x16 pixel block size, the accesses to fetch AS and PS images and write the final frame buffer are more efficient since twice as much data is requested and processed per memory request.

When optimizing the system for memory bandwidth and image processing time, configure the PXP to process 16x16 pixel blocks.

50.3.29 Interlaced Video Support

The PXP has some minimal ability to generate interlaced video content from a progressive source. There two available options, based on the bandwidth requirements and how software is managing video frames.

The PXP can either interlace on the input side (by reading every other line of input data) or on the output side (by writing the individual lines of video into two separate fields). Generally, output interleaving should be used since it is the most flexible mode (it allows scaling and full overlay support) and it only requires a single pass of the PXP to generate two separate output fields.

Input interleaving can be beneficial in cases where the PXP is running at 60fps, since it requires fewer fetches to produce the output data. There is no direct hardware support for input interleaving, in that, there is no configuration bit that can be set to alter how the PXP processes a frame for input interleaving. Input interleaving is achieved by simply setting the source frame buffer pitch value to twice the value it would normally be set to for the equivalent progressive frame. The output parameters also need to be consistent with the desired processing effect. For example, the vertical resolution would be set to account for the reduced resolution to process the interlaced input buffers.

50.3.30 LCDIF Handshake

The PXP and LCDIF support a mode where the internal SRAM can be used for the frame buffer to minimize external memory bandwidth required.

This is accomplished by creating two buffers in SRAM, a double buffer row of blocks, where each correspond to 8/16-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

Figure 50-14. Buffer in OCRAM

The storage required can be calculated for an 8x8 block size as

- storage = 16 (lines) * rotated_row_length * pixel_size

and for 16x16 block size as

- storage = 32 (lines) * rotated_row_length * pixel_size

where `pixel_size = 4` for 32bpp or 2 for 16bpp modes. The following table lists the storage requirements for common image sizes using 8x8 block size:

Image Size	Storage (16bpp)	Storage (24bpp)	Storage (32bpp)
320x240 (QVGA) - 0/180 rotation	10KB	15KB	20KB
320x240 (QVGA) - 90/270 rotation	7.5KB	11.5KB	15KB
640x480 (VGA) - 0/180 rotation	20KB	30KB	40KB
640x480 (VGA) - 90/270 rotation	15KB	22.5KB	30KB

The following diagram shows how the minimal rotation buffer would be organized. As the engine and LCD progress down the image, they continually swap roles of filling and emptying each eight-line buffer.

Figure 50-15. Minimal Rotation Buffer Organization

When this mode is enabled, the PXP will process one row of pixel blocks and write the results to the first SRAM buffer (buffer 0). The PXP will then alternate between writing subsequent rows to buffer 0 and buffer 1. After the PXP generates the data for one buffer, the LCDIF will begin reading that buffer and send the contents to the display device. Once the LCDIF finishes reading a buffer, it will start displaying from the other buffer while the PXP continues filling the previously processed buffer.

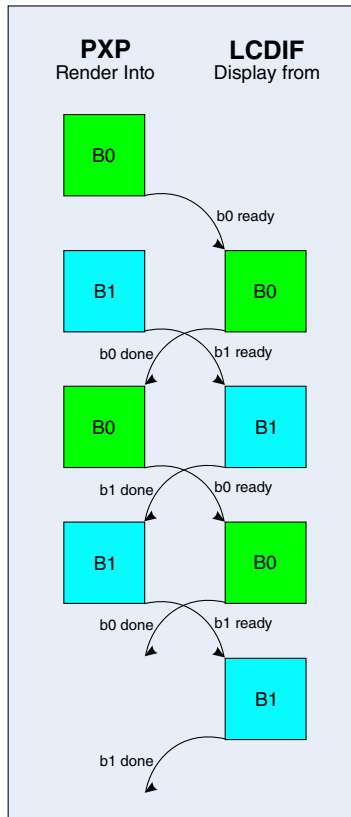

Figure 50-16. PXP and LCDIF Buffer Sharing

To accomplish the buffer sharing, the PXP and LCDIF will maintain buffer status using a pair of handshake signals. When a buffer is filled by the PXP, it will assert the `pxp_lcdif_bx_ready` (where x is 0 or 1) signal to indicate to the LCDIF that the buffer has valid data. The LCDIF will then release the buffer by asserting the `lcdif_pxp_bx_done` signal.

The basic protocol is shown in the diagram below:

Figure 50-17. Buffer Sharing Protocol

The PXP will continue to assert the `bx_ready` signal until the corresponding `bx_done` signal is sampled high for one clock cycle. It will then deassert the `bn_ready` until the next time the buffer has been filled. After the PXP samples the `bx_done` signal asserted, it is free to begin filling the buffer with the next block size lines of display data. If a buffer has not been released when the PXP is ready to process data for that buffer, it will suspend rendering operations until the buffer has been released by the LCDIF.

50.3.31 LCDIF Abort

When the memory subsystem is not loaded, the PXP should be able to render the buffers faster than the LCDIF can drain the buffers.

It is possible under some scenarios (high LCDIF output rates with high memory latency) that the PXP may not be able to keep up with the LCDIF, even in the SRAM mode of operation. When this happens, the LCDIF will signal that it has completed one of the buffers before the other has been rendered by the PXP. This condition will be detected by the PXP's control logic as an "LCDIF Abort", which will cause the PXP to abort processing in the current row and proceed to the following row. It will acknowledge the abort to the LCDIF by raising the `buffer_ready` signal for the current buffer to enable the LCDIF to begin displaying the partially-filled buffer. While an abort will create artifacts in the video display, it does minimize the artifacts by limiting them to the remaining pixels blocks in the current row versus ruining the entire frame buffer.

Figure 50-18. LCDIF Abort

50.3.32 Theory of Operation

The PXP can be used to accelerate graphics operations by offloading graphics processing from the processor. The block can perform alpha blending and color key substitution on two RGB graphics buffers.

The PXP is organized as having a processed surface (PS) and an alpha surface (AS) that can be blended with the processed surface. There are no restrictions on the location of the AS or PS within the output surface (OS). As the PXP processes NxN blocks, operations

are performed on a pixel by pixel basis. The AS and PS pixels are alpha blended, color keyed, process by CSC and LUT resources as individual pixel components. This allows efficient block processing with supporting arbitrary alignment for both the AS and PS surfaces. The resulting pixel block is then written to the corresponding block in the output buffer.

50.3.33 Pixel Handling

All pixels are internally represented as 24-bit values regardless of input or output pixel formats.

The pixels get converted in the AS and PS buffer engines to 24-bit pixel values.. There is also an 8-bit alpha value at stages up to the alpha blender within the PXP for blending within the RGB color space. Compositing of AS and PS images can only occur in the RGB color space. If compositing is not required, then YUV pixels can be transferred and processed at all PXP pixel resource components.. The color orientation of pixels within the PXP can be controlled by the CSC1, CSC2, and LUT resources.

For RGB, input pixels are converted into 24-bit pixel values using the following rules:

1. 32-bit ARGB8888 pixels are read directly with no conversion for both the AS and PS.
2. 32-bit RGB888 pixels are assumed to have an alpha value of 0xFF (full opaque).
3. 6-bit RGB565 and RGB555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of 0xFF (opaque). The expansion process replicates the upper pixel bits into the lower pixel bits (for instance a 16-bit RGB555 triplet of 0x1F/0x10/0x07 would be expanded to 0xFF/0x84/0x39).
4. 16-bit RGB1555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of either 0x00 or 0xFF, based on the 1-bit alpha value in the pixel. The ALPHA_MULTIPLY function is useful in this scenario to allow scaling of the opaque pixels to a semi-transparent value.

Alpha values can be passed through the entire PXP data path and output in ARGB888 and ARGB555 pixel modes. Also, output pixels can be assigned an alpha value using the REG_OUT_CTRL[ALPHA] register. 16-bit pixels values are formed from the most significant bits of the 24-bit pixel values.

When YUV/YCbCr output formats are selected, all pixels are internally represented as either RGB or YUV pixels values. The CSC2 or LUT can convert internal RGB/YUV pixels into the correct output format. In this way, any PS color space can be blended with AS RGB pixels and output in any color space.

50.3.34 Output Buffer Composition

The output buffer will be rendered by composing each pixel block from the associated PS and AS buffers.

The AS pixel buffer can be blended or color-keyed with the associated data from the PS buffer (either the PS image pixels or REG_PS_BACKGROUND register based on PS programmed coordinates).

Figure 50-19. Output Buffer Composition

50.3.35 PS Image Processing

As the PXP processes image buffers, it iterates over the output buffer by fetching the corresponding input buffer blocks and processing the pixels embedded in these.

50.3.36 Letterboxing

At each pixel coordinate, the control logic determines if the PS pixel (argument also applies to AS pixels) will be used in rendering the output pixel.

This is determined by checking the output pixel's coordinates against the REG_OUT_PS_ULC and REG_OUT_PS_LRC (ULC and LRC in short) register contents. For pixels outside this region, the PS pixel will be loaded with the pixel value from REG_PS_BACKGROUND, which can be used to effectively control the letterboxing color. There are no block size or block boundary restrictions when setting the ULC or LRC for either the AS or PS. The only restriction is that the ULC and LRC are within the OUT LRC extents.

Figure 50-20. OUT Buffer

50.3.37 Clipping source images

A subset of the PS buffer can be used in rendering the output buffer. The PXP_PS_BUF register can indicate an offset into the PS buffer that will be used for display within the OUTPUT buffer.

The pixel at the address defined in the PXP_PS_BUF register will be the pixel that is displayed at the pixel coordinate indicated by PXP_OUT_PS_ULC within the output buffer. Essentially, the PXP_PS_BUF register can be used to establish an offset into the PS buffer thus clipping all PS buffer pixels that are at a lower address. The PXP_PS_PITCH will always indicate the number of bytes that are vertically adjacent in

the PS buffer. The settings in the PXP_PS_BUF, PXP_OUT_PS_ULC, and PXP_OUT_PS_LRC will determine the subset of the PS buffer, or clipped PS source buffer, that will be used in the output buffer.

It is important to note that when scaling the PS buffer, the coordinates of the PS buffer within the output buffer need to be consistent with the scaling factors and original PS buffer size.

Figure 50-21. PS Buffer Scaling

When sourcing a subset of the PS image, it should fall completely within the PS buffer to avoid displaying incorrect data. The following conditions should be met:

$$x_base_addr_offset + x_scale * (LRC_X - ULC_X) \leq PS_pitch$$

$$y_base_addr_offset + y_scale * (LRC_Y - ULC_Y) \leq PS_size$$

The PXP hardware does not check for these conditions and will render the image as programmed. The following case could indicate invalid programming parameters for the PXP:

Figure 50-22. Example with Invalid Parameters

50.3.38 Color Key Processing

Pixels may be made transparent to the corresponding AS by using the PS color key registers.

If a PS pixel matches the range specified by the REG_PS_COLORKEYLOW and REG_PS_COLORKEYHIGH registers, the pixel from the associated AS will be displayed. If no AS is present for the pixel, a black pixel will be generated since the default AS pixel is 0x00000000 (transparent black pixel).

The most common use for this is when a bitmap does not support an alpha-field or for applications such as "green screen" where an image is substituted for a solid background color .

Figure 50-23. The PS image (player) and AS image (stadium)

The green portion of the background image can be color keyed to display the contents of the AS buffer for locations that match the color range. For this example, the color range is:

PS Colorkey: 00<R<80 70<G<ff 00<B<80

The resulting image becomes:

Figure 50-24. Resulting Image

50.3.39 In Place Processing (PS buffer is destination buffer)

The PXP also has the ability to process an image and write the resulting buffer back to the original PS buffer. This is referred to as "in place" rendering.

This could be useful for basic blit operations into the PS buffer. IN_PLACE operations are achieved by programming the OUT base address to the pixel location in the PS buffer that marks the upper left pixel of the update region. The actual region that is updated should be indicated by programming the ULC = (0,0) and the LRC = (X,Y). The region bounded by the coordinates will be updated, and the rest of the PS buffer will not be modified.

50.3.40 Alpha Surface (AS) Processing

The AS surface has a complete set of registers that determines how the AS effects the final OUT surface.

Most of the registers that exist for the PS surface also are defined for the AS surface where applicable. This is provided to replicate the SW interface for each PS and AS processes.

50.3.41 Alpha Handling

Alpha values in the AS are embedded in the source image pixels. For AS pixel formats that do not support an alpha value, the pixel is assigned an alpha value of 0xFF (opaque).

This can be modified by the AS control by setting either the ALPHA_MULTIPLY or ALPHA_OVERRIDE bit in the associated AS_CTRL register. If ALPHA_MULTIPLY is enabled, the 8-bit ALPHA value from the AS_CTRL register is multiplied by the source alpha before blending with the PS image. If the ALPHA_OVERRIDE bit is set, the 8-bit ALPHA value is simply substituted for the pixel.

50.3.42 Color Key Processing (AS_CTRL)

The AS_CTRL register also contains an ENABLE_COLORKEY bit that can be used to enable or disable color key substitution for the AS.

When enabled, the pixel values are compared to the ASCOLORKEYLOW and ASCOLORKEYHIGH registers to determine if a match has occurred. When an AS pixel matches the color key range, the pixel from the AS image is considered transparent and the corresponding PS pixel is rendered. If both the PS and AS pixels match their corresponding color key ranges, the AS pixel is displayed unmodified.

AS color keys are handled in a manner similar to PS color keys. The same images used in the PS color key example could be used with the images swapped. In this case, matches on the AS image to the ASCOLORKEY register would display the PS pixels.

50.4 Output Image Processing

Several PXP options affect the resulting output image.

50.4.1 Output Image Size

The PXP generates an output image in the resolution programmed by the REG_OUT_LRC. As the PXP processes pixels, it iterates over the NxN blocks (in output scan-block order) based on the final image resolution.

50.4.2 Output Format

The result of PXP operations are written to the buffer pointed to by the REG_OUT_BUF/REG_OUT_BUF2 registers. The pixel format is controlled by the REG_OUT_CTRL[FORMAT] bit-field.

32-bit pixels are formed directly from the internal 24-bit representations and 16-bit pixel formats are generated by truncating the internal 24-bit values to the appropriate number of bits. For formats supporting an alpha value, the PXP assigns the alpha using the 8-bit value in the REG_OUT_CTRL[ALPHA] field. For ARGB1555, the most significant alpha bit is appended to the output pixel. Also, for ARGB4444, the most significant nibble is appended to the output pixel. Single and dual buffer YUV output formats are also available. Since each pixel in the data path is represented by a full YUV444 24bpp value, decimation reduces the output in cases of YUV422/420 output formats.

50.4.3 Rotation/Flip operations

The PXP supports four rotation angles in conjunction with vertical and horizontal flip options. The flip operations effectively take place before the rotation.

Rotations of 0, 90, 180, and 270 degrees are supported and any combination of rotation and flip are supported. There is no performance difference between any of these modes of operation.

50.5 Queuing PXP transactions

The PXP supports a primitive ability to queue up one operation while the current operation is running. This is enabled through the use of the REG_NEXT register.

When this register is written, it enables the PXP to reload its current register contents with the data found at the location pointed to by this address when it completes processing of the current frame. This feature may be useful in helping to reduce the interrupt latency in servicing the PXP, especially in cases where the PXP and LCDIF are using the on-chip SRAM buffer handshake (since the PXP must begin generating next frame data immediately).

If the PXP is idle when the REG_NEXT register is written, the PXP treats this as an indication that it should immediately load the values at the pointer and begin processing the frame. This ability should allow software to use the same routines when programming the PXP (so that the first frame doesn't differ from subsequent frames).

When loading values from the NEXT register, all registers in the PXP are reloaded. Some register loads have no effect

After writing the REG_NEXT register, the PXP will set the REG_NEXT[ENABLED] bit of the REG_NEXT register to indicate that the next command has been queued. Software should first check the status of this bit to ensure that a previous command has not been enabled. Likewise, after programming the first frame in a sequence of frames, software should poll this bit until it is sampled logic 1'b0 before queuing the next operation.

The PXP will issue interrupts from frames as they complete, regardless of whether they were started by writing the control registers directly or using the REG_NEXT register. When software receives an interrupt, it should check/clear the PXP's status register as normal, poll the REG_PXP[ENABLED] bit, and then issue the next operation. A queued operation may be cancelled by issuing a CLEAR operation to the REG_PXP[ENABLED] register bit. The SET and TOGGLE operations should never be used with this register.

50.6 Error Handling

The PXP does minimal checking on the control registers, so it is important that these are correctly specified. The PXP does monitor the bus transactions for errors and will report errors in the status register.

Upon receipt of a bus error, the PXP will set the ERROR interrupt and abort any further operations. Bus errors can be generated from any system access that results in an error response returned from the internal SIM Bus errors in the PXP are signaled as either a read or a write error, but do not indicate the failing address. Software may deduce the failing address from the current block status indicators.

50.6.1 Known PXP Limitations/Issues

The PXP has the following known limitations:

1. When using the NEXT register, the interrupt enable setting should remain the same for all frames. If not, the PXP will change the interrupt enable register value and possible cause the loss of an interrupt.
2. Rotations of 180/270 are not supported when performing LCD handshakes

50.7 PXP Memory Map/Register Definition

PXP Hardware Register Format Summary

PXP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
221_8000	Control Register 0 (PXP_CTRL)	32	R/W	C000_0000h	50.7.1/3302
221_8010	Status Register (PXP_STAT)	32	R/W	0000_0000h	50.7.2/3304
221_8020	Output Buffer Control Register (PXP_OUT_CTRL)	32	R/W	0000_0000h	50.7.3/3306

50.7.1 Control Register 0 (PXP_CTRL)

The CTRL register contains controls for the PXP module.

PXP_CTRL: 0x000

PXP_CTRL_SET: 0x004

PXP_CTRL_CLR: 0x008

PXP_CTRL_TOG: 0x00C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 221_8000h base + 0h offset = 221_8000h

PXP_CTRL field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal PXP operation. Set this bit to one (default) to disable clocking with the PXP and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the PXP block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 RSVD4	Reserved, always set to zero.
28 EN_REPEAT	Enable the PXP to run continuously. When this bit is set, the PXP will repeat based on the current configuration register settings. If this bit is not set, the PXP will complete the process and enter the idle state ready to accept the next frame to be processed. This bit should be set when the LCDIF handshake mode is enabled so that the next frame is automatically generated for the next screen refresh cycle. If it not set and the handshake mode is enabled, the CPU will have to initiate the PXP for the next refresh cycle. When the PXP NEXT feature is used, it has priority over the REPEAT mode, in that the new register settings are fetched first, and then the next PXP operation will continue.
27–24 RSVD3	Reserved, always set to zero.
23 BLOCK_SIZE	Select the block size to process. 0x0 8X8 — Process 8x8 pixel blocks. 0x1 16X16 — Process 16x16 pixel blocks.
22 ROT_POS	This bit controls where rotation will occur in the PXP datapath. Setting this bit to 1'b0 will place the rotation resources at the output stage of the PXP data path. Image compositing will occur before pixels are processed for rotation. Setting this bit to a 1'b1 will place the rotation resources before image composition. Only the PS can be rotated in this configuration and AS will not be rotated.
21–12 RSVD1	Reserved, always set to zero.
11 VFLIP	Indicates that the output buffer should be flipped vertically (effect applied before rotation).
10 HFLIP	Indicates that the output buffer should be flipped horizontally (effect applied before rotation).

Table continues on the next page...

PXP_CTRL field descriptions (continued)

Field	Description
9–8 ROTATE	Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation. 0x0 ROT_0 — 0x1 ROT_90 — 0x2 ROT_180 — 0x3 ROT_270 —
7–5 Reserved	This read-only field is reserved and always has the value 0.
4 ENABLE_LCD_ HANDSHAKE	Enable handshake with LCD controller. When this is set, the PXP will not process an entire framebuffer, but will instead process rows of NxN blocks in a double-buffer handshake with the LCDIF. This enables the use of the onboard SRAM for a partial frame buffer.
3 LUT_DMA_IRQ_ ENABLE	LUT DMA interrupt enable. When set, the PXP will issue an interrupt when the LUT DMA has finished transferring data.
2 NEXT_IRQ_ ENABLE	Next command interrupt enable. When set, the PXP will issue an interrupt when a queued command initiated by a write to the PXP_NEXT register has been loaded into the PXP's registers. This interrupt also indicates that a new command may now be queued.
1 IRQ_ENABLE	Interrupt enable. NOTE: When using the PXP_NEXT functionality to reprogram the PXP, the new value of this bit will be used and may therefore enable or disable an interrupt unintentionally.
0 ENABLE	Enables PXP operation with specified parameters. The ENABLE bit will remain set while the PXP is active and will be cleared once the current operation completes. Software should use the IRQ bit in the PXP_STAT when polling for PXP completion.

50.7.2 Status Register (PXP_STAT)

The PXP Interrupt Status register provides interrupt status information.

PXP_STAT: 0x010

PXP_STAT_SET: 0x014

PXP_STAT_CLR: 0x018

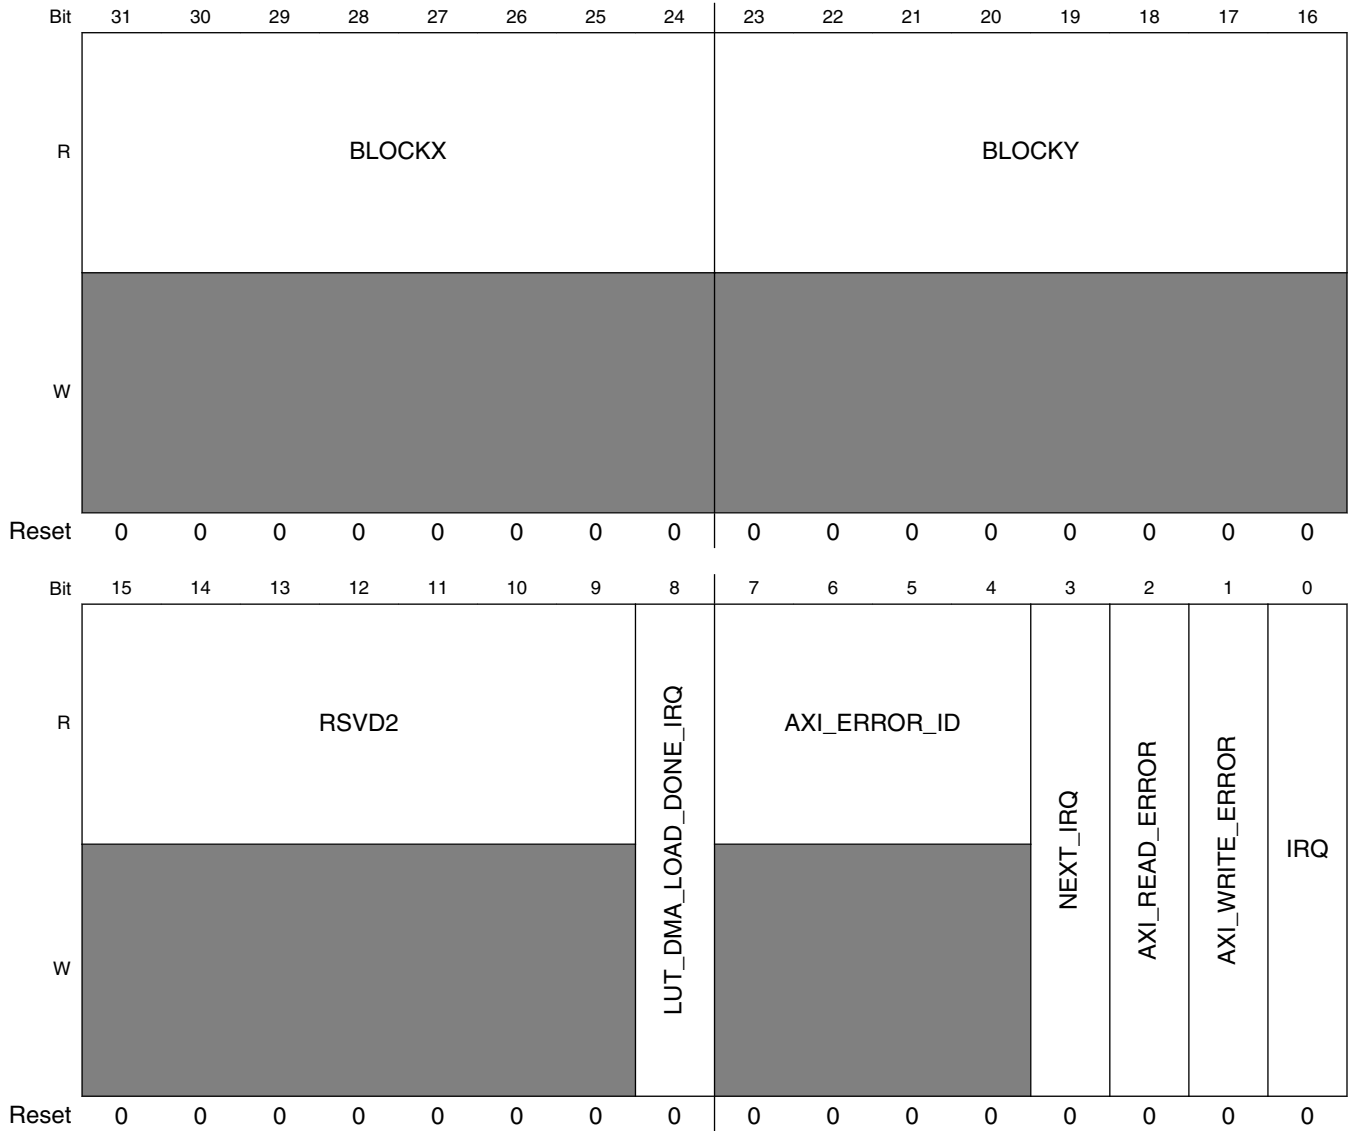

PXP_STAT_TOG: 0x01C

This register provides PXP interrupt status and the current X/Y block coordinate that is being processed.

EXAMPLE

```
PXP_STAT_CLR(BM_PXP_STAT_IRQ); // clear CSC interrupt
```

Address: 221_8000h base + 10h offset = 221_8010h

PXP_STAT field descriptions

Field	Description
31–24 BLOCKX	Indicates the X coordinate of the block currently being rendered.
23–16 BLOCKY	Indicates the X coordinate of the block currently being rendered.
15–9 RSVD2	Reserved, always set to zero.
8 LUT_DMA_LOAD_DONE_IRQ	Indicates that the LUT DMA transfer has completed.
7–4 AXI_ERROR_ID	Indicates the AXI ID of the failing bus operation.

Table continues on the next page...

PXP_STAT field descriptions (continued)

Field	Description
3 NEXT_IRQ	Indicates that a command issued with the "Next Command" functionality has been issued and that a new command may be initiated with a write to the PXP_NEXT register.
2 AXI_READ_ERROR	Indicates PXP encountered an AXI read error and processing has been terminated.
1 AXI_WRITE_ERROR	Indicates PXP encountered an AXI write error and processing has been terminated.
0 IRQ	Indicates current PXP interrupt status. The IRQ is routed through the pxp_irq when the IRQ_ENABLE bit in the control register is set.

50.7.3 Output Buffer Control Register (PXP_OUT_CTRL)

The OUT_CTRL register contains controls for the Output Buffer.

PXP_OUT_CTRL: 0x020

PXP_OUT_CTRL_SET: 0x024

PXP_OUT_CTRL_CLR: 0x028

PXP_OUT_CTRL_TOG: 0x02C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 221_8000h base + 20h offset = 221_8020h

PXP_OUT_CTRL field descriptions

Field	Description
31–24 ALPHA	When generating an output buffer with an alpha component, the value in this field will be used when enabled to override the alpha passed through the pixel data pipeline.
23 ALPHA_OUTPUT	Indicates that alpha component in output buffer pixels should be overwritten by PXP_OUT_CTRL[ALPHA]. If 0, retain their alpha value from the computed alpha for that pixel.
22–10 RSVD1	Reserved, always set to zero.
9–8 INTERLACED_OUTPUT	Determines how the PXP writes it's output data. Output interlacing should not be used in conjunction with input interlacing. Splitting frames into fields is most efficient using output interlacing. 2-plane output formats AND interlaced output is NOT supported. 0x0 PROGRESSIVE — All data written in progressive format to the OUTBUF Pointer. 0x1 FIELD0 — Interlaced output: only data for field 0 is written to the OUTBUF Pointer.

Table continues on the next page...

PXP_OUT_CTRL field descriptions (continued)

Field	Description
0x2	FIELD1 — Interlaced output: only data for field 1 is written to the OUTBUF2 Pointer.
0x3	INTERLACED — Interlaced output: data for field 0 is written to OUTBUF and data for field 1 is written to OUTBUF2.
7–5 RSVD0	Reserved, always set to zero.
FORMAT	Output framebuffer format. The UV byte lanes are synonymous with CbCr byte lanes for YUV output pixel formats. For example, the YUV2P420 format should be selected when the output is YCbCr 2-plane 420 output format.
0x0	ARGB8888 — 32-bit pixels
0x4	RGB888 — 32-bit pixels (unpacked 24-bit pixel in 32 bit DWORD.)
0x5	RGB888P — 24-bit pixels (packed 24-bit format)
0x8	ARGB1555 — 16-bit pixels
0x9	ARGB4444 — 16-bit pixels
0xC	RGB555 — 16-bit pixels
0xD	RGB444 — 16-bit pixels
0xE	RGB565 — 16-bit pixels
0x10	YUV1P444 — 32-bit pixels (1-plane XYUV unpacked)
0x12	UYVY1P422 — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes)
0x13	VYUY1P422 — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes)
0x14	Y8 — 8-bit monochrome pixels (1-plane Y luma output)
0x15	Y4 — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation)
0x18	YUV2P422 — 16-bit pixels (2-plane UV interleaved bytes)
0x19	YUV2P420 — 16-bit pixels (2-plane UV)
0x1A	YVU2P422 — 16-bit pixels (2-plane VU interleaved bytes)
0x1B	YVU2P420 — 16-bit pixels (2-plane VU)

50.7.4 Output Frame Buffer Pointer (PXP_OUT_BUF)

Output Framebuffer Pointer. This register points to the beginning of the output frame buffer. This pointer is used for progressive format and field 0 when generating interlaced output.

This register is used by the logic to point to the current output location for the output frame buffer.

EXAMPLE

```
PXP_OUT_BUF_WR( buffer );
```

Address: 221_8000h base + 30h offset = 221_8030h

PXP_OUT_BUF field descriptions

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

50.7.5 Output Frame Buffer Pointer #2 (PXP_OUT_BUF2)

Output Framebuffer Pointer #2. This register points to the beginning of the output frame buffer for either field 1 when generating interlaced output or for the UV buffer when in YUV 2-plane output modes. Both interlaced output AND 2-plane output modes are not supported in a single PXP operation. This register is not used as the pointer to the second buffer when in LCDIF_HANDSHAKE mode.

This register is used by the logic to point to the current output location for the field 1 or UV output frame buffer.

EXAMPLE

```
PXP_OUT_BUF_WR( field0 ); // buffer for interlaced field 0
PXP_OUT_BUF2_WR( field1 ); // buffer for interlaced field 1
```

Address: 221_8000h base + 40h offset = 221_8040h

**PXP_OUT_BUF2 field descriptions**

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

50.7.6 Output Buffer Pitch (PXP_OUT_PITCH)

This register contains the output buffer pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in output pixel address calculations.

EXAMPLE

PXP Memory Map/Register Definition

```
PXP_OUT_PITCH_WR( 68 * 4 ); // The output buffer pitch is 68 pixels times 32 bits per pixel
```

Address: 221_8000h base + 50h offset = 221_8050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	[Shaded]																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_OUT_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

50.7.7 Output Surface Lower Right Coordinate (PXP_OUT_LRC)

This register contains the size, or lower right coordinate, of the output buffer NOT rotated. It is implied that the upper left coordinate of the output surface is always [0,0]. When rotating the framebuffer, the PXP will automatically swap the X/Y, or WIDTH/HEIGHT, to accommodate the rotated size.

This register sets the size of the output frame buffer in pixels, not blocks. The frame buffer need not be a multiple of NxN pixels. Partial blocks will be written for output frame buffer sizes that are not divisible by N pixels in either dimension.

EXAMPLE

```
PXP_OUT_LRC[X]=319; // set width of output frame buffer to 320 pixels
PXP_OUT_LRC[Y]=243; // set height of output frame buffer to 244 pixels which is not
divisible by block size N
```

```
PXP_OUT_LRC_WR( BF_PXP_OUT_LRC_X(319) | BF_PXP_OUT_LRC_Y(243) );
```

Address: 221_8000h base + 60h offset = 221_8060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1								X							
W	[Shaded]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0								Y							
W	[Shaded]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_OUT_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	Indicates number of horizontal PIXELS in the output surface (non-rotated). The output buffer pixel width minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.
15–14 RSVD0	Reserved, always set to zero.
Y	Indicates the number of vertical PIXELS in the output surface (non-rotated). The output buffer pixel height minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.

50.7.8 Processed Surface Upper Left Coordinate (PXP_OUT_PS_ULC)

This register contains the upper left pixel coordinate for the Processed Surface in the OUTPUT buffer.

This register contains the upper left coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. If the value of the PXP_OUT_PS_ULC is greater than the PXP_OUT_LRC, then no PS pixels will be fetched from memory, but only PXP_PS_BACKGROUND pixels will be processed by the PS engine. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP_OUT_LRC extents will use the PS to render pixels into the output buffer.

EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x0002_0002); // Processed Surface upper left coordinate at (X,Y) = 2,2. The PS surface will not effect pixels in the first and second row and column of the output buffer.
```

Address: 221_8000h base + 70h offset = 221_8070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	RSVD0															
W			Y													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_OUT_PS_ULC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the processed surface (PS) in the output buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the processed surface in the output buffer.

50.7.9 Processed Surface Lower Right Coordinate (PXP_OUT_PS_LRC)

This register contains the lower right extent for the Processed Surface in the OUTPUT buffer.

This register contains the lower right coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP_OUT_LRC extents will use the PS to render pixels into the output buffer.

EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x03FF_03FF); // With this UL/LR pair of pixel coordinates, only one
pixel at OUT[X,Y]=1023,1023 will use the PS to contribute to its value.
PXP_OUT_PS_LRC_WR(0,0x03FF_03FF);
```

Address: 221_8000h base + 80h offset = 221_8080h

PXP_OUT_PS_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the processed surface (PS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the processed surface in the output frame buffer.

50.7.10 Alpha Surface Upper Left Coordinate (PXP_OUT_AS_ULC)

This register contains the upper left location for the Alpha Surface in the output buffer.

This register contains the upper left coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the upper left coordinates will use the AS to render pixels in the output buffer.

EXAMPLE

```
PXP_OUT_AS_ULC_WR(0,0x0001_0001); // Alpha Surface upper left coordinate at (X,Y) = 1,1.
The AS surface will not effect pixels in the first row or first column of the output buffer.
```

Address: 221_8000h base + 90h offset = 221_8090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	RSVD0															
W				Y												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_OUT_AS_ULC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.

Table continues on the next page...

PXP_OUT_AS_ULC field descriptions (continued)

Field	Description
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

50.7.11 Alpha Surface Lower Right Coordinate (PXP_OUT_AS_LRC)

This register contains the lower right extent for Alpha Surface in the output buffer.

This register contains the lower right coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are less than or equal to the lower right coordinates will use the AS to render pixels in the output buffer.

EXAMPLE

```
PXP_AS_LRC_WR(0,0x03FF_03FF); // Alpha Surface lower right coordinate at (X,Y) = 1023,1023.
```

Address: 221_8000h base + A0h offset = 221_80A0h

PXP_OUT_AS_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

50.7.12 Processed Surface (PS) Control Register (PXP_PS_CTRL)

The PS_CTRL register contains controls for the Processed Surface Buffer.

PXP_PS_CTRL: 0x0B0

PXP_PS_CTRL_SET: 0x0b4

PXP_PS_CTRL_CLR: 0x0B8

PXP_PS_CTRL_TOG: 0x0BC

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 221_8000h base + B0h offset = 221_80B0h

PXP_PS_CTRL field descriptions

Field	Description
31–12 RSVD1	Reserved, always set to zero.
11–10 DECX	Horizontal pre decimation filter control. 0x0 DISABLE — Disable pre-decimation filter. 0x1 DECX2 — Decimate PS by 2. 0x2 DECX4 — Decimate PS by 4. 0x3 DECX8 — Decimate PS by 8.
9–8 DECY	Verticle pre decimation filter control. 0x0 DISABLE — Disable pre-decimation filter. 0x1 DECY2 — Decimate PS by 2. 0x2 DECY4 — Decimate PS by 4. 0x3 DECY8 — Decimate PS by 8.
7–6 RSVD0	Reserved, always set to zero.
5 WB_SWAP	Swap bytes in words. For each 16 bit word, the two bytes will be swapped.
FORMAT	PS buffer format. To select between YUV and YCbCr formats, see bit 31 of the CSC1_COEF0 register. 0x4 RGB888 — 32-bit pixels (unpacked 24-bit format) 0xC RGB555 — 16-bit pixels 0xD RGB444 — 16-bit pixels 0xE RGB565 — 16-bit pixels 0x10 YUV1P444 — 32-bit pixels (1-plane XYUV unpacked) 0x12 UYVY1P422 — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 VYUY1P422 — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 Y8 — 8-bit monochrome pixels (1-plane Y luma output) 0x15 Y4 — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 YUV2P422 — 16-bit pixels (2-plane UV interleaved bytes) 0x19 YUV2P420 — 16-bit pixels (2-plane UV) 0x1A YVU2P422 — 16-bit pixels (2-plane VU interleaved bytes) 0x1B YVU2P420 — 16-bit pixels (2-plane VU) 0x1E YUV422 — 16-bit pixels (3-plane format) 0x1F YUV420 — 16-bit pixels (3-plane format)

50.7.13 PS Input Buffer Address (PXP_PS_BUF)

PS Input Buffer Address. This should be programmed to the starting address of the RGB data or Y (luma) data for the PS plane.

This register contains the pointer to the Luma/RGB buffer. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```

PXP_PS_BUF_WR(image_rgb); // RGB image
PXP_PS_BUF_WR(image_y);  // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data

```

Address: 221_8000h base + C0h offset = 221_80C0h

**PXP_PS_BUF field descriptions**

Field	Description
ADDR	Address pointer for the PS RGB or Y (luma) input buffer.

50.7.14 PS U/Cb or 2 Plane UV Input Buffer Address (PXP_PS_UBUF)

PS Chroma (U/Cb/UV) Input Buffer Address. This register points to the beginning of the PS U/Cb input buffer. In two plane operation, this register points to the beginning of the PS UV chroma input buffer.

This register contains the pointer to the Chroma U/Cb or 2 plane UV buffer. This register is unused when processing 1-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```

PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data

```

Address: 221_8000h base + D0h offset = 221_80D0h

**PXP_PS_UBUF field descriptions**

Field	Description
ADDR	Address pointer for the PS U/Cb or 2 plane UV Chroma input buffer.

50.7.15 PS V/Cr Input Buffer Address (PXP_PS_VBUF)

PS Chroma (V/Cr) Input Buffer Address. This register points to the beginning of the PS V/Cr input buffer. In one or two plane operation, this register is not used. In monochrome modes Y8 and Y4, the low 16 bits are used as the U/V data in the datapath instead of sourcing U/V data from external buffers. In this case, it represents a fixed value for U/V data.

This register contains the pointer to the Chroma V/Cr buffer. For Y8/Y4 modes, the low 16 bits are used as the monochrome U and V values in the data path. Bits [15:8] represent the U data byte, and bits [7:0] represent the V data byte. Other than with Y8/Y4 input buffer formats, this register is unused when processing 1 or 2-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```
PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 221_8000h base + E0h offset = 221_80E0h

PXP_PS_VBUF field descriptions

Field	Description
ADDR	Address pointer for the PS V/Cr Chroma input buffer.

50.7.16 Processed Surface Pitch (PXP_PS_PITCH)

This register contains the processed surface pitch in bytes.

Any byte value will indicate the vertical pitch of the PS source frame buffer. This value will be used in PS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input PS surface. For multi-plane formats, the Y buffer pitch should be programmed. For 2-plane YUV422, the UV pitch is the same as the Y pitch. For 3-plane YUV422, the U

and V pitch is 1/2 the Y pitch. For 2-plane YUV420, the UV pitch is 1/2 the Y pitch. For 3-plane YUV420, the U and V pitch is 1/4 the Y pitch. All source buffers should comply with these U and V resolution reductions with respect to their Y source buffers.

EXAMPLE

```
PXP_PS_PITCH_WR( 64 * 4 ); // The output buffer pitch is 64 pixels times 32 bits per pixel
```

Address: 221_8000h base + F0h offset = 221_80F0h

PXP_PS_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

50.7.17 PS Background Color (PXP_PS_BACKGROUND)

PS Background Pixel Color. This register provides a pixel value used when processing pixels outside of the region specified by the PS Coordinate registers. This value can effectively be used to set the color of the letterboxing region around the PS image.

This register contains a pixel value to be used for any PS pixels that fall outside the PS extents. This is effectively a background or letterbox color. The CSC1 control and datapath pixel format should be considered when selecting the background color.

EXAMPLE

```
PXP_PS_BACKGROUND_WR(0x00000000); // letterbox is black
PXP_PS_BACKGROUND_WR(0x00800000); // letterbox is dark red
PXP_PS_BACKGROUND_WR(0x00008000); // letterbox is dark green
PXP_PS_BACKGROUND_WR(0x00000080); // letterbox is dark blue
```

Address: 221_8000h base + 100h offset = 221_8100h

PXP_PS_BACKGROUND field descriptions

Field	Description
31-24 RSVD	Reserved, always set to zero.
COLOR	Background color (in 24bpp format) for any pixels not within the buffer range specified by the PS ULC/LRC.

50.7.18 PS Scale Factor Register (PXP_PS_SCALE)

PS Scale Factor. This register provides the scale factor for the PS buffer.

The maximum down scaling factor is 1/2 such that the output image in either axis is 1/2 the size of the source. The maximum up scaling factor is 2¹² for either axis. The reciprocal of the scale factor should be loaded into this register. To reduce the PS buffer by a factor of two in the output frame buffer, a value of 10.0000_0000_0000 should be loaded into this register. To scale up by a factor of 4, the value of 1/4, or 00.0100_0000_0000, should be loaded into this register. To scale up by 8/5, the value of 00.1010_0000_0000 should be loaded.

EXAMPLE

```
PXP_PS_SCALE_WR(0x10001000); // 1:1 scaling (0x1.000)
PXP_PS_SCALE_WR(0x08000800); // 2x scaling (0x0.800)
PXP_PS_SCALE_WR(0x20002000); // 1/2x scaling (0x2.000)
```

Address: 221_8000h base + 110h offset = 221_8110h

PXP_PS_SCALE field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 YSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the Y scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.
15 RSVD1	Reserved, always set to zero.
XSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the X scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.

50.7.19 PS Scale Offset Register (PXP_PS_OFFSET)

PS Scale Offset. This register provides the initial scale offset for the PS buffer.

The X and Y offset provides the ability to access the source image with a per sub-pixel granularity. This provides the capability to use all source pixels to effect the output PS image. The fixed offset values can be used for sub-pixel adjustments in the bilinear scaling filter. For example, when scaling an image down by a factor of 2, an initial offset of 0x0 would result in sub-sampling every other pixel. If a fixed offset of 0x800 (1/2), all pixels are used in scaling the final output pixel value. In this case, the first output pixel would be the sum of $(1/2 * P_0) + (1/2 * P_1)$. This fixed offset is applied after the decimation filter stage, and before the bilinear filter stage.

EXAMPLE

```
PXP_PS_SCALE_WR(0x2000_2000); // 1/2x scaling (0x2.000)
PXP_PS_OFFSET_WR(0x0800_0800); // half-pixel offset in both X and Y to ensure averaging
```

PXP Memory Map/Register Definition

versus pixel decimation

Address: 221_8000h base + 120h offset = 221_8120h

PXP_PS_OFFSET field descriptions

Field	Description
31–28 RSVD2	Reserved, always set to zero.
27–16 YOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the Y scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.
15–12 RSVD1	Reserved, always set to zero.
XOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the X scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.

50.7.20 PS Color Key Low (PXP_PS_CLRKEYLOW)

This register contains the color key low value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP_PS_CLRKEYLOW and PXP_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```

// colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green

```

Address: 221_8000h base + 130h offset = 221_8130h

PXP_PS_CLRKEYLOW field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFFFF and the high colorkey to 0x000000.

50.7.21 PS Color Key High (PXP_PS_CLRKEYHIGH)

This register contains the color key high value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP_PS_CLRKEYLOW and PXP_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```

// colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green

```

Address: 221_8000h base + 140h offset = 221_8140h

**PXP_PS_CLRKEYHIGH field descriptions**

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFFFF and the high colorkey to 0x000000.

50.7.22 Alpha Surface Control (PXP_AS_CTRL)

This register contains buffer control for the Alpha Surface 0 input buffer.

The Alpha Surface Parameter register provides additional controls for AS.

PXP Memory Map/Register Definition

EXAMPLE

```

u32 asparam;
    asparam = BF_PXP_ASPARAM_ENABLE (1);
    asparam |= BF_PXP_ASPARAM_ALPHA_CTRL (BV_PXP_ASPARAM_ALPHA_CTRL_ROPs);
    asparam |= BF_PXP_ASPARAM_FORMAT (BV_PXP_ASPARAM_FORMAT_ARGB8888);
    asparam |= BF_PXP_ASPARAM_ROP (BV_PXP_ASPARAM_ROP_XORAS);
PXP_ASPARAM_WR(0,asparam); // enable alpha surface to perform XOR ROP using RGB8888 AS
pixel format
    
```

Address: 221_8000h base + 150h offset = 221_8150h

PXP_AS_CTRL field descriptions

Field	Description
31-21 RSVD1	Reserved, always set to zero.

Table continues on the next page...

PXP_AS_CTRL field descriptions (continued)

Field	Description
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field. 0x0 MASKAS — AS AND PS 0x1 MASKNOTAS — nAS AND PS 0x2 MASKASNOT — AS AND nPS 0x3 MERGEAS — AS OR PS 0x4 MERGENOTAS — nAS OR PS 0x5 MERGEASNOT — AS OR nPS 0x6 NOTCOPYAS — nAS 0x7 NOT — nPS 0x8 NOTMASKAS — AS NAND PS 0x9 NOTMERGEAS — AS NOR PS 0xA XORAS — AS XOR PS 0xB NOTXORAS — AS XNOR PS
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in PXP_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS. 0x0 ARGB8888 — 32-bit pixels with alpha 0x4 RGB888 — 32-bit pixels without alpha (unpacked 24-bit format) 0x8 ARGB1555 — 16-bit pixels with alpha 0x9 ARGB4444 — 16-bit pixels with alpha 0xC RGB555 — 16-bit pixels without alpha 0xD RGB444 — 16-bit pixels without alpha 0xE RGB565 — 16-bit pixels without alpha
3 ENABLE_COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x0 Embedded — Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. 0x1 Override — Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x2 Multiply — Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. 0x3 ROPs — Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 RSVD0	Reserved, always set to zero.

50.7.23 Alpha Surface Buffer Pointer (PXP_AS_BUF)

Alpha Surface 0 Buffer Address Pointer. This register points to the beginning of the Alpha Surface 0 input buffer.

This register is used to indicate the base address of the AS buffer.

EXAMPLE

```
u32* alpha_ptr;
PXP_ASn_WR(0,alpha_ptr);
```

Address: 221_8000h base + 160h offset = 221_8160h

PXP_AS_BUF field descriptions

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

50.7.24 Alpha Surface Pitch (PXP_AS_PITCH)

This register contains the alpha surface pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in AS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input AS surface.

EXAMPLE

```
PXP_AS_PITCH_WR( 1920 * 4 ); // The output buffer pitch is HD resolution at 32 bits per pixel
```

Address: 221_8000h base + 170h offset = 221_8170h

PXP_AS_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

50.7.25 Overlay Color Key Low (PXP_AS_CLRKEYLOW)

This register contains the color key low value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```

// colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red

```

Address: 221_8000h base + 180h offset = 221_8180h

PXP_AS_CLRKEYLOW field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

50.7.26 Overlay Color Key High (PXP_AS_CLRKEYHIGH)

This register contains the color key high value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```

// colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red
    
```

Address: 221_8000h base + 190h offset = 221_8190h

PXP_AS_CLRKEYHIGH field descriptions

Field	Description
31-24 RSVD1	Reserved, always set to zero.
PIXEL	High range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

50.7.27 Color Space Conversion Coefficient Register 0 (PXP_CSC1_COEF0)

This register contains color space conversion coefficients in two's compliment notation.

The coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components.

EXAMPLE

```

// The equations used for Colorspace conversion are:
// R = C0*(Y+YOFFSET) + C1(V+UV_OFFSET)
// G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)
// R = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, Uvoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
    
```

Address: 221_8000h base + 1A0h offset = 221_81A0h

PXP_CSC1_COEF0 field descriptions

Field	Description
31 YCBCR_MODE	Set to 1 when performing YCbCr conversion to RGB. Set to 0 when converting RGB to YUV data. This bit changes the behavior of the scaler when performing U/V scaling.
30 BYPASS	Bypass the CSC unit in the scaling engine. When set to logic 1, bypass is enabled and the output pixels will be in the YUV/YCbCr color space. When set to logic 0, the CSC unit is enabled and the pixels will be converted based on the programmed coefficients.
29 RSVD1	Reserved, always set to zero.
28-18 C0	Two's compliment Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)
17-9 UV_OFFSET	Two's compliment phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)
Y_OFFSET	Two's compliment amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)

50.7.28 Color Space Conversion Coefficient Register 1 (PXP_CSC1_COEF1)

This register contains color space conversion coefficients in two's complement notation.

The Coefficient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's complement fixed point number with 8 bits right of the decimal.

EXAMPLE

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 221_8000h base + 1B0h offset = 221_81B0h

PXP_CSC1_COEF1 field descriptions

Field	Description
31-27 RSVD1	Reserved, always set to zero.
26-16 C1	Two's compliment Red V/Cr multiplier coefficient. YUV=0x123 (1.140) YCbCr=0x198 (1.596)
15-11 RSVD0	Reserved, always set to zero.
C4	Two's compliment Blue U/Cb multiplier coefficient. YUV=0x208 (2.032) YCbCr=0x204 (2.017)

50.7.29 Color Space Conversion Coefficient Register 2 (PXP_CSC1_COEF2)

This register contains color space conversion coefficients in two's complement notation.

The Coefficient 2 register contains coefficients used in the color space conversion algorithm. C2 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the green component. C3 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the green component. Both values should be coded as a two's complement fixed point number with 8 bits right of the decimal.

EXAMPLE

```
// NOTE: The default values for the CSCCOEF2 register are incorrect. C2 should be 0x76B and
C3 should be 0x79C for proper operation.
```

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UYoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 221_8000h base + 1C0h offset = 221_81C0h

PXP_CSC1_COEF2 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's complement Green V/Cr multiplier coefficient. YUV=0x76B (-0.581) YCbCr=0x730 (-0.813)
15–11 RSVD0	Reserved, always set to zero.
C3	Two's complement Green U/Cb multiplier coefficient. YUV=0x79C (-0.394) YCbCr=0x79C (-0.392)

50.7.30 Color Space Conversion Control Register. (PXP_CSC2_CTRL)

This register contains the control registers to configure the CSC module.

The CSC control register will configure the CSC module to perform color space conversion between the RGB/YUV/YCbCr color spaces.

EXAMPLE

```
//Converting from YUV/YCbCr color spaces to the RGB color space uses the
//following equation structure:
//
// R = A1(Y-D1) + A2(U-D2) + A3(V-D3)
```

PXP Memory Map/Register Definition

```

// G = B1(Y-D1) + B2(U-D2) + B3(V-D3)
// B = C1(Y-D1) + C2(U-D2) + C3(V-D3)
//
//Converting from the RGB color space to YUV/YCbCr color spaces uses the
//following equation structure:
//
// Y = A1*R + A2*G + A3*B + D1
// U = B1*R + B2*G + B3*B + D2
// V = C1*R + C2*G + C3*B + D3
//
//All math is signed, so all coefficients come in as two's comp numbers
//

```

Address: 221_8000h base + 1D0h offset = 221_81D0h

PXP_CSC2_CTRL field descriptions

Field	Description
31–3 RSVD	Reserved, always set to zero.
2–1 CSC_MODE	This field controls how the CSC unit operates on pixels when the CSC is not bypassed. 0x0 YUV2RGB — Convert from YUV to RGB. 0x1 YCbCr2RGB — Convert from YCbCr to RGB. 0x2 RGB2YUV — Convert from RGB to YUV. 0x3 RGB2YCbCr — Convert from RGB to YCbCr.
0 BYPASS	This bit controls whether the pixels entering the CSC2 unit get converted or not. When BYPASS is set, no operations occur on the pixels. When BYPASS is cleared, the selected CSC operation takes place.

50.7.31 Color Space Conversion Coefficient Register 0 (PXP_CSC2_COEF0)

This register contains color space conversion coefficients in two's complement notation.

Address: 221_8000h base + 1E0h offset = 221_81E0h

PXP_CSC2_COEF0 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 A2	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
A1	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

50.7.32 Color Space Conversion Coefficient Register 1 (PXP_CSC2_COEF1)

This register contains color space conversion coefficients in two's complement notation.

Address: 221_8000h base + 1F0h offset = 221_81F0h

PXP_CSC2_COEF1 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 B1	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
A3	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

50.7.33 Color Space Conversion Coefficient Register 2 (PXP_CSC2_COEF2)

This register contains color space conversion coefficients in two's complement notation.

Address: 221_8000h base + 200h offset = 221_8200h

PXP_CSC2_COEF2 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 B3	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
B2	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

50.7.34 Color Space Conversion Coefficient Register 3 (PXP_CSC2_COEF3)

This register contains color space conversion coefficients in two's complement notation.

Address: 221_8000h base + 210h offset = 221_8210h

PXP_CSC2_COEF3 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
C1	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

50.7.35 Color Space Conversion Coefficient Register 4 (PXP_CSC2_COEF4)

This register contains color space conversion coefficients in two's complement notation.

Address: 221_8000h base + 220h offset = 221_8220h

PXP_CSC2_COEF4 field descriptions

Field	Description
31–25 RSVD1	Reserved, always set to zero.
24–16 D1	Two's complement coefficient integer offset to be added.

Table continues on the next page...

PXP_CSC2_COEF4 field descriptions (continued)

Field	Description
15–11 RSVD0	Reserved, always set to zero.
C3	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

50.7.36 Color Space Conversion Coefficient Register 5 (PXP_CSC2_COEF5)

This register contains color space conversion coefficients in two's complement notation.

Address: 221_8000h base + 230h offset = 221_8230h

PXP_CSC2_COEF5 field descriptions

Field	Description
31–25 RSVD1	Reserved, always set to zero.
24–16 D3	Two's complement coefficient integer offset to be added.
15–9 RSVD0	Reserved, always set to zero.
D2	Two's complement D1 coefficient integer offset to be added.

50.7.37 Lookup Table Control Register. (PXP_LUT_CTRL)

This register is used to access/control the Monochrome Lookup table.

The Y8 LUT input mode will take the high order data path byte and transform it using the LUT memory. This is an 8-bit to 8-bit transformation. The two low order bytes bypass the LUT and are not transformed, but bypassed without modification. This option can be used for monochrome gamma correction. The Direct Lookup mode will use the high nibble of each data byte and truncate the low nibble to generate the lookup address, i.e.

R[7:0]G[7:0]B[7:0] -> R[7:4]G[7:4]B[7:4]. 4K pixels (12-bit address) with 2 bytes per pixel is supported in this mode. Cached Lookup mode will use the high order bits, R[7:3],G[7:2],B[7:3] or RGB565, to address the cached LUT memory. 64KB LUT tables, using 16KB of internal LUT memory, can be indirectly transformed to 16-bit output pixels (as in RGBW4444/RGB565). This is used for 16bpp gamma correction or EPD color panel support. Cache misses are internally managed by the PXP LUT Cache controller.

Address: 221_8000h base + 240h offset = 221_8240h

PXP_LUT_CTRL field descriptions

Field	Description
31 BYPASS	Setting this bit will bypass the LUT memory resource completely. No pixel transformations will occur at this stage of the PXP pixel processing pipeline.
30–26 RSVD3	Reserved, always set to zero.
25–24 LOOKUP_MODE	Configure the input address for the 16KB LUT memory. The address into the LUT uses different parts of the pixel data path bytes. The data path is

Table continues on the next page...

PXP_LUT_CTRL field descriptions (continued)

Field	Description
	<p>defined as three bytes, conceptually as RGB/YUV/YCbCr[23:0]. Also referred to as R/Y[7:0],G/U[7:0],B/V[7:0]</p> <p>0x0 CACHE_RGB565 — LUT ADDR = R[7:3],G[7:2],B[7:3]. Use all 16KB of LUT for indirect cached 128KB lookup.</p> <p>0x1 DIRECT_Y8 — LUT ADDR = 16'b0,Y[7:0]. Use only the first 256 bytes of LUT. Only the Y, or third data path byte, is transformed.</p> <p>0x2 DIRECT_RGB444 — LUT ADDR = R[7:4],G[7:4],B[7:4]. Use one 8KB bank of LUT selected by SEL_8KB.</p> <p>0x3 DIRECT_RGB454 — LUT ADDR = R[7:4],G[7:3],B[7:4]. Use all 16KB of LUT.</p>
23–18 RSVD2	Reserved, always set to zero.
17–16 OUT_MODE	<p>Select the output mode of operation for the LUT resource. There are four bytes [3-0] in the data path at the output of the LUT resource. Byte lane 3 is always bypassed and usually contains an alpha value. The LUT can be programmed to transform bytes 2,1,0 according to the options available in this field.</p> <p>0x0 RESERVED — Reserved, not valid when using the LUT to transform pixels.</p> <p>0x1 Y8 — R/Y byte lane 2 lookup, bytes 1,0 bypassed.</p> <p>0x2 RGBW4444CFA — Byte lane 2 = CFA_Y8, byte lane 1,0 = RGBW4444.</p> <p>0x3 RGB888 — RGB565->RGB888 conversion for Gamma correction.</p>
15–11 RSVD1	Reserved, always set to zero.
10 SEL_8KB	Selects which 8KB bank of memory to use for direct 12bpp lookup modes. Logic 0 indicates first 8KB, logic 1 indicates second 8KB. Two direct LUT arrays can be stored and one can be selected for a given PXP operation.
9 LRU_UPD	Least Recently Used Policy Update Control: 1=> block LRU update for hit after miss. 0=> update LRU for all hits including hit after miss.
8 INVALID	Invalidate the cache LRU and valid bits. This bit will automatically reset when set to a logic 1.
7–1 RSVD0	Reserved, always set to zero.
0 DMA_START	<p>Setting this bit will result in the DMA operation to load the PXP LUT memory based on PXP_LUT_ADDR_NUM_BYTES, PXP_LUT_ADDR_ADDR, and PXP_LUT_MEM_ADDR.</p> <p>This bit will automatically reset when set to a logic 1. Note: The LOOKUP_MODE must not be set to CACHE_RGB565 when starting and performing DMA transfers.</p>

50.7.38 Lookup Table Control Register. (PXP_LUT_ADDR)

This register is used to access/control the Monochrome Lookup table.

The Y8 LUT input mode will take the high order data path byte and transform it using the LUT memory. This is an 8-bit to 8-bit transformation. The two low order bytes bypass the LUT and are not transformed, but bypassed without modification. This option can be used for monochrome gamma correction. The Direct Lookup mode will use the high nibble of each data byte and truncate the low nibble to generate the lookup address, i.e. R[7:0]G[7:0]B[7:0] -> R[7:4]G[7:4]B[7:4]. 4K pixels (12-bit address) with 2 bytes per pixel is supported in this mode. Cached Lookup mode will use the high order bits, R[7:3],G[7:2],B[7:3] or RGB565, to address the cached LUT memory. 64KB LUT tables, using 16KB of internal LUT memory, can be indirectly transformed to 16-bit output pixels (as in RGBW4444/RGB565). This is used for 16bpp gamma correction or EPD color panel support. Cache misses are internally managed by the PXP LUT Cache controller.

Address: 221_8000h base + 250h offset = 221_8250h

PXP_LUT_ADDR field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 NUM_BYTES	Indicates the number of bytes to load via a DMA operation. This field must be divisible by 8 and the least significant 3 bits must be 0. The value 8 indicates load 8 bytes from the external address indicated by PXP_LUT_MEM_ADDR to the LUT memory location indicated by PXP_LUT_CTRL_ADDR.
15–14 RSVD1	Reserved, always set to zero.

Table continues on the next page...

PXP_LUT_ADDR field descriptions (continued)

Field	Description
ADDR	<p>LUT indexed address pointer. This address into the LUT memory is always four byte aligned for PIO access, and eight byte aligned for DMA access.</p> <p>The least two significant bits are not used to drive the LUT memory array. For PIO LUT access, when the LUT data register is written, the contents of the LUT at the address specified by this address field will be loaded with a 32-bit DWORD. This address pointer will be incremented after the LUT data is written. This will provide recursive writes to the LUT data register to initialize the entire LUT array with recursive writes to the LUT data register. For DMA access, this register indicates the LUT memory address of the 8 byte QWORD to be loaded. When using the NUM_BYTES field to load more than 8 bytes, the register should be programmed with the first LUT memory location to be filled and each load of the LUT memory will increment this address field until NUM_BYTES has been loaded.</p>

50.7.39 Lookup Table Data Register. (PXP_LUT_DATA)

This register is used to load data into the lookup table.

Address: 221_8000h base + 260h offset = 221_8260h

PXP_LUT_DATA field descriptions

Field	Description
DATA	Writing this field will load 4 bytes, aligned to four byte boundaries, of data indexed by the ADDR field of the PXP_LUT_CTRL register.

50.7.40 Lookup Table External Memory Address Register. (PXP_LUT_EXTMEM)

For DMA LUT memory loads, this is the base address from which data will be sourced to store into the LUT memory array. For Cached LUT memory pixel transformations, this register will store the base address of the full 64K pixel LUT translation table.

Address: 221_8000h base + 270h offset = 221_8270h

PXP_LUT_EXTMEM field descriptions

Field	Description
ADDR	This register contains the external memory address used for LUT memory operation. For DMA LUT memory loads, this is the base address from which data will be sourced to store into the LUT memory array. For Cached LUT memory pixel transformations, this register will store the base address of the full 64K pixel LUT translation table.

50.7.41 Color Filter Array Register. (PXP_CFA)

There are sixteen 2 bit values in this register each mapping a selected component to the output pixel. The two bit values are defined as 0=>R, 1=>G, 2=>B, and 3=>W. The first byte represents the repetitive pattern of RGBW pixels in the CFA for the first line segment of each processed PXP block. The second byte represents the pattern in the second line segment of the block, and so on. The first byte repeats two times for 8x8 macro block mode, and repeats four times for 16x16 block mode.

Address: 221_8000h base + 280h offset = 221_8280h

PXP_CFA field descriptions

Field	Description
DATA	This register contains the Color Filter Array pattern for decimation of RGBW4444 16 bit pixels to individual R, G, B, W values. The pattern represents a replicated 4x4 color filter array for the entire output frame buffer.

50.7.42 Histogram Control Register. (PXP_HIST_CTRL)

Provides control and status registers for the PXP's histogram classification algorithm.

Address: 221_8000h base + 290h offset = 221_8290h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD															
W	[Shaded]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD										PANEL_MODE		STATUS			
W	[Shaded]										[Shaded]		[Shaded]			
Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

PXP_HIST_CTRL field descriptions

Field	Description
31–6 RSVD	Reserved, always set to zero.
5–4 PANEL_MODE	<p>This value is used to specify the number of bits used in comparisons when matching pixels to histogram bins.</p> <p>All comparator values MUST be programmed such that their bit width is consistent with the value of this register field.</p> <p>For instance, if GRAY16 is selected, comparator values must be in the range of 0x0-0xF.</p> <p>0x0 GRAY4 — 4-bit grayscale 0x1 GRAY8 — 8-bit grayscale 0x2 GRAY16 — 16-bit grayscale 0x3 GRAY32 — 32-bit grayscale</p>
STATUS	<p>Indicates which histogram matched the processed bitmap.</p> <p>Bit[0] indicates that the bitmap pixels were fully contained within the HIST2 (black / white) histogram.</p> <p>Bit[1] indicates that the bitmap pixels were fully contained within the HIST4 (2-bit grayscale) histogram.</p> <p>Bit[2] indicates that the bitmap pixels were fully contained within the HIST8 (3-bit grayscale) histogram.</p> <p>Bit[3] indicates that the bitmap pixels were fully contained within the HIST16 (4-bit grayscale) histogram.</p>

50.7.43 2-level Histogram Parameter Register. (PXP_HIST2_PARAM)

This register specifies the valid values for a 2-level histogram. If all pixels in a bitmap match the 2-level histogram values, STATUS[0] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 2A0h offset = 221_82A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD																RSVD1			VALUE1				RSVD0			VALUE0					
W	[Shaded]																[Shaded]			[Shaded]				[Shaded]			[Shaded]					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0

PXP_HIST2_PARAM field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	White value for 2-level histogram
7–5 RSVD0	Reserved, always set to zero.
VALUE0	Black value for 2-level histogram

50.7.44 4-level Histogram Parameter Register. (PXP_HIST4_PARAM)

This register specifies the valid values for a 4-level histogram. If all pixels in a bitmap match the 4-level histogram values, STATUS[1] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 2B0h offset = 221_82B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
R	RSVD3				VALUE3								RSVD2				VALUE2								RSVD1				VALUE1				RSVD0				VALUE0			
W	[Shaded]				[Shaded]								[Shaded]				[Shaded]								[Shaded]				[Shaded]											
Reset	0	0	0	0	1	1	1	1	0	0	0	0	1	0	1	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0							

PXP_HIST4_PARAM field descriptions

Field	Description
31–29 RSVD3	Reserved, always set to zero.
28–24 VALUE3	GRAY3 (White) value for 4-level histogram
23–21 RSVD2	Reserved, always set to zero.
20–16 VALUE2	GRAY2 value for 4-level histogram
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	GRAY1 value for 4-level histogram
7–5 RSVD0	Reserved, always set to zero.
VALUE0	GRAY0 (Black) value for 4-level histogram

**50.7.45 8-level Histogram Parameter 0 Register.
(PXP_HIST8_PARAM0)**

This register specifies four of the valid values for an 8-level histogram. If all pixels in a bitmap match the 8-level histogram values, STATUS[2] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 2C0h offset = 221_82C0h

PXP_HIST8_PARAM0 field descriptions

Field	Description
31–29 RSVD3	Reserved, always set to zero.
28–24 VALUE3	GRAY3 value for 8-level histogram

Table continues on the next page...

PXP_HIST8_PARAM0 field descriptions (continued)

Field	Description
23–21 RSVD2	Reserved, always set to zero.
20–16 VALUE2	GRAY2 value for 8-level histogram
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	GRAY1 value for 8-level histogram
7–5 RSVD0	Reserved, always set to zero.
VALUE0	GRAY0 (Black) value for 8-level histogram

**50.7.46 8-level Histogram Parameter 1 Register.
(PXP_HIST8_PARAM1)**

This register specifies four of the valid values for an 8-level histogram. If all pixels in a bitmap match the 8-level histogram values, STATUS[2] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 2D0h offset = 221_82D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HIST8_PARAM1 field descriptions

Field	Description
31–29 RSVD7	Reserved, always set to zero.
28–24 VALUE7	GRAY7 (White) value for 8-level histogram
23–21 RSVD6	Reserved, always set to zero.
20–16 VALUE6	GRAY6 value for 8-level histogram

Table continues on the next page...

PXP_HIST8_PARAM1 field descriptions (continued)

Field	Description
15–13 RSVD5	Reserved, always set to zero.
12–8 VALUE5	GRAY5 value for 8-level histogram
7–5 RSVD4	Reserved, always set to zero.
VALUE4	GRAY4 value for 8-level histogram

**50.7.47 16-level Histogram Parameter 0 Register.
(PXP_HIST16_PARAM0)**

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match the 16-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 2E0h offset = 221_82E0h

PXP_HIST16_PARAM0 field descriptions

Field	Description
31–29 RSVD3	Reserved, always set to zero.
28–24 VALUE3	GRAY3 value for 16-level histogram
23–21 RSVD2	Reserved, always set to zero.
20–16 VALUE2	GRAY2 value for 16-level histogram
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	GRAY1 value for 16-level histogram

Table continues on the next page...

PXP_HIST16_PARAM0 field descriptions (continued)

Field	Description
7–5 RSVD0	Reserved, always set to zero.
VALUE0	GRAY0 (Black) value for 16-level histogram

50.7.48 16-level Histogram Parameter 1 Register. (PXP_HIST16_PARAM1)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match the 16-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 2F0h offset = 221_82F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HIST16_PARAM1 field descriptions

Field	Description
31–29 RSVD7	Reserved, always set to zero.
28–24 VALUE7	GRAY7 value for 16-level histogram
23–21 RSVD6	Reserved, always set to zero.
20–16 VALUE6	GRAY6 value for 16-level histogram
15–13 RSVD5	Reserved, always set to zero.
12–8 VALUE5	GRAY5 value for 16-level histogram
7–5 RSVD4	Reserved, always set to zero.
VALUE4	GRAY4 value for 16-level histogram

50.7.49 16-level Histogram Parameter 2 Register. (PXP_HIST16_PARAM2)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match the 16-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 300h offset = 221_8300h

PXP_HIST16_PARAM2 field descriptions

Field	Description
31–29 RSVD11	Reserved, always set to zero.
28–24 VALUE11	GRAY11 value for 16-level histogram
23–21 RSVD10	Reserved, always set to zero.
20–16 VALUE10	GRAY10 value for 16-level histogram
15–13 RSVD9	Reserved, always set to zero.
12–8 VALUE9	GRAY9 value for 16-level histogram
7–5 RSVD8	Reserved, always set to zero.
VALUE8	GRAY8 value for 16-level histogram

50.7.50 16-level Histogram Parameter 3 Register. (PXP_HIST16_PARAM3)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match the 16-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 221_8000h base + 310h offset = 221_8310h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HIST16_PARAM3 field descriptions

Field	Description
31–29 RSVD15	Reserved, always set to zero.
28–24 VALUE15	GRAY15 (White) value for 16-level histogram
23–21 RSVD14	Reserved, always set to zero.
20–16 VALUE14	GRAY14 value for 16-level histogram
15–13 RSVD13	Reserved, always set to zero.
12–8 VALUE13	GRAY13 value for 16-level histogram
7–5 RSVD12	Reserved, always set to zero.
VALUE12	GRAY12 value for 16-level histogram

50.7.51 PXP Power Control Register. (PXP_POWER)

PXP Memory Map/Register Definition

Address: 221_8000h base + 320h offset = 221_8320h

PXP_POWER field descriptions

Field	Description
31–12 CTRL	This register contains power control for the PXP.
11–9 ROT_MEM_LP_STATE	Select the low power state of the ROT memory. 0x0 NONE — Memory is not in low power state. 0x1 LS — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 DS — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 SD — Shut Down Mode. Shut Down periphery and core, no memory retention.
8–6 LUT_LP_STATE_WAY1_BANKN	Select the low power state of the LUT's WAY0-BANK0,1,2,3 memory. 0x0 NONE — Memory is not in low power state. 0x1 LS — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 DS — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 SD — Shut Down Mode. Shut Down periphery and core, no memory retention.
5–3 LUT_LP_STATE_WAY0_BANKN	Select the low power state of the LUT's WAY0-BANK1,2,3 memory. 0x0 NONE — Memory is not in low power state. 0x1 LS — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 DS — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 SD — Shut Down Mode. Shut Down periphery and core, no memory retention.
LUT_LP_STATE_WAY0_BANK0	Select the low power state of the LUT's WAY0-BANK0 memory. 0x0 NONE — Memory is not in low power state. 0x1 LS — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 DS — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 SD — Shut Down Mode. Shut Down periphery and core, no memory retention.

50.7.52 Next Frame Pointer (PXP_NEXT)

This register contains a pointer to a data structure used to reload the PXP registers at the end of the current frame.

To enable this functionality, software must write this register while the PXP is processing the current data frame (if the PXP is currently idle, this will also initiate an immediate load of registers from the pointer). The process of writing this register (WRITE operation) will set a semaphore in hardware to notify the control logic that a register reload operation must be performed when the current frame processing is complete. At

the end of a frame, the PXP will fetch the register settings from this location, signal an interrupt to software, then proceed with rendering the next frame of data. Software may cancel the reload operation by issuing a CLEAR operation to this register. SET and TOGGLE operations should not be used when addressing this register. All registers will be reloaded with the exception of the following: STAT, CSCCOEFn, NEXT. All other registers will be loaded in the order they appear in the register map. Once the pointer's contents have been loaded into the PXP's registers, the NEXT_IRQ interrupt will be issued (see the PXP_STATUS register).

EXAMPLE

```
// create register command structure in memory
u32* pxp_commands0[48], pxp_commands1;
u32 rc;

// initialize control structure for frame 0
pxp_commands0[0] = ...; // CTRL
pxp_commands0[1] = ...; // OUT Buffer
...
pxp_commands0[47] = ..; // Overlay7 param2

// initialize control structure for frame 1
pxp_commands1[0] = ...; // CTRL
pxp_commands1[1] = ...; // OUT Buffer
...
pxp_commands1[47] = ..; // Overlay7 param2

// poll until a command isn't queued
while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
PXP_NEXT_WR(pxp_commands0); // enable PXP operation 0 via command pointer

// poll until first command clears
while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
PXP_NEXT_WR(pxp_commands1); // enable PXP operation 1 via command pointer
```

Address: 221_8000h base + 400h offset = 221_8400h

PXP Memory Map/Register Definition

PXP_NEXT field descriptions

Field	Description
31–2 POINTER	A pointer to a data structure containing register values to be used when processing the next frame. The pointer must be 32-bit aligned and should reside in on-chip or off-chip memory.
1 RSVD	Reserved, always set to zero.
0 ENABLED	Indicates that the "next frame" functionality has been enabled. This bit reflects the status of the hardware semaphore indicating that a reload operation is pending at the end of the current frame.

Chapter 51

Quad Serial Peripheral Interface (QuadSPI)

51.1 Overview

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one or two external serial flash devices, each with up to four bidirectional data lines. The following figure is a block diagram of the QuadSPI module.

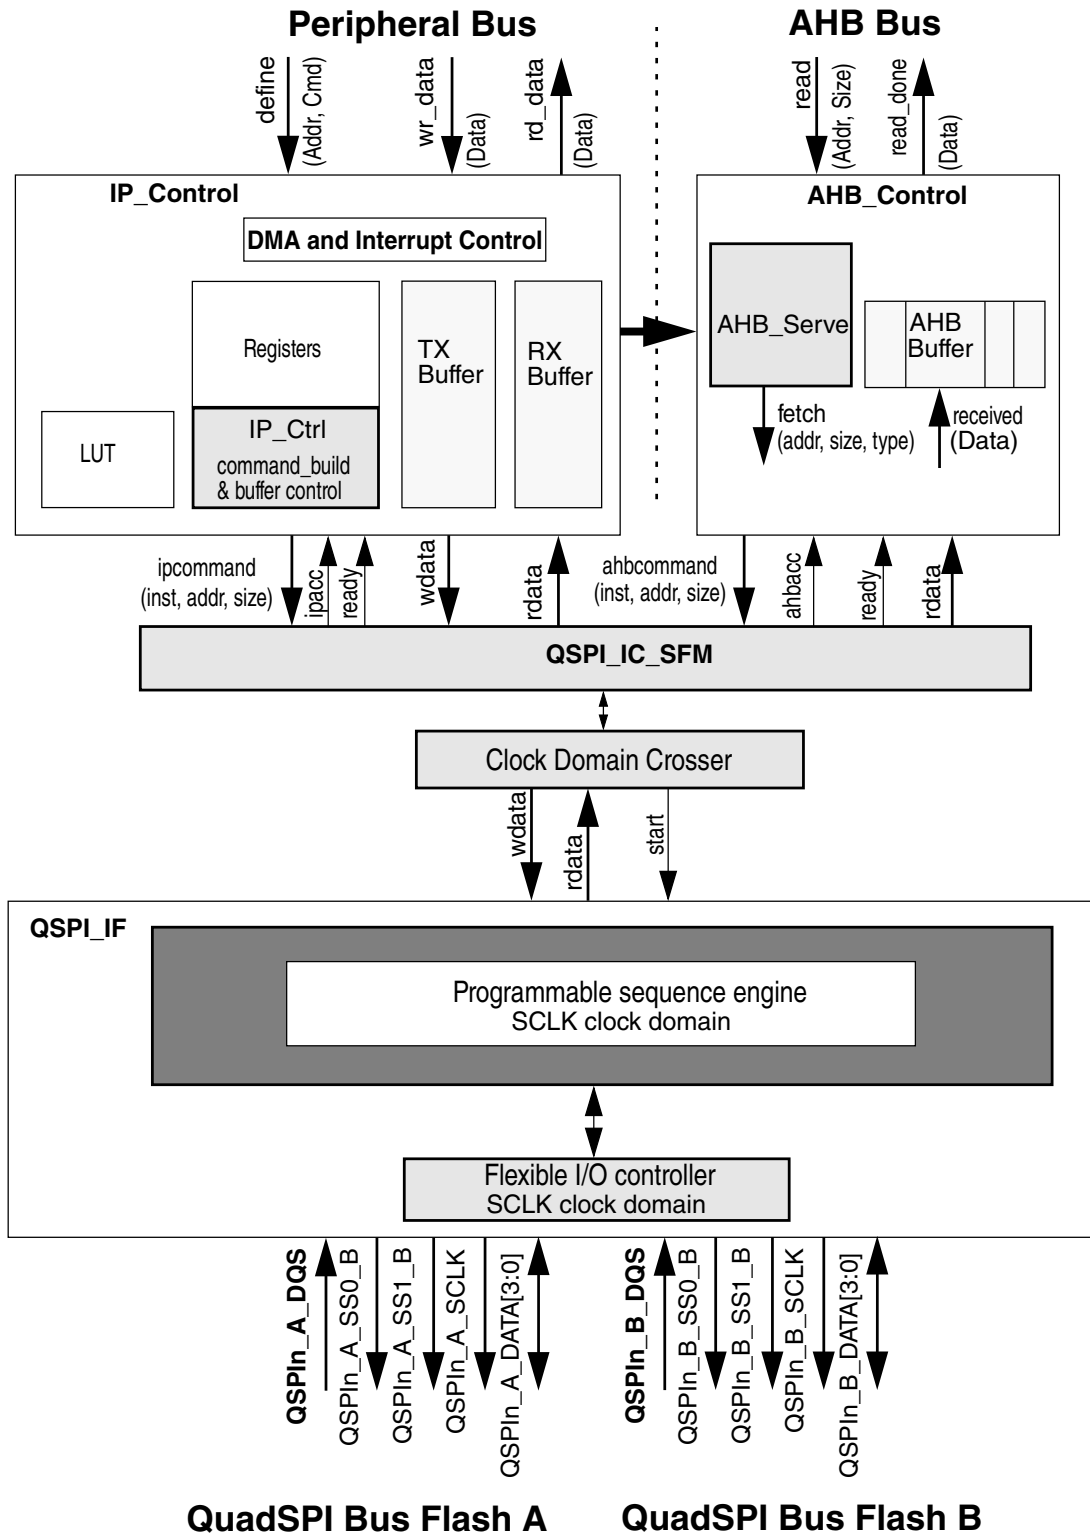

Figure 51-1. QuadSPI Block Diagram

The following figure describes the serial flash clock diagram in QuadSPI:

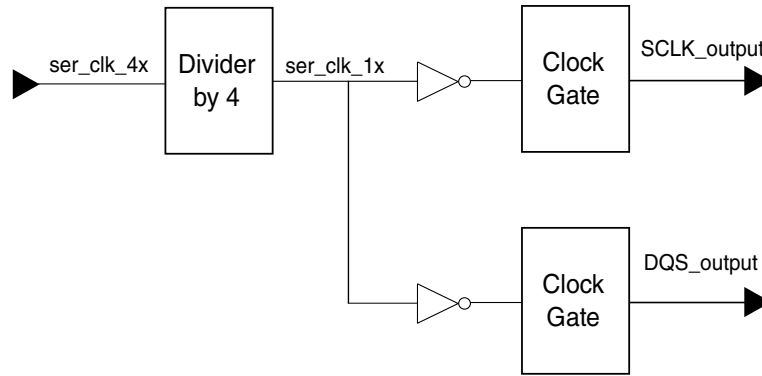

Figure 51-2. Flash Clock Diagram

ser_clk_4x is the serial clock root from CCM

ser_clk_1x' is generated clock from 'ser_clk_4x' divided by 4

SCLK_output is serial output clock generated from 'ser_clk_1x' with inverter and clock gate, it's used as Clock by external serial flash device.

DQS_output is serial flash data strobe signal generated from 'ser_clk_1x' with inverter and clock gate. This signal could be loopback from pad and used as sampling clock for serial flash data.

51.1.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices.
- Single, dual, quad mode of operation.
- DDR/DTR mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and SDR mode.
- Two identical serial flash devices can be connected and accessed in parallel for data read operations, forming one (virtual) flash memory with doubled readout bandwidth.
- DMA support to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access).
 - Inner loop size of DMA access can be configured.
- Multi master accesses with priority

- Flexible and configurable buffer for each master
- Thirteen interrupt conditions (see [Table 51-10](#))
- Memory mapped read access to connected flash devices.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations.
 - Supports 3-byte and 4-byte addressing.
 - TXFIFO size is 512Byte
 - RXFIFO size is 128Byte
 - AHB BUF size is 1KByte

51.1.2 QuadSPI Modes of Operation

This section provides information about the modes in which the QuadSPI module can be used.

51.1.2.1 Normal Mode

In this mode one or two external serial flash memory device can be accessed. Further details about this mode of operation can be found in [Modes of Operation\(Normal Mode\)](#) section.

51.1.2.2 Module Disable Mode

The Module Disable Mode is used for power management of the device containing the QuadSPI module, it is controlled by signals external to the QuadSPI. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in the Module Disable Mode.

51.1.3 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 51-1. Acronyms and Abbreviations

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select.
DMA	Direct Memory Access.
MB	Megabyte. Each MB is 1024 * 1024 bytes
IFM	Individual Flash Mode
PFM	Parallel Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a '1' to this field resets the flag

51.1.4 Glossary for QuadSPI module

Table 51-2. Glossary

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in Table 51-7 . Refer to AHB Commands for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level '0' to logic level '1' when negated, and an active high signal changes from logic level '1' to logic level '0'.

Table continues on the next page...

Table 51-2. Glossary (continued)

Term	Definition
QSPI_AMBA_BASE	First address of QuadSPI address space on system memory map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
RX Buffer PUSH Event	Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added. The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to Serial Flash Access Schemes for details.
Parallel Flash Mode	Read access to two serial flash devices attached to the QuadSPI module in parallel. Refer to Serial Flash Access Schemes for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to Table 51-20 for details on errors.
Single/Dual/Quad Instructions	Depending from the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines. <ul style="list-style-type: none"> • Single: Single line I/O with one data out and one data in line to/from the serial flash device. • Dual: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module • Quad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode-and/or dummy bytes, transmit and/or receive data.
LUT	Look-up-table.

51.2 External Signals

The following table describes the external signals of QSPI:

Table 51-3. QSPI External Signals

Signal	Description	Pad	Mode	Direction
QSPI1_A_DATA0	I/O data signal 1 port 0 for serial flash device A	QSPI1A_DATA0	ALT0	I/O
QSPI1_A_DATA1	I/O data signal 1 port 1 for serial flash device A	QSPI1A_DATA1	ALT0	I/O
QSPI1_A_DATA2	I/O data signal 1 port 2 for serial flash device A	QSPI1A_DATA2	ALT0	I/O

Table continues on the next page...

**Table 51-3. QSPI External Signals
(continued)**

Signal	Description	Pad	Mode	Direction
QSPI1_A_DATA3	I/O data signal 1 port 3 for serial flash device A	QSPI1A_DATA3	ALT0	I/O
QSPI1_A_SS0_B	Chip select 1 port 0 for serial flash device A	QSPI1A_SS0_B	ALT0	O
QSPI1_A_SS1_B	Chip select 1 port 1 for serial flash device A	QSPI1A_SS1_B	ALT0	O
QSPI1_A_DQS	Data strobe signal 1 to serial flash device A	QSPI1A_DQS	ALT0	I
QSPI1_A_SCLK	Serial clock output 1 to serial flash device A	QSPI1A_SCLK	ALT0	O
QSPI1_B_DATA0	I/O data signal 1 port 0 for serial flash device B	QSPI1B_DATA0	ALT0	I/O
QSPI1_B_DATA1	I/O data signal 1 port 1 for serial flash device B	QSPI1B_DATA1	ALT0	I/O
QSPI1_B_DATA2	I/O data signal 1 port 2 for serial flash device B	QSPI1B_DATA2	ALT0	I/O
QSPI1_B_DATA3	I/O data signal 1 port 3 for serial flash device B	QSPI1B_DATA3	ALT0	I/O
QSPI1_B_SS0_B	Chip select 1 port 0 for serial flash device B	QSPI1B_SS0_B	ALT0	O
QSPI1_B_SS1_B	Chip select 1 port 1 for serial flash device B	QSPI1B_SS1_B	ALT0	O
QSPI1_B_DQS	Data strobe signal 1 to serial flash device B	QSPI1B_DQS	ALT0	I
QSPI1_B_SCLK	Serial clock output 1 to serial flash device B	QSPI1B_SCLK	ALT0	O
QSPI2_A_DATA0	I/O data signal 2 port 0 for serial flash device A	NAND_WP_B	ALT2	I/O
QSPI2_A_DATA1	I/O data signal 2 port 1 for serial flash device A	NAND_READY_B	ALT2	I/O
QSPI2_A_DATA2	I/O data signal 2 port 2 for serial flash device A	NAND_CE0_B	ALT2	I/O
QSPI2_A_DATA3	I/O data signal 2 port 3 for serial flash device A	NAND_CE1_B	ALT2	I/O
QSPI2_A_SS0_B	Chip select 2 port 0 for serial flash device A	NAND_ALE	ALT2	O
QSPI2_A_SS1_B	Chip select 2 port 1 for serial flash device A	NAND_DATA06	ALT2	O
QSPI2_A_DQS	Data strobe signal 2 to serial flash device A	NAND_DATA07	ALT2	I
QSPI2_A_SCLK	Serial clock output 2 to serial flash device A	NAND_CLE	ALT2	O
QSPI2_B_DATA0	I/O data signal 2 port 0 for serial flash device B	NAND_DATA01	ALT2	I/O

Table continues on the next page...

**Table 51-3. QSPI External Signals
(continued)**

Signal	Description	Pad	Mode	Direction
QSPI2_B_DATA1	I/O data signal 2 port 1 for serial flash device B	NAND_DATA00	ALT2	I/O
QSPI2_B_DATA2	I/O data signal 2 port 2 for serial flash device B	NAND_WE_B	ALT2	I/O
QSPI2_B_DATA3	I/O data signal 2 port 3 for serial flash device B	NAND_RE_B	ALT2	I/O
QSPI2_B_SS0_B	Chip select 2 port 0 for serial flash device B	NAND_DATA03	ALT2	O
QSPI2_B_SS1_B	Chip select 2 port 0 for serial flash device B	NAND_DATA04	ALT2	O
QSPI2_B_DQS	Data strobe signal 2 to serial flash device B	NAND_DATA05	ALT2	I
QSPI2_B_SCLK	Serial clock output 2 to serial flash device B	NAND_DATA02	ALT2	O

51.2.1 Driving External Signals

The different phases of serial flash access scheme are shown in the following figure.

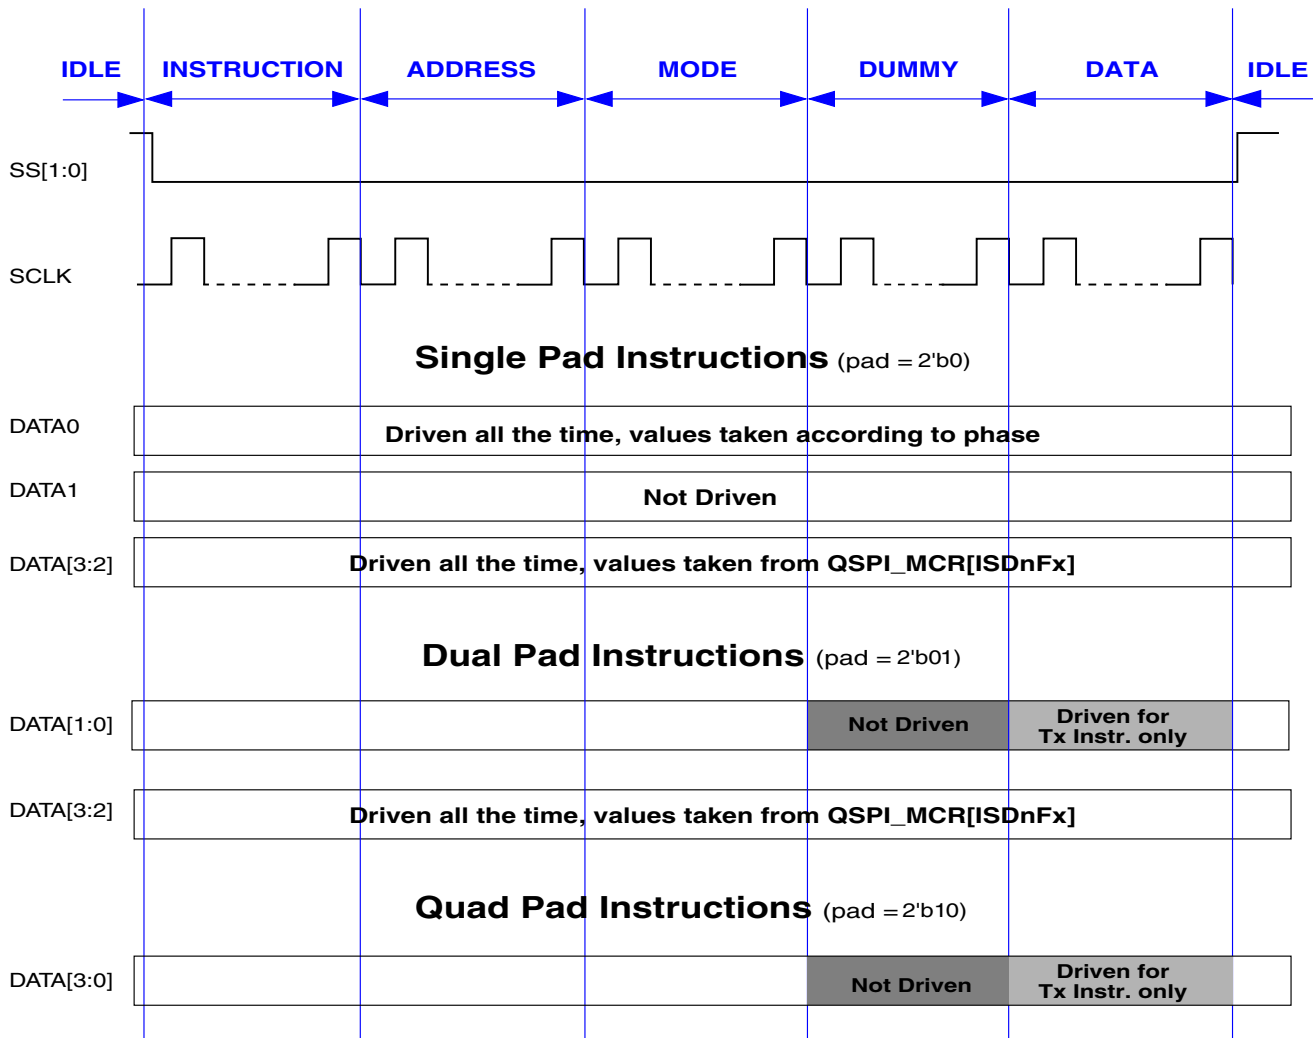

Figure 51-3. Serial Flash Access Scheme

The different phases and the I/O driving characteristics of the QuadSPI module are characterized in the following way:

- **IDLE:** Serial flash device not selected. No interaction with the serial flash device. All DATA signals driven.
- **INSTRUCTION:** Serial flash device selected. The instruction is sent to the serial flash device. All DATA signals are driven.
- **ADDRESS:** Serial Flash Address is sent to the device. All DATA signals are driven. Note that this phase is not applicable for all SFM Commands.
- **MODE:** Mode bytes are sent to the serial flash device. All DATA signals are driven. Note that this phase is not applicable for all SFM Commands.

- **DUMMY:** Dummy clocks are provided to the serial flash device. Refer to the [Figure 51-3](#) for the DATA signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.
- **DATA:** Serial flash data are sent to or received from the serial flash device. Refer to the preceding figure for the DATA signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.

The SS[1:0] and SCLK signals are driven permanently throughout all the phases.

In Individual Flash Mode this applies to the selected flash device. In Parallel Flash Mode this applies to both serial flash devices simultaneously.

51.3 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

51.3.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 51-4. Register Write Access Restrictions

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if $QSPI_MCR[MDIS] = 1$.

Table continues on the next page...

**Table 51-4. Register Write Access Restrictions
(continued)**

Condition	Description
Normal Mode	Write access only if the module is in <i>Normal Mode</i> .

• Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

51.3.2 Serial Flash Address Assignment

The serial flash address assignment may be modified by writing into [SFA1AD](#) and [SFA2AD](#) for device A and into [SFB1AD](#) and [SFB2AD](#) for device B. The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

Table 51-5. Serial Flash Address Assignment

Parameter	Function	Access Mode
QSPI_AMBA_BASE (31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(T PADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to Serial Flash A1
TOP_ADDR_MEMA2(T PADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to Serial Flash A2
TOP_ADDR_MEMB1(T PADB1)	Top address for the external flash B1 (first device of the dual die flash B, or the first of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 will be routed to Serial Flash B1
TOP_ADDR_MEMB2(T PADB2)	Top address for the external flash B2 (second device of the dual die flash B or the second of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 will be routed to Serial Flash A2

51.3.3 AMBA Bus Register Memory Map

QSPI_AMBA_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map..

Table 51-6. QuadSPI AMBA Bus Memory Map

Address	Register Name
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A	
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A for details and to Table 51-14 and Table 51-18 for information about the byte ordering.
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B	
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B for details and to Table 51-14 and Table 51-18 for information about the byte ordering.
Parallel Flash Mode	
QSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 0x01)	Parallel Flash Mode Refer to Parallel Flash Mode for details and to Table 51-17 and Table 51-18 for information about the byte ordering.
AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)	
QSPI_ARDB_BASE to... (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) Refer to Table 51-14 and Table 51-16 for information about the byte ordering.

Note

Any read access to non-implemented addresses will provide undefined results.

In case single die flash devices, TOP_ADDR_MEMA2 and TOP_ADDR_MEMB2 should be initialized/programmed to TOP_ADDR_MEMA1 and TOP_ADDR_MEMB1 respectively- in effect, setting the size of these devices to 0. This would ensure that the complete memory map is assigned to only one flash device.

Parallel Flash Mode is valid only for commands related to data read from the serial flash. The first device of flash A has to be paired with the first device of flash B and the second device of flash A has to be paired with the second device of flash B in parallel mode. Parallel mode is selected via the QSPI_BFGENCR[PAR_EN] bit for all masters in AHB driven mode and via the QSPI_IPCR[PAR_EN] in IP driven mode. In parallel mode, the incoming address (SFAR address in case of

IP initiated transactions and the incoming AHB address in case of AHB initiated transactions) is divided by 2 and sent to the two flashes connected in parallel.

Any IP Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[IUEF] flag and any AHB Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by SFADR [23:0] or SFADR [31:0] as given in the table above.

In Parallel Flash Mode, both flashes are read with the same starting address of 3/4 (as programmed in the instruction/operand in the sequence) bytes in size. This address is derived from SFADR [24:1] or SFADR [31:1] as given in the table above. The LSB of the SFADR field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

51.3.4 AHB Bus Register Memory Map Descriptions

This chapter contains definitions of registers in the AMBA address space.

51.3.4.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the QSPI_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.

- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

51.3.4.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address `QSPI_AMBA_BASE` the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address `0x0` corresponds to bus address `QSPI_AMBA_BASE` with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 51-14](#) and for 64 bit read access the byte ordering is given in [Table 51-18](#).

Table 51-7. Memory Mapped Individual Flash Mode - Flash A Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
<code>QSPI_AMBA_BASE + 0x00</code>	<code>QSPI_AMBA_BASE + 0x00</code>	<code>0x00_0000 to 0x00_0003</code>	A1
<code>QSPI_AMBA_BASE + 0x04</code>		<code>0x00_0004 to 0x00_0007</code>	
...		...	
<code>TOP_ADDR_MEMA1 - 0x08</code>	<code>TOP_ADDR_MEMA1 - 0x08</code>	<code>(TOP_ADDR_MEMA1 - 0x08) to (TOP_ADDR_MEMA1 - 0x04 - 0x01)</code>	
<code>TOP_ADDR_MEMA1 - 0x04</code>		<code>(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)</code>	
<code>TOP_ADDR_MEMA1 + 0x00</code>	<code>TOP_ADDR_MEMA1 + 0x00_0000</code>	<code>0x00_0000 to 0x00_0003</code>	A2
<code>TOP_ADDR_MEMA1 + 0x04</code>		<code>0x00_0004 to 0x00_0007</code>	
.....		...	
<code>TOP_ADDR_MEMA2 - 0x08</code>	<code>TOP_ADDR_MEMA2 - 0x08</code>	<code>(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)</code>	
<code>TOP_ADDR_MEMA2 - 0x04</code>		<code>(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)</code>	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

51.3.4.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address TOP_ADDR_MEMA2 the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address TOP_ADDR_MEMA2 with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 51-14](#) and for 64 bit read access the byte ordering is given in [Table 51-18](#).

Table 51-8. Memory Mapped Individual Flash Mode - Flash B Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA2 + 0x00	TOP_ADDR_MEMA2 + 0x00	0x00_0000 to 0x00_0003	B1
TOP_ADDR_MEMA2 + 0x04		0x00_0004 to 0x00_0007	
...		...	
TOP_ADDR_MEMB1 - 0x08	TOP_ADDR_MEMB1 - 0x08	(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 - 0x01)	B2
TOP_ADDR_MEMB1 - 0x04		(TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x01)	
TOP_ADDR_MEMB1 + 0x00	TOP_ADDR_MEMB1 + 0x00_0000	0x00_0000 to 0x00_0003	
TOP_ADDR_MEMB1 + 0x04		0x00_0004 to 0x00_0007	
.....		...	
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)	
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

51.3.4.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI_BFGENCR[PAR_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in [Table 51-16](#) and for 64 bit read access the byte ordering is given in [Table 51-18](#).

Table 51-9. Memory Mapped Parallel Flash Mode Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to Parallel mode and Dual Die Flashes .	0x00_0000	0x00_0000
QSPI_AMBA_BASE + 0x0000_0004		-	-
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0001	0x00_0001
QSPI_AMBA_BASE + 0x0000_000C		0x00_0002	0x00_0002
...	
TOP_ADDR_MEMB2 - 0x08	
TOP_ADDR_MEMB2 - 0x04	TOP_ADDR_MEMB2 - 0x08	0x00_0003	0x00_0003
...		0x00_0004	0x00_0004
...	TOP_ADDR_MEMB2 - 0x08	0x00_0005	0x00_0005
...		0x00_0006	0x00_0006
...	TOP_ADDR_MEMB2 - 0x08	0x00_0007	0x00_0007
...	
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 + 0x01

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to [Flash Read](#).

51.4 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 51-10. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rdfd	RBDF	RX Buffer Drain
ipi_int_overrun		Buffer Overflow/Underrun Error Logical OR from:
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
ipi_int_ored	IUEF	Peripheral Command Usage Error
	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, IUEF	Logical OR from all the QSPI_FR flags mentioned

51.5 Functional Description

This section provides the functional information of the QuadSPI module.

51.5.1 Serial Flash Access Schemes

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to 4 bidirectional data lines. Depending from the serial flash devices attached to the QuadSPI module the following access schemes are possible:

Table 51-11. Access Schemes for Serial Flash Data Access

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	Yes	N/a	Yes
Individual Flash Mode: Access to Flash B	N/a	Yes	Yes
Parallel Flash Mode: Read from Flash A and Flash B	N/a	N/a	Yes

Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

51.5.2 Modes of Operation

Refer to [QuadSPI Modes of Operation](#) for an overview over the possible operational modes of the QuadSPI block.

- Normal Mode can be used for write or read accesses to an external serial flash device.

- **Serial Flash Write:** Data can be programmed into the flash via the IP interface only. Refer to [Flash Programming](#) for further details.
- **Serial Flash Read:** Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see [Flash Read](#).
- **Stop Mode:** The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- **Module Disable Mode:** The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

51.5.3 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

51.5.3.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 51-12. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads	8 bit command value	Provide the serial flash with operand on the number of pads specified

Table continues on the next page...

Table 51-12. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
ADDR	6'd2	2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions .
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads ¹ specified
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads ² specified
READ	6'd7	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes. (For AHB transactions the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IPCR for IP initiated transactions.
WRITE			6'd8	Write data size in bytes
JMP_ON_CS	6'd9	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions .
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash ³
MODE4_DDR	6'd13	N=2'd{0,1}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash ⁴ .

Table continues on the next page...

Table 51-12. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
READ_DDR	6'd14	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes. (For AHB transactions the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IPCR for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IPCR register
DATA_LEARN	6'd16		8 bit Data learning pattern	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the QSPI_SMPR[DDRSMP] values are ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern. ⁵
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.
5. t is not recommended to have 0x00 or 0xFF as the data learning pattern.

A sequence of such instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed in the LUT is referred to by its index.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

51.5.3.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated. The size of buffer 0 is defined as being from 0 to QSPI_BUF0IND. The Size of buffer 1 is from QSPI_BUF0IND to

Functional Description

QSPI_BUF1IND, buffer2 is from QSPI_BUF1IND to QSPI_BUF2IND and buffer 3 is from QSPI_BUF2IND to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash. As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. [Figure 51-4](#) shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to [Look-up Table](#) for details.

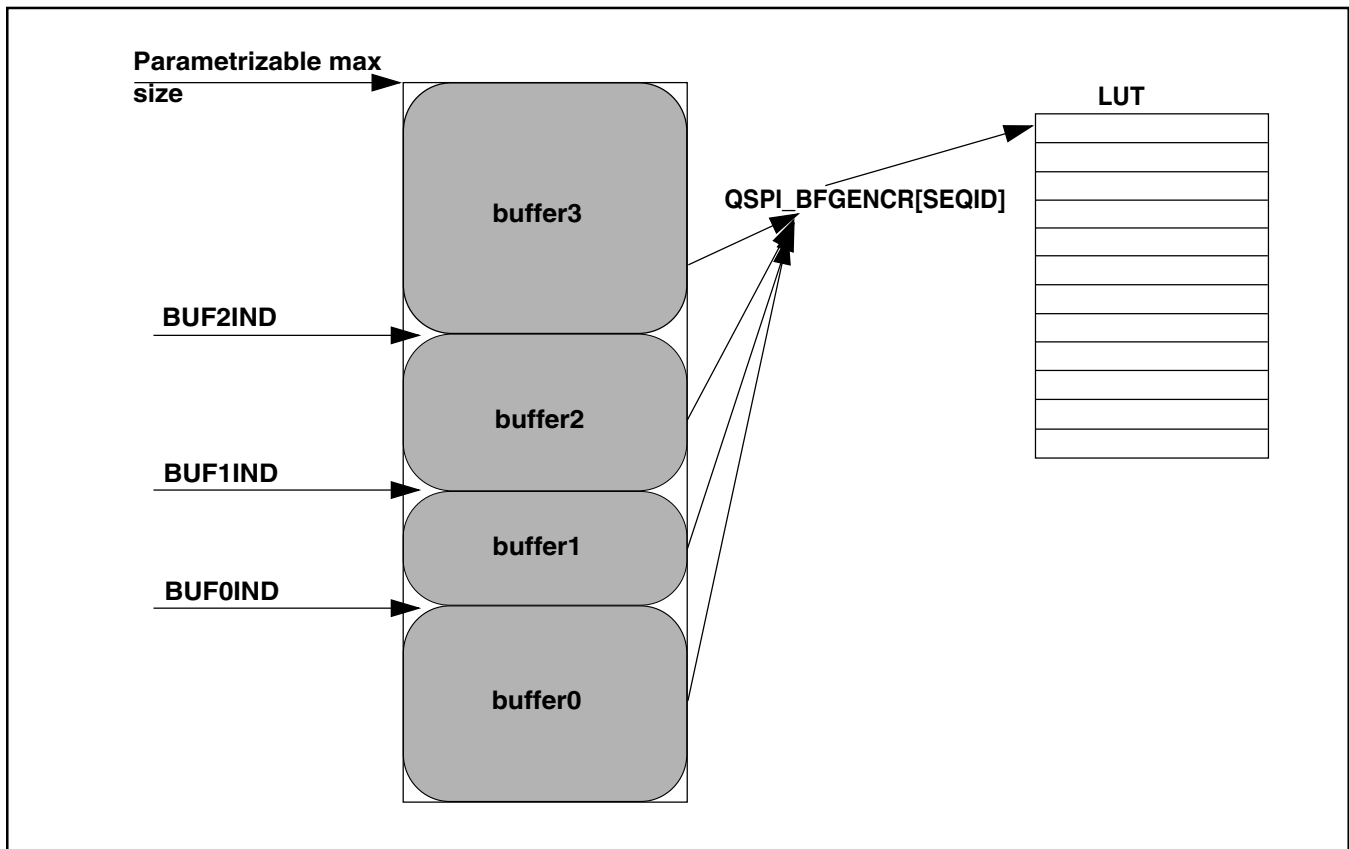

Figure 51-4. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes, the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from [SPNDST](#).

51.5.3.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

51.5.3.4 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

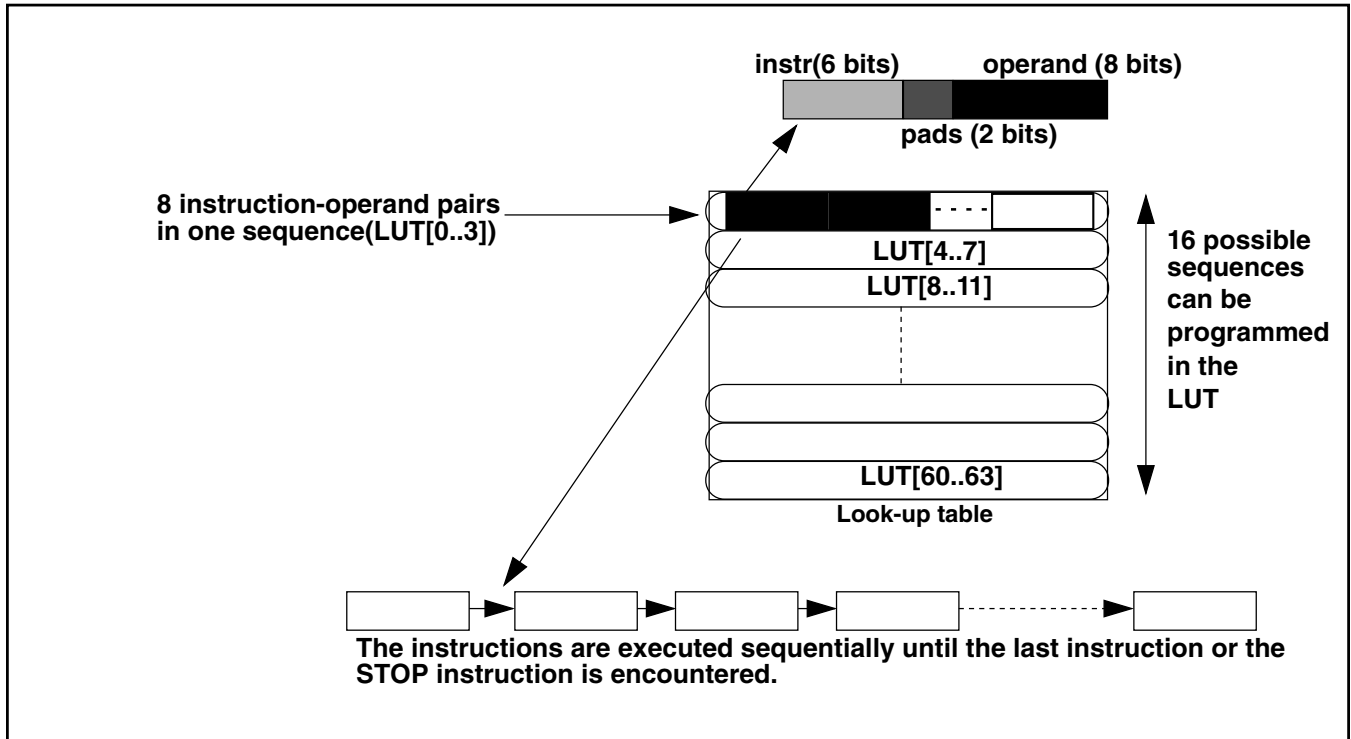

Figure 51-5. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in Table 51-13. After reset the complete LUT may be reprogrammed according to the device connected on board. In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key (**0x5AF05AF0**) in to the **LUTKEY**.
2. Write 0b01 to the **LCKCR**. Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key (**0x5AF05AF0**) into the **LUTKEY**
2. Write 0b10 to the **LCKCR**. Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from **QSPI_LCKCR[UNLOCK]** and **QSPI_LCKCR[LOCK]** bit.

Some example sequences are defined in [Example Sequences](#). The reset sequence at LUT index 0 is given in the following table.

Table 51-13. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

51.5.3.5 Issuing SFM Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit **QSPI_SR[BUSY]** is set.
3. Communication with the external serial flash device is started and the transaction is executed.
4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit **QSPI_SR[BUSY]** is reset. In case of an IP Command the **QSPI_FR[TFF]** flag is asserted.

Further details are given in below in [Flash Programming](#) and [Flash Read](#).

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

For IP Commands the required components need to be written into the following registers:

- Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to [Serial Flash Address Register \(QSPI_SFAR\)](#). For IP Commands not related to specific addresses, the base address of the related flash need to be programmed. For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.
- Write the sequence ID and data size details in the [IP Configuration Register \(QSPI_IPCR\)](#).
- Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to [IP Configuration Register \(QSPI_IPCR\)](#) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in [Command Arbitration](#).

- **Using AHB commands**

Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in [Flexible AHB buffers](#).

An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#) and [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#).

Again the possible error conditions are described in [Command Arbitration](#).

51.5.3.6 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check that the TX Buffer is empty. If the QSPI_SR[TXEDA] bit is set then the TX Buffer must be cleared by writing 1 into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register.

3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR) . At least four word of data must be written into the TX Buffer up to a maximum of 32.
4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed. The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register. The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **32** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented by four after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

51.5.3.7 Flash Read

Host access to the data stored in the external serial flash device is done in two steps: First the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. Reading Serial Flash Data into the QuadSPI Module Internal Buffers

A read access to the external serial flash device can be triggered in two different ways:

- **IP Command Read:** For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should

program the Serial Flash Address Register (QSPI_SFAR) and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QSPI_MCR[CLR_RXF] bit.

From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command the IP_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBCT[RXBRD].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

- **AHB Command Read:** For **reading flash data into the AHB Buffer** the user must setup a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should also program the buffer registers corresponding to the AHB master initiating the request, this depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module, refer to [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A](#), [Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B](#) and [Parallel Flash Mode](#).

On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the QSPI_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI_SR[AHB_ACC] status bit is set driving in turn the QSPI_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. Data Transfer from the QuadSPI Module Internal Buffers

The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

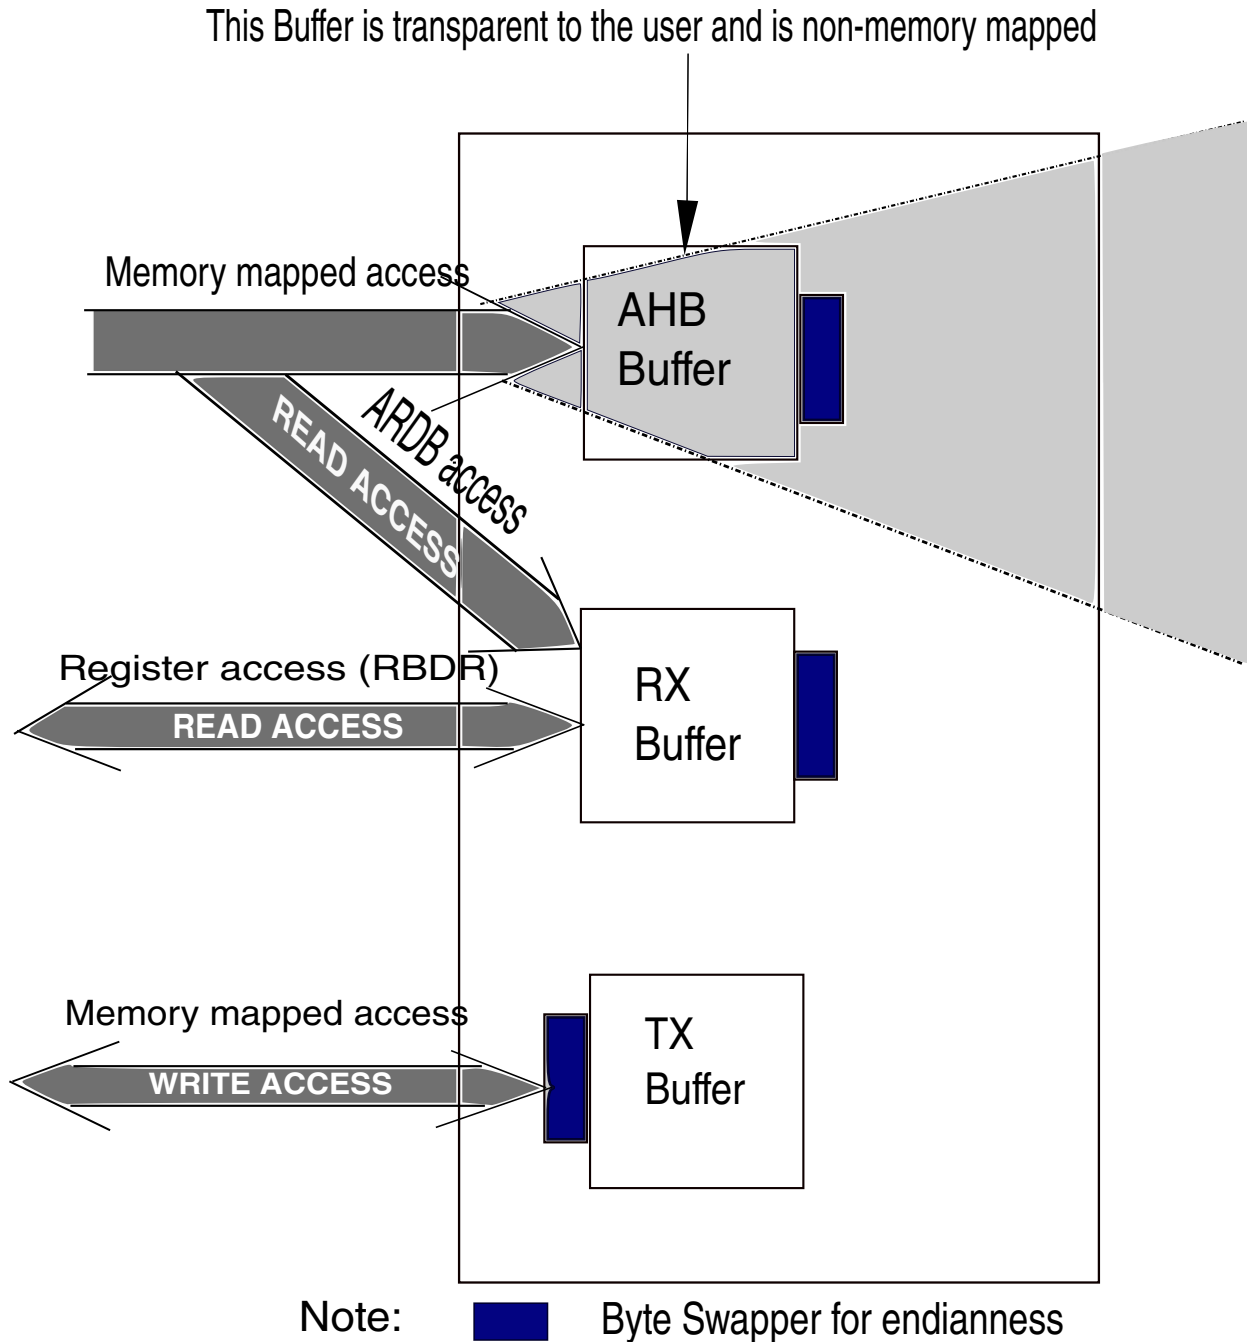

Figure 51-6. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR31

In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB31. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in [RX Buffer Data Registers 0 - 31 \(QSPI_RBDR0 - QSPI_RBDR31\)](#) and in [AHB RX Data Buffer \(QSPI_ARDB0 to QSPI_ARDB31\)](#).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDRn) or the AHB address space (QSPI_ARDBn). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module. The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in [DMA Usage](#).

DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDRn or QSPI_ARDBn related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in [Table 51-6](#) table *under the condition that the data requested are already present in the AHB Buffer or it is currently being*

read from the serial flash device by the instruction in progress. If this is not the case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data.

Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

51.5.3.8 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI_SFAR[SFADR] field - corresponds to bit position QSPI_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

- Flash A or Flash B in Individual Flash Mode
- All AHB data read commands with access size of 32 bit

Table 51-14. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0

Table continues on the next page...

Table 51-14. Byte Ordering in Individual Flash Mode (continued)

Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]
---	---------	---------	--------	-------

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

• Byte Ordering in Parallel Flash Mode

In Parallel Flash Mode each byte is combined out of 2 half bytes which are read in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI_RBDR0 register.

Table 51-15. Serial Flash Device Half Byte Ordering

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fbl0
1	fah1	fal1	fbh1	fbl1
2	fah2	fal2	fbh2	fbl2
3	fah3	fal3	fbh3	fbl3
4	fah4	fal4	fbh4	fbl4
5	fah5	fal5	fbh5	fbl5
6	fah6	fal6	fbh6	fbl6
7	fah7	fal7	fbh7	fbl7
8	fah8	fal8	fbh8	fbl8

The table entry naming reflects the half byte positioning in the serial flash devices:

- <fa>h0 means **Flash A**, <fb>h0 means Flash B.
- fa<h>0 means half byte in **high position**, fa<l>0 means half byte in low position.
- fah<0> means **physical byte address 0** in the serial flash device, fal<1> means physical byte address 1 in the serial flash device.

Table 51-16. Byte Ordering in Parallel Flash Mode - RX Buffer

QSPI_SFAR[SFADR] set to 0x000_0000								
QSPI_RBDR0 QSPI_ARDB0	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
QSPI_RBDR1 QSPI_ARDB1	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2
QSPI_SFAR[SFADR] set to 0x000_0001								
QSPI_RBDR0 QSPI_ARDB0	fal2	fbl2	fah2	fbh2	fal1	fbl1	fah1	fbh1
QSPI_RBDR1 QSPI_ARDB1	fal4	fbl4	fah4	fbh4	fal3	fbl3	fah3	fbh3

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

* Applicable only for single io mode.

Table 51-17. Byte Ordering in Parallel Flash Mode - AHB Buffer

AHB Address (32 Bit Access)	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
AHB Address 0x800_0004 (32 Bit Access)	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

Note

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

• **Buffer Entry Ordering for 64 Bit Read Access**

For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 51-18. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

51.5.3.9 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the [Flag Register \(QSPI_FR\)](#).

Table 51-19. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_FR)	DMA
Data Learn pattern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
IP Command Usage Error	IUEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-

Table continues on the next page...

Table 51-19. Interrupt and DMA Request Conditions (continued)

Condition	Flag(QSPI_FR)	DMA
IP Access during AHB Grant Error	IPGEF	-
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the [Flag Register \(QSPI_FR\)](#) and a Request Enable bit in the [DMA Request Select and Enable Register \(QSPI_RSER\)](#). The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- **Transmit Buffer Fill Interrupt Request:**

The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSPI_RSER[TBFIE]) is set. Refer to [TX Buffer Operation](#), for details about the assertion of the QSPI_FR[TBFF] flag.

- **Receive Buffer Drain Interrupt or DMA Request:**

The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- **Buffer Overflow/Underrun Interrupt Request:**

The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

- TBUF - TX Buffer Underrun, enabled by TBUIE
- RBOF - RX Buffer Overflow, enabled by RBOIE
- ABOF - AHB Buffer Overflow, enabled by ABOIE

The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TFUFIE] bit is set.

The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

If the IPAEF, IPIEF, IPGEF or IUEF flags in the QSPI_FR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

The IP Command Transaction Finished IRQ indicates the completion of the current IP Command. It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

51.5.3.10 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least four entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag. The TX buffer underrun flag is also asserted when TX buffer contains less than 128 bits of data and QuadSPI module tries to pull out data from it. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is all F's i.e. once the underrun flag is set under this condition, it will return F's until the required number of bytes are not sent. This has been done to ensure that the software need not to erase whole sector after underrun, just reprogramming from

failure point will serve the purpose. When this Sequence Command is finished, the `QSPI_FR[TBFF]` flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the `QSPI_TBSR[TRBFL]` field.

Refer to [TBSR](#) and [FR](#) for details about the TX Buffer related registers.

51.5.3.11 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode.

- **Extended Address Mode**

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the `ADDR` and `ADDR_DDR` command should be programmed with 8'd32 as the operand value. By default, the QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

51.6 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

51.6.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

51.6.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

51.6.2.1 IP Commands

Refer to [IPCR](#) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

Refer to [Table 51-20](#) below.

51.6.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in [Flash Read](#) for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

Refer to [Table 51-20](#) below.

51.6.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 51-20. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flags	ABSEF	Flash transaction is aborted	AHB sequence contains <ul style="list-style-type: none"> • WRITE instruction • WRITE_DDR instruction
	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
Miscellaneous Error Flags	DLPPF	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.
Miscellaneous Error Flags	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
Command Arbitration Errors	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and

Table continues on the next page...

**Table 51-20. Overview of QSPI_FR Error Flags
(continued)**

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
			<ul style="list-style-type: none"> • write attempt to QSPI_IPCR register. • write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
	IPAEF		<ul style="list-style-type: none"> • AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
	IPGEF		<ul style="list-style-type: none"> • Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
IP Command Error	IUEF		<ul style="list-style-type: none"> • IP Command Usage Error
Buffer Related Errors	RBOF	TFF is asserted on completion	<ul style="list-style-type: none"> • RX Buffer Overrun
	TBUF		<ul style="list-style-type: none"> • TX Buffer Underrun

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

51.6.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[IPIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for a description of the flags and [Command Arbitration](#), for details about possible command collisions.

51.6.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDx register) and the other masters by triggering AHB Commands (via

ARDBx Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer. Refer to [Figure 51-6](#) To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

51.6.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1.

51.6.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR31.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0), allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

51.6.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in [Exclusive Access to Serial Flash for AHB Commands](#) is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[PIEF] flag is asserted when the host tries to write into the QSPI_IPCR register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for details), this command is stalled until the currently running IP Command is finished.
- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to [FR](#) for the description of these flags.

When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of [Flash Read](#) section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

51.6.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to [SFAR](#) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to [AMBA Bus Register Memory Map](#) for details.

51.6.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

51.6.6.1 DMA Usage in Normal Mode

51.6.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading data from the RX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result.

AHB Bus Side (data read):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles

Initialization/Application Information

- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 8 bytes (64 bit read size): Assume 2 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI_RBCT[WMRK] field, therefore the overhead given above distributes among $(\text{QSPI_RBCT[WMRK]}+1)/2$ read accesses of 64 bit each.

The following table gives some examples for typical use cases:

Table 51-21. Access Duration Examples - Bus Clock Side

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop ¹	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
0	4	$12+2 = 14$	~117ns
1	8	$12+2 = 14$	~117ns
3	16	$12+4 = 16$	~133ns
7	32	$12+8 = 20$	~167ns
11	48	$12+12 = 24$	~200ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data read):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): 2 cycles for Quad DDR mode instructions in Parallel Flash Mode, 4 cycles for Quad (SDR) mode instruction in parallel flash mode or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 51-22. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop ¹	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM ² Quad	IFM Quad DDR	PFM ³ Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	9	5	3	~150ns	~83ns	~50ns
1	8	17	9	5	~282ns	~150ns	~83ns
3	16	33	17	9	~548ns	~282ns	~150ns
7	32	65	33	17	~1079ns	~548ns	~282ns
11	48	97	49	25	~1610ns	~813ns	~415ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Individual flash mode.
3. Parallel flash mode.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

51.6.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Only read operations are allowed in parallel mode. In case a write transaction is initiated in parallel mode, QSPI_FR[IUEF] is set. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

Figure 51-7. Flash addressing

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI_AMBA_BASE - 0x10000000
- QSPI_SFA1AD[TPADA1] - 0x20000000
- QSPI_SFA2AD[TPADA2] - 0x30000000
- QSPI_SFB1AD[TPADB1] - 0x40000000
- QSPI_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

$$\text{Flash Address} = (\text{Memory mapped address} - \text{QSPI_AMBA_BASE})/2$$

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

$$\text{Flash Address} = (\text{Memory mapped address} - \text{SFA2AD})/2$$

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

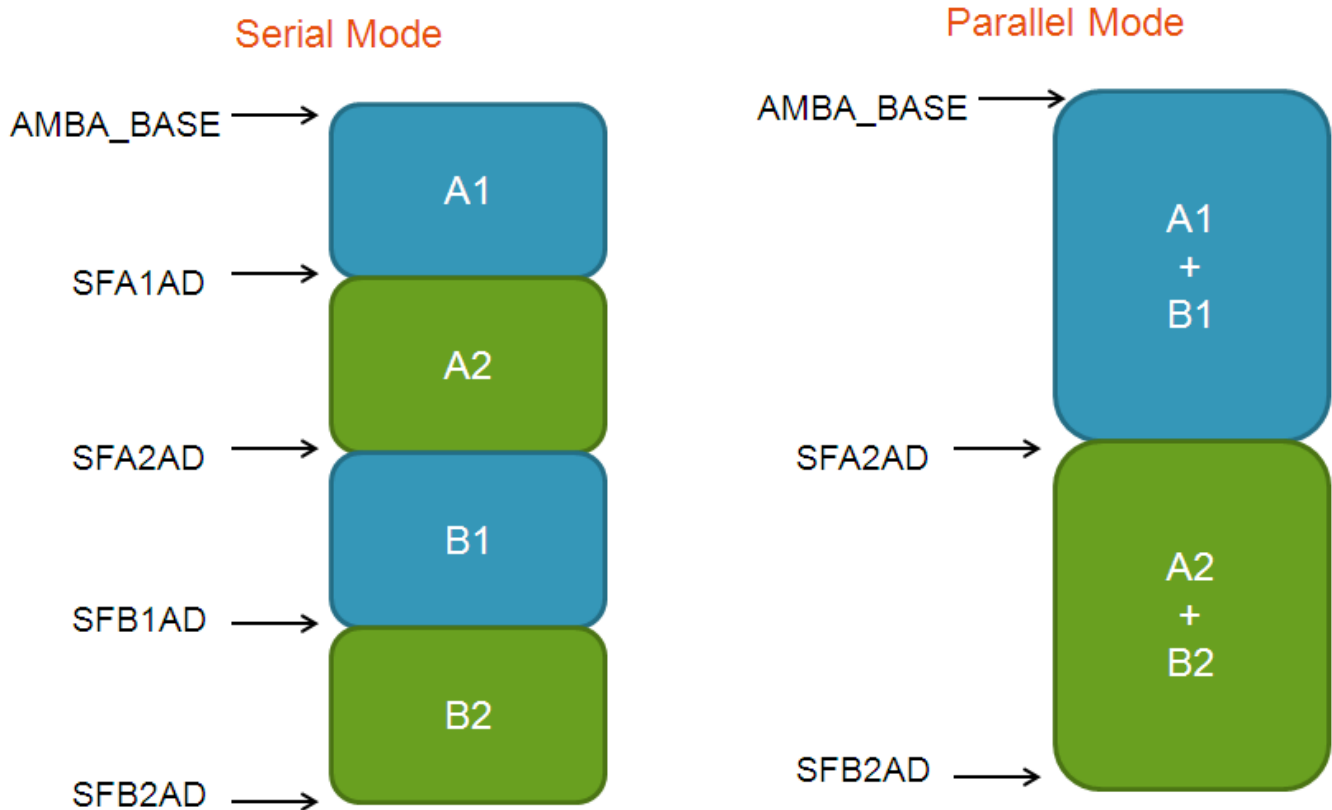

Figure 51-8. Memory map - Serial and Parallel

51.7 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

51.7.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 51-23. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

51.7.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flashes.

Table 51-24. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

51.7.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 51-25. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD

Table continues on the next page...

Table 51-25. Fast Dual I/O DT Read sequence (continued)

Instruction	Pad	Operand	Comment
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

51.7.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 51-26. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

51.7.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 51-27. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

51.7.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 51-28. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

51.7.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 51-29. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

51.7.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

Table 51-30. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

51.7.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

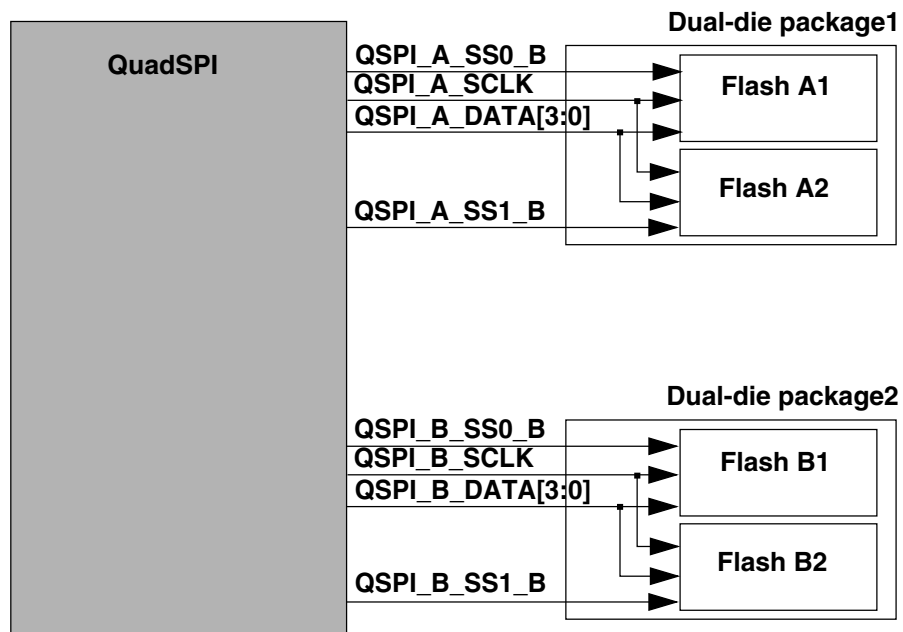

Figure 51-9. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

51.7.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI.

- System out of reset and flash available (300us)

- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.
- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
 - The total sizes of all the flashes connected on board
 - Whether DDR mode supported
 - Frequency of DDR operation
 - Continuous mode entry sequence
 - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
 - Quad Mode enabled
 - Dummy reads to enter into XIP
- QuadSPI is configured
 - Parallel enable set
 - LUT configured for highest performance reads
 - DDR mode enabled (if applicable)
 - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

51.8 Internal Sampling of Serial Flash Input Data

51.8.1 Internal Sampling of Serial Flash Input Data

Depending from the actual implementation there is a delay between the internal clocking in the QuadSPI module and the external serial flash device. Refer to the following figure for an overview of this scheme.

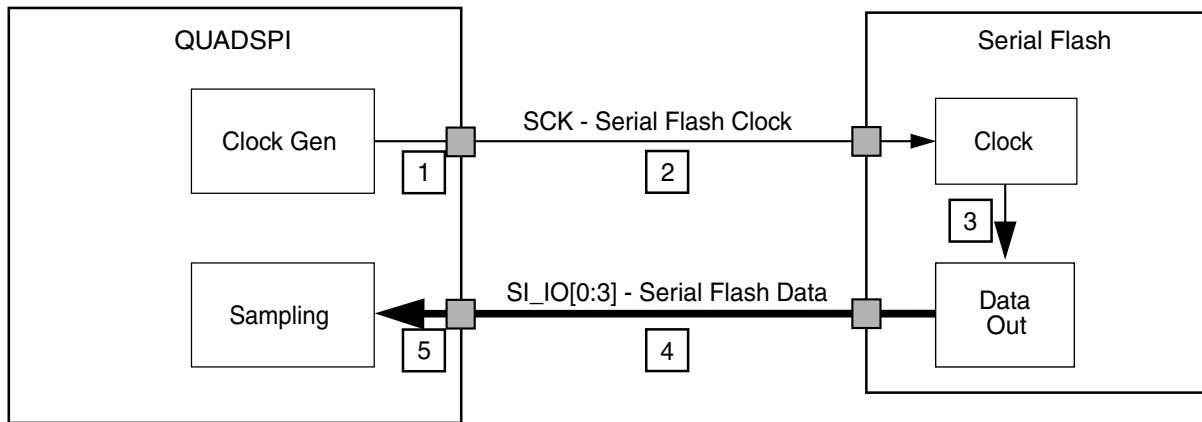

Figure 51-10. Serial Flash Sampling Clock Overview

Note

The arrival of the serial flash data in the sampling stage of the QuadSPI module are given in the following figure. Note that the amount of the total delay $t_{Del,total}$ is very specific to the characteristics of the actual implementation.

Note also that the serial flash device clock SCK is inverted with respect to the QuadSPI internal reference clock.

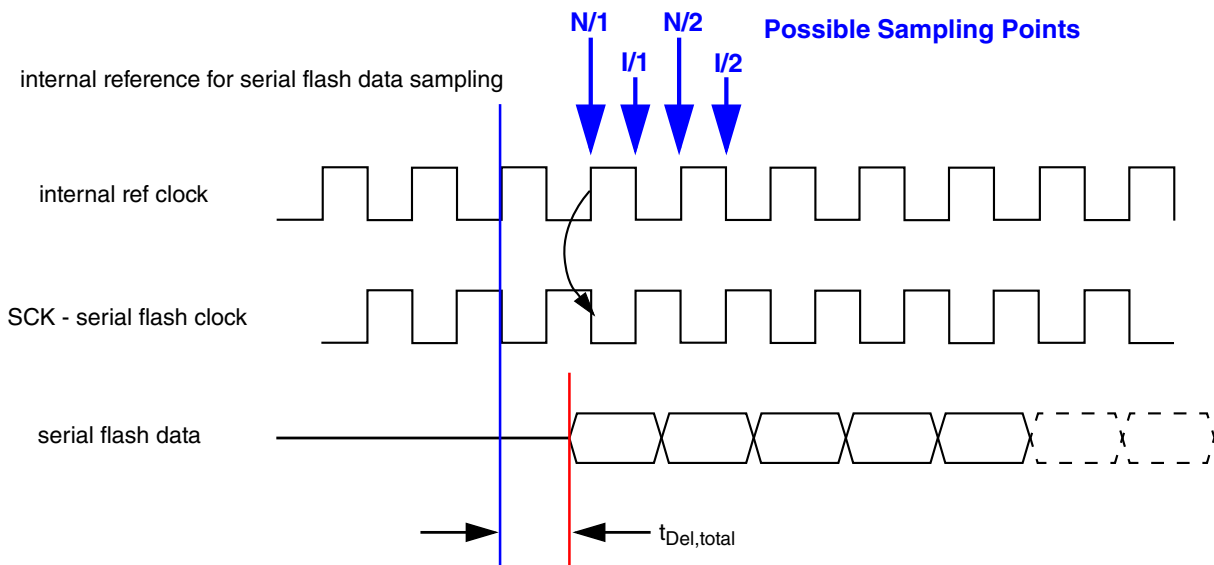

Figure 51-11. Serial Flash Sampling Clock Timing

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrive at the internal sampling stage of the QuadSPI module.

According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Input delay belonging to the data in input

The possible points in time for the sampling of the incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register, refer to [SMPR](#) for details. Note that the falling edges of the reference clock are not actually used, instead the inverted clock is used for sampling at these positions. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 51-31. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting ¹
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending from the actual delay and the serial flash clock frequency the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be 2 settings possible to capture the correct data since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending from the timing uncertainties it may turn out in actual applications that only one possible sample positions remains. This is subject to careful consideration depending from the actual implementation.

- The delay $t_{Del,total}$ is an absolute size to shift the point in time when the serial flash data get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SMPR register.

51.8.2 DDR Mode

When the serial flashes function in DDR mode, the data is valid for only half a clock cycle. This, along with the fact that the time for which the data is actually valid is smaller than half a clock cycle, requires that we provide closely spaced sampling points. The QuadSPI samples the incoming data at multiple sampling points provided by a 4x serial flash clock in DDR mode. The figure below shows the different sampling points as configured by QSPI_SMPR[DDRSMP]. The FSDLY/FSPHS and HSDLY/HSPHS bits are ignored for DDR instructions.

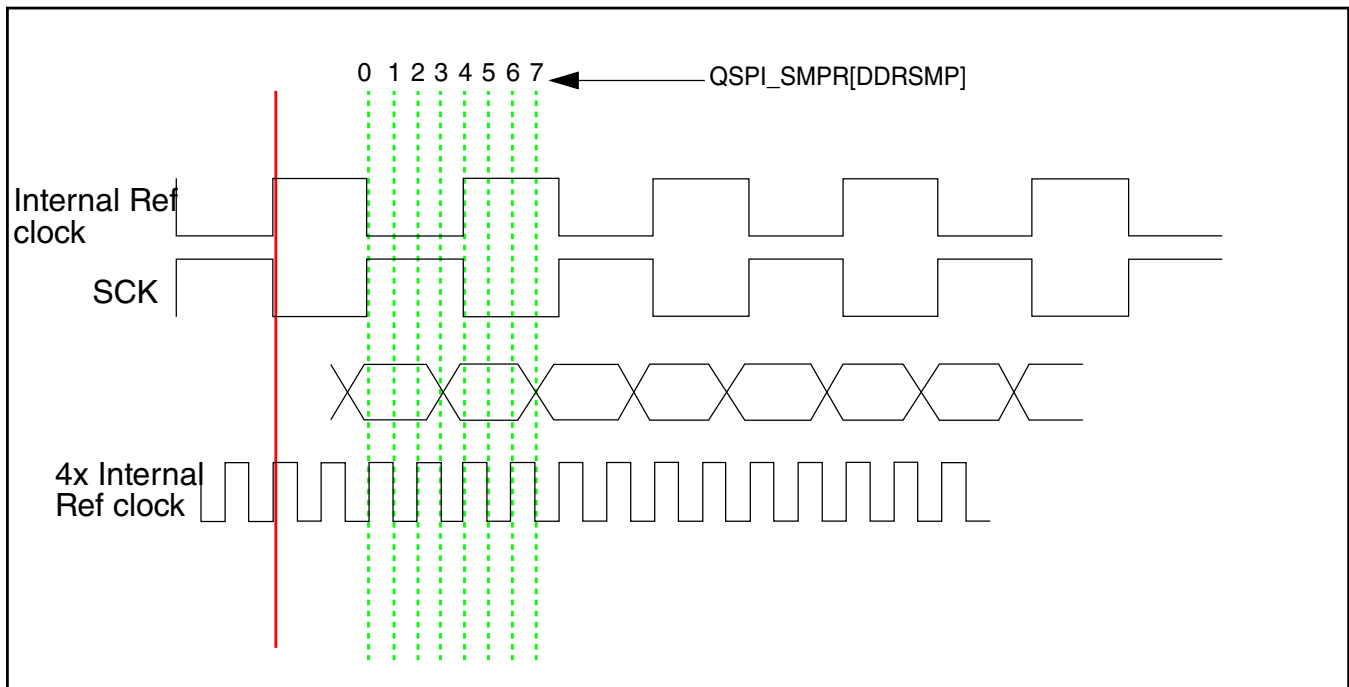

Figure 51-12. DDR sampling edges

Software should ensure that the correct sampling value is configured in the QSPI_SMPR[DDRSMP] register.

51.9 Serial Flash Data Input Timing

There are sampling modes for input flash data:

- Internal sampling - Input serial flash data is captured by internal serial clock. In SDR mode, serial data is sampled by serial clock 1x (ser_clk_1x) rise edge. In DDR mode, serial data is sampled by serial clock 4x (ser_clk_4x) rise edge.
- Loopback DQS sampling - Soc will output serial data strobe with internal serial clock. This serial data strobe would be loopback from pad and used to sample input serial data. In SDR mode, serial data is sampled by loopback DQS rise edge. In DDR mode, serial data is sampled by loopback DQS both edge

NOTE

DQS pad need to be set to force input for loopback.

- Flash DQS sampling - Some serial Flash device provide the data strobe output together with serial data. This strobe signal is used to sample input serial data directly. In SDR mode, serial data is sampled by Flash DQS rise edge. In DDR mode, serial data is sampled by Flash DQS both edge

Following table shows selection for sampling mode:

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Internal sampling	0	doesn't matter
Loopback DQS sampling	1	1
Flash DQS sampling	1	0

Serial flash data and clock path for input timing is shown in the following figure.

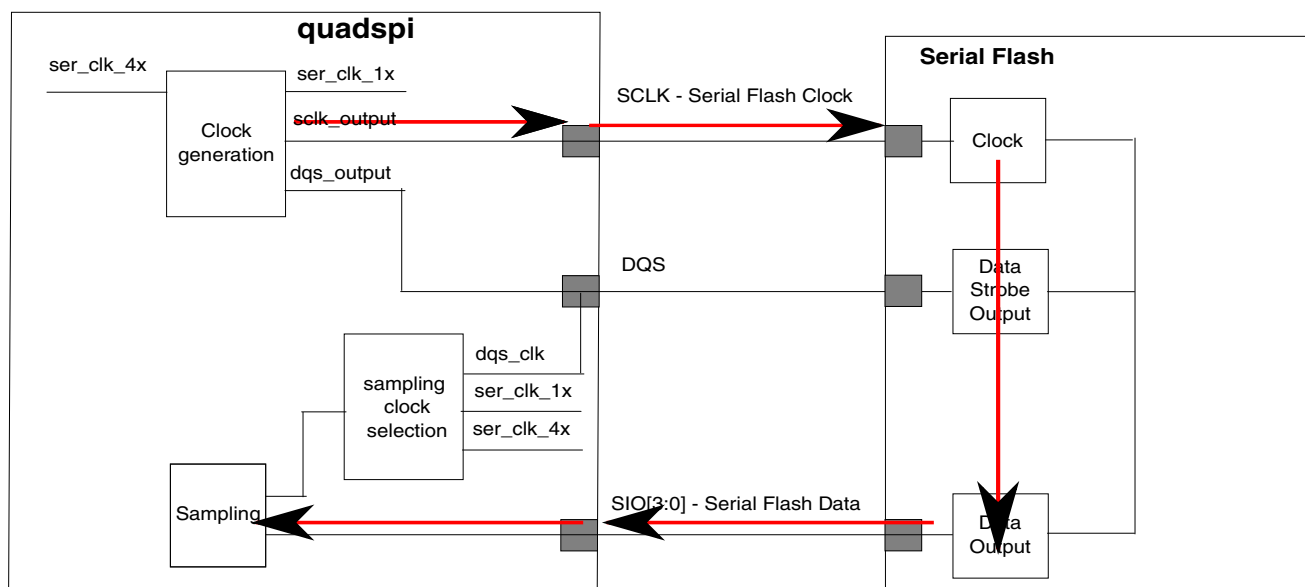

Figure 51-13. Serial flash data and clock path

NOTE

The red line is for data input path, the blue line is for DQS loopback path, and the purple line is for DQS input path from Serial Flash.

Total delay ($T_{total_delay_data}$) for serial flash data input is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to Output Valid time of external Serial Flash Device
4. Wire delay of serial flash data (SIO) from external serial Flash Device to SOC
5. Input delay of serial flash data from SIO pad to internal sample register

Total delay ($T_{total_delay_loopback_dqs}$) for loopback DQS clock is the sum of following delay:

1. Output delay of DQS clock from internal serial clock to DQS pad inside SOC
2. Input delay of DQS clock from DQS pad to internal sample register

Total delay ($T_{total_delay_flash_dqs}$) for Flash DQS clock is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to DQS Output time of external Serial Flash Device
4. Wire delay of serial flash data strobe (DQS) from external serial Flash Device to SOC
5. Input delay of DQS clock from DQS pad to internal sample register

51.9.1 Input timing in SDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the figure below.

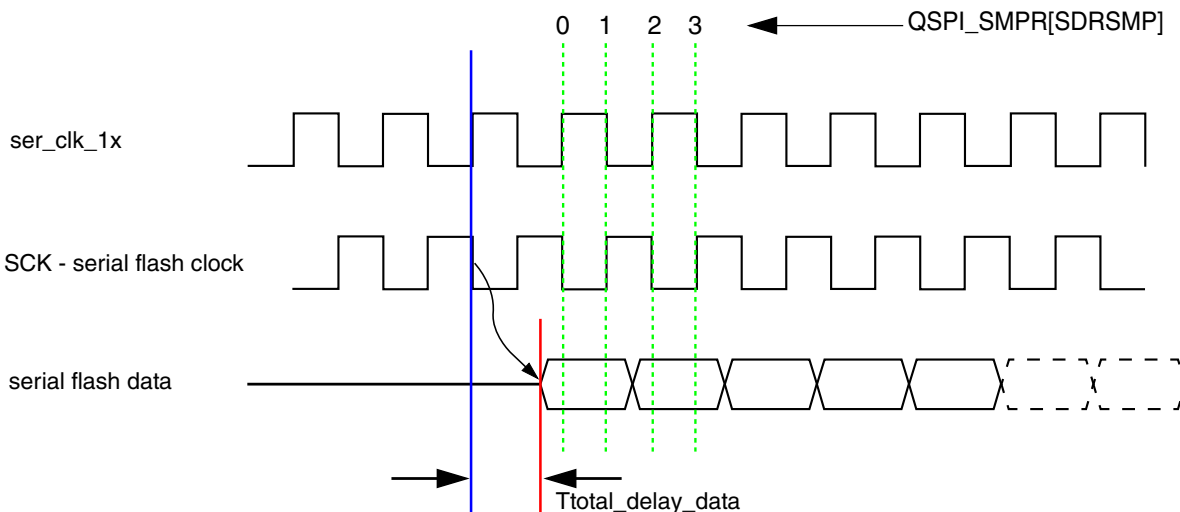

Figure 51-14. Internal sample SDR

There are four sample points for this sampling mode, which is determined by register field QSPI_SMPR.SDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

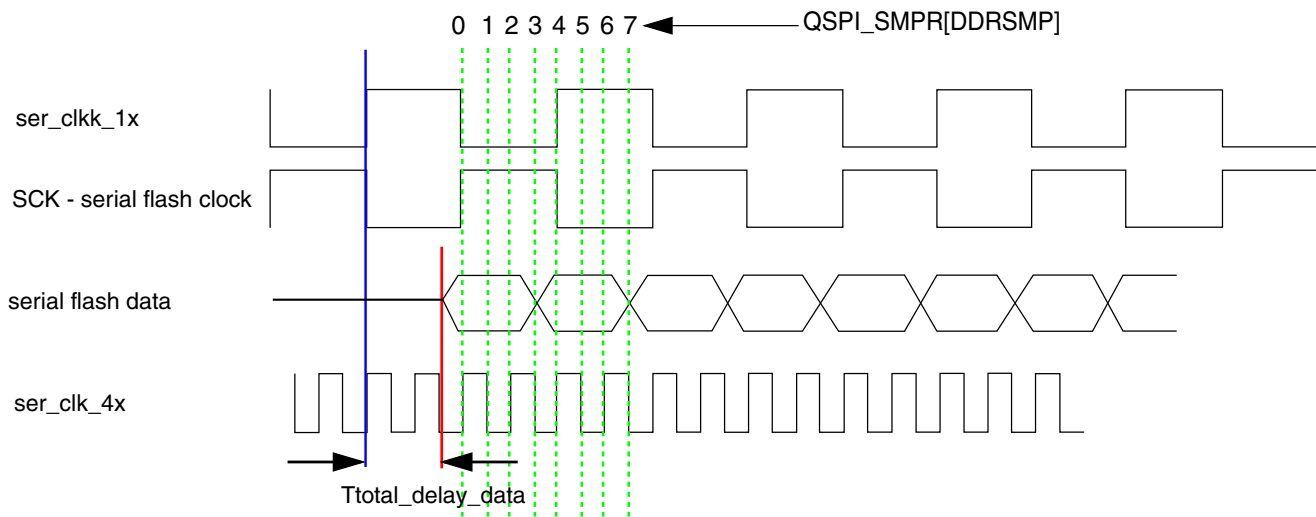

- For sample point N, Setup requirement is: $T_{cycle} * (N+2) / 2 > T_{total_delay_data,max}$
- For sample point N, Hold requirement is: $T_{total_delay_data,min} > T_{cycle} * N / 2$

NOTE

Tcycle is the cycle of ser_clk_1x. Ttotal_delay_data,max is maximum delay of serial data input path. Ttotal_delay_data,min is the minimum delay of serial data input path. N=0,1,2,3

51.9.2 Input timing in DDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

There are 8 sample points for this sampling mode, which is determined by register field DDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

- For sample point N, Setup requirement is: $T_{\text{cycle}} * (N+2)/8 > T_{\text{total_delay_data,max}}$
- For sample point N, Hold requirement is: $T_{\text{total_delay_data,min}} > T_{\text{cycle}} * N/8$

51.9.3 Input timing in SDR mode with loopback DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

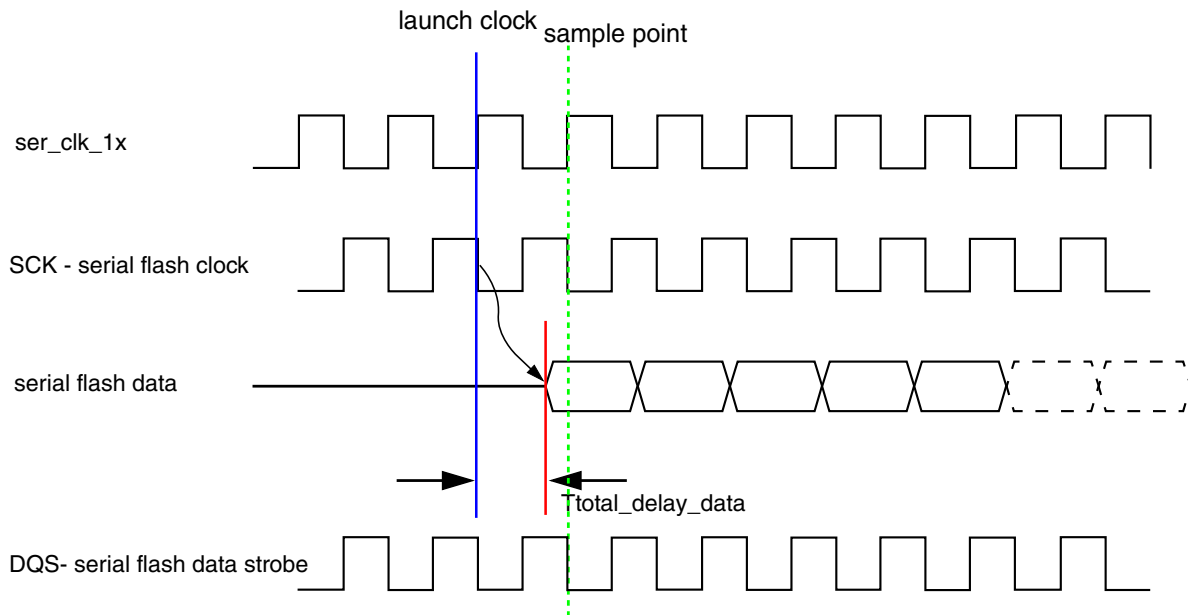

Figure 51-15. Input timing in SDR mode with loopback DQS sampling

In SDR mode and loopback sampling mode, DQS_PHASE_EN should be set 1.

For this sample point, the Setup requirement is: $T_{\text{cycle}} > \max(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}})$. The Hold requirement is: $\min(T_{\text{total_delay_data}} - T_{\text{total_delay_loopback_dqs}}) > 0$.

51.9.4 Input timing in DDR mode with loopback DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

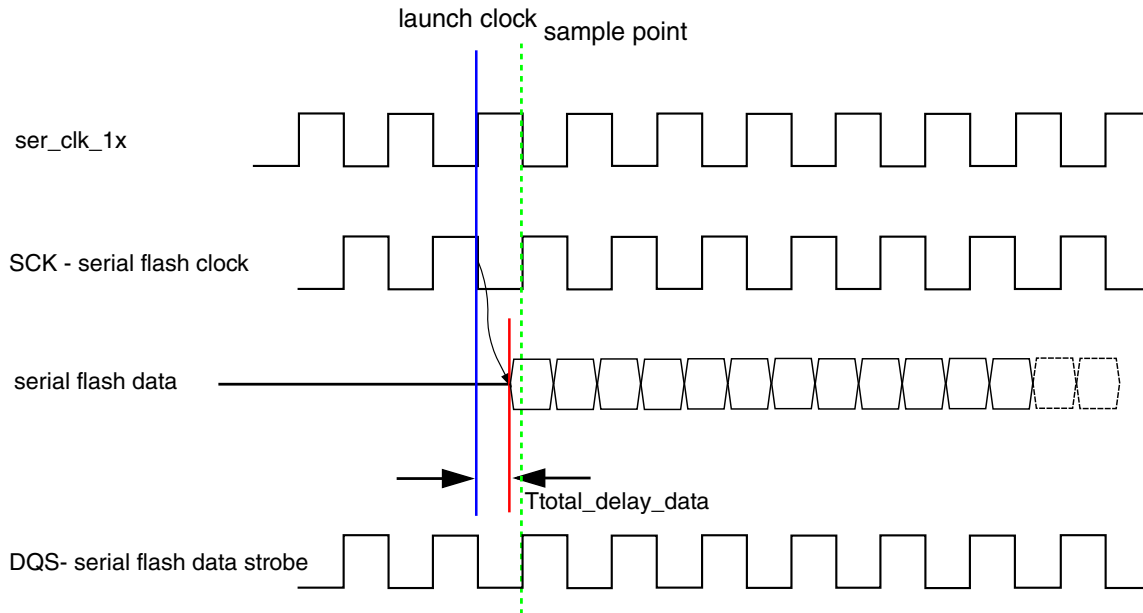

Figure 51-16. Input timing in DDR mode with loopback DQS sampling

In DDR mode and loopback sampling mode, `DQS_PHASE_EN` should be set 0.

For this sample point, the Setup requirement is: $T_{cycle} > \max(T_{total_delay_data} - T_{total_delay_loopback_dqs})$. The Hold requirement is: $\min(T_{total_delay_data} - T_{total_delay_loopback_dqs}) > 0$.

51.9.5 Input timing in SDR mode with flash DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

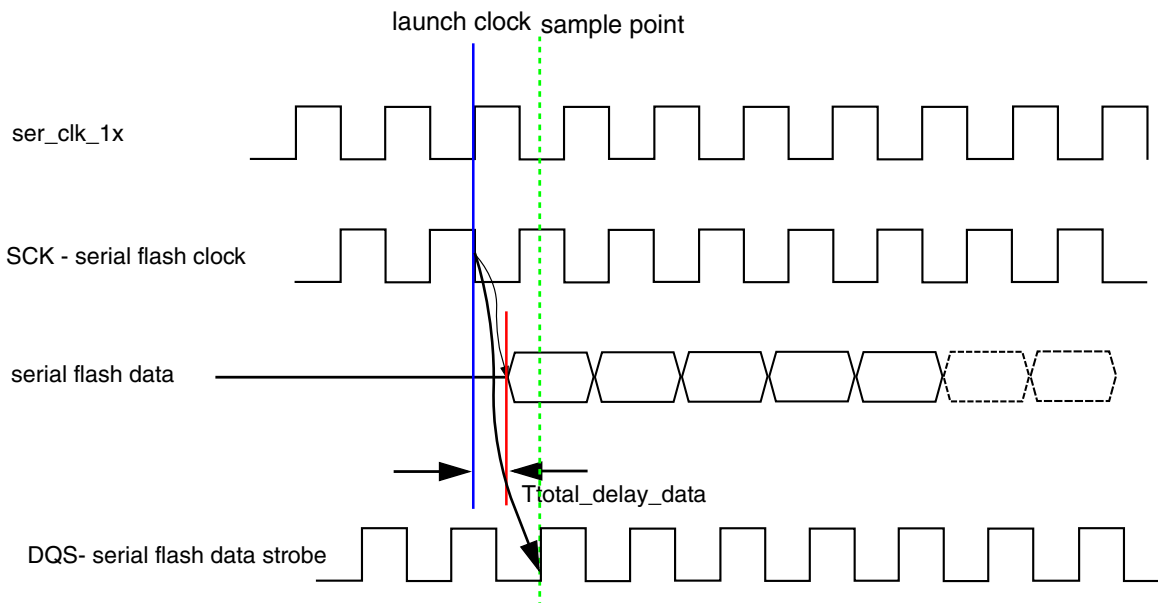

Figure 51-17. Input timing in SDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

51.9.6 Input timing in DDR mode with flash DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

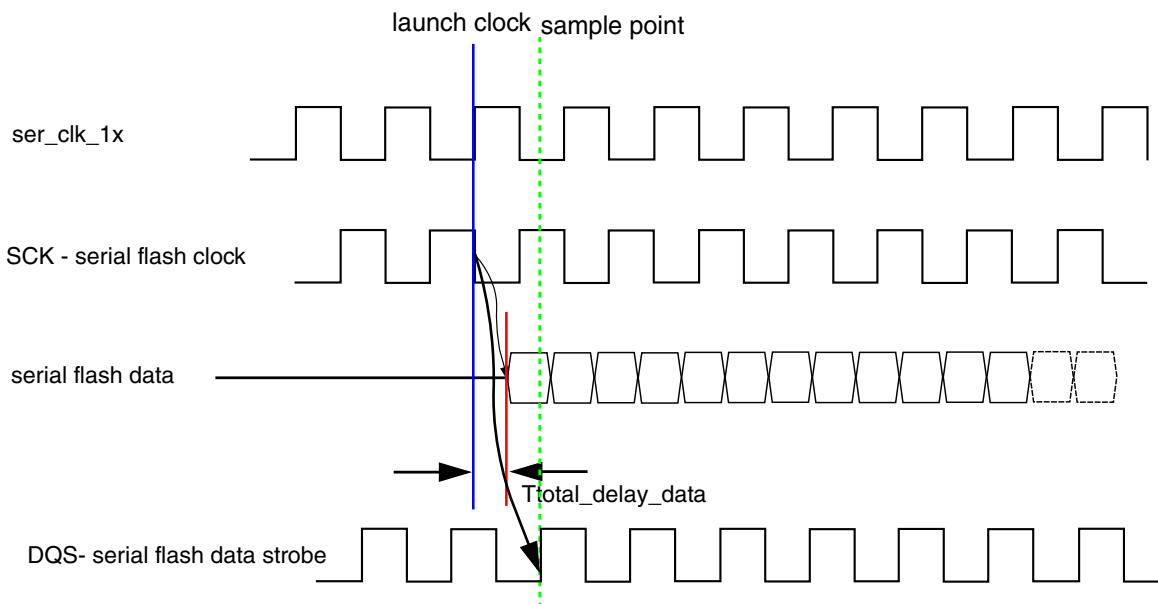

Figure 51-18. Input timing in DDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

51.9.7 Data Strobe Signal functionality

Some external serial flashes provide the data strobe (DQS/RDS) output which is fed directly to the QuadSPI module. The strobe (DQS/RDS) signal needs to be delayed to have the edges aligned to the data valid period. QuadSPI internally samples the incoming data at posedge of the strobe signal for SDR and on both the edges of the strobe signal for DDR. Refer to the figure for more detail.

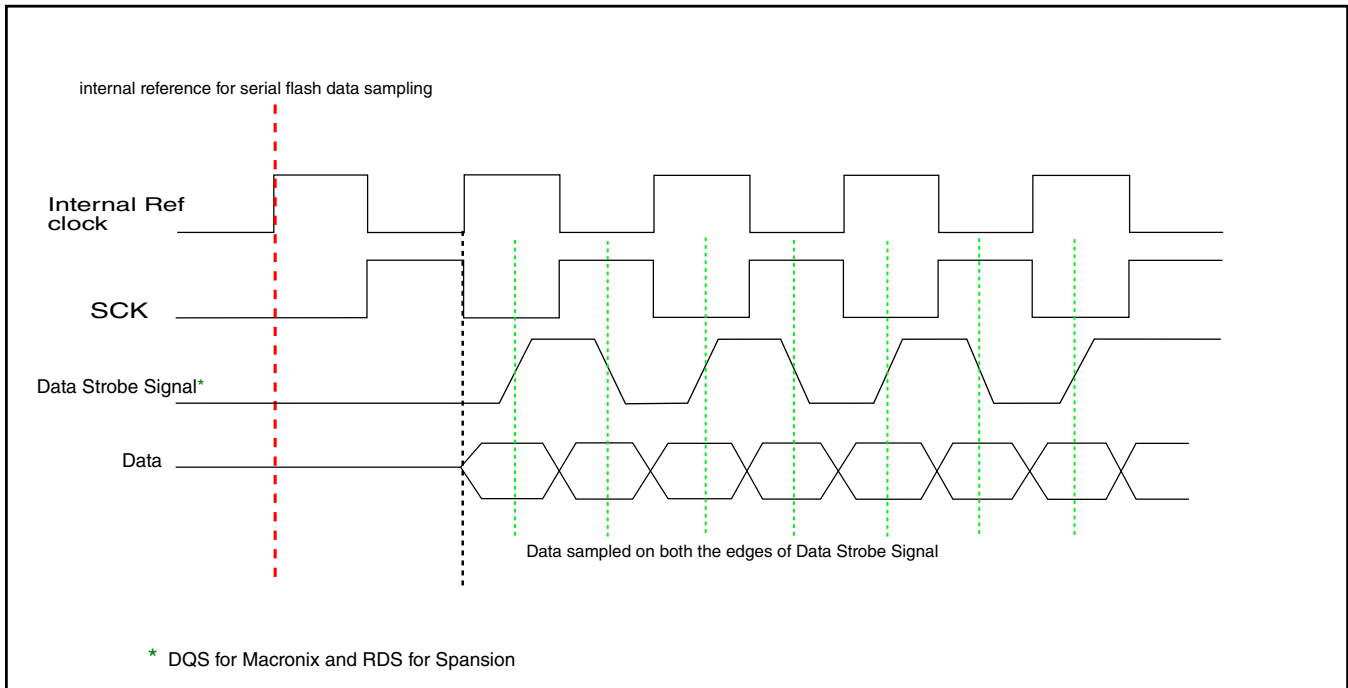

Figure 51-19. Data strobe signal functionality

51.10 Output timing in SDR mode

Output timing diagram in SDR mode is show in the following figure.

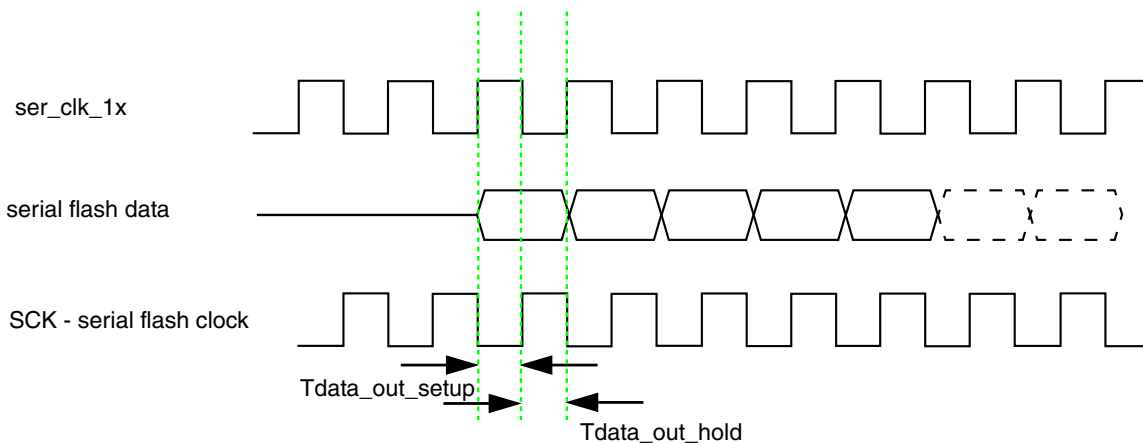

Figure 51-20. Output timing in SDR mode

In SDR mode, quadspi output serial data with internal serial clock rise edge 1x (ser_clk_1x). Flash Device has requirement on Data and Clock setup and hold timing.

51.11 Output timing in DDR mode

Output Timing diagram in DDR mode is show in the following figure.

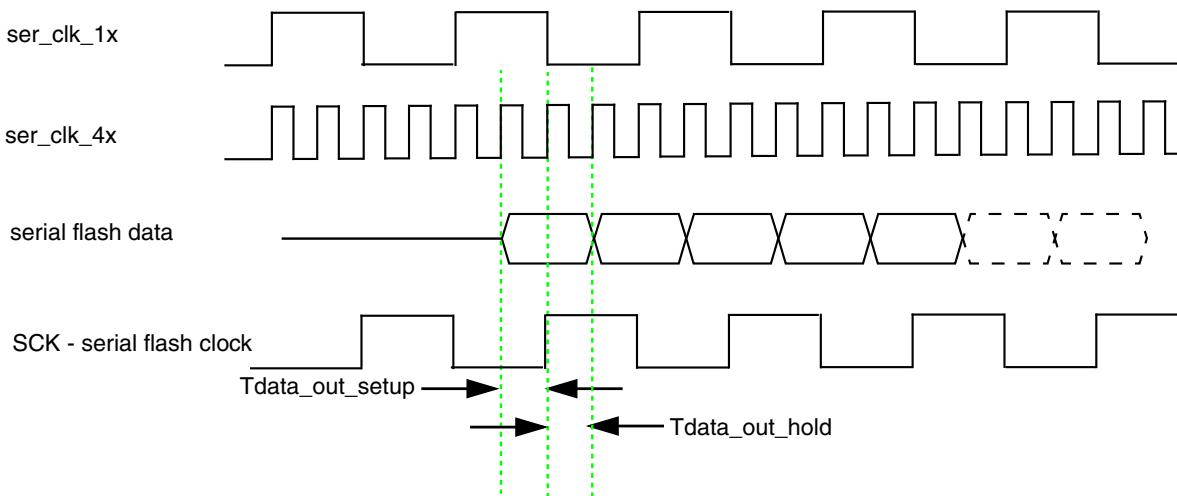

Figure 51-21. Output timing in DDR mode

In DDR mode, quadspi output serial data with internal serial clock both edge 1x (ser_clk_1x) and then delay one ser_clk_4x cycle for hold timing.

NOTE

TX_DDR_DELAY_EN should be set to 1 for DDR mode.

51.12 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)**51.12.1 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)****NOTE**

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

51.12.1.1 AHB RX Data Buffer register (ARDBn)

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in [Flash Read](#) section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to [Byte Ordering of Serial Flash Read Data](#) for the byte ordering scheme.

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

ARDBn field descriptions

Field	Description
ARXD	ARDB provided RX Buffer Data. Byte order (endianness) is identical to the RX Buffer Data Registers.

51.13 Peripheral Bus Register Descriptions

This section provides the peripheral bus register information of the QuadSPI module.

This section provides the memory map and register definitions of the QuadSPI module.

QuadSPIx_MCR field descriptions

Field	Description
31 Reserved	This field is reserved. This field should always be set to 0.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
30 DQS_PHASE_EN	This bit controls internal DQS output phase. If DQS_EN and DQS_LOOPBACK_EN are both set to 1, this bit should be set in SDR mode, and cleared in DDR mode. If either DQS_EN or DQS_LOOPBACK_EN is set to 0, this bit is ignored.
29 TX_DDR_DELAY_EN	Quadspi generate serial data with serial clock 1x (ser_clk_1x) both edge. TX data will be delayed by 1 serial clock 4x (ser_clk_4x) cycle when this bit is set. This bit should be set in DDR mode and cleared in SDR mode. 1'b1 TX data delay is enabled 1'b0 TX data delay is disabled
28–25 Reserved	This field is reserved. This field should always be set to 0.
24 DQS_LOOPBACK_EN	Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. This bit is a don't care when DQS_EN is set to 0. 1'b1 DQS loopback sampling enabled 1'b0 DQS loopback sampling disabled
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. Please refer to , for more information. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidate the TX Buffer content. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidate the RX Buffer. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable: 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
6 DQS_EN	DQS enable: This field is valid for both SDR and DDR mode. For more details Refer Data Strobe Signal Functionality 0 DQS disabled. 1 DQS enabled- When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5-4 Reserved	This field is reserved.
3-2 END_CFG	Defines the endianness of the QSPI module. For more details refer to Byte Ordering Endianness
1 SWRSTHD	Software reset for AHB domain 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.
0 SWRSTSD	Software reset for Serial Flash domain 0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

51.13.2 IP Configuration Register (QuadSPIx_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to [Normal Mode](#), for details about the command triggering and command execution.

Write:

- $QSPI_SR[IP_ACC]=0$

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
R	Reserved								SEQID								Reserved	PAR_EN
W	Reserved								SEQID								Reserved	PAR_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		

Peripheral Bus Register Descriptions

QuadSPIx_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this bit -field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
IDATSZ	IP data transfer size: Defines the data transfer size in bytes of the IP command.

51.13.3 Flash Configuration Register (QuadSPIx_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- $QSPI_SR[AHB_ACC] = 0$
- $QSPI_SR[IP_ACC] = 0$

Address: Base address + Ch offset

QuadSPIx_FLSHCR field descriptions

Field	Description
31–12 Reserved	This field is reserved. Reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles.
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles.

51.13.4 Buffer0 Configuration Register (QuadSPIx_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of the BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	ADATSZ								Reserved				MSTRID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable: When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer.

51.13.5 Buffer1 Configuration Register (QuadSPIx_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of the BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Peripheral Bus Register Descriptions

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer.

51.13.6 Buffer2 Configuration Register (QuadSPIx_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of the BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	Reserved																ADATSZ						Reserved				MSTRID					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.

Table continues on the next page...

QuadSPIx_BUF2CR field descriptions (continued)

Field	Description
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer.

51.13.7 Buffer3 Configuration Register (QuadSPIx_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of the BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the ALLMST field is set, any transaction where the master port number does not match any of the buffer MSTRID fields will be routed to this buffer. In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable: When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.

Table continues on the next page...

QuadSPIx_BUF3CR field descriptions (continued)

Field	Description
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer.

51.13.8 Buffer Generic Configuration Register (QuadSPIx_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–12 SEQID	

Table continues on the next page...

QuadSPIx_BFGENCR field descriptions (continued)

Field	Description
	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table . NOTE: If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

51.13.9 Buffer0 Top Index Register (QuadSPIx_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned, as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 give 16bytes etc.

The size of buffer0 is the difference between the BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF0IND field descriptions

Field	Description
31–3 TPINDEX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

51.13.10 Buffer1 Top Index Register (QuadSPIx_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less. The size of buffer1 is the difference between the BUF1IND and BUF0IND.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF1IND field descriptions

Field	Description
31–3 TPINDX1	Top index of buffer 1.
Reserved	This field is reserved.

51.13.11 Buffer2 Top Index Register (QuadSPIx_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. The size of buffer2 is the difference between the BUF2IND and BUF1IND.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- $QSPI_SR[AHB_ACC] = 0$

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF2IND field descriptions

Field	Description
31–3 TPINDX2	Top index of buffer 2.
Reserved	This field is reserved.

51.13.12 Serial Flash Address Register (QuadSPIx_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24bit mode, only bits 23-0 are sent to the flash, in 32bit mode, bits 27-0 are used with bits 31-28 driven to 0. Refer to [Table 51-5](#) for the mapping between the access mode and the QSPI_SFAR content and to [Normal Mode](#) for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in [Table 51-5](#).

Write:

- $QSPI_SR[IP_ACC] = 0$

Address: Base address + 100h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter, indicates how many entries of 4 bytes have been removed from the RX Buffer. For example a value of 0x2 would indicate 8bytes have been removed It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDP]. The QSPI_RSER[RBDDE] defines which pop has to be done. For further details please refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) and "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read section.
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level, indicates how many entries of 4 bytes are still available in the RX Buffer. For example a value of 0x2 would indicate 8bytes are available.
Reserved	This field is reserved.

51.13.15 RX Buffer Control Register (QuadSPIx_RBCT)

This register contains control data related to the receive data buffer.

Write:

- $QSPI_SR[IP_ACC] = 0$

Address: Base address + 110h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout: This bit specifies the access scheme for the RX Buffer readout. 0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to Exclusive Access to Serial Flash for AHB Commands . 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR31.

Table continues on the next page...

QuadSPIx_RBCT field descriptions (continued)

Field	Description
7–5 Reserved	This field is reserved.
WMRK	RX Buffer Watermark: This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted. The value should be entered as the number of 4byte entries minus 1. For example a value of 0x0 would set the watermark to 4bytes, 1 to 8bytes, 2 to 12bytes etc. For details, refer to DMA Usage .

51.13.16 TX Buffer Status Register (QuadSPIx_TBSR)

This register contains information related to the transmit data buffer.

Address: Base address + 150h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

QuadSPIx_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written into the QSPI_MCR[CLR_TXF] bit. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TBDR for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

51.13.17 TX Buffer Data Register (QuadSPIx_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 128 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to [Table 51-14](#) for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bytes will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- $QSPI_SR[TXFULL] = 0$

32-bit write access required

Address: Base address + 154h offset

QuadSPIx_TBDR field descriptions

Field	Description
TXDATA	<p>TX Data</p> <p>On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly.</p> <p>On a read access, the last data written to the register is returned.</p>

51.13.18 Status Register (QuadSPiX_SR)

The QSPI_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer and TX Buffer and the AHB Buffer.

Address: Base address + 15Ch offset

QuadSPIx_SR field descriptions

Field	Description
31–29 DLPSMP	Data learning pattern sampling point: The sampling point found by the controller with the data learning pattern. <ul style="list-style-type: none"> • This is used for DDR only. • If the learning fails, this field will return garbage and DLPFF bit will be set. •
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full: Asserted when no more data can be stored.
26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 TXEDA	Tx Buffer Enough Data Available Asserted when TX Buffer contains enough data for any pop operation to take place. There must be atleast 128bit data available in TX FIFO for any pop operation otherwise QSPI_FR[TBUF] will be set.

Table continues on the next page...

QuadSPIx_SR field descriptions (continued)

Field	Description
23 RXDMA	RX Buffer DMA: Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full: Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded: Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full: Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full: Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full: Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full: Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty: Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty: Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty: Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty: Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending: Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration .
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access: Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access: Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy: Asserted when module is currently busy handling a transaction to an external flash device.

51.13.19 Flag Register (QuadSPIx_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write: Enabled Mode

Address: Base address + 160h offset

QuadSPiX_FR field descriptions

Field	Description
31 DLPPF	Data Learning Pattern Failure Flag: Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern. The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30 Reserved	This field is reserved.
29–28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag: Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag: Set when the module tried to pull data although TX Buffer was empty or the buffer contains less than 128 bits of data. The application must ensure that the buffer never goes empty during a transaction expect for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid tx underrun. The application must clear the TX Buffer in response to this event by writing a 1 into the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag: Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to Table 51-12 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag: Set when not all the data read from the serial flash device could be pushed into the RX Buffer. The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device. The content of the RX Buffer is not changed.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
16 RBDF	<p>RX Buffer Drain Flag: Will be set if the QuadSPI_SR[RXWE] status bit is asserted.</p> <p>Writing 1 into this bit triggers one of the following actions:</p> <ul style="list-style-type: none"> • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. <p>The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished.</p> <p>Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.</p>
15 ABSEF	<p>AHB Sequence Error Flag: Set when the execution of an AHB Command is started with an WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p> <p>The AHB bus request which triggered this command is answered with an ERROR response.</p>
14 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
13 Reserved	<p>Reserved</p> <p>This field is reserved.</p>
12 ABOF	<p>AHB Buffer Overflow Flag: Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly.</p> <p>The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device.</p> <p>The content of the AHB Buffer is not changed.</p>
11 IUEF	<p>IP Command Usage Error Flag: Set when in parallel flash mode the execution of an IP Command is started and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to Table 51-12 table for the related commands.</p> <p>Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.</p>
10–8 Reserved	<p>This field is reserved.</p>
7 IPAIEF	<p>IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs:</p> <ul style="list-style-type: none"> • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAIEF flag is ignored.
6 IPIEF	<p>IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs:</p> <ul style="list-style-type: none"> • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored • Write access to the QSPI_SFAR register. • Write access to the QSPI_RBCT register.
5 Reserved	<p>This field is reserved.</p>

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
4 IPGEF	IP Command Trigger during AHB Grant Error Flag: Set when the following condition occurs: <ul style="list-style-type: none"> A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag: Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

1. QSPI_BUFxCR implies anyone of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR

51.13.20 Interrupt and DMA Request Select and Enable Register (QuadSPIx_RSER)

The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

>

51.13.21 Sequence Suspend Status Register (QuadSPIx_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: Base address + 168h offset

Peripheral Bus Register Descriptions

QuadSPIx_SPNDST field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

51.13.22 Sequence Pointer Clear Register (QuadSPIx_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

51.13.27 RX Buffer Data Register (QuadSPIx_RBDRn)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to [Table 51-14](#) for the byte ordering scheme.

QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: Base address + 200h offset + (4d × i), where i=0d to 31d

QuadSPIx_RBDRn field descriptions

Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in Byte Ordering of Serial Flash Read Data .

51.13.28 LUT Key Register (QuadSPIx_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to [Look-up Table](#) for details.

Write:Anytime

Address: Base address + 300h offset

QuadSPIx_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

51.13.29 LUT Lock Configuration Register (QuadSPi_x_LCKCR)

The LUT lock configuration register is used along with QSPI_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI_LUTKEY register for the lock or unlock operation to be successful. Refer to [Look-up Table](#) for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Write: Just after writing the LUT Key Register

(QSPI_LUTKEY)

Address: Base address + 304h offset

Chapter 52

Resource Domain Controller (RDC)

52.1 Overview

The Resource Domain Controller (RDC) provides robust support for the isolation of destination memory mapped locations such as peripherals and memory to a single core, a bus master, or set of cores and bus masters.

Many of today's processors have multiple cores for increased performance and flexibility. In some cases, the cores serve different functions (e.g. user level applications versus real time machine control) and in such cases the software for each core may be developed by different providers.

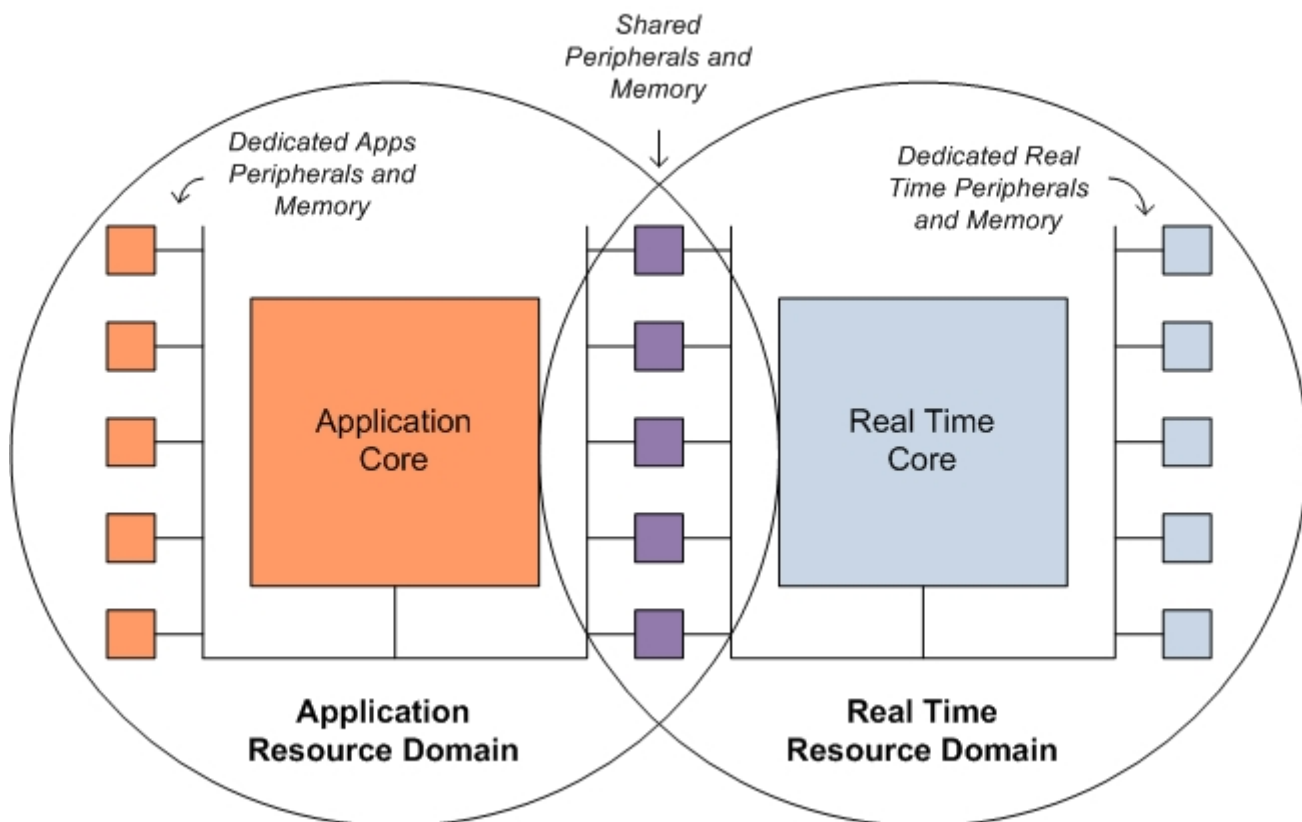

Figure 52-1. Dedicated and Shared Peripherals

For efficiency reasons the code on the cores may share chip resources such as peripherals and memory. The sharing of chip resources between the somewhat independent processing domains allows for the opportunity of data collisions where information stored in peripherals or memory by a process on one core is overwritten by software running on another core. Without careful collaboration between the two operating systems inadvertent malfunction or degradation in performance may result.

The RDC provides a mechanism to allow boot time configuration code to establish resource domains by assigning cores, bus masters, peripherals and memory regions to domain identifiers. Once configured, bus transactions are monitored to restrict accesses initiated by cores and bus masters to their respective peripherals and memory.

For shared peripherals, the RDC provides a semaphore-based locking mechanism to provide for temporary exclusivity while the domain software uses the peripheral. Once the software of one domain has finished the task and finished with the peripheral then it may release the semaphore making the peripheral available to the other domain.

52.1.1 Features

Resource domain subsystem has the following features:

- Assignment of cores, bus masters, peripherals, and memory regions to a resource domain
- Fixed memory resolution of 128 Bytes for small address spaces and 4 KB for large address spaces
- Four resource domain identifiers
- Memory read/write access controls for each resource domain and region
- Optional semaphore-based, hardware-enforced exclusive access of shared peripherals to a resource domain
- Prioritized access permissions for overlapping memory regions
- Automatic restoration of resource domain access permissions to memory regions in the power-down domain

52.2 Functional Description

The RDC is the central location for creation of isolated resource domains and for the enablement of semaphore-based access also known as “safe sharing”. Configuration software assigns one of four resource domain identifiers to each core and bus master, and allocates each memory region and peripheral to one or more resource domains.

Memory Read or Write access privileges for each resource domain are declared for each memory region. In addition, the software configuration determines which shared peripherals (those peripherals allocated to more than one domain) require safe sharing by setting the semaphore-required configuration for each peripheral.

The RDC configuration information is sent to the fabric ports, memories gaskets, semaphore controller, and peripherals to control access based on domain assignments. The fabric uses the domain identifier associated with each port to include this information along with the bus transaction. When the slave gasket encounters a bus transaction it makes a comparison of the transaction domain ID to the RDC-provided list of allowed domains. If the transaction domain ID is on the list then access may be permitted.

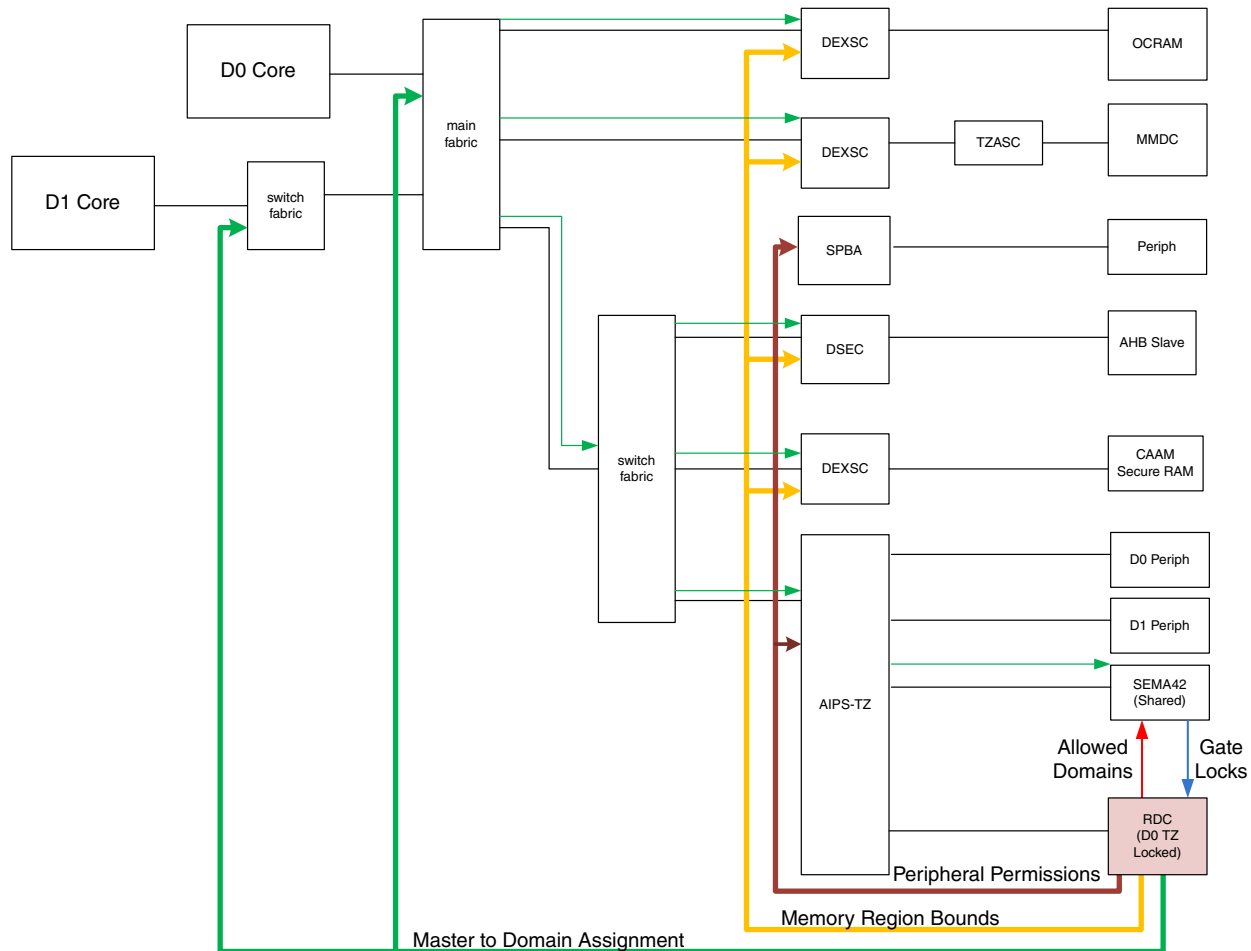

Figure 52-2. Example RDC Connections

For shared peripherals, RDC permits more than one domain access to a single peripheral. RDC also provides three ways to control synchronized use of shared peripherals. These methods include hardware-enforced synchronization, software-based semaphores, or no synchronization. The latter may be suitable for well-tuned multi-core operating systems that handle synchronization in the core platform, for instance.

For hardware-enforced synchronization, also known as "safe sharing", ownership of the peripheral must be claimed in the semaphore controller before access is allowed to the shared peripheral. The "semaphore required" bit (SREQ) is set in the PDAP register corresponding to the shared peripheral which causes the RDC to require that a semaphore is obtained by a domain before access by that domain to the shared peripheral is allowed. During the time that the domain has the semaphore in possession its bus masters have exclusive access to the peripheral.

When the semaphore is released then no domain masters have access until the semaphore is obtained again. When the SREQ is set, RDC does not allow masters to obtain semaphores of peripherals to which it is not allocated; the master must have designated access in the D-registers of the corresponding PDAP register (e.g. D3R bit set for Domain 3 access of the shared peripheral). There is a one-to-one mapping between the semaphore controller gate and the resource domain controller peripheral. The mapping of PDAP registers and peripherals can be found in the Peripheral Map section of the RDC chapter.

52.2.1 Domain ID

The RDC provides for an isolation of domain resources by use of a identifier called the Domain ID (DID). A core and its resources including memory, bus masters, and peripherals are all associated with a single DID. When software or a DMA attempts to access a peripheral or memory, the corresponding bus transaction includes the DID along with the other bus control information such as Read, Write, and privilege mode.

52.2.2 Resource Assignment

The RDC allows assignment of peripherals and memories to one or more domains while each bus master or core is placed in one of four domains. The masters are assigned a domain in the MDA register. A peripheral is given R/W access permissions to each domain in the PDAP register. Memory regions are bound by address space in start and end registers, the MRSA and MREA. Each memory region is assigned one or more allowed domains and R/W permissions in the MRC control register. Memory regions must be enabled before the permissions are active. Otherwise the permissions are not restricted.

The RDC itself should be isolated to ensure that only a trustworthy resource manager can configure the RDC registers. This process may either be present initially, during secure boot, or during the runtime in the secure world, for example. If the operating system does not support a runtime trusted execution then during the secure boot process the RDC configuration can be locked to prevent further modification after the operating systems are running.

52.2.3 Safe Sharing

For shared peripherals, the RDC can be configured to require a domain to obtain a semaphore lock before access to the peripheral is allowed. This feature helps prevent collisions from processes on separate cores that may want to use the same peripheral at the same time. The RDC sends a list of eligible domains to the semaphore module for each gate/peripheral. The eligible domains are those that are set in the peripheral domain access permissions (PDAP) registers. There is a one-to-one correspondence between semaphore gates and peripherals so each gate in the semaphore block represents a peripheral. The RDC receives semaphore locks from the hardware semaphore module (SEMA42). A semaphore lock is acquired when a core or bus master from a given domain requests a lock for a particular gate. The semaphore module compares the request's domain ID against the list of eligible domain IDs. If the domain ID is on the list and the lock is available then the lock is set and a signal is sent back to the RDC module indicating a lock has been acquired for a particular gate and to which domain ID the lock belongs. The RDC then restricts access to the corresponding peripheral to only transactions originating from the domain that has the lock. Another domain, though on the shared list to access the peripheral, must then wait until the lock is released before acquiring the lock and gaining access to the peripheral. To enable this feature of hardware enforcement for the semaphore locks, the SREQ bit is set in the RDC resource register.

If the SREQ is set, then when a process determines it needs a shared peripheral, it must first lock the resource in the semaphore module. Once the resource is locked, the semaphore module sends a signal to the RDC indicating the domain has access to the resource. The RDC will then set the access permissions to allow that domain access to the peripheral.

For a domain to acquire a lock on a peripheral, the domain must have been assigned to the peripheral in the RDC Peripheral Domain Access Permissions register (PDAP). The semaphore module only allows safe-sharing locks for those domains that are assigned to the peripheral. The semaphore module does not consider the access type (Read or Write) when allowing domains to acquire locks.

The SEMA42 module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Module definition supporting 64 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cpX is meant to represent core processor X
 - Gates appear as an n -entry byte-size array with read and write accesses ($n = 16, 32, 64$).

- Processors lock gates by writing "Master_index" to the appropriate gate and must read back the gate value to verify the lock operation was successful. The Master_index value for the processors can be found in Table 14-7. Also note that after locking, the gate register contains the master_id value of the locking processor (in bits [3:0]), and also the value of the locking domain (in bits [5:4]).
- Once locked, the gate is unlocked by a write of zeroes from the locking processor.
- The number of implemented gates is specified by a hardware configuration define.
- Each hardware gate appears as a 16-state, 4-bit state machine.
 - 16-state implementation
 - if gate = 0x0, then state = unlocked
 - if gate = 0x1, then state = locked by processor (master_index) 0
 - if gate = 0x2, then state = locked by processor (master_index) 1
 - ...
 - if gate = 0xF, then state = locked by processor (master_index) 14
 - Uses the logical bus master number (master_index) as a reference attribute plus the specified data patterns to validate all write operations.
 - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.
- Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.
- Memory-mapped IPS slave peripheral platform module
 - Interface to the IPS bus for programming-model accesses

52.2.4 Resource Domain Control and Security Considerations

Conceptually, the RDC configuration is independent of the processor privilege mode and security domain. It is intended to allow for isolation between core processing environments to prevent collisions and increase reliability. Access between resource domains is mutually exclusive and each domain should be in control of its own privilege modes and access rights.

However, it is important to realize multi-core processors may have a multiple resource domains but only one overarching security domain. Chip security controls reside in one resource domain. In this configuration, a domain can affect at least one level of access privileges in the other domain. This may be acceptable but clarity and care is needed to ensure expected functionality.

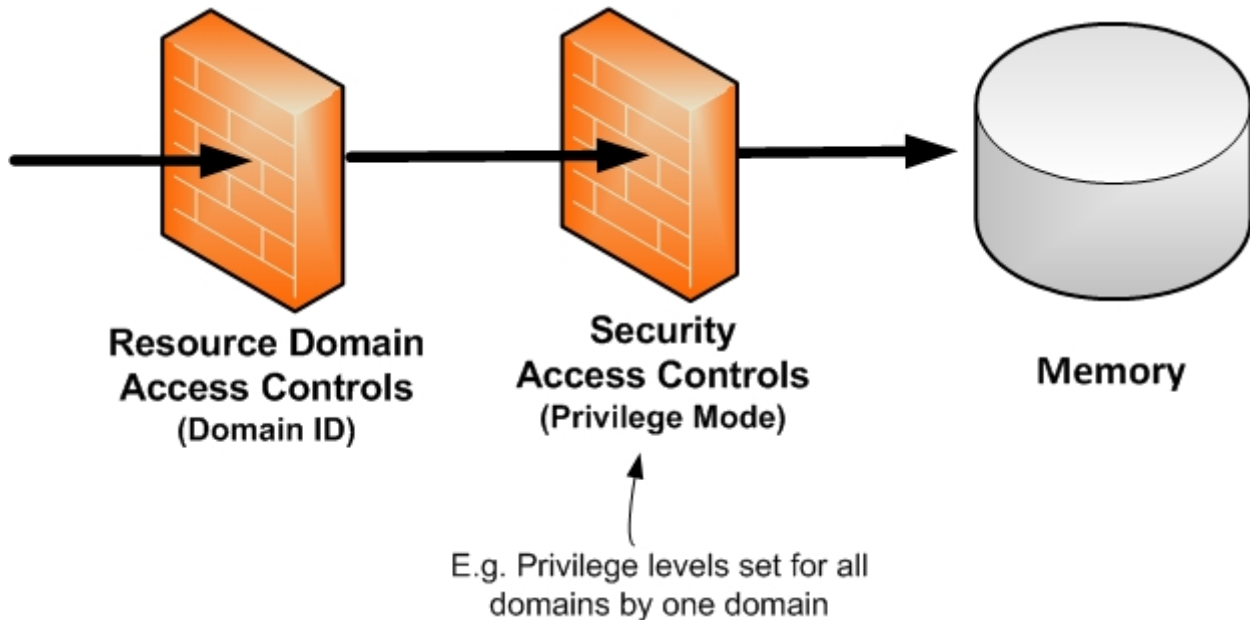

Figure 52-3. Access Control to Memory

Therefore, access to the security controls should be restricted to the most trustworthy operating mode of the core and privilege levels should be coordinated to ensure that shared peripherals and memory regions are accessible by both cores. For instance, if a memory region is designated for secure accesses then all domain masters that share that region must have secure privileges.

52.3 Modes of Operation

The RDC provides access controls to the resource domain subsystem. When the device is in a low power mode then some memory regions in the subsystem may be powered off. RDC responds to the impacted memory regions by automatically reconfiguring the memory regions once power returns and blocking access to those memory regions until the reconfiguration process is complete.

52.3.1 Low Power Modes

The RDC loads configuration information for memory regions (MRSA, MRSE, MRC) into access control mechanisms (gaskets) at the memory interface. The location of this configuration information may reside inside power domains that lose power during sleep modes for energy savings. To restore configuration information upon return from sleep mode, the RDC receives a global power control signal indicating power is restored. The RDC then automatically reconfigures the memory regions with the configuration information.

During reconfiguration, access is blocked to the previously powered down memories. When the RDC completes reconfiguration it issues an interrupt and allows access to the memory regions. Only the powered down regions are blocked during the reconfiguration. Memory regions in the "always-on" power domain (still powered during sleep mode) remain available according to the programmed access rights. If no memory regions were enabled then the powered down regions are available immediately when power is restored.

The figure below shows the Global Power Control signal which RDC uses to invalidate the configuration upon deassertion and to restore the configuration when re-asserted. The configuration is valid and bus transactions allowed once the memory regions have been restored.

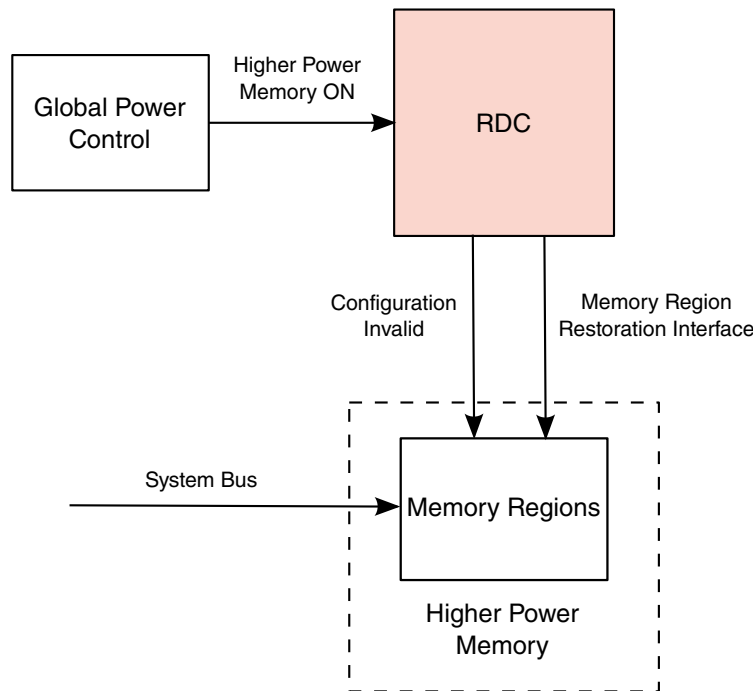

Figure 52-4. Memory Restoration Signaling

52.4 Programming Interface

This section provides product specific details describing the mapping of resources - peripherals, bus masters, and memory regions - to corresponding resource domain controls RDC registers.

The RDC and RDC_SEMA42 register maps are combined in this chapter. The base address for the one RDC map and two SEMA42 maps are each separated by 4KB. While there are two SEMA42 submodules and therefore two sets of SEMA42 registers, this chapter describes one. Please refer to the peripheral memory map for the base addresses of the RDC and SEMA42 modules.

52.4.1 Master Assignment Registers

Table 52-1. Master Assignment Mapping

Master	RDC MDA register

ENET1 RX	RDC_MDA23
ENET2 TX	RDC_MDA24
ENET2 RX	RDC_MDA25
SDMA port	RDC_MDA26

52.4.2 Peripheral Mapping

Each peripheral has a corresponding resource domain assignment register in the RDC and semaphore lock register in the RDC_SEMA42 module. The following table shows allocation of the RDC PDAP and RDC_SEMA4 GATE registers for peripheral resource domain assignment.

NOTE

Access control of the RDC registers can be programmed using the respective PDAP register. The default setting of the PDAP register for the RDC allows access from all domains. Use caution when restricting access of the RDC registers to avoid conditions where access to the RDC registers is needed but no master is assigned to a domain with access rights to the RDC.

1. Memory region based domain control is not supported for QuadSPI. The RDC can be used to allow and deny access to the QuadSPI for writes using the RDC PDAP registers 58 and 59 (QSPI1 and QSPI2, respectively). But this does not provide granularity within the QSPI memory space. There can only be one region covering the entire QSPIn memory space using a PDAP register

52.4.3 Memory Region Map

The number of memories with domain isolation support varies per device. The number of memory regions for a particular memory and the size of those regions varies per memory gasket. Each region of memory has a set of registers to define the boundaries of the region based on start and end addresses, a control register to set the domain access permissions and enable the region, and a status register to determine if access was denied to a region.

For this device, refer to the table below to determine the memories with domain support, the number of regions for each memory, the region resolution, the identifying numbers for the sets of memory region registers, and the addresses of the RDC registers to access the sets of Memory Region registers.

Table 52-3. Memory Region Mapping

Memory/Port	Number of Regions	Region Resolution	Memory Region Register Set Number (e.g. MRSA, MREA, MRC, MRVS)	Register Address Range
MMDC	8	4 KB	0-7	0x800-0x87C
QSPI1	8	4 KB	8-15	0x880-0x8FC
QSPI2	8	4 KB	16-23	0x900-0x97C

RDC_VIR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–20 NRGN	Number of Memory Regions Indicates the number of memory regions in this instance of the RDC.
19–12 NPER	Number of Peripherals Indicates the number of peripherals that can be isolated or safe-shared
11–4 NMSTR	Number of Masters Indicates the number of masters supported by this instance of RDC.
NDID	Number of Domains Indicates the number of domain ids supported by this instance of the RDC. Add one to the register value to get the actual number of domains.

52.5.2 Status (RDC_STAT)

RDC_PDAPn field descriptions

Field	Description
31 LCK	Peripheral Permissions Lock When set prevents further modification of the Peripheral Domain Access Permissions (sticky bit until reset) 0 Not Locked 1 Locked
30 SREQ	Semaphore Required When set the hardware semaphore state enforces the semaphore lock. If a domain has access permissions and a semaphore has locked a shared peripheral then only the domain holding the semaphore signal can access this peripheral. 0 Semaphores have no effect 1 Semaphores are enforced
29–8 Reserved	This field is reserved.
7 D3R	Domain 3 Read Access 0 No Read Access 1 Read Access Allowed
6 D3W	Domain 3 Write Access 0 No Write Access 1 Write Access Allowed
5 D2R	Domain 2 Read Access 0 No Read Access 1 Read Access Allowed
4 D2W	Domain 2 Write Access 0 No Write Access 1 Write Access Allowed
3 D1R	Domain 1 Read Access

Table continues on the next page...

RDC_PDAP_n field descriptions (continued)

Field	Description
	0 No Read Access 1 Read Access Allowed
2 D1W	Domain 1 Write Access 0 No Write Access 1 Write Access Allowed
1 D0R	Domain 0 Read Access 0 No Read Access 1 Read Access Allowed
0 D0W	Domain 0 Write Access 0 No Write Access 1 Write Access Allowed

52.5.7 Memory Region Start Address (RDC_MRSA_n)

Address: 20F_C000h base + 800h offset + (16d × i), where i=0d to 54d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:

- x = Undefined at reset.

RDC_MRSA_n field descriptions

Field	Description
31–7 SADR	Start address for memory region Lower bound (inclusive) modulo the defined granularity byte size of a region. The region size (granularity) is defined for each Memory/Port in the Memory Region Map section. Region boundaries are aligned to the minimum possible region size for the Memory/Port.
Reserved	This field is reserved.

52.5.8 Memory Region End Address (RDC_MREAn)

Address: 20F_C000h base + 804h offset + (16d × i), where i=0d to 54d

- * Notes:
- x = Undefined at reset.

RDC_MREAn field descriptions

Field	Description
31–7 EADR	Upper bound for memory region Upper bound (exclusive) modulo the defined granularity byte size of a region. The region size (granularity) is defined for each Memory/Port in the Memory Region Map section. Region boundaries are aligned to the minimum possible region size for the Memory/Port.
Reserved	This field is reserved.

52.5.9 Memory Region Control (RDC_MRCn)

Address: 20F_C000h base + 808h offset + (16d × i), where i=0d to 54d

RDC_MRCn field descriptions

Field	Description
31 LCK	Region Lock Locks all region fields from further modification except ENA, which can be set but not reset after LCK is set. LCK is a sticky bit. 0 No Lock. All fields in this register may be modified. 1 Locked. No fields in this register may be modified except ENA, which may be set but not cleared.
30 ENA	Region Enable Activates the memory region. If the region is not activated then the permissions and address boundaries have not affect and the region will be fully accessible.

Table continues on the next page...

RDC_MRCn field descriptions (continued)

Field	Description
	0 Memory region is not defined or restricted. 1 Memory boundaries, domain permissions and controls are in effect.
29–8 Reserved	This field is reserved.
7 D3R	Domain 3 Read Access to Region 0 Processing Domain 3 does not have Read access to the memory region 1 Processing Domain 3 has Read access to the memory region
6 D3W	Domain 3 Write Access to Region 0 Processing Domain 3 does not have Write access to the memory region 1 Processing Domain 3 has Read access to the memory region
5 D2R	Domain 2 Read Access to Region 0 Processing Domain 2 does not have Read access to the memory region 1 Processing Domain 2 has Read access to the memory region
4 D2W	Domain 2 Write Access to Region 0 Processing Domain 2 does not have Write access to the memory region 1 Processing Domain 2 has Write access to the memory region
3 D1R	Domain 1 Read Access to Region 0 Processing Domain 1 does not have Read access to the memory region 1 Processing Domain 1 has Read access to the memory region
2 D1W	Domain 1 Write Access to Region 0 Processing Domain 1 does not have Write access to the memory region 1 Processing Domain 1 has Write access to the memory region
1 D0R	Domain 0 Read Access to Region 0 Processing Domain 0 does not have Read access to the memory region 1 Processing Domain 0 has Read access to the memory region
0 D0W	Domain 0 Write Access to Region 0 Processing Domain 0 does not have Write access to the memory region 1 Processing Domain 0 has Write access to the memory region

52.5.10 Memory Region Violation Status (RDC_MRVS_n)

Address: 20F_C000h base + 80Ch offset + (16d × i), where i=0d to 54d

RDC_MRVS_n field descriptions

Field	Description
31–5 VADR	Violating Address The address of the denied access. The first access violation is captured. Subsequent violations are ignored until the status register is cleared. Contents are cleared upon reading the register. Clearing of contents occurs only when the status is read by the memory region's associated domain ID (s).
4 AD	Access Denied Access to a memory region denied. This bit is cleared when this bit is written by one of the allowed domains.
3–2 Reserved	This field is reserved.
VDID	Violating Domain ID The domain ID of the denied access. The first access violation is captured. Subsequent violations are ignored until the status register is cleared. Contents are cleared upon reading the register. 00 Processing Domain 0 01 Processing Domain 1 10 Processing Domain 2 11 Processing Domain 3

52.6 RDC SEMA42 Memory Map/Register Definition

Only Supervisor Mode accesses are allowed on these registers. User accesses generate an error termination.

52.6.1 Gate Register (RDC_SEMAPHORE_x_GATE_n)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number (`master_index`) in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value nor the appropriate lock value (`master_index + 1`) are simply treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes. Processor dex values can be found in [Table 15-7](#).

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–5 LDOM	Bits 6-5 are read-only bits. They indicate which domain had currently locked the gate. 00 The gate is locked by domain 0. (True if bits [3:0] do not equal 0000.) 01 The gate has been locked by domain 1. 10 The gate has been locked by domain 2. 11 The gate has been locked by domain 3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
GTFSM	Gate Finite State Machine. The state of the gate reflects the last processor that locked it, which can be useful during system debug. The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor with master_index = 0. 0010 The gate has been locked by processor with master_index = 1. 0011 The gate has been locked by processor with master_index = 2. 0100 The gate has been locked by processor with master_index = 3. 0101 The gate has been locked by processor with master_index = 4. 0110 The gate has been locked by processor with master_index = 5. 0111 The gate has been locked by processor with master_index = 6. 1000 The gate has been locked by processor with master_index = 7. 1001 The gate has been locked by processor with master_index = 8. 1010 The gate has been locked by processor with master_index = 9. 1011 The gate has been locked by processor with master_index = 10. 1100 The gate has been locked by processor with master_index = 11. 1101 The gate has been locked by processor with master_index = 12. 1110 The gate has been locked by processor with master_index = 13. 1111 The gate has been locked by processor with master_index = 14.

52.6.2 Reset Gate Write (RDC_SEMAPHOREx_RSTGT_W)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the RDC Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the RDC_SEMA42RSTGT memory location. The least significant byte (RDC_SEMA42RSTGT[RSTGDP]) must be 0xE2; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the RDC_SEMA42RSTGT location. For this write, the lower byte (RDC_SEMA42RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the upper byte (RDC_SEMA42RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.
3. Reads of the RDC_SEMA42RSTGT location return information on the 2-bit state machine (RDC_SEMA42RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (RDC_SEMA42RSTGT[RSTGMS]), and the gate number(s) last cleared (RDC_SEMA42RSTGT[RSTGTN]). Reads of the RDC_SEMA42RSTGT register do not affect the secure reset finite state machine in any manner.

Address: Base address + 40h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDC_SEMAPHOREx_RSTGT_W field descriptions

Field	Description
15-8 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.
RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.

52.6.3 Reset Gate Read (RDC_SEMAPHOREx_RSTGT_R)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the RDC Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the RDC_SEMA42RSTGT memory location. The least significant byte (RDC_SEMA42RSTGT[RSTGDP]) must be 0xE2; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the RDC_SEMA42RSTGT location. For this write, the lower byte (RDC_SEMA42RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the upper byte (RDC_SEMA42RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.
3. Reads of the RDC_SEMA42RSTGT location return information on the 2-bit state machine (RDC_SEMA42RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (RDC_SEMA42RSTGT[RSTGMS]), and the gate number(s) last cleared (RDC_SEMA42RSTGT[RSTGTN]). Reads of the RDC_SEMA42RSTGT register do not affect the secure reset finite state machine in any manner.

Address: Base address + 40h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RDC_SEMAPHOREx_RSTGT_R field descriptions

Field	Description
15–8 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write.

Table continues on the next page...

RDC_SEMAPHOREx_RSTGT_R field descriptions (continued)

Field	Description
	If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.
7-6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5-4 RSTGSM	<p>Reset Gate Finite State Machine. Reads of the RDC_SEMA42RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as:</p> <p>00 Idle, waiting for the first data pattern write.</p> <p>01 Waiting for the second data pattern write.</p> <p>10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software will never be able to observe this state.</p> <p>11 This state encoding is never used and therefore reserved.</p>
RSTGMS	<p>Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs.</p> <p>The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.</p>

Chapter 53

ROM Controller with Patch (ROMC)

53.1 Overview

The Read Only Memory Controller with ROM Patch (ROMC) acts as an interface between the ARM advanced high-performance bus (AHB - Lite) and the Read Only Memory. The ROMC consists of a ROM Controller and a ROM Patch. The ROM Patch is used to either patch code routines or fix data tables in the ROM area. There is an IP Bus interface to access the ROM Patch Registers and. The figure below depicts the main functional sub-blocks of the ROMC.

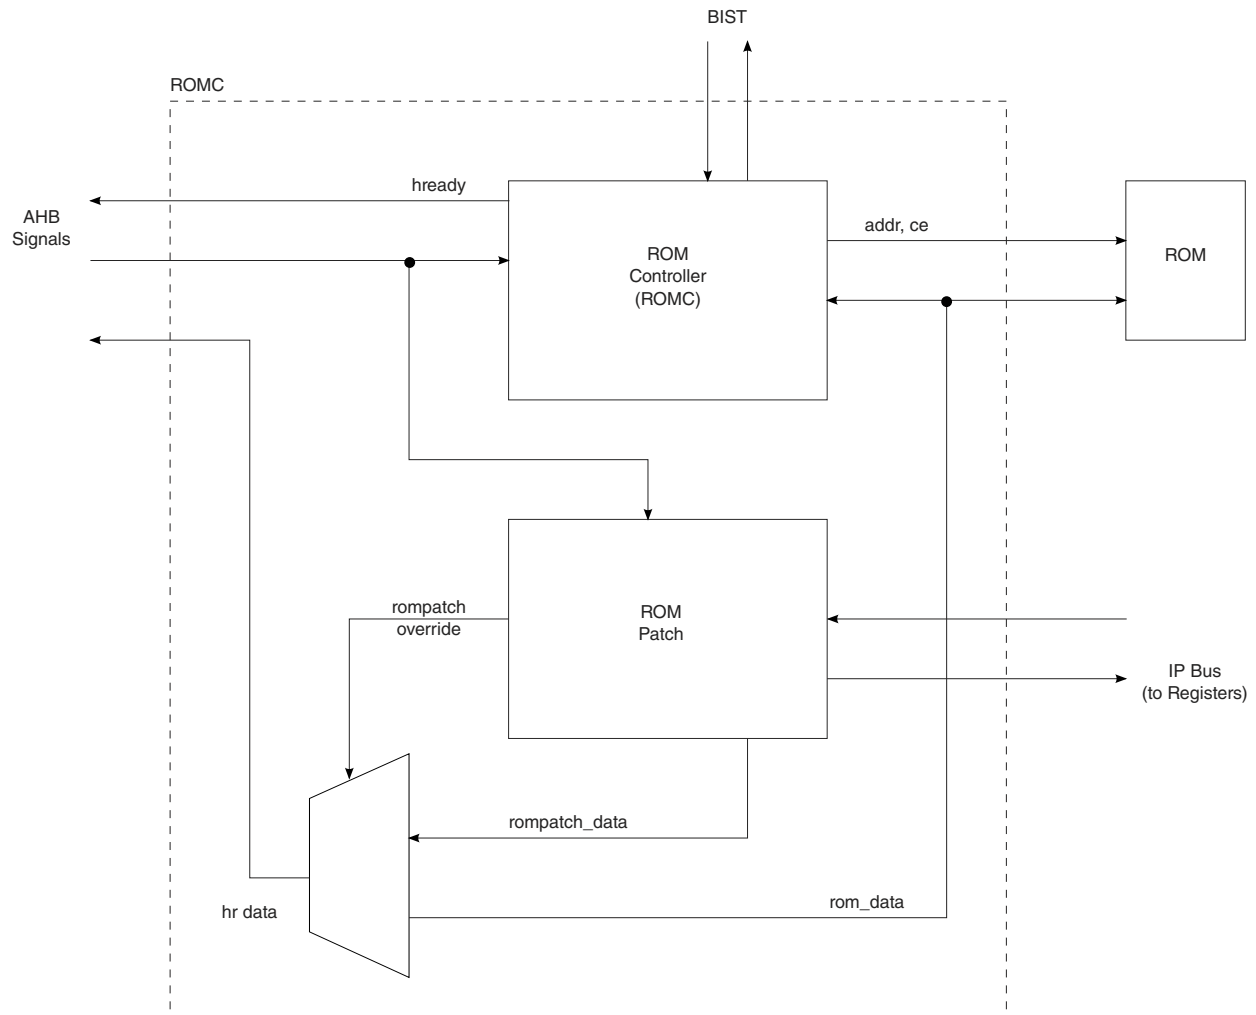

Figure 53-1. ROMC Block Diagram

53.1.1 Features

- Supports ROM size ranges from 16 Kbyte up to 4 Mbyte with increments of 1 Kbyte
- Supports opcode patching for a maximum of 16 different addresses in 4 Mbytes of ROM space
- Supports one-word data fixes for a max of 8 memory locations in 4 Mbytes of ROM space
- Supports patching of the Reset Vector (at 0x0000_0000) to allow external booting

53.1.2 Modes of Operation

There are two modes of operation: normal mode and BIST mode.

In normal mode (`ipt_bist_en = 0`), the ROMC ensures correct reads from the ROM, assuming the memory complies with the characteristics and requirements for which the ROMC was designed.

53.1.2.1 Low Power Mode

There are two clock enables that are used to switch off parts of the ROMC logic when inactive. The first clock enable is used to disable the ROM Controller when the master connected to the AHB interface is not initiating a read to the ROM. The second clock enable is used to disable the registers used to program the ROM patch feature when the registers are not being accessed.

53.2 Clocks

The table found here describes the clock sources for ROMCP.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 53-1. ROMCP Clocks

Clock name	Clock Root	Description
hclk	ahb_clk_root	System / bus clock
hclk_reg	ipg_clk_root	System access clock
96krom_CLK	ahb_clk_root	ROM clock

53.3 Memory Map

53.3.1 ROM Memory Map in detail

The ROMC supports ROM sizes with a range of 16 Kbyte to 4 Mbyte with an increment of 1 Kbyte. The 16 Kbyte lower limit was chosen because the minimum size of security code on an ARM platform is approximately 16 Kbyte of code, which is only accessible in supervisor mode. Note that it is the MMU that controls whether any region of memory is secure.

Functional Description

The exception vectors must be secured as well, and must be put in the same area as the security code. Since they must reside at address 0x0000_0000, the entire 16 Kbyte of ROM which can only be accessible in supervisor mode is located at the very beginning of the platform memory map.

If the user chooses not to use the security code, a memory size smaller than 16 Kbyte can be connected to the platform (minimum of 1 Kbyte). The MMU can be programmed to allow any kind of access into this memory. However, if the ROM size is less than 16 Kbyte, memory aliasing will occur for all invalid addresses greater than the memory size but within the 16 Kbyte of space.

For ROM sizes bigger than 16 Kbyte, the rest of its physical size resides at the address starting at 0x0040_4000 (4 M+16 Kbyte) going up to [0x0040_4000 + (mem. size - 16Kbyte)]. .

53.4 Functional Description

This section is divided up into the ROM Controller Functional Description and the ROMC functional description.

53.4.1 ROM Controller (ROMC) Functional Description

53.4.1.1 Functionality overview

The ROMC serves two main functions. First, as an interface between the AHB-Lite bus on an ARM platform and the ROM. Second, it drives and receives several signals for the BIST engine. In normal mode of operation, the ROMC monitors the AHB-Lite for memory access requests and performs the memory operation to the ROM.

The ROMC includes the option to wait state all accesses from either the ARM or non-ARM masters to ROM in the event that timing requirements will not allow single hclk clock cycle reads. If a wait state is required, the static inputs rom_wait_arm or rom_wait_alt_mstr can be set to 1 and accesses will take two hclk clock cycles. If wait states are not required, rom_wait_arm or rom_wait_alt_mstr can be set to 0 and accesses will take one hclk clock cycle to complete.

53.4.2 ROMC Functional Description

53.4.2.1 ROMC Disabling

All the bits in the ROMC_ROMPATCHENL register are cleared on Reset, disabling all the address comparators. Once the comparators have been enabled, the ROMC functions of data fixing and opcode patching can be quickly disabled by setting the DIS bit in the ROMC_ROMPATCHCNTL register. This bit is used to enable secure operations in which patching functions need to be disabled. This bit is cleared on Reset.

53.4.2.2 ROMC Event Priority

The ROMC has a total of 16 address comparators. The first 8 (0 through 7) comparators can be programmed for the data fixing function (through the 8 data fix enable bits in the ROMC_ROMPATCHCNTL register) while the rest are for opcode patching by default. This allows for potential multiple matching events involving both data fixing and opcode patch types. In these cases the ROMC assigns the highest priority to a data fixing event.

For example, if the ROMC is set up to data fix a certain address with comparator 4 and also opcode patch the same address with comparator 7, it will let comparator 4 have higher priority in indicating a match, and data from ROMC_ROMPATCHD4 will be put on the rompatch_romc_hrdata bus as the override value.

If multiple address matches of the same type level occur concurrently, then the ROMC will choose the source number based on the one with the highest source number. For example, the ROMC is setup to data fix the same location with address comparators 4 and 7, then address comparator 7 will have higher priority in indicating a match, and the value from ROMC_ROMPATCHD7 will be put on the rompatch_romc_hrdata bus as the override value. The same priority applies for an opcode patch event, except the override data is in the form of an SWI instruction with the comment field set to the source number with the highest priority.

53.4.2.3 Data Fixing

The data fixing feature allows ROM data to be updated by direct replacement when it is being read. This data usually originates from data tables, but can include ARM instructions. To enable data fixing on a certain address, this address value is written in to one of the first eight (0 through 7) of ROMC_ROMPATCHAxx registers and the same numbered bit set in the ROMC_ROMPATCHENL and ROMC_ROMPATCHCNTL registers. The data to be used for replacement is placed in the corresponding ROMC_ROMPATCHDxx.

The ROMC looks for a read access to ROM (either code fetch or data load) by snooping the AHB interface for read transactions. The address is compared with the values stored in the ROMC_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC places the value in the corresponding ROMC_ROMPATCHDxx register on the read data bus by overriding the read data coming from the actual ROM (see the mux in [Figure 53-1](#)). The value on the read data bus is maintained until hready is asserted to terminate the access. In data fixing, the entire word is replaced so if a byte or half-word access occurs on a "data fix" location, the entire data word is replaced. The word being replaced is word aligned. (The two LSBs of the matching ROMC_ROMPATCHAxx are ignored in the data fix operation.)

53.4.2.4 Opcode Patching

The opcode patch feature provides the ARM core a mechanism to fetch updated versions of code routines that were originally programmed in ROM. This patching mechanism makes use of the SWI (software interrupt instruction) and a table of function pointers residing in writable memory. The opcode being patched is replaced with a SWI instruction by the ROMC. Subsequent processing of the SWI reads from a function pointers table to obtain the address of the replacement code. Execution resumes with this code patch.

To enable opcode patching of a certain address, this address value is written into one of the ROMPATCHAxx registers and the corresponding bit set in the ROMPATCHENL to enable the associated comparator. The register's LSB (ROMC_ROMPATCHxx[0]) should be set if THUMB mode patching is in effect for this address. The ROMC identifies a ROM read access by snooping the AHB interface. The address is compared with the values stored in the ROMC_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC generates the opcode of a software interrupt (SWI) instruction with the comment field containing the number of the matching address comparator. This opcode and comment is placed on the read data bus until hready is asserted by the ROM controller to terminate the read access.

The type of SWI generated, (that is, either ARM or THUMB), is determined by the LSB of the ROMC_ROMPATCHAxx register associated with the opcode patch. This bit is cleared for ARM mode (32 bits). The ROMC generates a 32-bit SWI (opcode field is 0xEF, occupying bits [31:24] of the word), with the least significant 5 bits of the 24-bit comment field (bits [23:0]) containing the number of the matching address comparator. The rest of the comment field is filled with zeros. This means that the ROMC will use 16 of the 16777216 possible software interrupts. The ROMC overrides the read data from the ROM.

If the LSB of the matching ROMC_ROMPATCHAxx register is set, the opcode patch is in THUMB mode (16 bits or half word). The ROMC generates a 16-bit SWI instruction (opcode field is 0xDF, occupying bits [15:8] of the half word) with the least significant 5 bits of the 8-bit comment field containing with the source number of the address comparator. The rest of the comments field is filled with zeros. This means that the ROMC will use 16 of the 256 possible software interrupts. The ROMC puts this 16 bit SWI instruction value on the proper half of the rompatch_romc_hrdata bus. The other half is zeroed out. Which half of the bus contains the SWI opcode and comment depends on the mode (Big Endian or Little Endian) and the bit 1 of the matching ROMC_ROMPATCHAxx register. In Little Endian mode, the lower half is bits {15:0} and the upper half is bits {31:16}. The order is reversed in Big Endian mode.

In Little Endian mode (bigend signal negated), if bit 1 of the matching ROMC_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the lower 16 bits of the read data bus and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten by the ROMC data. If ROMC_ROMPATCHAxx[1] is set (upper half word selected), the SWI instruction is put on the upper 16 bits of the read data bus and the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten.

In Big Endian mode (bigend asserted), if bit 1 of the matching ROMC_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the upper 16 bits of the read data bus while the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten. If ROMC_ROMPATCHAxx[1] is set (upper word selected), the SWI instruction is put on the lower 16 bits and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten.

The eventual execution of the SWI causes the ARM to save the CPSR in SPSR_SVC, the address of the next instruction after the SWI in R14_SVC, enter Supervisor mode, and fetch the SWI vector at 0x8, which then takes it to a handler for further processing as described in the next section.

53.4.2.4.1 Typical Software Response to Opcode Patch

When the SWI handler executes it needs to determine whether the SWI was generated by the ROMC. This is done by loading the SWI instruction and extracting its comment field. The state of the ARM core (ARM or THUMB) when the SWI was executed dictates whether to load the instruction word (ARM) or half word (THUMB). This state information can be determined by testing the T bit (bit 5) of the SPSR. If it's set, the execution was in THUMB mode.

By convention, if the comment field of the SWI is greater than 16, the software interrupt was initiated by software (i.e. an operating system call), and a branch is taken to the appropriate handler routine for further processing. If the comment field is less than 16, the SWI was generated by the ROMC performing a code patch operation. In this case, the software then reads from a table of function pointers, using the value in the SWI comment field as the index into the table. The value that is read is the address of the code patch. This value is loaded into the PC to begin the execution of the code patch. The following code segment illustrates a typical handling of the SWI.

```

stmfd      sp!, {r0-r1,lr}          @ push register onto SWI stack
mrs       r0, spsr                 @ get saved status register

ldmfd     sp!, {r0-r1,pc}^       @ >= 16: pop registers from stack

```

53.4.2.5 External Boot Feature

Following a Reset event, the ARM issues an instruction fetch of the Reset Vector from address 0x0. This instruction, normally residing in ROM is usually a branch to a Reset handler or boot code which also normally resides in ROM. The ROMC external boot feature allows the bypassing of this code, using a different boot code residing perhaps in external memory.

This feature uses the data fix mechanism and works as follows: if the boot_int signal is negated when a Reset event occurred, the ROMC will perform a data fix of the Reset Vector at 0x0 with the following instruction (opcode 0xE59FF00C):

```

ldr       pc, [pc, #12]          @ read 0x0000_0014 for reset_vector

```

The value of PC when this instruction is executed is 8 so that a PC relative offset of 12 makes the source address 20 or 0x14. When this instruction executes, the ARM core reads from address 0x0000_0014, triggering a ROMC data fix operation which places the

value taken from the external boot address on the read data bus, with the two LSBs zeroed out. This value is returned to the ARM to be placed in the PC causing code fetch and execution to start from that address.

53.4.2.6 Alternate Masters and ROMC

The ROMC sits on the AHB bus of the internal ROM (ROMC). This means that the ROMC can modify values on the read data bus going to the master. Therefore, any master which reads an opcode patched or data patched location will read patched data.

53.5 ROMCP Memory Map/Register Definition

All registers are accessible through an IP Bus and can only be accessed in privileged mode. These registers can only be written with 32-bits stores and are clocked by hclk_reg.

The ROMC register placement was originated from the AWPT design used in the ARM7 platform of Neptune

ROMC memory map

53.5.1 ROMC Data Registers (ROMC_ROMPATCHnD)

The ROMC data registers (ROMC_ROMPATCH7D through ROMC_ROMPATCH0D) store the data to use for the 8 1-word data fix events. Each register is associated with an address comparator (7 through 0). When a data fixing event occurs, the value in the data register corresponding to the comparator that has the address match is put on the romc_hrdata[31:0] bus until romc_hready is asserted by the ROM controller to terminate the access. A MUX external to the ROMC will select this data over that of romc_hrdata[31:0] in returning read data to the ARM core. The selection is done with the control bus rompatch_romc_hrdata_ovr[1:0] with both bits asserted by the ROMC.

If more than one address comparators match, the highest-numbered one takes precedence, and the value in corresponding data register is used for the patching event.

Address: 21A_C000h base + D4h offset + (4d × i), where i=0d to 7d

ROMC_ROMPATCHnD field descriptions

Field	Description
DATAx	Data Fix Registers - Stores the data used for 1-word data fix operations. The values stored within these registers do not affect the writes to the memory system. They are selected over the read data from ROM when a data fix event occurs.

ROMC_ROMPATCHnD field descriptions (continued)

Field	Description
	If any part of the 1-word data fix is read, then the entire word is replaced. Therefore, a byte or half-word read will cause the ROMC to replace the entire word. The word is word address aligned.

53.5.2 ROMC Control Register (ROMC_ROMPATCHCNTL)

The ROMC control register (ROMC_ROMPATCHCNTL) contains the block disable bit and the data fix enable bits. The block disable bit provides a means to disable the ROMC data fix and opcode patching functions, even when the address comparators are enabled. The External Boot feature is not affected by this bit. The eight data fix enable bits (0 through 7), when set, assign the associated address comparators to data fix operations

NOTE

Bits 27 and 22 always read as 1s.

Address: 21A_C000h base + F4h offset = 21A_C0F4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

29 DIS	ROMC Disable -- This bit, when set, disables all ROMC operations. This bit is used to enable secure operations. 0 Does not affect any ROMC functions (default) 1 Disable all ROMC functions: data fixing, and opcode patching
28–8 -	This field is reserved. Reserved
DATAFIX	Data Fix Enable - Controls the use of the first 8 address comparators for 1-word data fix or for code patch routine. 0 Address comparator triggers a opcode patch 1 Address comparator triggers a data fix

53.5.3 ROMC Enable Register High (ROMC_ROMPATCHENH)

The ROMC enable register high (ROMC_ROMPATCHENH) and ROMC enable register low (ROMC_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC_ROMPATCHENH and the upper half of ROMC_ROMPATCHENL are read-only. ROMC_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: 21A_C000h base + F8h offset = 21A_C0F8h

ROMC_ROMPATCHENH field descriptions

Field	Description
-	This field is reserved. Reserved

53.5.4 ROMC Enable Register Low (ROMC_ROMPATCHENL)

The ROMC enable register high (ROMC_ROMPATCHENH) and ROMC enable register low (ROMC_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC_ROMPATCHENH and the upper half of ROMC_ROMPATCHENL are read-only. ROMC_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: 21A_C000h base + FCh offset = 21A_C0FCh

ROMC_ROMPATCHENL field descriptions

Field	Description

ENABLE	<p>Enable Address Comparator - This bit enables the corresponding address comparator to trigger an event.</p> <p>0 Address comparator disabled</p> <p>1 Address comparator enabled, ROMC will trigger a opcode patch or data fix event upon matching of the associated address</p>

53.5.5 ROMC Address Registers (ROMC_ROMPATCHnA)

The ROMC address registers (ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15) store the memory addresses where opcode patching begins and data fixing occurs. The address registers ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15 are each 21 bits wide and dedicated to one 4 Mbyte memory space. Bits 21 through 2 are address bits, to be compared with romc_haddr[21:2] for a match; bit 1 is also an address bit used for half word selection. Bit 0 is the mode bit (set to 1 for THUMB mode). 1-word data fixing can only be used on the first 8 of the address comparators. ROMC_ROMPATCHA0 through ROMC_ROMPATCHA15 are associated each with address comparators 0 through 15.

Address: 21A_C000h base + 100h offset + (4d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	Address Comparator 1 matched
15	Address Comparator 15 matched

Chapter 54

Synchronous Audio Interface (SAI)

54.1 Overview

The synchronous audio interface (SAI) supports full-duplex serial interfaces with frame synchronization such as I²S, AC97, TDM, and codec/DSP interfaces.

54.1.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

NOTE

About data lines and audio channels: Typically there are one or more data lines for TX and RX sides of the SAI peripheral, depending on the device's design. Each SAI data line may support 1 - 32 audio channels (or audio words).

- Transmitter with independent bit clock and frame sync supporting 1 data line
- Receiver with independent bit clock and frame sync supporting 1 data line
- Maximum Frame Size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 32 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error

54.1.2 Block diagram

The following block diagram also shows the module clocks.

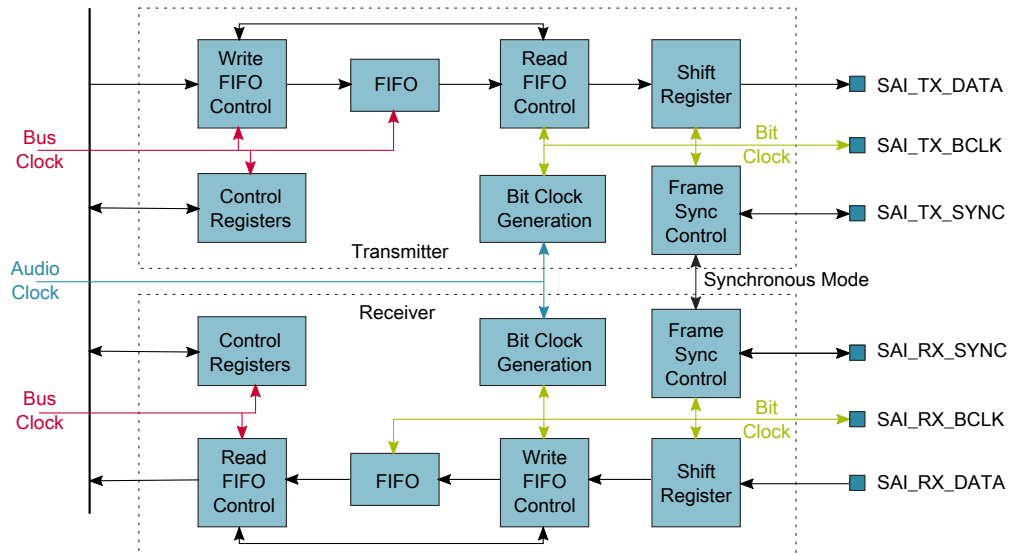

Figure 54-1. I²S/SAI block diagram

54.1.3 Modes of operation

The module operates in these MCU power modes: Run mode, stop modes, and Debug mode.

54.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

54.1.3.2 Stop modes

In Stop mode, the transmitter is disabled after completing the current transmit frame, and, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented—not acknowledged—while waiting for the transmitter and receiver to be disabled at the end of the current frame.

54.1.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

54.2 External Signals

The following table describes the external signals of SAI:

Table 54-1. SAI External Signals

Signal	Description	Pad	Mode	Direction
SAI1_TX_BCLK	Transmit bit clock 1	CSI_DATA00	ALT7	I/O
		RGMI2_TD3	ALT2	
SAI1_RX_BCLK	Receive bit clock 1	RGMI2_TD1	ALT2	I/O
		CSI_DATA02	ALT7	
SAI1_TX_SYNC	Transmit frame sync 1	CSI_DATA01	ALT7	I/O
		RGMI2_TD2	ALT2	
SAI1_RX_SYNC	Receive frame sync 1	RGMI2_TD0	ALT2	I/O
		CSI_DATA03	ALT7	
SAI1_TX_DATA0	Transmit data 1	CSI_HSYNC	ALT7	O
		RGMI2_TXC	ALT2	
SAI1_RX_DATA0	Receive data 1	CSI_VSYNC	ALT7	I
		RGMI2_TX_CTL	ALT2	
SAI2_TX_BCLK	Transmit bit clock 2	KEY_COL0	ALT7	I/O
		RGMI1_TD3	ALT2	
SAI2_RX_BCLK	Receive bit clock 2	KEY_COL4	ALT7	I/O
		RGMI1_TD1	ALT2	
SAI2_TX_SYNC	Transmit frame sync 2	KEY_COL1	ALT7	I/O
		RGMI1_TD2	ALT2	
SAI2_RX_SYNC	Receive frame sync 2	KEY_ROW4	ALT7	I/O
		RGMI1_TD0	ALT2	
SAI2_TX_DATA0	Transmit data 2	KEY_ROW0	ALT7	O
		RGMI1_TXC	ALT2	
SAI2_RX_DATA0	Receive data 2	KEY_ROW1	ALT7	I
		RGMI1_TX_CTL	ALT2	

54.3 Functional description

This section provides a complete functional description of the block.

54.3.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

54.3.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

54.3.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

54.3.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

54.3.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

54.3.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

54.3.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

54.3.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

54.3.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

54.3.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
 - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

54.3.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 32×32 -bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

54.3.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 54-2](#) for LSB First configurations and [Figure 54-3](#) for MSB First configurations.

Figure 54-2. SAI first bit shifted, LSB first

Figure 54-3. SAI first bit shifted, MSB first

54.3.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

54.3.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

54.3.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

54.3.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

54.3.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

54.3.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels repeat the last valid word read from the transmit FIFO until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

The FIFO error flag can generate only an interrupt.

54.3.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

54.3.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

54.4 Memory map and register definition

A read or write access to an address from offset and above will result in a bus error.

I2S memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
21D_4000	SAI Transmit Control Register (I2S1_TCSR)	32	R/W	0000_0000h	54.4.1/3535

I2Sx_TCSR field descriptions

Field	Description
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0 Transmitter is disabled. 1 Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures transmitter operation in Stop mode. This field is ignored and the transmitter is disabled in all stop modes. 0 Transmitter disabled in Stop mode. 1 Transmitter enabled in Stop mode.
29 DBGE	Debug Enable

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
	<p>Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode.</p> <p>0 Transmitter is disabled in Debug mode, after completing the current frame. 1 Transmitter is enabled in Debug mode.</p>
28 BCE	<p>Bit Clock Enable</p> <p>Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame.</p> <p>0 Transmit bit clock is disabled. 1 Transmit bit clock is enabled.</p>
27–26 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
25 FR	<p>FIFO Reset</p> <p>Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set.</p> <p>0 No effect. 1 FIFO reset.</p>
24 SR	<p>Software Reset</p> <p>When set, resets the internal transmitter logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.</p> <p>0 No effect. 1 Software reset.</p>
23–21 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
20 WSF	<p>Word Start Flag</p> <p>Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.</p> <p>0 Start of word not detected. 1 Start of word detected.</p>
19 SEF	<p>Sync Error Flag</p> <p>Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag.</p> <p>0 Sync error not detected. 1 Frame sync error detected.</p>
18 FEF	<p>FIFO Error Flag</p> <p>Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag.</p> <p>0 Transmit underrun not detected. 1 Transmit underrun detected.</p>

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0 No enabled transmit FIFO is empty. 1 Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0 Transmit FIFO watermark has not been reached. 1 Transmit FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
	Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

54.4.2 SAI Transmit Configuration 1 Register (I2Sx_TCR1)

Address: Base address + 4h offset

I2Sx_TCR1 field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TFW	Transmit FIFO Watermark Configures the watermark level for all enabled transmit channels.

54.4.3 SAI Transmit Configuration 2 Register (I2Sx_TCR2)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 8h offset

I2Sx_TCR2 field descriptions

Field	Description
31–30 SYNC	<p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation.</p> <p>00 Asynchronous mode. 01 Synchronous with receiver. 10 Synchronous with another SAI transmitter. 11 Synchronous with another SAI receiver.</p>
29 BCS	<p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC).</p> <p>When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC).</p> <p>0 Use the normal bit clock source. 1 Swap the bit clock source.</p>
28 BCI	<p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock .</p> <p>0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.</p>
27–26 MSEL	<p>MCLK Select</p> <p>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.</p> <p>NOTE: Depending on the device, some Master Clock options might not be available. See the chip configuration details for the availability and chip-specific meaning of each option.</p> <p>00 Master Clock (MCLK) 1 option selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.</p>
25 BCP	<p>Bit Clock Polarity</p> <p>Configures the polarity of the bit clock.</p> <p>0 Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.</p>

Table continues on the next page...

I2Sx_TCR2 field descriptions (continued)

Field	Description
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
23–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

54.4.4 SAI Transmit Configuration 3 Register (I2Sx_TCR3)

This register must not be altered when TCSR[TE] is set.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
R	0								0								TCE
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0								WDFL								
W	[Shaded]																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

I2Sx_TCR3 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. A channel must be enabled before its FIFO is accessed. 0 Transmit data channel N is disabled. 1 Transmit data channel N is enabled.
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
WDFL	Word Flag Configuration

Table continues on the next page...

I2Sx_TCR3 field descriptions (continued)

Field	Description
	Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

54.4.5 SAI Transmit Configuration 4 Register (I2Sx_TCR4)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R		0		0		0		0		0		FRSZ

I2Sx_TCR4 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2Sx_TCR4 field descriptions (continued)

Field	Description
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0 LSB is transmitted first. 1 MSB is transmitted first.
3 FSE	Frame Sync Early 0 Frame sync asserts with the first bit of the frame. 1 Frame sync asserts one bit before the first bit of the frame.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 Frame sync is active high. 1 Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 Frame sync is generated externally in Slave mode. 1 Frame sync is generated internally in Master mode.

54.4.6 SAI Transmit Configuration 5 Register (I2Sx_TCR5)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2Sx_TCR5 field descriptions (continued)

Field	Description
20–16 WOW	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

54.4.7 SAI Transmit Data Register (I2Sx_TDRn)

Address: Base address + 20h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_TDRn field descriptions

Field	Description
TDR	Transmit Data Register The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

54.4.8 SAI Transmit FIFO Register (I2Sx_TFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + 40h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0						WFP								
W	[Reserved]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								RFP							
W	[Reserved]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_TFRn field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

54.4.9 SAI Transmit Mask Register (I2Sx_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: Base address + 60h offset

I2Sx_TMR field descriptions

Field	Description
TWM	<p>Transmit Word Mask</p> <p>Configures whether the transmit word is masked (transmit data pin tristated and transmit data not read from FIFO) for the corresponding word in the frame.</p> <p>0 Word N is enabled. 1 Word N is masked. The transmit data pins are tri-stated when masked.</p>

54.4.10 SAI Receive Control Register (I2Sx_RCSR)

Address: Base address + 80h offset

I2Sx_RCSR field descriptions

Field	Description
31 RE	<p>Receiver Enable</p> <p>Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame.</p> <p>0 Receiver is disabled. 1 Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.</p>
30 STOPE	<p>Stop Enable</p> <p>Configures receiver operation in Stop mode. This bit is ignored and the receiver is disabled in all stop modes.</p> <p>0 Receiver disabled in Stop mode. 1 Receiver enabled in Stop mode.</p>
29 DBGE	<p>Debug Enable</p> <p>Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode.</p> <p>0 Receiver is disabled in Debug mode, after completing the current frame. 1 Receiver is enabled in Debug mode.</p>
28 BCE	<p>Bit Clock Enable</p> <p>Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame.</p> <p>0 Receive bit clock is disabled. 1 Receive bit clock is enabled.</p>
27–26 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
25 FR	<p>FIFO Reset</p> <p>Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set.</p> <p>0 No effect. 1 FIFO reset.</p>
24 SR	<p>Software Reset</p> <p>Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.</p> <p>0 No effect. 1 Software reset.</p>
23–21 Reserved	<p>This field is reserved. This read-only field is reserved and always has the value 0.</p>
20 WSF	<p>Word Start Flag</p> <p>Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.</p>

Table continues on the next page...

I2Sx_RCSR field descriptions (continued)

Field	Description
	0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0 Receive overflow not detected. 1 Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0 No enabled receive FIFO is full. 1 Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0 Receive FIFO watermark not reached. 1 Receive FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts.

54.4.18 SAI Receive Mask Register (I2Sx_RMR)

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Address: Base address + E0h offset

I2Sx_RMR field descriptions

Field	Description
RWM	<p>Receive Word Mask</p> <p>Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame.</p> <p>0 Word N is enabled. 1 Word N is masked.</p>

Chapter 55

Smart Direct Memory Access Controller (SDMA)

55.1 Overview

The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by off-loading the ARM core in dynamic data routing.

55.1.1 Block Diagram

The figure below shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units, and the scheduler.

Figure 55-1. SDMA Block Diagram

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in [Instruction Memory Map](#) and [Data Memory Map](#)).

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the ARM platform. Every channel contains a corresponding channel script located in RAM and/or ROM that can be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to "conditionally yield" the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two yield instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (yieldge), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the "Channel Pending (EP)" register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The ARM platform control block contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This block also contains all other control registers that the ARM platform can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The "receive register full" and "transmit register empty" signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

55.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with two-level, priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
 - Auto-flush and prefetch capability
 - Flexible address management (increment, decrement, and no address changes on source and destination address)
 - Misaligned data-transfer support
 - Uni-directional and bi-directional flows (copy mode)
 - Up to eight-word buffers for configurable burst transfers
- Support of byte-swapping
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-Kbyte ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-Kbyte RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
 - Configurable clock options for the SDMA core and the ARM platform DMA units
 - 1:2 ratio with maximum of SDMA core running at ARM platform Peripheral Bus speed and DMA running at max DMA frequency.
 - 1:1 ratio when both SDMA core and ARM platform DMA clocks are set to the ARM platform Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the ARM platform
- The SDMA RISC engine (arithmetic and logic operations), which is referred to as the "SDMA core."
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.

- The peripheral DMA unit that is hooked-up to the ARM platform Crossbar Switch to service ARM peripherals
- The burst DMA unit is able to perform burst accesses to the external memory
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

55.2 External Signals

The table found here describes the external signals of SDMA.

Table 55-1. SDMA External Signals

Signal	Description	Pad	Mode	Direction
SDMA_EXT_EVENT0	Event 0 signal	GPIO1_IO08	ALT2	IO
		KEY_ROW0	ALT6	
		SD2_DATA2	ALT4	
SDMA_EXT_EVENT1	Event 1 signal	GPIO1_IO09	ALT2	IO
		KEY_COL0	ALT6	

55.3 Clocks

The table found here describes the clock sources for SDMA

. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information. For functional information regarding module clocks, see [SDMA Clocks and Low Power Modes](#).

Table 55-2. SDMA Clocks

Clock name	Clock Root	Description
events_sync_clk (clk)	ahb_clk_root	ARM peripheral / events clock
ips_hostctrl_clk	ipg_clk_root	Host control clock
ap_ahb_clk	ahb_clk_root	ARM platform bus clock
core_clk	ipg_clk_root	Module / Core clock
tck	-	JTAG access clock

55.4 Functional Description

The figure below shows the SDMA topology, and is composed of the following components:

- SDMA Core ([SDMA Core](#))
- SDMA Scheduler ([Scheduler](#))
- Functional Units:
 - Burst DMA ([Burst DMA Unit](#))
 - Peripheral DMA ([Peripheral DMA Unit](#))
- ARM platform Control for ARM control register access.
- Internal RAM and ROM Memory ([SDMA Programming Model](#))
- OnCE debug Port ([The OnCE Controller](#))

The functional unit bus provides access by the SDMA core to the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

Figure 55-2. SDMA Connections

55.4.1 SDMA Core

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing.

The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

55.4.1.1 SDMA Core Structure

The figure found here shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

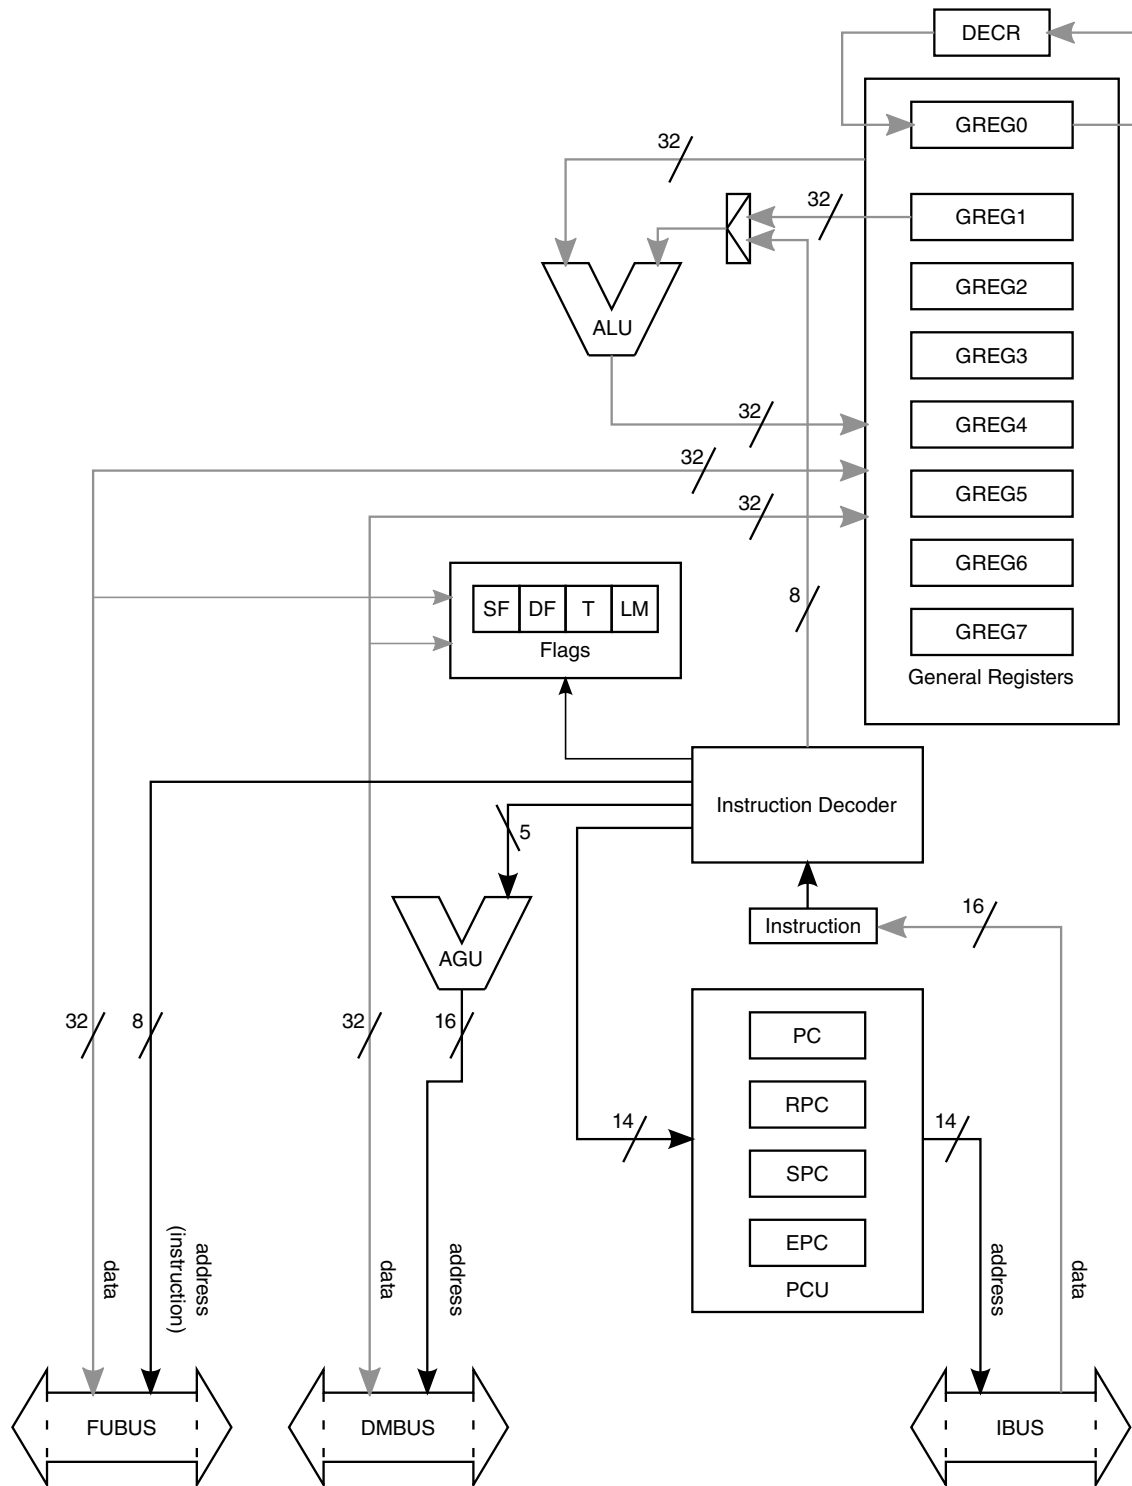

Figure 55-3. SDMA Core

- The Program Control Unit (PCU) is described in [Program Control Unit \(PCU\)](#). It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA

core instruction register prior to their decoding. The PCU contains the following registers:

- The Program Counter (PC) contains the address of the current instruction.
- The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
- The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
- End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.
- The other core registers are the general purpose registers (GREGn) and the flags.
 - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
 - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in [Figure 55-3](#).
 - The flags reflect the status of operations:
 - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
 - LM is set when the core is executing instructions inside a hardware loop.
 - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register's contents into itself (For example, the instruction: mov R0,R0).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that

are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).

- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

55.4.1.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine, as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA.

It contains the PC, RPC, SPC, and EPC registers that are described in [SDMA Core Structure](#).

55.4.1.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. Standard: Most of the instructions belong to this category, and always last 1 cycle.
2. ldf/stf: These are respectively the load and store instructions that access the functional units. They last $1+n$ cycles where n is the number of wait-states of the targeted functional unit.
3. ld/st: These are the load and store instructions that access the memory and peripherals. They last $1+n$ cycles where n is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. Branch: These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. Loop, Modified Load or Store: The hardware loop instruction modifies the potential behavior of any load or store inside the loop (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the ld/st/ldf/stf original execution delay). Although there is

usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.

6. Done: The done, yield, or yieldg instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in [Context Switching](#)).

55.4.1.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see [Real-Time Debug Outputs](#)) or the OnCE status register(see [OnCE Status Register \(OSTAT\)](#)).

The PCU state is a four-bit field that can take the values shown in the following table. [Figure 55-4](#) shows the possible state transitions and the corresponding conditions.

Table 55-3. PCU States

Value	State	Description
0	Program	This is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	The SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.

Table continues on the next page...

Table 55-3. PCU States (continued)

Value	State	Description
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in Channel 0 Boot Address (SDMAARM_CHN0ADDR)).
15	Restore	The context switch FSM is restoring the next channel context.

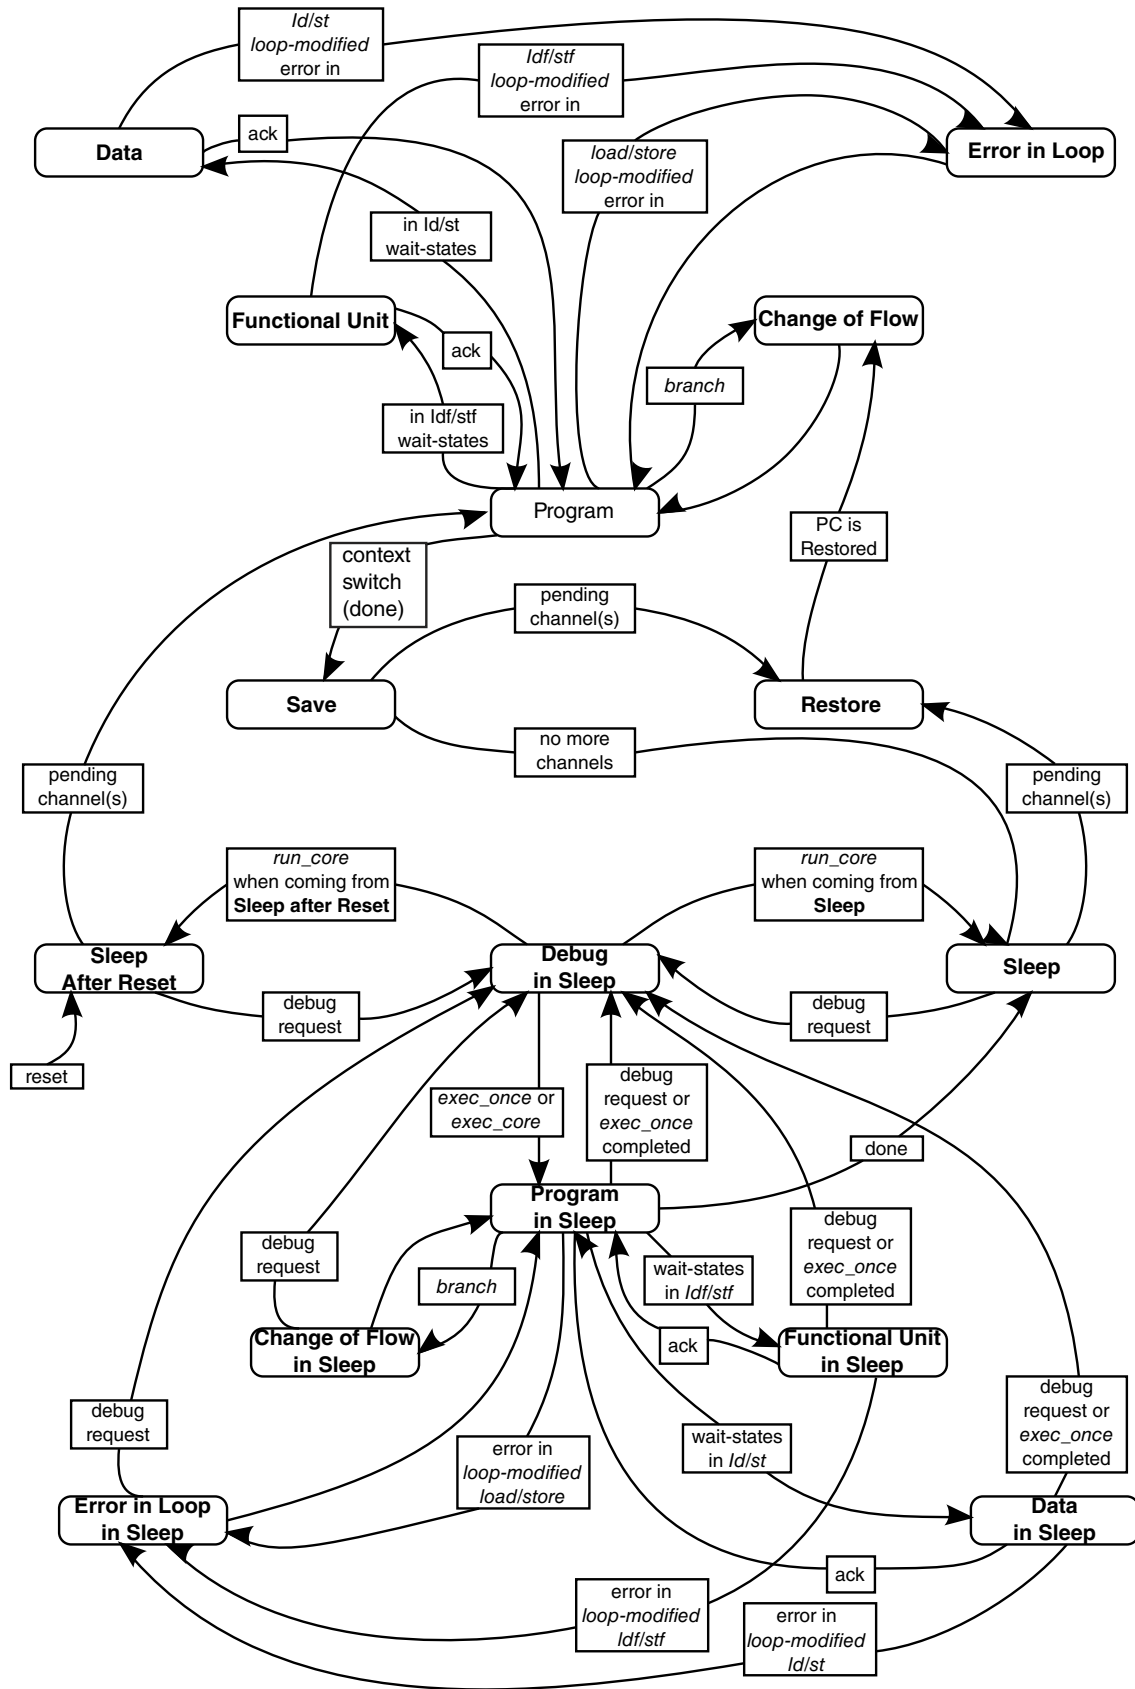

Figure 55-4. PCU State Diagram

55.4.1.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write.

Program and data memory is further described in [Address Space](#).

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

55.4.2 Scheduler

All channel scheduling hardware is included in the Scheduler.

55.4.2.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority.

The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service

- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

55.4.2.2 Channels and DMA Requests

55.4.2.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional.

The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the ARM platform software.

55.4.2.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

55.4.2.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels).

The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event.

Every channel also has a three-bit register that indicates its priority.

55.4.2.3 Scheduler Functional Description

[Scheduler Overview](#) describes the behavior of the SDMA scheduler—from the channel enabling conditions to the highest priority pending channel selection.

55.4.2.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the ARM platform to control its behavior.

The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top priority and its associated channel, and selects the next active channel when the current channel yields.

The following figure shows a functional overview.

Figure 55-5. SDMA Hardware Scheduler

55.4.2.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage.

The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

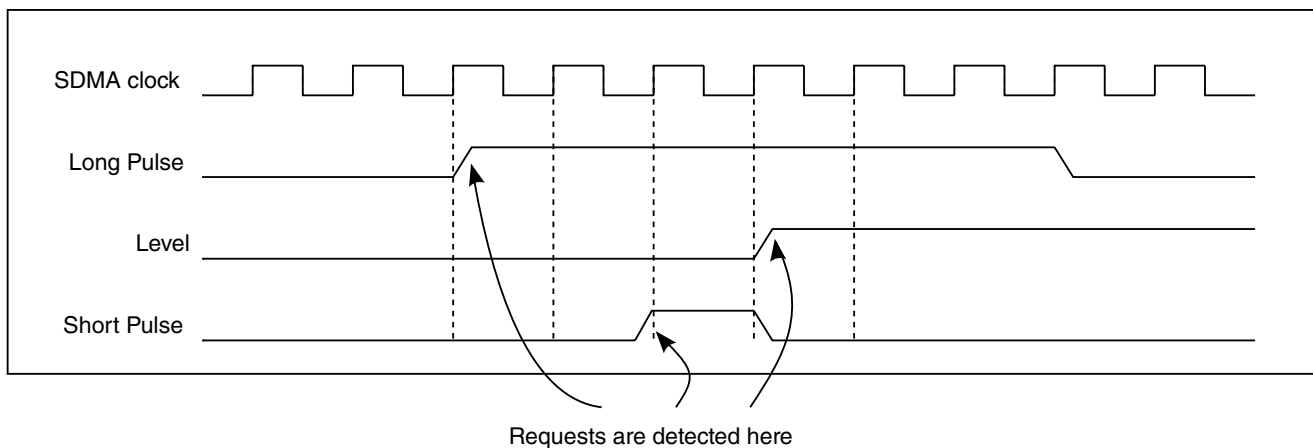

Figure 55-6. Examples of Valid DMA Requests

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

55.4.2.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated.

This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

Functional Description

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by the following equation:

$$EP = EP \text{ or } CHNENBLn$$

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. The following table illustrates an example configuration.

NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

55.4.2.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel *n* by setting bit *n* of the register EP, but this bit is already set, meaning channel *n* is already pending. This can come from an overrun/underrun condition.

This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the ARM platform when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

55.4.2.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable.

Registers EO, DO, HO and HE, are controlled by the ARM platform. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The *i*th channel is runnable if (and only if) the condition below is true:

$$(HE[i] \text{ or } HO[i]) \text{ and } (DO[i]) \text{ and } (EP[i] \text{ or } EO[i])$$

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i])

The registers in these equations are controlled as follows:

- ARM platform (host) channel enable flag HE[i] may be set or cleared by the ARM platform with the HSTART and STOP_STAT registers. It can also be cleared by the i^{th} channel script.

Typical usage is for the ARM platform to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.

- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i^{th} channel script.
- The ARM platform channel override flag HO[i] may be set or cleared by the ARM platform. When set, it enables the i^{th} channel to run without the involvement of the ARM platform.

Typical usage is for the ARM platform to set this flag for channels that do not need ARM platform supervision such as channels that are controlled by DMA request events (EP).

- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the ARM platform. When set, it prevents the i^{th} channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of a done or notify instruction. The done instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the notify instruction does not. The done and notify instructions can clear either HE[i] or EP[i] (never more than one at a time).

Table 55-5. Runnable Channel Selection Control

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the done or notify instructions.
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the done or notify instructions

55.4.2.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities.

It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a yield, yieldge, or done instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority.

The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a yield, not a yieldge), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a yield(ge) or a done instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the following table. The grayed cells correspond to unusual cases that should not occur with a typical usage of the SDMA.

Table 55-6. Channel Switching Decision with a yield, yield(ge), or done

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yield (done 0)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next ¹
	Not runnable	Not runnable	none	none ² (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next ¹ (occurs when the channel was disabled by the ARM platform)
yieldge (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next ¹
			Current < Next	Next ¹

Table continues on the next page...

Table 55-6. Channel Switching Decision with a yield, yield(ge), or done (continued)

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
	Not runnable	Not runnable	none	none ² (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next ¹ (occurs when the channel was disabled by the ARM platform)
done (done>1)	Not runnable	Not runnable	none	none ²
	Runnable	Not runnable	none	Current ³ (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next ¹
	Runnable	Runnable	none	Current ³ (occurs when the done instruction does not disable the channel runnable condition)

1. Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes
2. Current channel context is saved and SDMA enters IDLE mode
3. Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in [Scheduler Pipeline Timing Diagram](#).

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since $24 > 13$.
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.
- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a yieldge; it is preempted by channel 29. After a period of time, channel 29 runs a yieldge, it is then preempted by channel 23 that is the selected channel since channel 29 is the current channel. Later, channel 23 runs a yieldge and is preempted

Functional Description

by channel 29. Channels 23 and 29 will go on switching after every yield until one of them terminates. It is only at that point that channel 7 becomes eligible again.

- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a yield instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a yield and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number $11 < 18$).

55.4.2.3.7 Scheduler State Diagram

The [Figure 55-7](#) summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in [Scheduler Pipeline Timing Diagram](#).

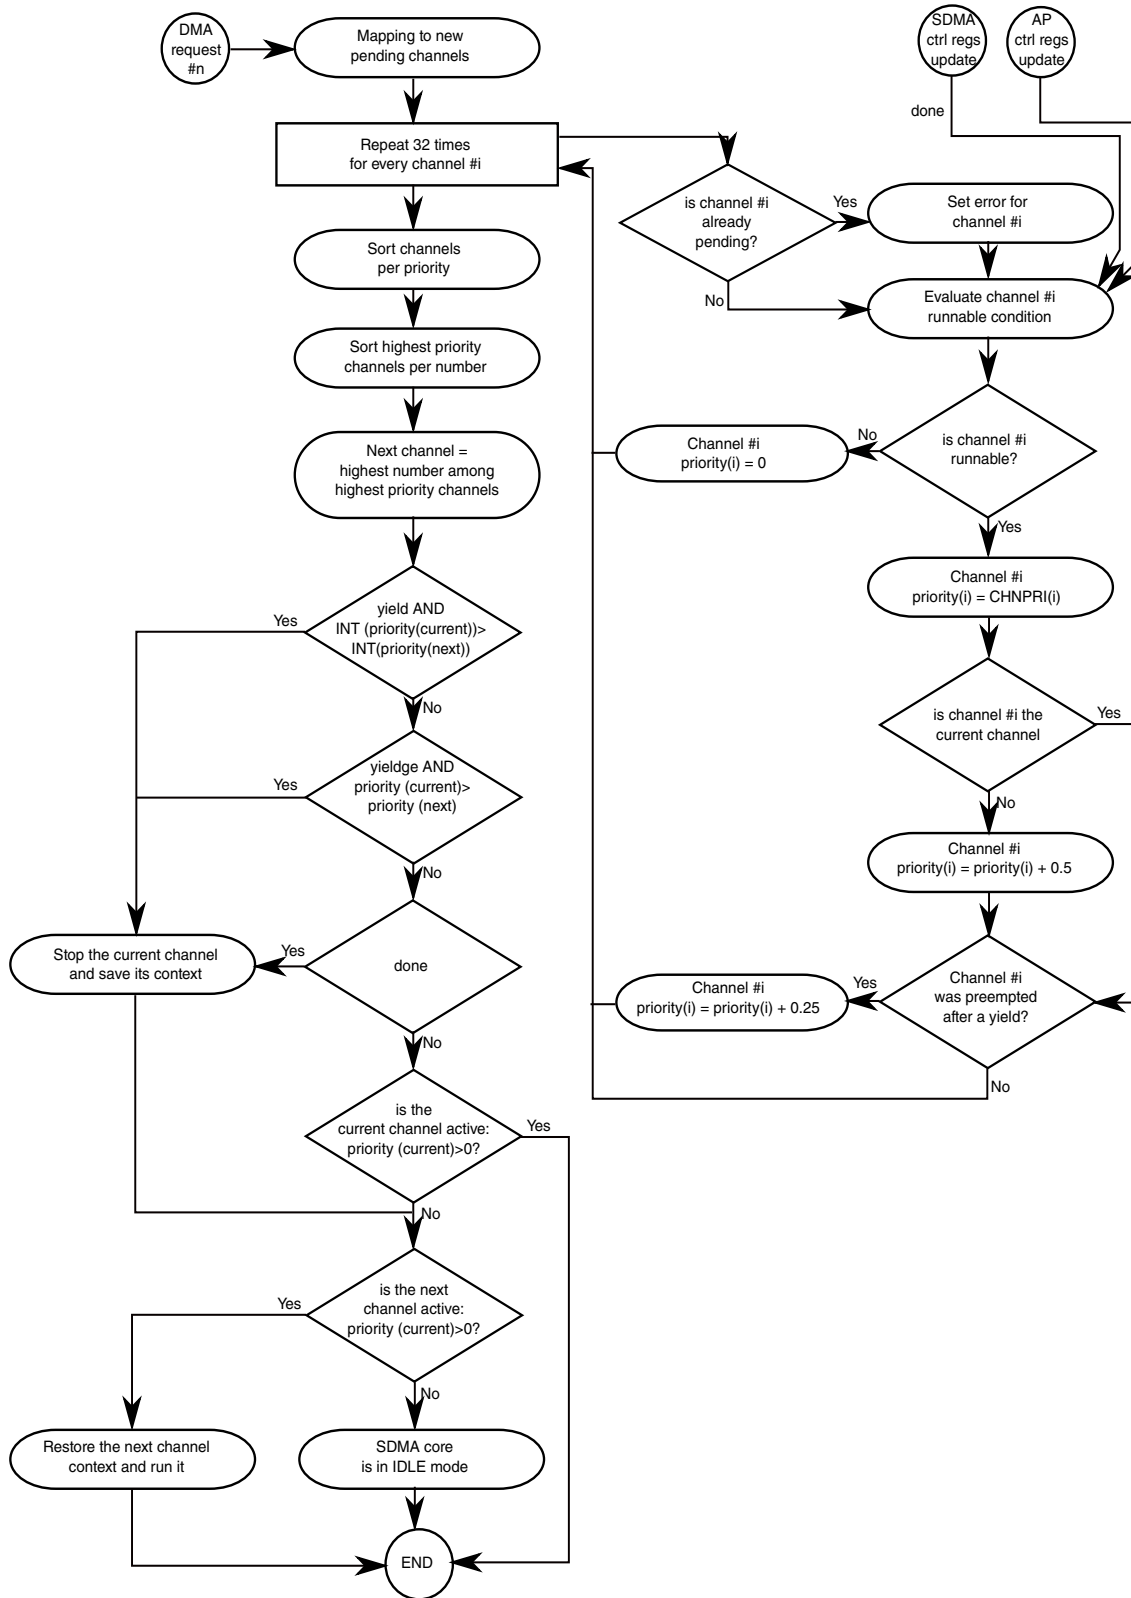

Figure 55-7. Scheduler State Diagram

55.4.2.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate.

The figure below shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

Figure 55-8. Scheduler Timing Diagram

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a done instruction or the ARM platform with a write access through the corresponding control port on their respective peripheral bus).

55.4.2.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. Refer to the respective chapters for this information.

55.4.2.3.10 Examples: How to Start a Channel

A channel can be started when the following equation is true for channel *i*:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by ARM platform software:
 - Initially, configure HO[i]=0, DO[i]=1, and EO[i]=1 using registers indicated in [Table 55-5](#).
 - ARM platform software triggers the channel by writing to the HSTART register to set HE[i]=1, thereby setting the above equation true.
2. To start a channel triggered by DMA request event.
 - Initially, configure HO[i]=1, DO[i]=1, and EO[i]=0 using registers indicated in [Table 55-5](#).
 - The DMA request is asserted to trigger the channel by setting EP[i]=1, which makes the above equation true.

55.4.2.4 Context Switching

On execution of a done or yield(ge) instruction, the current channel may be changed either because it has finished (which necessarily happens when the done instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the yield(ge) is executed).

Upon a channel change the SDMA goes through a context switch procedure.

When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in [Context Switching-Programming](#) and [Table 55-11](#). There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total RAM space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

55.4.2.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the ARM platform in the CONFIG control register.

The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)-which leaves very few registers to save when the switch is decided-resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.
- In a "static" context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootloader channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

55.4.2.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the ARM platform.

The context switch procedure is as follows:

1. Load the current context's spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

On a *done* or *yield(ge)* that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.

3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a *done* or *yield(ge)* instruction. That means the current channel cannot be modified by the ARM platform, even if it is no more runnable or if its priority is modified.

The ARM platform can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a *done* instruction. That feature should only be used to stop the SDMA in emergency cases.

4. Load the context base-address of the new channel.

In "static" mode, all the registers are restored. In either "dynamic" modes, only the PCU registers are restored.

The new channel is running. In "static" mode, no more activity regarding context restoring or saving is performed. In either "dynamic" modes, the registers are restored in the background every time an access to the context RAM is possible, and priority is given to restoring the registers that are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In "dynamic" and "dynamic with no loop" modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In "dynamic" and "dynamic with no loop" modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In "dynamic power" and "static" modes, the contents of the context RAM remain unchanged until the channel terminates with a done or gets preempted.

55.4.2.4.3 Context Map in Memory

Refer to [Context Switching-Programming](#).

55.4.3 Functional Units

The functional units are small systems that are used by the SDMA core to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units' registers via the FUBUS. This is done with the ldf and stf instructions.

The following sections provide introductions to the available functional units. [Functional Units Programming Model](#) provides descriptions the functional units' behaviors.

55.4.3.1 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the ARM platform memory.

It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the ARM platform memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the ARM platform memory at once or twice the SDMA core frequency
- Copy data from one ARM platform memory location to another ARM platform memory location at the ARM platform bus speed, which provides a very high throughput
- Control the method for addressing the ARM platform memory (automatic increment of addresses or frozen addresses—the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the ARM platform memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the ARM platform memory. Or, it forces a flush when a data transfer must terminate.
- In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the ARM platform memory.

In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory. This error status is retrieved by a later access to the burst DMA.

Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory is caught.

- Handle address alignment issues between the ARM platform memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding ARM platform address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the ARM platform memory space.

This unit structure and registers are described in [Burst DMA Structure](#) and [Burst DMA Registers](#).

55.4.3.1.1 Burst DMA Structure

The burst DMA is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

The burst DMA is depicted in the figure below.

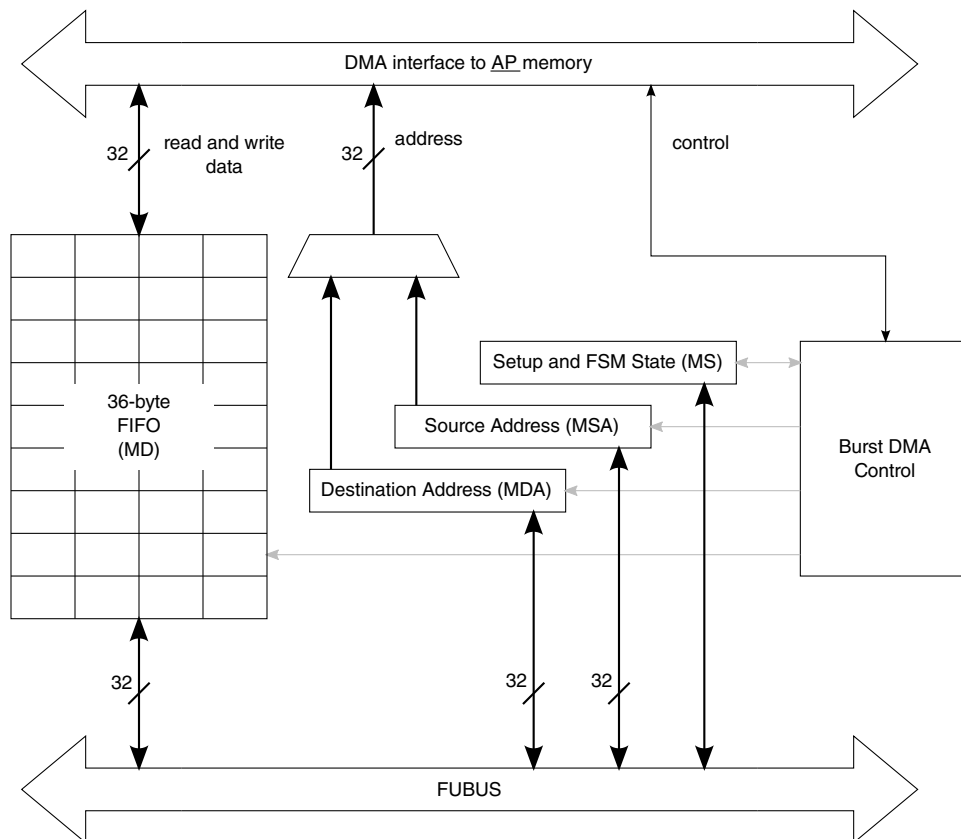

Figure 55-9. Burst DMA Structure

55.4.3.1.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- MSA (Memory Source Address) - Holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- MDA (Memory Destination Address) - Holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.
- MD (Memory Data) - Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the

FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the ARM platform memory).

- When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the ARM platform memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to ARM platform memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the ARM platform memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the ARM platform memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to ARM platform memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- MS (Memory Setup) - Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

55.4.3.1.3 Burst DMA Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both.

Every case requires a different procedure, as listed in the following sections:

55.4.3.1.3.1 Data Retrieval from the ARM platform Memory

The following steps retrieve data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from ARM platform memory, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

55.4.3.1.3.2 Storing Data Into the ARM platform Memory

The following steps store data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).
- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the ARM platform memory and the error status of the transfer is available in the DF flag.

55.4.3.1.3.3 Transferring Data Between Two ARM platform Memory Locations-Burst DMA Unit

The following steps copy data between two ARM platform memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

55.4.3.2 Peripheral DMA Unit

The peripheral DMA unit is the second functional unit that connects the SDMA to the ARM platform memory.

Unlike the burst DMA, it does not support burst transfers and is optimized for accessing peripherals. It does not provide control to assign a privilege level to the DMA access. Its feature list comprises the following:

- Access to the ARM platform peripherals or memory at once or twice the SDMA core frequency

- Data copy from one ARM platform memory location to another ARM platform memory location at memory bus speed, improving throughput
- Control of the method for addressing the ARM platform memory (automatic increment or decrement of addresses or frozen addresses, the first ones aimed at accessing RAM-like memory and the last one aimed at accessing single-address FIFOs)
- Selectable automatic prefetch when reading data from the ARM platform memory. In prefetch mode, the peripheral DMA automatically fetches another data-without waiting for the SDMA core to request it-when its data register is empty, which improves the throughput
- Selectable automatic flush. In this mode, the SDMA core may only be stalled when it tries writing data and the previous write operation is not finished yet; whereas, in forced flush mode, the core is stalled until the data is effectively written to the ARM platform memory.
- In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory or the peripheral. This error status is retrieved by a later access to the peripheral DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory has been caught.

This unit structure and registers are described in [Peripheral DMA Structure](#) and [Peripheral DMA Registers](#).

55.4.3.2.1 Peripheral DMA Structure

The peripheral DMA is made up of a 32-bit data register, two address registers, and a controlling state-machine. The state-machine manages clock adaptation, when required.

It is shown in the following figure.

Figure 55-10. Peripheral DMA structure

55.4.3.2.2 Peripheral DMA Registers

According to [Figure 55-10](#), the peripheral DMA has four registers that may be read or written by the SDMA core:

- *PD* (*Peripheral Data*) is the DMA 32-bit data register.
- *PSA* (*Peripheral Source Address*) holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads a new data from PD.

- *PDA (Peripheral Destination Address)* holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes a new data into PD.
- *PS (Peripheral Setup)* contains the state of the peripheral DMA control, two configuration fields that define the way address registers are modified after every data access, two additional configuration fields that define the data size to access the source and destination devices, and another field that contains the latest transfer error status.

55.4.3.2.3 Peripheral DMA Data Transfers

There are three typical usages that involve the peripheral DMA, whether it is the data transfer start-point, endpoint, or both.

Every case requires a different procedure, as described in [Data Retrieval from the ARM platform Memory or Peripheral](#), [Storing Data into the ARM platform Memory or Peripheral](#), and [Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit](#).

55.4.3.2.3.1 Data Retrieval from the ARM platform Memory or Peripheral

The following steps retrieve data from ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the source (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the source address register itself (PSA) with an address that is aligned to the programmed data size.
- Read data from PD using the ldf PD instruction as many times as needed. If an error occurs during the fetch from the ARM platform memory or peripheral, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from PD.

55.4.3.2.3.2 Storing Data into the ARM platform Memory or Peripheral

The following steps store data to ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the destination (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the destination address register itself (PDA) with an address that is aligned to the programmed data size.

- Store data into PD using the *stf PD* instruction as many times as needed.
- When the transfer is finished and if the peripheral DMA worked in automatic flush mode, force the flush of PD. This instruction is stalled until PD contents are effectively sent to the ARM platform memory or peripheral, and the error status of the transfer is available in the DF flag.

55.4.3.2.3.3 Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit

The following steps copy data between two ARM platform memory locations using the peripheral DMA unit:

- Set up the PS fields to reflect the modes and data size for the source and destination addresses (all the combinations of addressing modes are possible, but both data sizes must be identical), then initialize the source address register (PSA) and the destination address register (PDA). Both addresses must be aligned with the programmed data size.
- Use as many *stf PD* instructions with the *COPY* flag as needed. Every instruction triggers a single read from the source address; a single write of the received data immediately follows. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the peripheral DMA to check the error status.

55.4.4 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The ARM platform loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in [Locked Mode](#).

55.4.4.1 Locked Mode

The LOCK bit in the SDMA_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM.

After initial RAM contents are uploaded, ARM platform software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a '1', the SDMA is "locked" until reset.

The LOCK bit can be read in the SDMA's internal memory map in the LOCK register (see Section [SDMA LOCK \(SDMAARM_SDMA_LOCK\)](#)). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation (see [SDMA Scripts](#)).

While SDMA is locked, attempts to write to the SDMA_LOCK, CHN0ADR, ILLINSTADDR, and ONCE_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET_LOCK_CLR bit in the SDMA_LOCK register is set. Since SDMA_LOCK register cannot be updated if SDMA is locked, the SRESET_LOCK_CLR bit must be configured before setting the LOCK bit. The SRESET_LOCK_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE_ENB register cannot be written to prevent the OnCE under ARM platform control from being used to gain access to SDMA internal memory. If ARM platform control of the OnCE is enabled before setting the LOCK bit, the ARM platform can use the ONCE for debug purpose after LOCK is set.

55.4.5 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions.

Refer to [Figure 55-4](#) for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a SoftBkpt instruction from the channel script or receive a debug request. When either happens, the SDMA enters its "Classical" *Debug* state, which is described in [OnCE and Real-Time Debug](#).
- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the `exec_core` instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a SoftBkpt is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. The following table summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in [OnCE and Real-Time Debug](#).

Table 55-7. SDMA in Debug Mode

Instruction	Debug	Debug in Sleep
<code>exec_once</code>	<p><code>exec_once <instruction></code></p> <p>SDMA executes the <instruction> and returns to the <i>Debug</i> state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.</p>	<p><code>exec_once <instruction></code></p> <p>SDMA executes the <instruction> and returns to the <i>Debug in Sleep</i> state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.</p>
<code>run_core</code>	<p><code>run_core <instruction></code></p> <p>SDMA executes the <instruction>, leaves the <i>Debug</i> state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.</p>	<p><code>run_core <instruction></code></p> <p>SDMA executes the <instruction> and returns to its <i>Sleep</i> or <i>Sleep after Reset</i> initial state. This command must not be used with an instruction that modifies the PC value.</p>
<code>exec_core</code>	<p><code>exec_core <instruction></code></p> <p>It is similar to <code>run_core</code> except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the <i>Debug</i> state and starts executing instructions from this new PC value.</p>	<p><code>exec_core <instruction></code></p> <p>If the previous state was <i>Sleep after Reset</i>, the SDMA returns to this state, and <code>Chn0Addr</code> value overrides the PC value.</p> <p>Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.</p>

NOTE

The feature `exec_core` in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC

value. The SDMA will be ready to boot at the Chn0Addr address.

55.4.6 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller block and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA.

Root clock control is available from the SoC clock controller block.

There are numerous clock sources that are used in the SDMA. They belong to one of two possible clock domains listed in the following table, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the ARM platform/SDMA clock domain, all clocks must come from the same DPLL. The ARM platform DMA interfaces (peripheral DMA and burst DMA) receive their clock from the ARM platform DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the ARM platform DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum ARM platform DMA frequency, the SDMA core clock is tied to the ARM platform peripheral clock frequency.

The ARM platform Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

Table 55-8. Clocking Scheme

Clock Domain	Source Clock	Comments
ARM platform	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-blocks.
	ARM platform DMA	DMA interface for the peripheral DMA and the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	ARM platform peripheral	Connection to the ARM platform peripheral bus. It is a sub-frequency of the main clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the JTAG interface works properly when the frequency of TCK is lower than 1/8th of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

55.4.6.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

55.4.6.1.1 Coarse Clock Gating

Every sub-block clock comes from one of the five available sources, and is gated with the sub-block specific enabling condition.

The following table displays the sub-block clocks and their source. It also indicates the relationships that may exist between different sub-blocks clock enables.

Table 55-9. Sub-blocks Clocks

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-block clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-block clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-block clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-block clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the ARM platform modifies the channel running conditions.	None
ARM platform Control	SDMA Main Core & ARM platform peripheral	The ARM platform peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on <i>SDMA main clock</i> ; it is active when the ARM platform or the SDMA modifies the contents of one of these registers.	None
Burst DMA	SDMA Main Core & ARM platform DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled	Disabled when Core sub-block clock is disabled

Table continues on the next page...

Table 55-9. Sub-blocks Clocks (continued)

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
		during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	
Peripheral DMA	SDMA Main Core & ARM platform DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the ARM platform peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to Synchronization Implementation .	When enabled, all other clocks are systematically on (clock gating is off)

55.4.6.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis.

Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

55.4.6.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG.

Functional Description

The following table describes these modes, and shows how to switch from one mode to another.

Table 55-10. Power Modes

Power Mode	Sub-blocks							Comments
	Core	Mem ories	Sche duler	ARM platf orm Control	Burs t DMA	Perip heral DMA	OnC E	
SLEEP	off ¹	off	wait ²	wait	off	off	off	Set when the PCU state is either <i>Sleep</i> or <i>Sleep after Reset</i> and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on ³	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: <i>Program, Data, Change of Flow, Error in Loop, Debug, Functional Unit, Save, or Restore</i> .
DEBUG	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either <i>clk_gating_off</i> pin high or ONCE_ENB[0] set).

1. *off*: no clock
2. *wait*: only clocked when accessed or stimulated
3. *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in [SLEEP Mode](#).

55.4.6.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode.

However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in [Stop Mode Response](#).

55.4.6.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

55.4.6.1.3.3 DEBUG Mode

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA.

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

55.4.6.1.4 Stop Mode Response

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode.

If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMA's clocks can be turned off.

55.4.6.2 Reset

After reset (either received from the reset block or a software reset required by the ARM platform), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated.

Activating a channel can be done by the ARM platform after programming a positive priority and setting the channel bit in the EVTpend register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes.

55.4.7 Software Interface

Appendix A fully describes the SDMA Application Programming Interface (API).

55.4.8 Initialization Information

This section discusses the following:

- [Hardware Reset](#)
- [Channel Script Execution](#)
- [Initialization and Script Execution Setup Sequence](#)

55.4.8.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents.

The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The ARM platform will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the ARM platform first creates some channel control blocks (CCB) and buffer descriptors (BD) in ARM platform memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (SDMA_MC0PTR) to the address of the first control block. [Data Structures for Boot Code and Channel Scripts](#) provides an overview of the data structure for the CCB and BD's. The SDMA_HSTART, SDMA_HOSTOVR and SDMA_EVTOVR registers are then configured according to [Runnable Channels Evaluation](#) to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (SDMA_CHN0ADDR) in the program memory. The reset value of SDMA_CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (SDMA_MC0PTR) to determine the location of the Channel Control Block (SDMA_CCB) in ARM platform memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for

channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its ARM platform Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the SDMA_CHN0ADDR register in the ARM platform programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

55.4.8.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters allowed to the buffer. All these items must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the ARM platform by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The ARM platform selects which trigger conditions that must occur for the channel to start by configuring the SDMA_CHNENBL, SDMA_HOSTOVR and SDMA_EVTOVR registers. The trigger events include ARM platform setting HE (SDMA_HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can become active according to its priority compared with other runnable channels when the selected trigger(s) cause the condition described in [Runnable Channels Evaluation](#) to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to [SDMA Scripts](#) for complete script documentation. [Buffer Descriptor Format](#) provides an overview of the buffer descriptor format.

55.4.8.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and SDMA_CHNENBLn registers have unpredictable contents after this reset.
- Initialize SDMA_CHNENBLn registers to map DMA request events to desired channels.
- Configure SDMA_CHNPRIn registers to select priority for runnable channels. A non-zero priority is required for the channel to run.
- Configure the SDMA_CONFIG register to select DMA to SDMA core clock ratio .
- Set up channel control blocks and buffer descriptors in ARM platform to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference [Data Structures for Boot Code and Channel Scripts](#).
- Configure SDMA_MC0PTR register with base address of ARM platform Channel Control Block base address.
- Initialize SDMA_CHNENBLn registers to map DMA request events to associated channel. Reference [Mapping DMA Requests to Pending Channels](#).
- Configure SDMA_CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure SDMA_HOSTOVR (HO) and SDMA_EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference [Runnable Channels Evaluation](#).
- Set bit 0 of the SDMA_HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] and DO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_SDMA_INTR register, or by optional interrupt to the ARM platform.
- Set the LOCK bit in the SDMA_SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scripts can now be run by enabling the selected software or hardware trigger event according to [Runnable Channels Evaluation](#).

55.4.9 SDMA Programming Model

This section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the ARM platform memory maps. The ARM platform processor has no access to any hardware resource described, except when those resources are described in ARM Platform Memory Map and Control Register Summary. .

55.4.9.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time.

This chapter lists the components of every channel state.

55.4.9.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the loop instruction, but otherwise can be used for any purpose.

55.4.9.3 Functional Unit State

Each channel context has some state that is part of the functional units.

The specific allocation of this state is part of the functional unit definition that is described in [Burst DMA Unit Programming](#), [Peripheral DMA Unit Programming](#) .

This state must be saved/restored on context switches.

55.4.9.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction.

A low order bit of zero selects the most significant half of the word.¹

55.4.9.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.

1. For example, big-Endian.

- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (CLRF and loop). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.
- Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the loop instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.

- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the loop instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch GReg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

55.4.9.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions.

Instructions are available to transfer its contents to and from a general register.

55.4.9.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the loop instruction to the location immediately following it.

55.4.9.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the loop instruction to the location of the next instruction after the loop.

55.4.9.4 Context Switching-Programming

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units.

The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode ([Context Switching](#)), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a done or yield(ge) instruction, SDMA goes into "real" context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel i is $CONTEXT_BASE + 24*i$ or $CONTEXT_BASE + 32*i$ where $CONTEXT_BASE$ equals 0x0800. The table below presents the layout of a channel context in memory:

Table 55-11. Layout of a Channel Context in Memory for SDMA

55.4.9.5 Address Space

The SDMA has four internal buses which are listed here.

- The Instruction bus reads instructions from the memory. Its address map is described in [Instruction Memory Map](#).
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in [Data Memory Map](#).

- The Functional Units bus (FUBUS) accesses the , Burst DMA, Peripheral DMA . The addressing mechanism is further detailed in [Functional Units Programming Model](#).
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

55.4.9.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus. Each address corresponds to a 16-bit data location.

Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a jmp to handle routines.

Table 55-12. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Block Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	-	0	4 Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	-	0	8 Kbyte internal RAM with channels context and user data/routines.

55.4.9.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA.

This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)

Functional Description

- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the ARM platform)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GRegn). The mapping between the general purpose register contents and the address bus is given in the following table:

Table 55-13. GRegn to DMBUS Address Mapping

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 55-14. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbyte	4 Kbyte internal ROM with boot code and standard routines

55.4.10 SDMA Initialization

Appendix A describes the setup of the SDMA . This section provides a quick description of several initialization procedures.

NOTE

There may be differences with the actual implementation in the API.

55.4.10.1 Hardware Reset-SDMA

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content.

The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

55.4.10.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register-detailed in [Configuration Register \(SDMAARM_CONFIG\)](#)-to determine the ARM platform DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (see [Channel Enable RAM \(SDMAARM_CHNENBL_n\)](#)).
3. Program the channel control registers-[Channel Event Override \(SDMAARM_EVTOVR\)](#), [Channel BP Override \(SDMAARM_DSPOVR\)](#), Channel

BP Override (SDMA_HOSTOVR), and [Channel Event Pending \(SDMAARM_EVTPEND\)](#)-according to the channel allocation.

4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A).
5. Trigger channel 0 with the [Channel Start \(SDMAARM_HSTART\)](#) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

55.4.10.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the [Configuration Register \(SDMAARM_CONFIG\)](#)[Channel Enable RAM \(SDMAARM_CHNENBL \$n\$ \)](#), [Channel Event Override \(SDMAARM_EVTOVR\)](#), [Channel BP Override \(SDMAARM_DSPOVR\)](#), [Channel ARM platform Override \(SDMAARM_HOSTOVR\)](#), and [Channel Event Pending \(SDMAARM_EVTPEND\)](#).
2. Use the OnCE (either via its JTAG interface or its ARM platform control registers) to download any code in the SDMA RAM. [Accessing the Memory](#) describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in [Channel 0 Boot Address \(SDMAARM_CHN0ADDR\)](#). (This register default address points to the standard boot script.)

55.4.10.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The ARM platform manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the ARM platform via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the ARM platform can enable any channel that becomes active and begins fetching and executing instructions from its script.

55.4.11 Instruction Description

The following sections introduce the instruction of the SDMA.

Instruction set details are available in [Instruction Set](#).

55.4.11.1 Scheduling Instructions

The following are scheduling instructions:

- **done**-The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The done 5 has a special usage reserved for debug, as explained in [Debug Instructions](#).
- **yield**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.
- **yieldge**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- **notify**-The notify instruction affects the scheduling bits, but does not cause rescheduling.

55.4.11.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied.

Otherwise, control passes to the next sequential instruction.

- **BF**-Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- **BT**-Branch if True. The branch is taken if the T bit in the processor status is one (true).

- **BSF-Branch if Source Fault.** The branch is taken if the SF bit in the processor status is one.
- **BDF-Branch if Destination Fault.** The branch is taken if the DF bit in the processor status is one.

55.4.11.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer.

Absolute transfers have a 14-bit address field that replaces the current PC.

- **JMP-Jump.** Causes the processor to jump to an absolute address encoded in the instruction itself.
- **JSR-Jump to Subroutine.** Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.
- **JMPR-Jump through Register.** Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- **JSRR-Jump to Subroutine through Register.** Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

55.4.11.4 Subroutine Return Instructions

The following are subroutine return instructions:

- **RET-Return from Subroutine.** The RET restores the contents of RPC to PC.
- **LDRPC-Load from RPC to Register.** THE LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

55.4.11.5 Loop Instruction

The following is a loop instruction:

LOOP-Enters Loop Mode. Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

55.4.11.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- CLRF-Clear Fault Flags. This instruction clears any combination of SF and DF.
- MOV r,s-This moves data from GReg[s] to GReg[r].
- LDI r,immediate-This loads GReg[r] with a zero-extended immediate value.

55.4.11.7 Logic Instructions

The following are logic instructions:

- XORr,s-This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- XORIr,immediate-This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- ORr,s-This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].
- ORIr,immediate-This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- ANDNr,s-This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- ANDNIr,immediate-This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- ANDr,s-This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- ANDIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

55.4.11.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- ADD r,s-This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- ADDI r,immediate-This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

- SUB r,s-This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- SUBIr,immediate-This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

55.4.11.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- CMPEQ r,s-This sets T when registers GReg[r] and GReg[s] are equal.
- CMPEQIr,immediate-This sets T when register GReg[r] and the zero-extended immediate value are equal.
- CMPLTr,s-This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- CMPHS r,s-This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

55.4.11.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- TSTr,s-This performs an and between GReg[r] and GReg[s], and sets T if the result is not zero.
- TSTIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and sets T if the result is not zero.

55.4.11.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3 , b_2 , b_1 , b_0 .

- RORBr-The rotate right byte. The result is b_0 , b_3 , b_2 , b_1 .

- REVB_r-The reverse bytes in word. The result is b_0, b_1, b_2, b_3 .
- REVBLO_r-The reverse, two low-order bytes. The result is b_3, b_2, b_0, b_1 .

55.4.11.12 Bit Shift Instructions

The following are bit shift instructions:

- ROR1_r-The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- LSR1_r-The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- ASR1_r-The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- LSL1_r-The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

55.4.11.13 Bit Manipulation Instructions

- BCLR_{r,n}-The bit clear is immediate; clears bit number i in register r .
- BSET_{r,n}-The bit set is immediate; sets bit number i in register r .
- BTST_{r,n}-The bit test is immediate; tests bit number i in register r (T becomes equal to the selected register bit).

55.4.11.14 SDMA Memory Access Instructions

All memory accesses are 32 bits.

Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s.

All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault.

What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- LDr,(b,d)-The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- ST_r,(b,d)-The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

55.4.11.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus.

Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See [Functional Units Programming Model](#).

There are two functional unit instructions, as follows:

- LDFr,fub-The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- STFr,fub-The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

55.4.11.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the [Illegal Instruction Trap Address \(SDMAARM_ILLINSTADDR\)](#) register (the default value is 0x0001).

ILLEGAL-Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

55.4.11.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT-The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug block only.

- done 5-This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in [Saving the Context](#).
- CpShReg-This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in [Restoring the Context](#).

55.4.12 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus.

Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in the following table. In order to establish a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 55-15. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit Programming	SDMSA	Memory Source Address Register	Memory Source Address Register (MSA)
	MDA	Memory Destination Address Register	Memory Destination Address Register (MDA)
	MD	Memory Data Buffer Register	Memory Data Buffer Register (MD) (Write) Burst DMA Write (stf) (Read) Burst DMA Read (Idf)
	MS	Memory State Register	State Register (MS)
Peripheral DMA Unit Programming	PSA	Peripheral Source Address Register	Peripheral Source Address Register (PSA)
	PDA	Peripheral Destination Address Register	Peripheral Destination Address Register (PDA)
	PD	Peripheral Data Buffer Register	Peripheral Data Register (PD) (Write) Peripheral DMA Write (stf)-Write Mode

Table continues on the next page...

Table 55-15. Functional Unit Registers (continued)

Functional Unit	Register	Register Name	Section/Page
			(Read) Peripheral DMA Read (ldf)-Read Mode
	PS	Peripheral State Register	Peripheral State Register (PS)

More information regarding the functional units can be found in [Peripheral DMA Unit](#), and [Burst DMA Unit](#).

55.4.12.1 Burst DMA Unit Programming

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus.

There are four registers associated with the burst DMA unit: a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS). The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

55.4.12.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EXTMC memory associated with the next read data transfer. It has byte granularity.

Reading the register with the ldf instruction has no side effects, and gives the address value in the EXTMC memory of the next data that is read by the SDMA during an ldf MD instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen-In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)-In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

55.4.12.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EXTMC memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the `ldf` instruction has no side effects. It gives the address value in the EXTMC memory where the next SDMA data (`stf r,MD` instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen-In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)-The MDA register is incremented by the number of bytes transferred during write cycles.

55.4.12.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO.

This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode).

The MD register is in write mode after a writing in MDA or after an `stf MD` instruction.

In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EXTMC controller are based on burst accesses.

An `ldf r,MD|SIZE` instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An `stf r,MD|SIZE` instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

Functional Description

When DMA is used for data transfer between SDMA and EXTMC (reading or writing), no immediate error is possible because the block manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EXTMC memory mapping. The only potential error, in this mode, would be the error sent back by the EXTMC controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in [Burst DMA Unit Error Management](#).

55.4.12.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

Table 55-16. SDMA_MS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																

Table 55-17. SDMA_MS Field Descriptions

Field	Description
31-22	Reserved
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen-MSA is not modified. 1 Incremented-MSA is incremented by the number of transferred bytes during read access.
19-18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses.

Table continues on the next page...

**Table 55-17. SDMA_MS Field Descriptions
(continued)**

Field	Description
dtype	0 Frozen-MDA is not modified. 1 Incremented-MDA is incremented by the number of transferred bytes during write access.
15-12	Reserved
11 y	Conditional Yielding selector. When selected, theyield/yieldge instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by stf MD instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an ldf MD instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 <i>reserved</i> 10 Error mode 11 error read burst
7-6	Reserved
5-0 n	Number of bytes in the MD FIFO.

55.4.12.1.5 Burst DMA Write (stf)

When received from a stf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 55-18. STF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy				sz
MS								

Table 55-19. STF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in the table below (unused bits should always be cleared).

Table 55-20. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.

Table continues on the next page...

**Table 55-20. Burst DMA STF Instruction List
(continued)**

Binary	Assembly	Comments
00_0_1_00_00	stf r,MSAIFR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSAIPF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.
00_1_1_00_00	stf r,MSAIPFIFR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDAIFR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MDISZ0IFL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MDISZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MDISZ8IFL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MDISZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MDISZ16IFL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MDISZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MDISZ32IFL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MDICPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of r register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MSISZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as clref MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the stf r,MD instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an ldf

Functional Description

from MS before terminating a channel in order to check the final error status. (The ldf from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every stf MD instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

55.4.12.1.6 Burst DMA Read (ldf)

When received from an ldf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 55-21. LDF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD		p					sz	
MS								

Table 55-22. LDF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The table below lists the possible write instructions (unused bits should always be cleared).

Table 55-23. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an ldf MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MDISZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MDISZ8IPF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MDISZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MDISZ16IPF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MDISZ32	32-bit (word) read
00_1_0_10_11	ldf r,MDISZ32IPF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

55.4.12.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed.

When the RISC core requires a prefetch ($p = 1$) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32'nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an stf MDISZ8 is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an stf MDISZ16 is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an stf MDISZ32 is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.
- Therefore, if an stf MDISZ32 is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (stf) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

For example, consider the case where data is written using a byte access, stf MDISZ8. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.

- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EXTMC controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush (which occurs only at the beginning of a misaligned write transfer) no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

55.4.12.1.8 Data Alignment and Endianness-Burst DMA Unit

55.4.12.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). The following table shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 55-24. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0

Table continues on the next page...

Table 55-24. FIFO Read Configuration (continued)

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
					z1 z2 z3 t0
10	x2 x3 y0 y1	sz8	00 00 00 x2	11	x3 y0 y1 y2
	y2 y3 z0 z1				y3 z0 z1 z2
	z2 z3 t0 t1 and so on...	sz16	00 00 x2 x3	00	y0 y1 y2 y3

	z3 t0 t1 t2 and so on...	sz16	00 00 x3 y0	01	y1 y2 y3 z0
		sz32	x3 y0 y1 y2	11	z1 z2 z3 t0
					y3 z0 z1 z2
					z3 t0 t1 t2

55.4.12.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. The following table shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 55-25. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww	sz8	?? ?? ?? x0	01	tt uu vv ww
	?? ?? ?? ??				x0 ?? ?? ??
	?? ?? ?? ?? and so on...	sz16	?? ?? x0 x1	10	?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww
					x0 x1 ?? ??
					?? ?? ?? ??
					tt uu vv ww
					x0 x1 x2 x3
					?? ?? ?? ??
01	tt uu vv ww	sz8	?? ?? ?? x0	10	tt uu vv ww

Table continues on the next page...

Table 55-25. FIFO Write Configuration (continued)

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
	xx ?? ?? ?? ?? ?? ?? ?? and so on...				xx x0 ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	11	tt uu vv ww xx x0 x1 ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	01	tt uu vv ww xx x0 x1 x2 x3 ?? ?? ??

		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an ldf MD is executed after stf MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a stfMD|SZ0|FL instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

55.4.12.1.8.3 Endianness-Burst DMA Unit

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian.

Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

55.4.12.1.9 Burst DMA Unit Copy Mode

A mechanism is available to perform fast ARM-to-ARM transfers.

Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag).

It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an stf MD|CPY is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)-given by the SDMA general register (4 LSB)-is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Burst DMA copy mode example

```

ldi r0,@src
stf r0,MSA // Source address setup
ldi r1,@dst
stf r1,MSA // Destination address setup
ldi r0,0x64 // data transfer counter
ldi r1,0x8

MAIN_XFER:
cmphs r0,r1 // Is r0 >= 0x8
bf LAST_XFER // If not, jump to last transfer label
stf r1,MD|CPY // Copy 8 words from MSA to MDA address.
subi r0,0x8 // Decrement counter
jmp MAIN_XFER // return to main transfer loop

LAST_XFER:
stf r0,MD|CPY

```

The main transfer loop is executed 12 times; then r0 equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

55.4.12.1.10 Burst DMA Unit Error Management

Another point to consider is the management of errors.

Because the DMA immediately sends an acknowledge to the RISC core (except for the stf MS|SZO|FLS instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access.

This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the ldf copy or stf copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after ldf instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a stf MDICOPY instruction will cancel the error mode. The following table shows when an immediate error is sent back according to the executed instruction.

Table 55-26. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (IU IPF) stf rn, MDA stf rn, MDICOPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the stf MDICOPY, a copy loop is executed.
stf rn, MS	NO	MS is updated.

Table continues on the next page...

Table 55-26. Possibilities in ERROR READ BURST Mode (continued)

DMA Instruction	Immediate Error	Comments
ldf rn, MS ldf rn, MSA ldf rn, MDA	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 55-27. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an stf MSISZ0 instruction.
ldf rn, MS ldf rn, MSA ldf rn, MDA	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	Yes	Whatever the DMA direction (read or write), an ldf rn triggers an immediate error.

55.4.12.1.11 Conditional Yielding-Burst DMA Unit

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Hardware Loop

```

loop
load Rn,source           // can be ldf or ld
<computation>           // can be done through functional units
store Rn,dest            // can be st or stf
done 0                    // yield

```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes-conditional or always-true-for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

55.4.12.2 Peripheral DMA Unit Programming

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the ARM platform.

Its goal is to perform data transfers between any blocks connected to the DMA bus of this platform. These blocks are either peripherals or memories. The peripheral DMA could be seen as the ARM platform DMA controller.

The DMA performs data transfers in three modes:

Functional Description

- Read mode, where data is read from peripherals or from memory connected to the ARM platform and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode-When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.
- Incremented mode-When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.
- Decrement mode-In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

55.4.12.2.1 Peripheral Source Address Register (PSA)

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the `ldf` instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an `ldf MD` instruction. Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all `ldf MD` instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (`ssize`). If source is a memory in incremented mode, first programmed in word mode (`stf PSA|SZ32I`), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the `stf PSA` instruction as described in the write section. The `ssize` and `stpe` registers are part of the DMA status register (`PS`).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

55.4.12.2.2 Peripheral Destination Address Register (PDA)

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (`PDA`) to store the address value
- A 2-bit register (`dtype`) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (`dsize`) to store the destination target data path size (byte, half-word, or word)

Reading the register with the `ldf` instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an `stfMD` instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the `stf PDA` instruction and may also generate an error in case of incorrect programming.

55.4.12.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to `PD` will automatically flush the new input data.

Functional Description

The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an ldf instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag-part of PS-is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

55.4.12.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer.

Although all PS fields can be written by an stf instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

Table 55-28. PS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ssize		stype		dsize		dtype	
W																
R	0	0	0	0	0	d	e		0	0	0	0	0	n		
W																

Table 55-29. PS Field Descriptions

Field	Description
31-24	Reserved
23-22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics. 00 reserved 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

Table continues on the next page...

Table 55-29. PS Field Descriptions (continued)

Field	Description
21-20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
19-18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics. 00 <i>reserved</i> 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
17-16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
15-11	Reserved
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by stf PD instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an ldf PD instruction. Reading PDA or PSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 <i>reserved</i> 10 Error mode 11 Error read
7-3	Reserved
2-0 n	number of bytes in PD

NOTE

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

55.4.12.2.5 Peripheral DMA Write (stf)-Write Mode

When written by an stf instruction, the function code bits are interpreted as follows:

Table 55-30. STF Code Bits

Register	7	6	5	4	3	2	1	0	
PSA	s		p	ar	am		sz		
PDA									
PD			pdsel						
PS			pssel						

Table 55-31. STF Code Bits Field Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3-2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen-Address registers are not modified after the transfer. 01 Incremented-Address registers are incremented by the number of transferred bytes. 10 Decrement-Address registers are decremented by the number of transferred bytes. 11 Updated-PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1-0 sz	Transfer Size 00 <i>reserved</i> 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5-0 pdsel	PD access selector 001000 is the only valid option
5-0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible stf instructions, the following table provides only a short list of all the possible write instructions:

Table 55-32. Peripheral DMA STF Instruction List

Table continues on the next page...

Table 55-32. Peripheral DMA STF Instruction List (continued)

Binary	Assembly	Comments
11_01_10_01 11_01_10_10 11_01_10_11	stf Rn, PDAISZ8 ID stf Rn, PDAISZ16ID stf Rn, PDAISZ32ID	<ul style="list-style-type: none"> Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. Destination address is in incremented mode: PDA = PDA-1, 2, or 4 after write PD.
11_01_11_01 11_01_11_10 11_01_11_11	stf Rn, PDAISZ8 IU stf Rn, PDAISZ16 IU stf Rn, PDAISZ32 IU	<ul style="list-style-type: none"> Update destination pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. PDA value is not modified by Rn bytes present in PD are lost
11_00_10_00	stf Rn, PD	<ul style="list-style-type: none"> Write "dsize" bytes of Rn in PD and automatically flush to destination target
11_11_11_11	stf Rn, PS	<ul style="list-style-type: none"> Write status register
11_00_11_00	stf Rn, clrefPS	<ul style="list-style-type: none"> Clear error flag if set

NOTE

When writing PD, size information is not important: It is embedded in the dsize field of PDA register. If dsize is 1, 2, or 4, then one, two, or four bytes from Rn is written to the PD register, and automatically flushed out to the destination target.

55.4.12.2.6 Peripheral DMA Read (ldf)-Read Mode

When received from an ldf instruction, the function code bits are interpreted as follows.

Table 55-33. LDF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s			ar	a			
PDA								
PD			p	cpy				
PS			pssel					

Table 55-34. LDF Code Bits Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA

Table continues on the next page...

Table 55-34. LDF Code Bits Descriptions (continued)

Field	Description
	1 PDA
4 copy (PD)	Copy Mode 0 standard access 1 copy mode access
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5-0 pssel	PS access selector 111111 is the only valid option to read PS

Table 55-35. Peripheral DMA LDF Instruction List

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PDIPF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PDICOPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are <i>not</i> the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

NOTE

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

55.4.12.2.7 Peripheral DMA Unit Copy Mode

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers.

Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for transfers that involve two targets of the same data path width.

Functional Description

Since copy mode is invoked with an ldf instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

55.4.12.2.8 Error Management

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

55.4.12.2.8.1 Immediate Errors

The following table lists all incorrect DMA register setups.

Table 55-36. Immediate Errors with Peripheral DMA

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSAISZ16IF stf Rn, PSAISZ16II stf Rn, PDAISZ16IF stf Rn, PDAISZ16II	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSAISZ32IF stf Rn, PSAISZ32II stf Rn, PDAISZ32IF stf Rn, PDAISZ32II	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]-PDA[1:0]	DMA instruction	Comments
0x01 0x10 0x11	stf Rn, PSAISZ32IU stf Rn, PDAISZ32IU	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSAISZ16IU stf Rn, PDAISZ16IU	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	Comments	
stf Rn,PD ldf Rn,PD		If PDA size (dsize) has never been set up before an stf PD instruction (dsize=0) If PSA size (ssize) has never been set up before an ldf PD instruction (ssize=0)
ldf Rn,PDICPY		Copy mode is possible only between two targets whose data path width is identical. It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.

55.4.12.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an ldf PD or stf PD instruction would be the error of the previous DMA cycle.

Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral).

When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: [Read Error \(First Phase\)](#), [Write Error and Read Error \(Second Phase\)](#), and [Copy Mode Errors](#) handling.

55.4.12.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next ldf PD instruction and writing PSA, PDA, or PD will cancel the error flag.

The block returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. The following table details which instructions can be executed in this mode.

Table 55-37. Possibilities in ERROR READ Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn, PDICOPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the ldf PDICOPY, a copy loop is executed.
stf rn, PS	NO	PS is updated.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

55.4.12.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in [Read Error \(First Phase\)](#), when an ldf PD is executed while the block is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, stf instructions may raise an immediate error, and ldf instructions will not (as detailed in the table below).

Table 55-38. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an stf PS instruction.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Whatever the DMA direction (read or write), an ldf rn, PD instruction will show an immediate error.

55.4.12.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in [Read Error \(First Phase\)](#) and [Write Error and Read Error \(Second Phase\)](#) : It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an ldf instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another ldf instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual stf PD instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual stf PD instruction.

55.4.12.2.8.6 Error Check Example

The following code illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first bdf instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the ldf PS

instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an ldf command sets the SF flag and any error returned on an stf instruction sets the DF flag. This can create a situation as shown in the example where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an ldf instruction.

Peripheral DMA Error Check

```

    clrf    0           // Clear SF and DF flags
    stf    R4, PD      // Write data to memory
    bdf    error_routine // Check for immediate error from write to PD.
    ldf    r3, PS      // Read PS (PS value in R3 can be ignored)
    bsf    error_routine // Check for bus error from "stf R4,PD"
                // SF is set because it is a ldf instruction, even though
                // the original error was a destination fault

```

55.4.12.2.9 Peripheral DMA Unit Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a stf PD instruction—assuming PDA is correctly programmed—it is automatically flushed to the destination.

An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

55.4.12.3 OnCE and Real-Time Debug

The On-Chip Emulation block (OnCE) is the debug interface to the SDMA.

It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core. The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

55.4.12.3.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the ARM platform Control interface when the OnCE is controlled by the ARM platform, as described in the "Using BP" section.

55.4.12.3.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core.

A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see [ARM platform Channel 0 Pointer \(SDMAARM_MC0PTR\)](#)): You can modify them through a regular memory access or the ARM platform control interface.

55.4.12.3.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

55.4.12.3.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode.

No hardware step execution mode is implemented in the OnCE, but this feature may be implemented at the software level with this instruction.

55.4.12.3.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status.

Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

55.4.13 The OnCE Controller

The OnCE controller receives commands from the ARM platform or from the JTAG controller. Each command is interpreted before being sent to the core.

55.4.13.1 OnCE Commands

A small set of commands supports the communication between the OnCE and the external world.

This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE. Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: The following table presents their formats.

Table 55-39. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TARM platform controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE. The nature of the associated data field is clearly identified. The dmov command is followed by a 32-bit data value (which is a data value for the SDMA); the exec_once and the exec_core commands are followed by a 16-bit data value (which is an instruction for the SDMA); the rstatus command is followed by a 16-bit control value (which is the content of the OnCE status register); the rbuffer command is followed by a 32-bit data value. The

debug_rqst and the run_core commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

55.4.13.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one ARM platform access to the OnCE is provided.

55.4.13.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal.

It produces shift-enable signals (shift_ir and shift_dr), and updates enable signals (update_ir and update_dr). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the shift_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp_en), instruction enable signal (inst_en), data enable (data_en), and status enable signal (stat_en).

During the shift_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the ARM platform access is enabled.

55.4.13.2.2 Using the ARM platform

The ARM platform access to the OnCE is not the standard access, but it is required if the JTAG is not available.

For example, if the SDMA ROM is out of use on a chip in production, and the ARM platform needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an ARM platform access to the OnCE.

To drive the OnCE, the ARM platform uses some registers contained in the ARM platform Control block of the SDMA. These registers are accessed through the ARM platform peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the ARM platform Control block is listed below:

- **ONCE_ENB** register (1 bit, read/write)-This 1-bit register enables the ARM platform access to the OnCE. When this bit is set, the signals from the JTAG are ignored. When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.
- **ONCE_CMD** register (4 bits, read/write)-This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing "0001" in this register, a `dmov` command is executed.

NOTE

On the ARM platform side, the `rstatus` and `bypass` commands are not supported. This register is reset on a JTAG reset.

- **ONCE_DATA** register (32 bits, read/write)-This 32-bit register is connected to the SDMA data register. This register is used when executing a `dmov` or `rbuffer` command.

NOTE

Before requesting a `dmov` command, the 32-bit data to transfer must be written in the **ONCE_DATA** register. At the end of the execution, the register is updated with `GReg1` former value. This register is reset on a JTAG reset.

- **ONCE_INSTR** register (16 bits, read/write)-This 16-bit register is connected to the SDMA instruction register. This register is used when executing an `exec_core` or an `exec_once` command.

NOTE

Before requesting an `exec_core` or an `exec_once` command, the appropriate instruction must be written in the **ONCE_INSTR** register. This register is reset on a JTAG reset.

- ONCE_STAT register (16 bits, read only)-A read access to the ONCE_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the ARM platform controls the OnCE, therefore no register is defined in the ARM platform Control block to access the bypass register.

55.4.13.2.3 Conflicts Between the JTAG and the ARM platform Accesses

When ARM platform access to the SDMA OnCE is enabled (that is, when the bit in the ONCE_ENB register is set), the JTAG access is disabled. This guarantees that the block is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a dmov command from debug mode (with neither 0xffffffff nor 0x0 as dmov value: 0x5a5a5a5a is good).
- Execute another dmov command (the value here is not important).
- The returned value from the latter dmov command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

55.4.13.3 Executing a Command from the OnCE

All the commands defined in [OnCE Commands](#) can be accessed through the JTAG. The ARM platform can access all these commands except the rstatus command.

On the ARM platform side, the OnCE status is directly accessed by reading the ONCE_STAT register.

55.4.13.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: rstatus and rbuffer. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: `dmov`, `run_core`, `exec_core`, `exec_once`, and `debug_rqst`. These commands are core status dependent, as follows:

- During user mode only the `debug_rqst` is taken into account.
- During debug mode, all these commands are taken into account except the `debug_rqst`. For example, an `exec_once` command requested while not in debug mode has no effect.

55.4.13.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is sent after decoding the `update_dr` state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the ARM platform side, the request is sent after detecting a write access to the `ONCE_CMD` register. All the registers involved in this operation must be loaded first.

The following is an example of an `exec_core` command execution from the ARM platform side: After writing '010' in the `ONCE_CMD` register, the OnCE controller asks the SDMA to execute the instruction contained in the `ONCE_INSTR` register. The instruction involved should be available in the `ONCE_INSTR` register before the beginning of the execution.

55.4.13.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- `rstatus` command execution-The `rstatus` command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the `capture_dr` state, and shifted out after 16 TCK clock cycles in the `shift_dr` state. The `rstatus` command is not supported on the ARM platform side, but a status register is provided instead. The `rstatus` may be performed in both debug and user modes.
- `dmov` command execution-The `dmov` command accesses SDMA internal registers. Executing a `dmov` instruction exchanges the 32-bit data values between the SDMA data register and the general register `GReg[1]`.
- If the JTAG is used, the content of `GReg1` is captured in the SDMA data register during the `capture_dr` state, then it is shifted out after 32 TCK clock cycles in the `shift_dr` state. During the `update_dr` state, `GReg1` is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the ARM platform side, the data values

contained in GReg1 and the SDMA data register are exchanged after detecting a write access to the ONCE_CMD register. The ONCE_DATA register must therefore be loaded first.

- **exec_once** command execution-The **exec_once** command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.
- Change of flow instructions as well as instructions that may cause a context switch are not supported: The comprehensive list comprises **done/yield/yiedge** (except **done 5**), **BF**, **BT**, **BSF**, **BDF**, **JMP**, **JSR**, **JMPR**, **JSRR**, **RET**, and **LOOP**, as well as all the illegal instructions.

No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the **rstatus OnCE** command, monitoring the **debug_mode** pin, or checking the [OnCE Status Register \(SDMAARM_ONCE_STAT\)](#) register via the ARM platform control interface.

NOTE

Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the **shift_dr** state. A request is sent to the core when the **update_dr** state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- **run_core** command execution-The **run_core** command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in [Restoring the Context](#).
- If the JTAG is used, a 1-bit bypass value is shifted in the **bypass** register in the **shift_dr** state. The SDMA is rerun when the **update_dr** state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the core is rerun when detecting a write access to the ONCE_CMD register.
- **exec_core** command execution-The **exec_core** command resumes program execution from any address. The 16-bit instruction provided with the **exec_core** overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted

from any address. After executing an `exec_core` command, the SDMA leaves debug mode. The `exec_core` command is usually used with a `jmp` instruction.

- If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the `shift_dr` state. The SDMA is rerun when the `update_dr` state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the SDMA reruns when detecting a write access to the `ONCE_CMD` register. The `ONCE_INSTR` register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a jump to address 0x100 instruction.
- `debug_rqst` command execution-The `debug_rqst` command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the `shift_dr` state. A debug request is sent to the SDMA when the `update_dr` state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the debug request is sent when detecting a write access to the `ONCE_CMD` register. When the SDMA is already in debug mode, this command is simply ignored.
- `rbuffer` command execution-The `rbuffer` command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is captured in the SDMA data register during the `capture_dr` state. The register is completely shifted out after maintaining the `shift_dr` state during 32 TCK clock cycles. If the OnCE is driven from the ARM platform side, the content of the RTB is captured in the `ONCE_DATA` register after detecting a write access to the `ONCE_CMD` register.
- `bypass` command execution-This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

55.4.13.4 Registers Descriptions

See [SDMACORE](#), and [SDMAARM](#), for detailed information on each register.

55.4.13.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request.

This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

55.4.13.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers—the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: `addra_cond` or `addrb_cond`. Every address register is cleared on a JTAG reset.

55.4.13.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

55.4.13.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the `data_cond` condition.

The event cell data register is cleared on a JTAG reset.

55.4.13.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data.

Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

55.4.13.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode.

Refer to [Real Time Buffer](#) for more details.

55.4.13.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions.

The event cell control register is cleared on a JTAG reset. See also [OnCE Event Detection Unit](#) for more details.

55.4.13.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer.

See [Trace Buffer](#) for more details.

55.4.13.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register.

Refer to [OnCE Status Register \(SDMAARM_ONCE_STAT\)](#) for detailed description of the individual fields in the OSTAT register.

The following figure shows the OSTAT structure.

Table 55-40. OnCE Status Register (OnCE)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PST[3:0]				RCV	EDR	ODR	SWB	MST					ECCR[2:0]		

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the ARM platform control interface, and when ECCR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an rstatus command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the ARM platform access. Executing the rstatus command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the exec_once command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

55.4.13.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

55.4.13.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see [Figure 55-11](#)) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, $TCK < CLK/8$, limitation guarantees that all operations are performed as expected.

55.4.13.5.2 Synchronization Implementation

The figure found here shows the synchronization mechanism.

Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge_detected and negedge_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to yield the TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

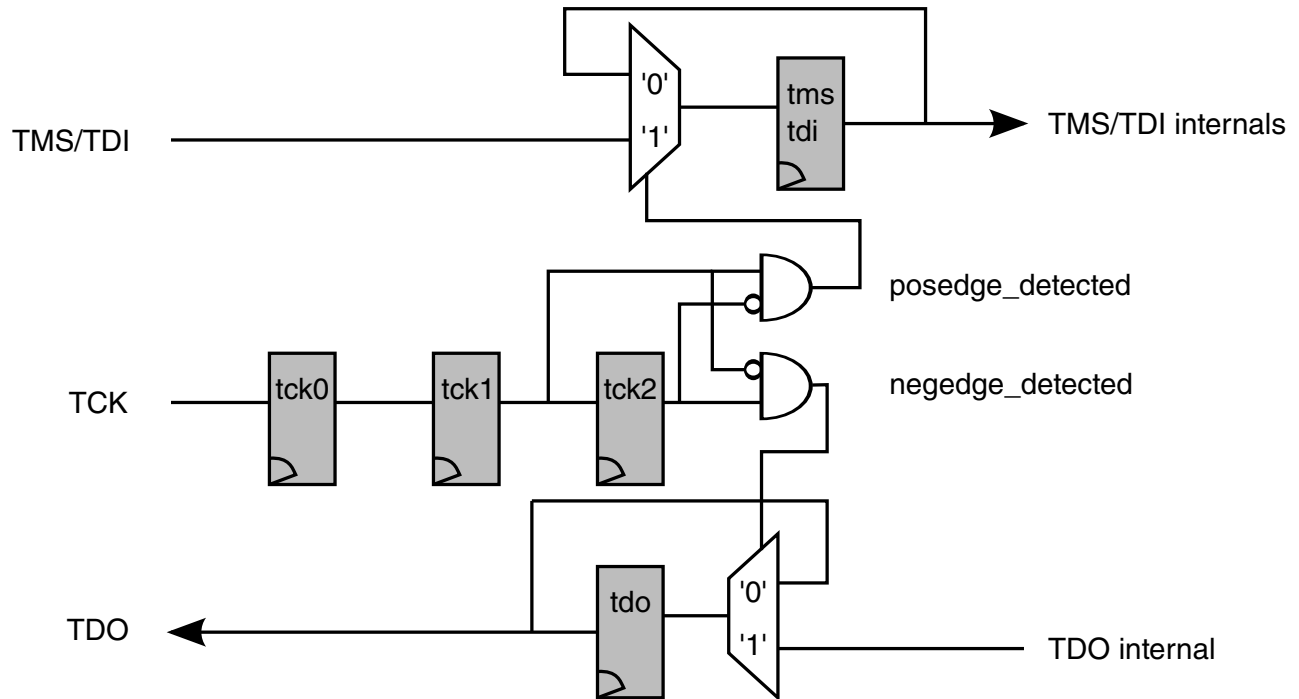

Figure 55-11. OnCE Synchronization Layer

The following figure shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

Figure 55-12. Synchronization Timings

55.4.13.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

55.4.14 Using the OnCE

This section provides the elements necessary to run the OnCE during a debug process.

In addition to the basic set of commands described in [OnCE Commands](#), more complex commands can be built to meet users' requirements.

55.4.14.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed.

This is the case for instances when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the `clk_gating_off` input.
- For the ARM platform access, the SDMA clock gating is automatically turned off when the ARM platform access is enabled (see [OnCE Enable \(SDMAARM_ONCE_ENB\)](#)).

55.4.14.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA.

It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA.

Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

55.4.14.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch.

The request is ignored when the core is already in debug mode. Refer to [Figure 55-4](#), which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

55.4.14.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see [Activating Clocks in Debug Mode](#)). The debug request line should be not be maintained high when the SDMA is in debug mode.

NOTE

The `debug_rqst` command (from the OnCE command set) is not supported during system reset.

55.4.14.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a `debug_rqst` command.

The `debug_rqst` command can be sent by the JTAG access or by an access on the ARM platform side (if the ARM platform access is enabled).

55.4.14.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

55.4.14.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus.

See [OnCE Event Detection Unit](#) for more details.

55.4.14.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the `exec_once` command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution.

Some instructions are not supported by the `exec_once` command: `done/yield/yiedge` (except `done 5`), `BF`, `BT`, `BSF`, `BDF`, `JMP`, `JSR`, `JMPR`, `JSRR`, `RET`, and `LOOP`, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

55.4.14.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the ARM platform and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);           // executing my_command with a data field
my_command(-);                    // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an ARM platform access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in); // returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

55.4.14.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like `dmov` or `exec_once`), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus();           // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-);      // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

55.4.14.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags.

Functional Description

Use the general register GReg[1] as an intermediate register to export the entire context of the SDMA.

The following example shows how to save GReg[0], GReg[1], GReg[2] and GReg[3]. The sequence of commands used to export additional general registers is very similar to this.

Save GReg[0], GReg[1], GReg[2], and GReg[3]

```
GReg1_data = dmov(-); // the value exported is the content of
GReg[1]
exec_once("mov GReg1,GReg0"); // puts the content of GReg[0] into
GReg[1]
GReg0_data = dmov(-); // the value exported is the content of
GReg[0]
exec_once("mov GReg1, GReg2"); // puts the content of GReg[2] into
GReg[1]
GReg2_data = dmov(-); // the value exported is the content of
GReg[2]
exec_once("mov GReg1, GReg3"); // puts the content of GReg[3] into
GReg[1]
GReg3_data = dmov(-); // the value exported is the content of
GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a done 5, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5"); // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Exporting the Context

```
dmov(ctx_base_addr); // loading GReg[1] with the channel
context_base_address
exec_once("ld GReg0, (GReg1,0)"); // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)"); // get SPC-EPC into GReg1
Loop_data = dmov(-); // read back the value of Loop registers
exec_once("mov GReg1, GReg0"); // puts the PC info into GReg1
PC_data = dmov(-); // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

55.4.14.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE.

The example found hereshows how it is possible to modify the current channel context.

Modifying the Current Channel Context

```
dmov(Loop_data); // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1"); // copy to GReg[0]
dmov(PC_data); // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1"); // copy to GReg[2]
dmov(ctx_base_addr); // put channel context base address into
GReg[1]
exec_once("st GReg0, (GReg1,1)"); // restore Loop context
exec_once("st GReg2, (GReg1,0)"); // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once("cpShReg"); // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

The following example shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Restoring the General Register Context

```
dmov(GReg3_data); // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1"); // restore GReg[3]
dmov(GReg2_data); // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1"); // restore GReg[2]
dmov(GReg0_data); // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1"); // restore GReg[0]
dmov(GReg1_data); // restore GReg[1]
```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a mov instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a mov to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The cpShReg instruction is meant to provide a means for changing these register contents via the context memory.

55.4.14.5.4 Accessing the Memory

In the example shown here, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```
macro READ:                dmov(target_addr);                // put the target
address in GReg[1]        exec_once("ld GReg1, (GReg1, 0)");    // execute the
load instruction          res_data = dmov(-);                // exports the result
data value
```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```
macro WRITE:                dmov(target_addr);                // puts the
target address in GReg[1]  exec_once("mov GReg0, GReg1");        // puts the target
address in GReg[0]        dmov(target_data);                // puts the target
data in GReg[1]          exec_once("st GReg1, (GReg0, 0)");    // performs the
store operation
```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

55.4.14.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA.

Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-);                // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the `exec_core` command. The data field provided with this command must be the encoding of a jump instruction.

```
exec_core("jmp start_addr"); // rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

55.4.14.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

The following example shows the macro functions READ and WRITE, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2);           // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the "bkpt_addr"
instr_save = READ(bkpt_addr/2);         // save the instruction before
overwriting                               // store the bkpt instruction
STORE("bkpt instruction",bkpt_addr/2);
in memory
exec_core("jmp run_addr");              // rerun the SDMA
rstatus(-);                             // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);          // restore the instruction
overwritten
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

55.4.14.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

55.4.14.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers.

Functional Description

A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true.

Figure 55-13. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic block that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

The following figure shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference values located in memory mapped registers—the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

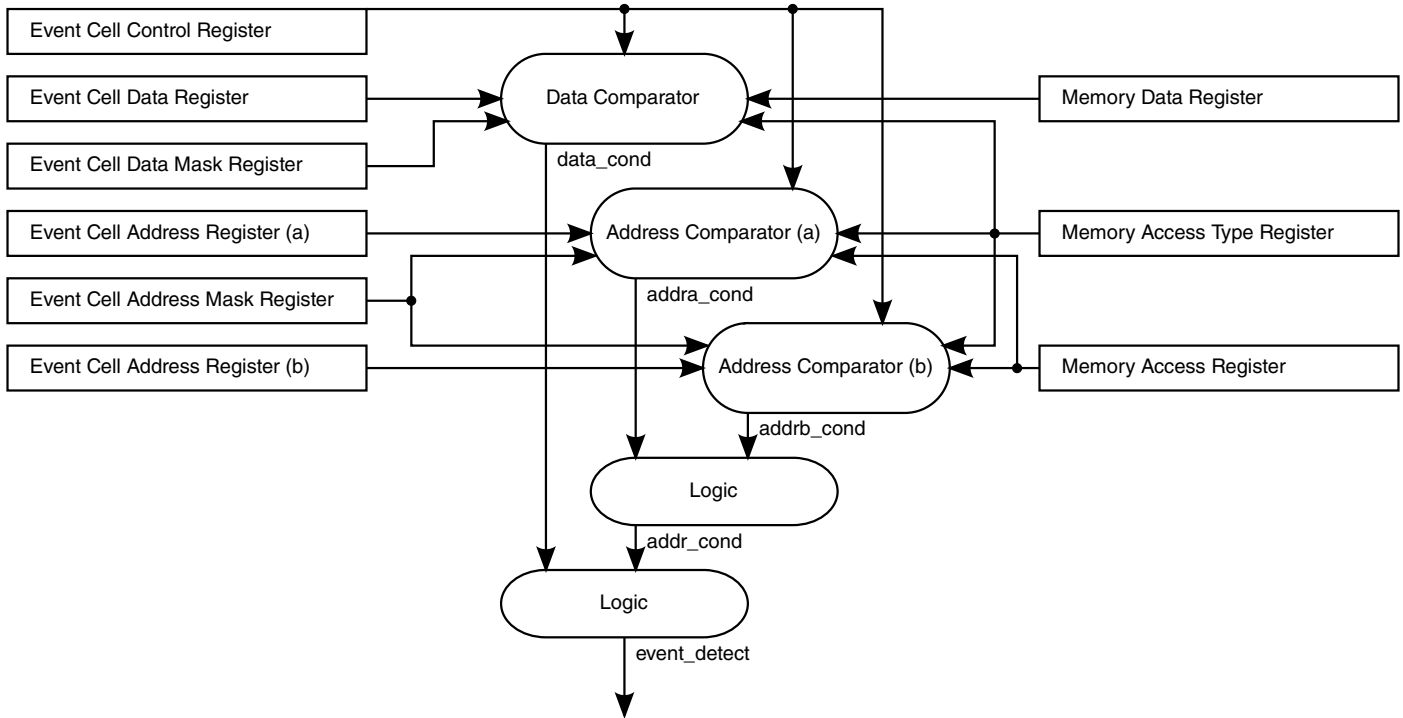

Figure 55-14. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

55.4.14.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

55.4.14.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE.

When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port `clk_gating_off`. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

When the OnCE is accessed through the ARM platform Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE_ENB register (see [OnCE Enable \(SDMAARM_ONCE_ENB\)](#)) is set. A write access to this register is possible even when the OnCE clock is not running. If the ARM platform access is used, the bit in the ONCE_ENB register must be set before any attempt to access any other OnCE register.

55.4.14.7.2 Resets

The OnCE reset is different from the SDMA main reset.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

55.4.14.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution.

The content of this register may be exported through JTAG ports without stopping the core.

55.4.14.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution.

The following figure shows an overview of the Trace Buffer.

Figure 55-15. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

Functional Description

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is as follows:

```
exec_once("mov r1, TB");           // stores the oldest change-of-flow in
GReg1
dmov(-);                          // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

55.4.14.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE.

Executing an `rbuffer` command (see [The OnCE Controller](#) for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a `rbuffer` command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

55.4.14.8.3 Emulation Pin

The `debug_matched_event` emulation pin reflects the matching condition status detected by the Event Detection Unit.

Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

55.4.14.8.4 Real-Time Debug Outputs

The table found here shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 55-41. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	<p>The core_state bits reflect the state of the SDMA core.</p> <ul style="list-style-type: none"> • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the core idle state); the "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel</p>
debug_yield	<p>Pulse that is active when a yield (done 0) or a yieldge (done 1) instruction is executed.</p> <p>0 - 1 yield/yieldge executed</p>
debug_core_run	<p>Active when the SDMA core is executing instructions.</p> <p>0 Debug or sleep mode</p>

Table continues on the next page...

Table 55-41. Real-Time Debug Output Pins (continued)

Pin	Description
	1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (ld, st, ldf, or stf instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, "no access" is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 PSA 6 PDA 7 PD 8 PS 9 RESERVED 10 RESERVED 11 RESERVED 12 RESERVED 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register

Table continues on the next page...

Table 55-41. Real-Time Debug Output Pins (continued)

Pin	Description
	18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1) (as described in SDMAARM). The following two parameters are available for every line: <ul style="list-style-type: none"> • CNF-Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]-Gives the number of the DMA request or channel to monitor

The `matched_event` emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the [Configuration Register \(SDMAARM_CONFIG\)](#) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

55.5 Instruction Set

55.5.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

```

x...x - don't care

rrr - destination/source general register

sss - additional source general register

bbb - general register used as address base register

dddd - address displacement

nnnnn - bit number
uuuuuuuu - function unit command bits

pppppppp - branch displacement (signed)

iiiiiii - 8-bit immediate

jjj - control bit to clear

ff - flag to clear
00000jjj00000000 - done (done,yield,wait)
00000jjj00000001 - notify

55.5.2 SDMA Instruction Set

This section describes all the useful instructions from the SDMA set.

Table 55-42. SDMA Instruction List

Instruction	Description	Page
ADD	Addition	ADD (Addition)
ADDI	Add with Immediate Value	ADDI (Add with Immediate Value)
AND	Logical AND	AND (Logical AND)
ANDI	Logical AND with Immediate Value	ANDI (Logical AND with Immediate Value)
ANDN	Logical AND NOT	ANDN (Logical AND NOT)
ANDNI	Logical AND with Negated Immediate Value	ANDNI (Logical AND with Negated Immediate Value)
ASR1	Arithmetic Shift Right by 1 Bit	ASR1 (Arithmetic Shift Right by 1 Bit)
BCLRI	Bit Clear Immediate	BCLRI1 (Bit Clear Immediate)
BDF	Conditional Branch if Destination Fault	BDF (Conditional Branch if Destination Fault)
BF	Conditional Branch if False	Functional Units Programming Model
BSETI	Bit Set Immediate	BSETI (Bit Set Immediate)
BSF	Conditional Branch if Source Fault	BSF (Conditional Branch if Source Fault)
BT	Conditional Branch if True	BT (Conditional Branch if True)
BTSTI	Bit Test immediate	BTSTI (Bit Test immediate)
CLRF	Clear ARM platform flags	CLRF (Clear ARM platform flags)
CMPEQ	Compare for Equal	CMPEQ (Compare for Equal)
CMPEQI	Compare with Immediate for Equal	CMPEQI (Compare with Immediate for Equal)
CMPHS	Compare for Higher or Same	CMPHS (Compare for Higher or Same)
CMPLT	Compare for Less Than	CMPLT (Compare for Less Than)
cpShReg	Update Context of PCU Registers and Flags	cpShReg (Update Context of PCU Registers and Flag)
DONE	DONE, Yield	DONE (DONE, Yield)
ILLEGAL	ILLEGAL Instruction	ILLEGAL (ILLEGAL Instruction)
JMP	Unconditional Jump Immediate	JMP (Unconditional Jump Immediate)
JMPR	Unconditional Jump	JMPR (Unconditional Jump)
JSR	Unconditional Jump to Subroutine Immediate	JSR (Unconditional Jump to Subroutine Immediate)
JSRR	Unconditional Jump to Subroutine	JSRR (Unconditional Jump to Subroutine)
LD	Load Register	LD (Load Register)
LDF	Load Register from Functional Unit	LDF (Load Register from Functional Unit)

Table continues on the next page...

**Table 55-42. SDMA Instruction List
(continued)**

Instruction	Description	Page
LDI	Load Register with Immediate Value	LDI (Load Register with Immediate Value)
LDRPC	Load from RPC to Register	LDRPC (Load from RPC to Register)
LOOP	Hardware Loop	LOOP (Hardware Loop)
LSL1	Logical Shift Left by 1 Bit	LSL1 (Logical Shift Left by 1 Bit)
LSR1	Logical Shift Right by 1 Bit	LSR1 (Logical Shift Right by 1 Bit)
MOV	Logical Move	MOV (Logical Move)
NOTIFY	Notify to ARM platform	NOTIFY (Notify to ARM platform)
OR	Logical OR	OR (Logical OR)
ORI	Logical OR with Immediate Value	ORI (Logical OR with Immediate Value)
RET	Return from Subroutine	RET (Return from Subroutine)
REVB	Reverse Byte Order	REVB (Reverse Byte Order)
REVBLO	Reverse Low Order Bytes	Reverse Low Order Bytes(REVBLO)
ROR1	Rotate Right by 1 Bit	ROR1 (Rotate Right by 1 Bit)
RORB	Rotate Right by 1 Byte	RORB (Rotate Right by 1 Byte)
SOFTBKPT	Software Breakpoint	SOFTBKPT (Software Breakpoint)
ST	Store Register	ST (Store Register)
STF	Store Register in Functional Unit	STF (Store Register in Functional Unit)
SUB	Subtract	SUB (Subtract)
SUBI	Subtract with Immediate	SUBI (Subtract with Immediate)
TST	Test with Zero	TST (Test with Zero)
TSTI	Test Immediate	TSTI (Test Immediate)
XOR	Logical Exclusive OR	XOR (Logical Exclusive OR)
XORI	Exclusive OR with Immediate	XORI (Exclusive OR with Immediate)

55.5.2.1 ADD (Addition)

Operation:

$$\text{GReg}[r] \leftarrow \text{GReg}[s] + \text{GReg}[r]$$

$$T \leftarrow (\text{GReg}[r] == 0)$$

Assembler:

Syntax: `add r,s`

Example: `add 0,3`

ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Instruction Set

Cycles: 1

Description: Performs the ADDition of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*. The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.2 ADDI (Add with Immediate Value)

Operation:

$GReg[r] \leftarrow GReg[r] + \text{immediate}$

$T \leftarrow (GReg[r] == 0)$

Assembler:

Syntax: `addi r,immediate`

Example: `add 6,112`

ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Adds a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.3 AND (Logical AND)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s] \ \& \ \text{GReg}[r]$

Assembler:

Syntax: `and r,s`

Example: `and 1,2`

AND GReg[1] and GReg[2] and store the result in GReg[1]

Instruction Set

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register s and the destination general register r , and stores the result in the destination general register r .

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.4 ANDI (Logical AND with Immediate Value)

Operation:

$GReg[r] \leftarrow GReg[r] \& \text{immediate}$

Assembler:

Syntax: `andi r,immediate`

Example: `andi 7,45`

AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.5 ANDN (Logical AND NOT)**Operation:**

GReg[r] ← ~GReg[s] & GReg[r]

Assembler:

Syntax: andn r, s

Example: andn 3, 4

AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Instruction Set

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

Table 55-43. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	0	s	s	s

Instruction Fields:

rrr /sss - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.6 ANDNI (Logical AND with Negated Immediate Value)

Operation:

$GReg[r] \leftarrow GReg[r] \& \sim immediate$

Assembler:

Syntax: `andni r,immediate`

Example: `andni 0,2`

AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.7 ASR1 (Arithmetic Shift Right by 1 Bit)**Operation:**

$$\text{GReg}[r] : \{b_{31}, b_{30}, \dots, b_1, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, b_{31}, b_{30}, \dots, b_1\}$$
Assembler:

Syntax: asr1 r

Example: asr1 3

divide by 2 the signed value of GReg[3] and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Instruction Set

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

Table 55-44. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.8 BCLRI1 (Bit Clear Immediate)

Operation:

$\text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, 0, b_{(i-1)}, \dots, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, b_{(i)}, b_{(i-1)}, \dots, b_0\}$

Assembler:

Syntax: `bclri r,i`

Example: `bclri 1,12`

clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
----	----	----	----	----	----	---	---	---	---	---	---	---	---	---	---

Table continues on the next page...

0	0	0	0	0	r	r	r	0	0	1	i	i	i	i	i
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiii - immediate value:

00000 - 0

00001 - 1

...

11110 - 30

11111 - 31

55.5.2.9 BDF (Conditional Branch if Destination Fault)

Operation:

if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

Assembler:

Syntax: bdf label

Example: bdf LLL

Jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Set

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

55.5.2.10 BF (Conditional Branch if False)

Operation:

```
if (T == 0)
PC ← PC + 1 + displacement
else
PC ← PC + 1
```

Assembler:

Syntax: bf label

Example: bf LLL

Jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```

00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)

```

55.5.2.11 BSETI (Bit Set Immediate)

Operation:

$$GReg[r] : \{b31, \dots, b(i+1), 1, b(i-1), \dots, b0\} \leftarrow GReg[r] : \{b31, \dots, b(i+1), b(i), b(i-1), \dots, b0\}$$

Assembler:

Syntax: `bseti r,i`

Example: `bseti 6,5`

Set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number *i* in the selected General Register.

Instruction Format

Instruction Set

0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiii - bit number field:

00000 - 0

00001 - 1

...

11110 - 30

11111 - 31

55.5.2.12 BSF (Conditional Branch if Source Fault)

Operation:

if (SF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

Assembler:

Syntax: `bsf label`

Example: `bsf LLL`

Jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

55.5.2.13 BT (Conditional Branch if True)

Operation

```
if (T == 1)
PC ← PC + 1 + displacement
else
PC ← PC + 1
```

Assembler

```
Syntax: bt label

bt LLL
```

Jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

Instruction Set

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

55.5.2.14 BTSTI (Bit Test immediate)

Operation:

$T \leftarrow \text{GReg}[r]:b(i)$

Assembler:

Syntax: `btsti r,i`

Example: `btsti 2,29`

Test bit 29 in GReg[2] and copy its value in flag T

CPU flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

Instruction Format:

Table 55-45. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiii - bit number field:

0000 - 0

0001 - 1

...

11110 - 30

11111 - 31

55.5.2.15 CLRF (Clear ARM platform flags)

Operation:

```
if (ff%2 == 0)
```

```
SF ← 0
```

```
if (ff/2 == 0)
```

```
DF ← 0
```

Assembler:

```
Syntax: clrf ff
```

```
Example: clrf 2
```

Instruction Set

Clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the ARM platform fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear

SF 11 - no clear

55.5.2.16 CMPEQ (Compare for Equal)

Operation:

$T \leftarrow (GReg[s] == GReg[r])$

Assembler:

Syntax: `cmpeq r,s`

Example: `cmpeq 7,5`

Compare GReg[7] and GReg[5] and set flag T if they are equal

CPU flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

Instruction Fields:**rrr / sss - register field:**

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

55.5.2.17 CMPEQI (Compare with Immediate for Equal)**Operation:**

$$T \leftarrow (\text{GReg}[r] == \text{immediate})$$
Assembler:

Syntax: `cmpeqi r,immediate`

Example: `cmpeqi 2,13`

Compare GReg[2] and decimal value 13 and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:**rrr - destination register field:**

000 - GReg[0]

Instruction Set

001 - GReg[1]
010 - GReg[2]
011 - GReg[3]
100 - GReg[4]
101 - GReg[5]
110 - GReg[6]
111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0
00000001 - 1
...
11111110 - 254
11111111 - 255

55.5.2.18 CMPHS (Compare for Higher or Same)

Operation:

$T \leftarrow (\text{GReg}[r] \geq \text{GReg}[s])$

Assembler:

Syntax: `cmphs r,s`

Example: `cmphs 0,1`

Compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

Instruction Fields:**rrr / sss - register field:**

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

55.5.2.19 CMPLT (Compare for Less Than)**Operation:**

$$T \leftarrow (\text{GReg}[r] < \text{GReg}[s])$$
Assembler:

Syntax: `cmplt r,s`

Example: `cmplt 7,4`

Compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

rrr / sss - register field:

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]

Instruction Set

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.20 cpShReg (Update Context of PCU Registers and Flag)

Assembler:

Syntax: cpShReg

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC,LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done 5 operation.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

55.5.2.21 DONE (DONE, Yield)

Operation:

```
if (jjj&6 == 2) HE[CCR] ← 0
```

```
if (jjj == 3) HI[CCR] ← 1
```

```
if (jjj == 4) EP[CCR] ← 0
```

```
if ((jjj == 0) && (NCP > CCP)) CCR ← NCR
```

```
else if ((jjj == 1) && (NCP >= CCP))
```

```
CCR ← NCR
```

```
else
```

```
CCR ← NCR
```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

Assembler:

Syntax: done jjj

Example: done 3

Clear HE bit for the current channel, send an interrupt to the ARM platform for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding ARM platform by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched. If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending). If no flag is modified, the reschedule can allow the replacement of the current channel by another channel with a priority strictly greater than the current channel priority (yield). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (yieldge). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

jjj - Channel Flags field:

000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)

001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)

010 - Clear HE for the current channel and reschedule 011 - Clear HE, set HI for the current channel and reschedule 100 - Clear EP for the current channel and reschedule

101 - Reserved for debug to copy relevant registers into context memory

110 - RESERVED

111 - RESERVED

For the scheduling rules, refer to [Scheduler Functional Description](#). Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a ARM platform start via the [Channel Start \(SDMAARM_HSTART\)](#) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a ARM platform start via the [Channel Start \(SDMAARM_HSTART\)](#) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the ARM platform upon closure;
- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

55.5.2.22 ILLEGAL (ILLEGAL Instruction)

Operation:

$PC \leftarrow 0001$

Assembler:

Syntax: `illegal`

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format

Table 55-46. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

55.5.2.23 JMP (Unconditional Jump Immediate)

Operation:

PC \leftarrow absolute_address

Assembler:

Syntax: jmp label

Example: jmp LLL

The assembler translates the label to the exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaaaa - address field:

00000000000000 - 0

000000000000001 - 1

...

111111111111110 - 16382

111111111111111 - 16383

55.5.2.24 JMPR (Unconditional Jump)

Operation:

PC \leftarrow GReg[r]

Instruction Set

Assembler:

Syntax: `jmp r`

Example: `jmp 0`

Jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.25 JSR (Unconditional Jump to Subroutine Immediate)

Operation:

$RPC \leftarrow PC + 1$

$PC \leftarrow \text{absolute_address}$

Assembler:

Syntax: `jsr r`

Example: `jsr LLL`

Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaaaa - address field:

0000000000000000 - 0

0000000000000001 - 1

...

1111111111111110 - 16382

1111111111111111 - 16383

55.5.2.26 JSRR (Unconditional Jump to Subroutine)

Operation:

$RPC \leftarrow PC + 1$

$PC \leftarrow GReg[r]$

Assembler:

Syntax: jsrr r

Example: jsrr 5

Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

Instruction Set

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.27 LD (Load Register)

Operation:

```
GReg[r] ← [GReg[b] + displacement]
```

```
if (transfer_error)
```

```
SF ← 1
```

```
else
```

```
SF ← 0
```

Assembler:

```
Syntax: ld r, (b, displacement)
```

```
Example: ld 1, (2, 23)
```

Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

rrr / bbb - register field:

000 - GReg[0]

001 - GReg[1]

...

111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1

...

11111 - 31

55.5.2.28 LDF (Load Register from Functional Unit)

Operation:

GReg[r] ← [fu_address]

if (transfer_error)

SF ← 1

else

SF ← 0

fu_address is an 8-bit field and depends on addressed functional unit

Assembler:

Syntax: ldf r, fu_address

Example: ldf 0, 13

Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Instruction Set

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- [Burst DMA Read \(ldf\)](#) for Burst DMA
- [Peripheral DMA Read \(ldf\)-Read Mode](#) for Peripheral DMA

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

ffffff - functional unit source register and action (unspecified values are reserved):

00000000 - MSA

00000100 - MDA

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - MS

00101001 - MD byte - prefetch

00101010 - MD halfword - prefetch

00101011 - MD word - prefetch

01000000 - DSA

11000000 - PSA
 11001000 - PD
 11010000 - PDA
 11011000 - PD in copy mode (rrr contents are lost)
 11101000 - PD - prefetch next data
 11111111 - PS

55.5.2.29 LDI (Load Register with Immediate Value)

Operation:

GReg[r] ← immediate

Assembler:

Syntax: ldi r,immediate

Example: ldi 6,1

loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]

Instruction Set

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.30 LDRPC (Load from RPC to Register)

Operation:

GReg[r] ← RPC

Assembler:

Syntax: ldrpc r

Example: ldrpc 3

copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

55.5.2.31 LOOP (Hardware Loop)

Operation:

```

if (ff%2 == 0)
    SF ← 0
if (ff/2 == 0)
    DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
    PC ← PC + loop_size + 1
else
    {
        SPC ← PC + 1
        EPC ← PC + loop_size + 1
        LM ← 1
        PC ← PC + 1
    }

```

during every instruction execution in the loop:

```

if ((SF == 1) || (DF == 1))
    {
        LM ← 0
        PC ← EPC
    }
else if ((PC + 1) == EPC)
    {
        GReg[0] ← GReg[0] - 1
        if (GReg[0] == 0)
            {
                LM ← 0
                PC ← EPC
            }
    }

```

Instruction Set

```
    }  
    else  
        PC ← SPC  
    }  
else  
    PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)  
    T ← 1  
else  
    T ← 0
```

Assembler:

Syntax: `loop n{,ff}`

Example: `loop 3,1`

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the ff field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The loop instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times. The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body). The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF

or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

Limitations:

1. 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. 2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. 3. The empty loop (0 instruction in the body) is forbidden.
4. 4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

Instruction Fields:

ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear SF

11 - no clear

nnnnnnnn - loop size

00000000 - empty loop: forbidden value

00000001 - 1 instruction in the loop

00000010 - 2 instructions in the loop

...

11111111 - 255 instructions in the loop

55.5.2.32 LSL1 (Logical Shift Left by 1 Bit)

Operation:

Instruction Set

$\text{GReg}[r] : \{b30, \dots, b1, b0, 0\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$

Assembler:

Syntax: `lsl1 r`

Example: `lsl1 2`

multiplies by 2 the value in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.33 LSR1 (Logical Shift Right by 1 Bit)

Operation:

$\text{GReg}[r] : \{0, b31, b30, \dots, b1\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$

Assembler:

Syntax: `lsr1 r`

Example: `lsr1 4`

divides by 2 the unsigned value contained in GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

rrr - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.34 MOV (Logical Move)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s]$

Assembler:

Syntax: `mov r,s`

Example: `mov 4,0`

copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register *s* to the destination General Register *r*.

Instruction Format

Instruction Set

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.35 NOTIFY (Notify to ARM platform)

Operation:

```
if (jjj & 4 == 0)
{
    if (jjj&2 == 2)
        HE[CCR] ← 0
    if (jjj&1== 1)
        HI[CCR] ← 1
}
else if (jjj == 4)
    EP[CCR] ← 0
else
```

(CCR stands for Current Channel Register)

Assembler:

Syntax: notify jjj

Example: notify 3

clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding ARM platform by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

jjj - Channel Flags field:

000 - unused

001 - set HI for the current channel

010 - clear HE for the current channel

011 - clear HE, set HI for the current channel

100 - clear EP for the current channel

101 - RESERVED

110 - RESERVED

111 - RESERVED

55.5.2.36 OR (Logical OR)

Operation:

$GReg[r] \leftarrow GReg[s] \mid GReg[r]$

Assembler:

Syntax: `or r,s`

Example: `or 3,6`

ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Instruction Set

Description: Performs the OR of the source General Register *s* and the destination General Register *r*, and stores the result in the destination General Register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.37 ORI (Logical OR with Immediate Value)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \mid \text{immediate}$

Assembler:

Syntax: `ori r,immediate`

Example: `ori 1,56`

ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

Description: Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:**rrr - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.38 RET (Return from Subroutine)**Operation:**

PC ← RPC

Assembler:

Syntax: ret

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

55.5.2.39 REVB (Reverse Byte Order)

Operation:

$GReg[r] : \{B3, B2, B1, B0\} \leftarrow GReg[r] : \{B0, B1, B2, B3\}$

Assembler:

Syntax: revb r

Example: revb 5

reverses bytes order in GReg[5]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.40 Reverse Low Order Bytes(REVBLO)

Operation:

$GReg[r] : \{B3, B2, B0, B1\} \leftarrow GReg[r] : \{B3, B2, B1, B0\}$

Assembler:

Syntax: revblo r

Example: revblo 0

reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.41 ROR1 (Rotate Right by 1 Bit)**Operation:**

$$\text{GReg}[r] : \{b_0, b_{31}, b_{30}, \dots, b_1\} \leftarrow \text{GReg}[r] : \{b_{31}, b_{30}, \dots, b_1, b_0\}$$
Assembler:

Syntax: ror1 r

Example: ror1 3

rotates bits to the right in GReg[3]

CPU Flags: Unaffected

Instruction Set

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.42 RORB (Rotate Right by 1 Byte)

Operation:

$\text{GReg}[r] : \{B0, B3, B2, B1\} \leftarrow \text{GReg}[r] : \{B3, B2, B1, B0\}$

Assembler:

Syntax: `rorb r`

Example: `rorb 2`

rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

Instruction Fields:**rrr - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.43 SOFTBKPT (Software Breakpoint)**Operation:**

Stops the current script and enters debug mode

Assembler:

softbkpt

CPU Flags: Unaffected

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in [OnCE and Real-Time Debug](#).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

55.5.2.44 ST (Store Register)**Operation:**

[GReg[b] + displacement] ← GReg[r]

if (transfer_error)

Instruction Set

DF ← 1

else

DF ← 0

Assembler:

Syntax: st r, (b, displacement)

Example: st 7, (0,9)

stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

rrr / bbb - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1

...

11111 - 31

55.5.2.45 STF (Store Register in Functional Unit)

Operation:

```
[fu_address] ← GReg[r] 0
```

```
if (transfer_error) 0
```

```
DF ← 1 0
```

```
else 0
```

```
DF ← 0
```

fu_address is an 8-bit field

Assembler:

Syntax: `stf r, fu_address`

Example: `stf 3, 0x2B`

stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Table 55-47. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	1	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the STF instruction usage with each functional unit:

- [Burst DMA Write \(stf\)](#) for Burst DMA
- [Peripheral DMA Write \(stf\)-Write Mode](#) for Peripheral DMA

Instruction Fields:

rrr - register field:

Instruction Set

000 - GReg [0]

001 - GReg [1]

010 - GReg [2]

011 - GReg [3]

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

ffffff - functional unit destination register and action (unspecified values are reserved):

00000000 - MSA in incremented mode

00000100 - MDA in incremented mode

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - clear MS error flag

00001111 - MS

00010000 - MSA in frozen mode

00010100 - MDA in frozen mode

00011000 - MD in copy mode - number of words in rrr

00100000 - MSA in incremented mode - start prefetch

00101000 - MD no data - flush

00101001 - MD byte - flush

00101010 - MD halfword - flush

00101011 - MD word - flush

00110000 - MSA in frozen mode - start prefetch

11000001 - PSA in frozen mode - 8-bit data width
11000010 - PSA in frozen mode - 16-bit data width
11000011 - PSA in frozen mode - 32-bit data width
11000101 - PSA in incremented mode - 8-bit data width

55.5.2.46 SUB (Subtract)

Operation:

$$\text{GReg}[r] \leftarrow \text{GReg}[r] - \text{GReg}[s]$$
$$T \leftarrow (\text{GReg}[r] == 0)$$

Assembler:

Syntax: `sub r,s`

Example: `sub 4,7`

SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register *s* from the destination General Register *r*, and stores the result in the destination General Register *r*. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

Instruction Fields:

rrr / sss - register fields:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

55.5.2.47 SUBI (Subtract with Immediate)**Operation:** $GReg[r] \leftarrow GReg[r] - \text{immediate}$ $T \leftarrow (GReg[r] == 0)$ **Assembler:**Syntax: `sub r,immediate`Example: `sub 1,255`

SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

Instruction Set

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.48 TST (Test with Zero)

Operation:

$T \leftarrow ((\text{GReg}[s] \ \& \ \text{GReg}[r]) \neq 0)$

Assembler:

Syntax: `tst r,s`

Example: `tst 2,3`

ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

Instruction Fields:**rrr / sss - register field:**

000 - GReg[0]
 001 - GReg[1]
 010 - GReg[2]
 011 - GReg[3]
 100 - GReg[4]
 101 - GReg[5]
 110 - GReg[6]
 111 - GReg[7]

55.5.2.49 TSTI (Test Immediate)**Operation:**

$$T \leftarrow ((\text{GReg}[r] \ \& \ \text{immediate}) \neq 0)$$
Assembler:

Syntax: `tsti r,immediate`

Example: `tsti 5,13`

ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:**rrr - destination register field:**

000 - GReg[0]

Instruction Set

001 - GReg [1]

010 - GReg [2]

011 - GReg [3]

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.50 XOR (Logical Exclusive OR)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s] \wedge \text{GReg}[r]$

Assembler:

Syntax: `xor r,s`

Example: `xor 0,3`

XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg [0]
 001 - GReg [1]
 010 - GReg [2]
 011 - GReg [3]
 100 - GReg [4]
 101 - GReg [5]
 110 - GReg [6]
 111 - GReg [7]

55.5.2.51 XORI (Exclusive OR with Immediate)

Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \wedge \text{immediate}$

Assembler:

Syntax: `xori r,immediate`

Example: `xor 7,5`

XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg [0]
 001 - GReg [1]
 010 - GReg [2]
 011 - GReg [3]

Software Restrictions

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

55.5.2.52 YIELD, YIELDGE (DONE, Yield)

By default, unsupported assembler syntax. Can be aliased to the corresponding done instructions (yield = done 0; yieldge = done 1). Refer to the done instruction description [DONE \(DONE, Yield\)](#).

55.6 Software Restrictions

55.6.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior.

An example of the sequence which could result in undefined results is shown in the following example:

Instruction sequence not supported

```
stf r1, MSA|PF          ; Update source address, triggers data pre-fetch in the
                        ; background
mov R0,R0               ; Execute multiple assembly instructions, none of which
                        ; read
mov R0,R0               ; or write data to/from MD
stf MD|SZ0|FL          ; Flush FIFO without writing data. If the pre-fetch is still
                        ; in progress when this instruction is executed, there
                        ; could be undefined operation
```

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Work-Around to previous example

```

stf r1, MSA|PF      ; Update source address, triggers data pre-fetch.
mov R0,R0           ; Execute multiple assembly instructions, none of which
                   ; read
mov R0,R0           ; or write data to/from MD
ldf r2, MD          ; dummy read of MD to ensure pre-fetch is complete
                   ; before the next instruction
stf MD|SZ0|FL      ; Flush FIFO without writing data

```

55.7 Application Notes

55.7.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application.

The boot code is run after reset when channel 0 is started by the ARM platform. The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the ARM platform memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation (see [SDMA Scripts](#)).

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

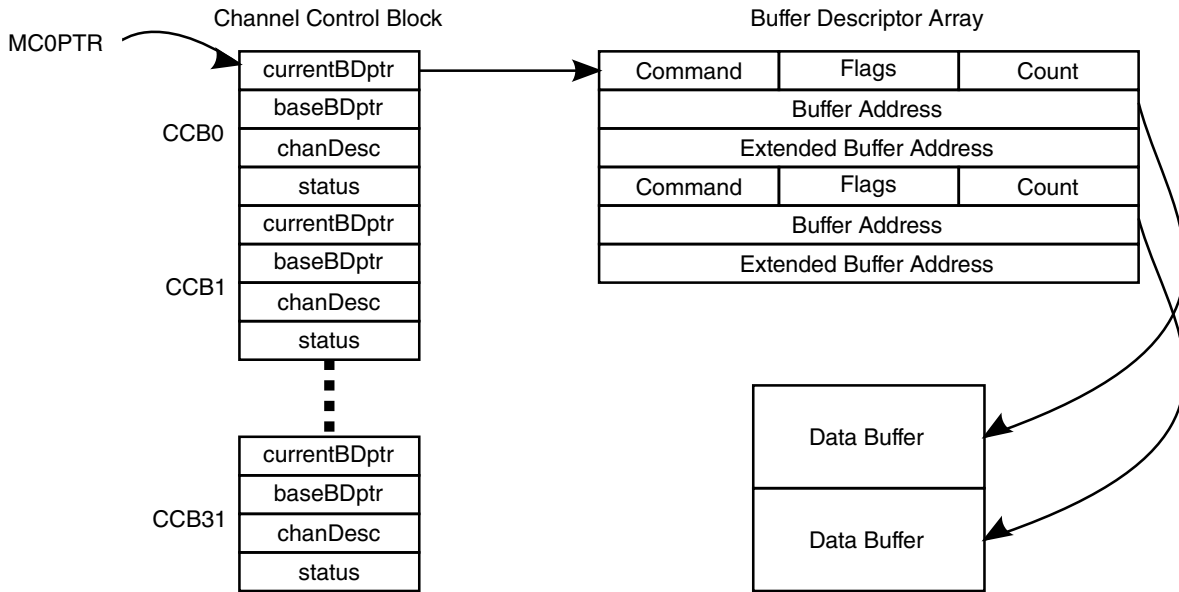

Figure 55-16. Data Structures Layout

The previous figure shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MC0PTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described [Buffer Descriptor Format](#).

55.7.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as, shown in the figure found here.

A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the ARM platform processor memory. The CCB contains a pointer to the base BD as well as the current BD.

Table 55-48. Buffer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Address																															
Extended Buffer Address																															

Table 55-49. Buffer Descriptor Field Descriptions

Field	Description
31-24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootload script are defined in Buffer Descriptor Commands for Bootload scripts . Refer to the individual script definition in script library documents in SDMA Scripts for command field definitions for other scripts.
23	Reserved
22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over. This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set. For example, when the DSP prepares a single buffer descriptor with count equals to 25 and ARM platform prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to ARM platform, the DSP buffer descriptor is normally closed while the ARM platform buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the ARM platform. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	CONTinuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers. The Continuous bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the ARM platform wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONTinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 ARM platform owns the buffer. 1 SDMA owns the buffer
15-0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31-0	Buffer address. Address pointer to the data buffer.
31-0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit $W=1$, the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the ARM platform with $D=0$, and the remainder owned by the SDMA with $D=1$. The count field of the buffer descriptor indicates how much data has been transmitted.

If ARM platform has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONTInous* bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3rd BD. The SDMA script opens and processes BD#1. Since *CONTInous* bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3rd BD, if *CONTInous* is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONTInous* bit and *Wrap* bits are both set in the 3rd BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONTInous* bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desires the SDMA to fill them again. Basically, if the ARM platform expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the ARM platform to set the *Done* bit of a buffer descriptor at an appropriate time.

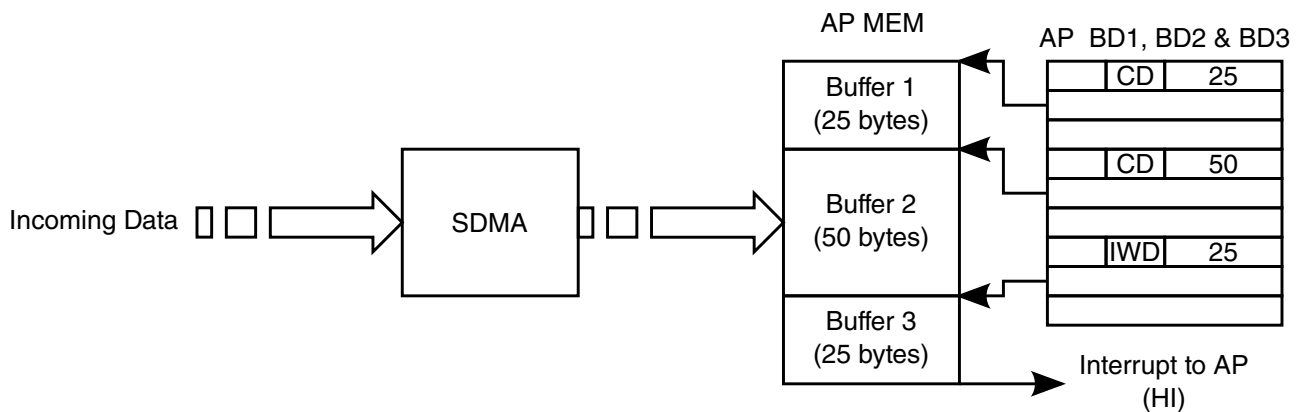

Figure 55-17. Buffer Descriptor Flow

The previous figure shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the CONTinuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The Done bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the ARM platform because the Interrupt flag is set in the 3rd BD. The CONTinuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the Wrap flag was set in the 3rd BD. It is the ARM platform responsibility to set the Done bit of all the BD if it wants to use the same buffers.

55.7.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script.

The following table lists the buffer descriptor commands defined for the channel 0 bootload script.

Table 55-50. Channel Zero Buffer Descriptor Commands

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
cccc_c111 (0x07 CHN)	C0_SETCTX	Load Context for channel cccc into SDMA RAM from ARM platform memory buffer	ARM Platform memory source address	-
cccc_c011 (0x03 CHN)	C0_GETCTXT	Copy Context for channel ccccc from SDMA RAM to ARM platform memory buffer	ARM platform memory destination address	-

The Channel 0 bootload commands are summarized as follows:

- **C0_SET_[PM-DM]**: load the buffer descriptor data in the SDMA local memory at the address pointed to by the "extended buffer address" field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0_SET_PM is used, the count field is expressed in "shorts" (16-bit

half words), this command can be used to download scripts. When C0_SET_DM is used, the count field is expressed in "long" (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.

- C0_GET_[PM-DM]: write to the buffer descriptor's data buffer the content of the SDMA local memory from the address pointed to by the "extended buffer address" field for the length defined by the count in the buffer descriptor. C0_GET_PM is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in "shorts"; while C0_GET_DM is used to dump to the buffer descriptor's data buffer, so the count field is in "longs."
- C0_SETCTX: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination address in SDMA memory. Then the C0_SET_DM command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.
- Command value: (in binary) cccc c111, where ccccc is the channel number (5 bits). For instance, 0x0F means set context for channel 1, 0xFF means set context for channel 31.
- C0_GETCTX: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the C0_GET_DM command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.
- Command value: (in binary): cccc c011, where ccccc is the channel number (5 bits). For instance, 0x03 means get context of channel 1, 0xFB means get context of channel 31.

NOTE

To download channel context, C0_SETDM and C0_SETCTXT command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the C0_SETDM, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

55.7.1.3 Example of Buffer Descriptors for Channel 0.

Figure 55-19 illustrates the buffer descriptors that must be set in ARM platform memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in the following figure.

Figure 55-18. Example of SDMA RAM After Boot Session

SDMA Register

Channel Control Block

Channel 0 Buffer Descriptor Array

 BD1 - SET CONTEXT CH#1
 Interrupt = 0,
 Cont=1, Done = 1

 BD2 - SET CONTEXT CH#4
 Interrupt = 0,
 Cont=1, Done = 1

 BD3 - SET CONTEXT CH#10
 Interrupt = 0,
 Cont=1, Done = 1

 BD4 - SET_PM
 Interrupt = 0,
 Cont=1, Done = 1

 BD5 - SET_PM
 Interrupt = 0,
 Cont=1, Done = 1

 BD6 - SET_PM
 Interrupt = 1,
 Cont=0, Done = 1

SDMA RAM

AP Memory Space

55.7.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed.

The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure below shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

The structure is divided in 4 areas:

- Channel status registers
- General purpose registers
- Functional units state registers reflecting the state of the ARM platform DMAs (Burst and Peripheral DMA).
- Scratch RAM

The details of the channel context status registers are described in the following figure.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0_SETPM command.

31	30	29	16	15	14	13	0
SF	—	RPC	T	—	PC		
LM		EPC	DF	—	SPC		

SF: Source fault while loading data
 RPC: Return program counter
 T: Test bit: status of arithmetic and test instructions
 PC: Program counter
 LM: Loop mode
 EPC: Loop end program counter
 DF: Destination fault while storing data
 SPC: Loop Start program counter

Figure 55-20. SDMA State Registers (ShPC, ShLoop)

55.7.2 Typical Data Transfer Supported by SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units.

The ARM platform memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See the following table for the summary.

Table 55-51. Typical Data Transfers Summary

Data Transfer	Peripheral DMA	Burst DMA	Comments
ARM platform External Memory ↔ ARM platform External Memory		3	Copy mode Script example, see Burst DMA Unit Copy Mode and External Memory to External Memory .
ARM platform Peripheral ↔ ARM platform Peripheral	3		Copy mode if same data path width Script example, see Peripheral to Peripheral Transfer .
ARM platform External Memory ↔ ARM platform Peripheral	3	3	Data transit through SDMA Script example, see Transfer Between Peripheral and External Memory .
ARM platform External Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Transfer Between External Memory and Internal Memory .
ARM platform Internal Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Internal Memory to Internal Memory .
ARM platform Internal memory ↔ ARM platform Peripheral	3		Data transit through SDMA Script example, see Transfer Between Peripheral and Internal Memory .

NOTE

These scripts are provided as examples of how to use DMA blocks to perform required data transfers: They are not "official" programs.

55.7.2.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory.

For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register.

The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

Data Moves in External Memory

```

1      stf r1,MSA                // Source address setup
2      stf r2,MDA                // Destination address setup
3      ldi r0,0x64                // 64 words must be transferred from MSA to
MDA
4      ldi r1,0x8

MAIN_XFER:
5      cmphs r0,r1                // Is r0 >= 0x8
6      bf LAST_XFER              // If not, jump to last transfer label
7      stf r1,MD|CPY              // Copy 8 words from MSA to MDA address.
8      subi r0,0x8                // Decrement counter
9      jmp MAIN_XFER              // return to main transfer loop

LAST_XFER:
10     stf r0,MD|CPY              // perform last transfer

```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN_XFER), r1 always equals 8, so burst lengths are 8 words. On the last ldf |CPY instruction (10), r1 equals the remainder of r0 divided by 8; therefore, the length of bursts triggered in copy mode equal r1 value, which is between 1 and 7.

55.7.2.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used.

It is programmed in copy mode, so no data will transmit through the SDMA general register used in the ldf instruction, but the contents of the general register are lost. The SDMA core only monitors the transfer.

55.7.2.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

Same Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ16|F           //r1=0x1002 Source address register setup
2      stf r2, PDA|SZ16|F           //r2=0x2006 Destination address register
setup
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                   //loop counter is 10
//MAIN LOOP TRANSFER
copy_loop:
5      loop 2,0
6      ldf r7,PD|CPY                //Reads 1 half-word from src and writes to
dest.
7      yield
8      bdf ERROR_DURING_XFER
ERROR_ADDR_SETUP:
           //correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
           //flag error is set,
           //PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware loop instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute the next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction ldf is a multi-cycle instruction.

55.7.2.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag.

The following example shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

Different Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ32|F|PF          //r1=0x1000 and prefetch data
2      stf r2, PDA|SZ16|F           //r2=0x2006
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                    //loop counter is 10
//MAIN LOOP TRANSFER
main_loop_xfer_16_16:
5      loop 6,0
6      ldf r7,PD                     //copy 32-bit of PD in r7
7      stf r7,PD                     //store 16 LSB of r7 in PD and a flush is
executed
8      rorb r7
9      rorb r7                       //16 MSB --> 16 LSB
10     stf r7,PD                     //store 16 LSB of r6 in PD and a flush.
11     yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the ldf will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

55.7.2.3 Transfer Between Peripheral and External Memory

55.7.2.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from word peripheral to the external memory would be as follows:

Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, PSA|SZ16|F|PF          //r1=0x1000 and prefetch 32-bit data
2      stf r2, MDA                    //r2=0x2000, setup burst DMA destination
address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64                    //loop counter is 100
5
//MAIN LOOP TRANSFER
6      loop 3,0
```

Application Notes

```

7          ldf r1,PD|PF          // read 32 bits of PD and initiate a new read
access.
8          stf r1,MD|32          // store 32 bits of r1 in the MD fifo.
9          yield
10         ldf r1,PD             // last word data is read
11         stf r1,MD|32|FL      // to flush all remaining bytes of MD

```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. The following figures show how the peripheral DMA and burst DMA work in parallel.

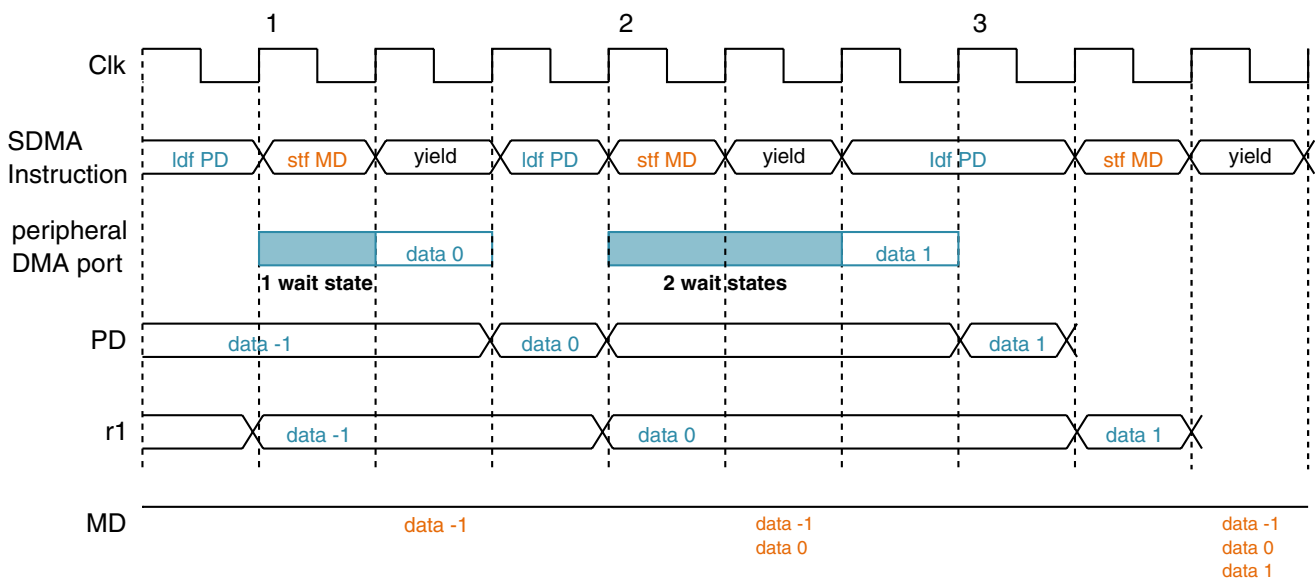

Figure 55-21. Peripheral to External Memory Example (1)

As seen in the figure above, the read access triggered by the `ldf PD` instruction is symbolized by the blue bar when in progress. After wait states, the read data (data 0, data 1) is stored in PD on the `clk` rising edge. On edge 2, data 0 is available in PD so it can be transferred to the SDMA general register `r1`, and then stored in MD FIFO. On edge 3, data 1 is not in PD; therefore, SDMA is stalled on the `ldf` instruction, which lasts two cycles. The figure below shows an example of when MD FIFO is full with data.

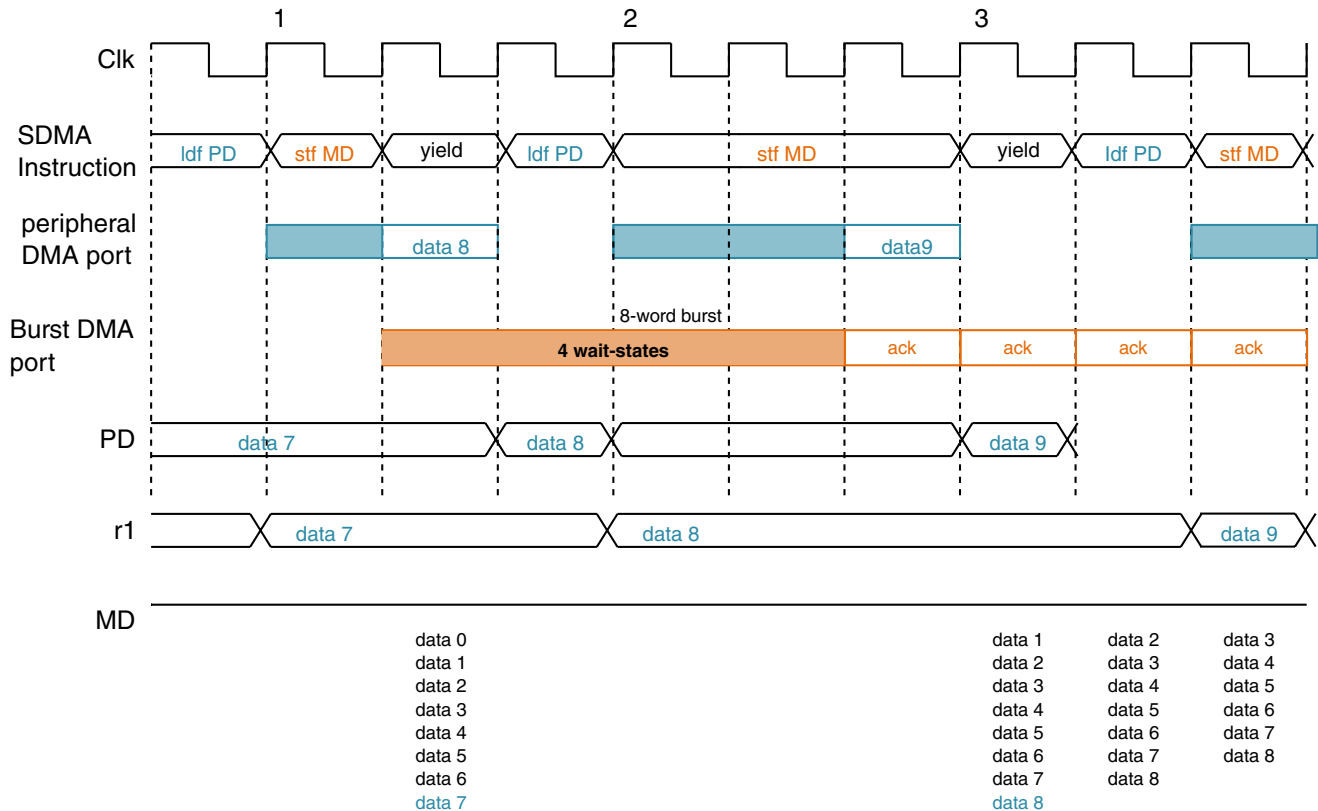

Figure 55-22. Peripheral to External Memory Example (2)

In the previous figure, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction stf because no acknowledge was received, MD FIFO is full, and there is no empty slot to store data 9. When an acknowledge is sampled by the burst DMA, FIFO is shifted and data 8 is written. As long as there is at least one empty slot in MD FIFO, the stf MD instruction lasts one cycle.

55.7.2.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from external memory to a word peripheral would be as follows:

External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, MSA|PF           //r1=0x1000 and starts a 8-word read burst
2      stf r2, PDA|SZ32|P       //r2=0x2010, setup peripheral DMA destination address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64              //loop counter is 100
//MAIN LOOP TRANSFER
6      loop 3,0
```

ARM Platform Memory Map and Control Register Definitions

```
7         ldf r1,MD|32|PF          // read 32 bits of MD and initiate a new read access
                                     // if MD is empty after this reading.
8         stf r1,PD                // store 32 bits of r1 in the PD.
9         yield
10        ldf r1,MD|32             // last word data is read
11        stf r1,PD                // last write access
```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

55.7.2.4 Transfer Between External Memory and Internal Memory

Since the internal memory (ARM platform RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in [Transfer Between Peripheral and External Memory](#) can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

55.7.2.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in [Peripheral to Peripheral Transfer](#) can be reused with a different programming of the peripheral DMA address registers.

55.7.2.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode.

The SDMA script is very similar to the one described in [Peripheral to Peripheral Transfer](#), except for the peripheral DMA address registers programming.

55.8 ARM Platform Memory Map and Control Register Definitions

The ARM platform controls the SDMA by means of several interface registers. Those registers are described in the current section.

All registers are clocked with the SDMA clock (which means the ARM platform must ensure that the SDMA clock is running when it wants to access any register).

55.8.1 ARM platform Channel 0 Pointer (SDMAARM_MC0PTR)

Address: 20E_C000h base + 0h offset = 20E_C000h

SDMAARM_MC0PTR field descriptions

Field	Description
MC0PTR	Channel 0 Pointer contains the 32-bit address, in ARM platform memory, of channel 0 control block (the boot channel). Appendix A fully describes the SDMA Application Programming Interface (API). The ARM platform has a read/write access and the SDMA has a read-only access.

55.8.2 Channel Interrupts (SDMAARM_INTR)

Address: 20E_C000h base + 4h offset = 20E_C004h

SDMAARM_INTR field descriptions

Field	Description
HI[31:0]	The ARM platform Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the ARM platform. This register is a "write-ones" register to the ARM platform. When the ARM platform sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding <code>done</code> instruction is executed.

55.8.3 Channel Stop/Channel Status (SDMAARM_STOP_STAT)

Address: 20E_C000h base + 8h offset = 20E_C008h

SDMAARM_STOP_STAT field descriptions

Field	Description
HE	This 32-bit register gives access to the ARM platform Enable bits. There is one bit for every channel. This register is a "write-ones" register to the ARM platform. When the ARM platform writes 1 in bit <i>i</i> of this register, it clears the HE[<i>i</i>] and HSTART[<i>i</i>] bits. Reading this register yields the current state of the HE[<i>i</i>] bits.

55.8.4 Channel Start (SDMAARM_HSTART)

Address: 20E_C000h base + Ch offset = 20E_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	HSTART_HE																																
W	w1c																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_HSTART field descriptions

Field	Description
HSTART_HE	<p>The HSTART_HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the ARM platform to trigger a channel a second time before the first trigger is processed.</p> <ul style="list-style-type: none"> This register is a "write-ones" register to the ARM platform. Neither HSTART[<i>i</i>] bit can be set while the corresponding HE[<i>i</i>] bit is cleared. When the ARM platform tries to set the HSTART[<i>i</i>] bit by writing a one (if the corresponding HE[<i>i</i>] bit is clear), the bit in the HSTART[<i>i</i>] register will remain cleared and the HE[<i>i</i>] bit will be set. If the corresponding HE[<i>i</i>] bit was already set, the HSTART[<i>i</i>] bit will be set. The next time the SDMA channel <i>i</i> attempts to clear the HE[<i>i</i>] bit by means of a <code>done</code> instruction, the bit in the HSTART[<i>i</i>] register will be cleared and the HE[<i>i</i>] bit will take the old value of the HSTART[<i>i</i>] bit. Reading this register yields the current state of the HSTART[<i>i</i>] bits. This mechanism enables the ARM platform to pipeline two HSTART commands per channel.

55.8.5 Channel Event Override (SDMAARM_EVTOVR)

Address: 20E_C000h base + 10h offset = 20E_C010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EO																															
W	EO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_EVTOVR field descriptions

Field	Description
EO	The Channel Event Override register contains the 32 EO[<i>i</i>] bits. A bit set in this register causes the SDMA to ignore DMA requests when scheduling the corresponding channel.

55.8.6 Channel BP Override (SDMAARM_DSPOVR)

Address: 20E_C000h base + 14h offset = 20E_C014h

SDMAARM_DSPOVR field descriptions

Field	Description
DO	This register is reserved. All DO bits should be set to the reset value of 1. A setting of 0 will prevent SDMA channels from starting according to the condition described in Runnable Channels Evaluation . 0 - Reserved 1 - Reset value.

55.8.7 Channel ARM platform Override (SDMAARM_HOSTOVR)

Address: 20E_C000h base + 18h offset = 20E_C018h

SDMAARM_HOSTOVR field descriptions

Field	Description
HO	The Channel ARM platform Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the ARM platform enable bit (HE) when scheduling the corresponding channel.

55.8.8 Channel Event Pending (SDMAARM_EVTPEND)

Address: 20E_C000h base + 1Ch offset = 20E_C01Ch

SDMAARM_EVTPEND field descriptions

Field	Description
EP	<p>The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the ARM platform to determine what channels are pending after the reception of a DMA request.</p> <ul style="list-style-type: none"> Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTpend register according to the received DMA requests. The EP[i] bit may be cleared by the <code>done</code> instruction when running the channel <i>i</i> script. This is a "write-ones" mechanism: Writing a '0' does not clear the corresponding bit.

55.8.9 Reset Register (SDMAARM_RESET)

Address: 20E_C000h base + 24h offset = 20E_C024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	[Reserved]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0														RESCHED	RESET
W	[Reserved]														[Reserved]	[Reserved]
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_RESET field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMAARM_RESET field descriptions (continued)

Field	Description
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a <code>done</code> instruction. This enables the ARM platform to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

55.8.10 DMA Request Error Register (SDMAARM_EVTERR)

Address: 20E_C000h base + 28h offset = 20E_C028h

SDMAARM_EVTERR field descriptions

Field	Description
CHNERR	This register is used by the SDMA to warn the ARM platform when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel. <ul style="list-style-type: none"> • An interrupt is sent to the ARM platform if the corresponding channel bit is set in the INTRMASK register. • This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the ARM platform or during SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the ARM platform tries to set the EP[i] bit, whereas, that EP[i] bit is already set.

55.8.11 Channel ARM platform Interrupt Mask (SDMAARM_INTRMASK)

Address: 20E_C000h base + 2Ch offset = 20E_C02Ch

SDMAARM_INTRMASK field descriptions

Field	Description
HIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit HIMASK[i] is set, the HI[i] bit is set and an interrupt is sent to the ARM platform when a DMA request error is detected on channel <i>i</i> (for example, EVTERR[i] is set).

55.8.12 Schedule Status (SDMAARM_PSW)

Address: 20E_C000h base + 30h offset = 20E_C030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																NCP[2:0]			NCR[4:0]				CCP[2:0]			CCR[4:0]					
W	0

SDMAARM_PSW field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning. 0 No running channel 1 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel. 0 No running channel 1 Active channel priority
CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA. SDMA. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

55.8.13 DMA Request Error Register (SDMAARM_EVTERRDBG)

Address: 20E_C000h base + 34h offset = 20E_C034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CHNERR																															
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_EVERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVERR, except reading it does not clear its contents. This address is meant to be used in debug mode. The ARM platform OnCE may check this register value without modifying it.

55.8.14 Configuration Register (SDMAARM_CONFIG)

Address: 20E_C000h base + 38h offset = 20E_C038h

SDMAARM_CONFIG field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 DSPDMA	This bit's function is reserved and should be configured as zero. 0 - Reset Value 1 - Reserved
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–5 Reserved	This read-only field is reserved and always has the value 0.
4 ACR	ARM platform DMA / SDMA Core Clock Ratio. Selects the clock ratio between ARM platform DMA interfaces (burst DMA and peripheral DMA) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 ARM platform DMA interface frequency equals twice core frequency 1 ARM platform DMA interface frequency equals core frequency
3–2 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMAARM_CONFIG field descriptions (continued)

Field	Description
CSM	<p>Selects the Context Switch Mode. The ARM platform has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase.</p> <p>NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used.</p> <p>0 static 1 dynamic low power 2 dynamic with no loop 3 dynamic</p>

55.8.15 SDMA LOCK (SDMAARM_SDMA_LOCK)

Address: 20E_C000h base + 3Ch offset = 20E_C03Ch

SDMAARM_SDMA_LOCK field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.
1 SRESET_LOCK_CLR	<p>The SRESET_LOCK_CLR bit determine if the LOCK bit is cleared on a software reset triggered by writing to the RESET register. This bit cannot be changed if LOCK=1. SREST_LOCK_CLR is cleared by conditions that clear the LOCK bit.</p> <p>0 Software Reset does not clear the LOCK bit. 1 Software Reset clears the LOCK bit.</p>

Table continues on the next page...

SDMAARM_SDMA_LOCK field descriptions (continued)

Field	Description
0 LOCK	<p>The LOCK bit is used to restrict access to update SDMA script memory through ROM channel zero scripts and through the OnCE interface under ARM platform control.</p> <p>The LOCK bit is set:</p> <ul style="list-style-type: none"> • The SDMA_LOCK, ONCE_ENB, CH0ADDR, and ILLINSTADDR registers cannot be written. These registers can be read, but writes are ignored. • SDMA software executing out of ROM or RAM may check the LOCK bit in the LOCK register Lock Status Register (SDMACORE_SDMA_LOCK) to determine if certain operations are allowed, such as up-loading new scripts. <p>Once the LOCK bit is set to 1, only a reset can clear it. The LOCK bit is cleared by a hardware reset. LOCK is cleared by a software reset only if SRESET_LOCK_CLR is set.</p> <p>0 LOCK disengaged. 1 LOCK enabled.</p>

55.8.16 OnCE Enable (SDMAARM_ONCE_ENB)

Address: 20E_C000h base + 40h offset = 20E_C040h

SDMAARM_ONCE_STAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	<p>The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows:</p> <ul style="list-style-type: none"> • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore</p>
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	<p>This flag is raised when the OnCE is controlled from the ARM platform peripheral interface.</p> <p>0 The JTAG interface controls the OnCE. 1 The ARM platform peripheral interface controls the OnCE.</p>
6–3 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMAARM_ONCE_STAT field descriptions (continued)

Field	Description
ECDR	<p>Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addra_cond, addrb_cond, and data_cond conditions. The value of those fields is given by the EDR bits.</p> <p>0 1 matched addra_cond 1 1 matched addrb_cond 2 1 matched data_cond</p>

55.8.20 OnCE Command Register (SDMAARM_ONCE_CMD)

Address: 20E_C000h base + 50h offset = 20E_C050h

SDMAARM_ONCE_CMD field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
CMD	<p>Writing to this register will cause the OnCE to execute the command that is written. When needed, the ONCE_DATA and ONCE_INSTR registers should be loaded with the correct value before writing the command to that register. For a list of the OnCE commands and their usage, see OnCE and Real-Time Debug.</p> <p>NOTE: 7-15 reserved</p> <p>0 rstatus 1 dmov 2 exec_once 3 run_core 4 exec_core 5 debug_rqst 6 rbuffer</p>

55.8.21 Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR)

Address: 20E_C000h base + 58h offset = 20E_C058h

SDMAARM_ILLINSTADDR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
ILLINSTADDR	The Illegal Instruction Trap Address is the address where the SDMA jumps when an illegal instruction is executed. It is 0x0001 after reset. The value of ILLINSTADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

55.8.22 Channel 0 Boot Address (SDMAARM_CHN0ADDR)

Address: 20E_C000h base + 5Ch offset = 20E_C05Ch

SDMAARM_CHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context,

Table continues on the next page...

SDMAARM_CHN0ADDR field descriptions (continued)

Field	Description
	<p>which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism.</p> <p>The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set.</p> <p>0 24 words per context 1 32 words per context</p>
CHN0ADDR	<p>This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80).</p> <p>The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.</p>

55.8.23 DMA Requests (SDMAARM_EVT_MIRROR)

Address: 20E_C000h base + 60h offset = 20E_C060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_EVT_MIRROR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EVENTS[47:32]	This register reflects the DMA requests received by the SDMA for events 47-32. The ARM platform and the SDMA have a read-only access. There is one bit associated with each of DMA request events. This information may be useful during debug of the blocks that generate the DMA requests. The EVT_MIRROR2 register is cleared following read access. 0 - DMA request event not pending 1- DMA request event pending

55.8.25 Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1)

Address: 20E_C000h base + 70h offset = 20E_C070h

SDMAARM_XTRIG_CONF1 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 CNF3	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by the reception of a DMA request or by the starting of a channel script execution. 0 channel 1 DMA request
29–24 NUM3[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
23 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMAARM_XTRIG_CONF1 field descriptions (continued)

Field	Description
22 CNF2	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
21–16 NUM2[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
15 Reserved	This read-only field is reserved and always has the value 0.
14 CNF1	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
13–8 NUM1[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
7 Reserved	This read-only field is reserved and always has the value 0.
6 CNF0	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
NUM0[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .

55.8.26 Cross-Trigger Events Configuration Register 2 (SDMAARM_XTRIG_CONF2)

Address: 20E_C000h base + 74h offset = 20E_C074h

SDMAARM_SDMA_CHNPRIn field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
CHNPRIn	This contains the priority of channel number <i>n</i> . Useful values are between 1 and 7; 0 is reserved by the SDMA hardware to determine when there is no pending channel. Reset value is 0, which prevents the channels from starting.

55.8.28 Channel Enable RAM (SDMAARM_CHNENBLn)

Address: 20E_C000h base + 200h offset + (4d × i), where i=0d to 47d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ENBLn																															
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_CHNENBLn field descriptions

Field	Description
ENBLn	This 32-bit value selects the channels that are triggered by the DMA request number <i>n</i> . If ENBLn[i] is set to 1, bit EP[i] will be set when the DMA request <i>n</i> is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the ARM platform to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

55.9 BP Memory Map and Control Register Definitions

The following section describes SDMA control registers available to the BP.

NOTE

These registers are physically implemented in all platforms, but are not accessible when the SDMA BP control port is not connected. Reset values are calculated to allow the system to work when those registers cannot be accessed.

All registers are clocked with the SDMA clock (which means the SDMA clock must be running when the BP wants to access any register).

SDMABP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20E_C000	Channel 0 Pointer (SDMABP_DC0PTR)	32	R/W	0000_0000h	55.9.1/3772
20E_C004	Channel Interrupts (SDMABP_INTR)	32	w1c	0000_0000h	55.9.2/3773
20E_C008	Channel Stop/Channel Status (SDMABP_STOP_STAT)	32	R/W	0000_0000h	55.9.3/3773
20E_C00C	Channel Start (SDMABP_DSTART)	32	R	0000_0000h	55.9.4/3774
20E_C028	DMA Request Error Register (SDMABP_EVTERR)	32	R	0000_0000h	55.9.5/3774
20E_C02C	Channel DSP Interrupt Mask (SDMABP_INTRMASK)	32	R/W	0000_0000h	55.9.6/3775
20E_C034	DMA Request Error Register (SDMABP_EVTERRDBG)	32	R	0000_0000h	55.9.7/3775

55.9.1 Channel 0 Pointer (SDMABP_DC0PTR)

Address: 20E_C000h base + 0h offset = 20E_C000h

SDMABP_DC0PTR field descriptions

Field	Description
DC0PTR	Channel 0 Pointer contains the 32-bit address, in BP memory, of the array of channel control blocks starting with the one for channel 0 (the control channel). This register should be initialized by the BP before it enables a channel (for example, channel 0). See the API document SDMA Scripts User Manual for the use of this register. The BP has a read/write access and the SDMA has a read-only access.

55.9.2 Channel Interrupts (SDMABP_INTR)

Address: 20E_C000h base + 4h offset = 20E_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_INTR field descriptions

Field	Description
DI	The BP Interrupts register contains the 32 DI[i] bits. If any bit is set, it will cause an interrupt to the BP. <ul style="list-style-type: none"> This register is a "write-ones" register to the BP. When the BP sets a bit in this register, the corresponding DI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced; failure to do so will cause continuous interrupts. The SDMA is responsible for setting the DI[i] bit corresponding to the current channel when the corresponding <code>done</code> instruction is executed.

55.9.3 Channel Stop/Channel Status (SDMABP_STOP_STAT)

Address: 20E_C000h base + 8h offset = 20E_C008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABP_STOP_STAT field descriptions

Field	Description
DE	This 32-bit register gives access to the BP (DSP) Enable bits, DE. There is one bit for every channel. <ul style="list-style-type: none"> This register is a "write-ones" register to the BP. When the BP writes 1 in bit <i>i</i> of this register, it clears the DE[i] and DSTART[i] bits. Reading this register yields the current state of the DE[i] bits.

55.9.4 Channel Start (SDMABP_DSTART)

Address: 20E_C000h base + Ch offset = 20E_C00Ch

SDMABP_DSTART field descriptions

Field	Description
DSTART_DE	<p>The DSTART_DE registers are 32 bits wide with one bit for every channel.</p> <ul style="list-style-type: none"> • When a bit is written to 1, it enables the corresponding channel. • Two physical registers are accessed with that address (DSTART and DE), which enables the BP to trigger a channel a second time before the first trigger was processed. • This register is a "write-ones" register to the BP. Neither DSTART[i] bit can be set while the corresponding DE[i] bit is cleared. • When the BP tries to set the DSTART[i] bit by writing a one (if the corresponding DE[i] bit is clear), the bit in the DSTART[i] register will remain cleared and the DE[i] bit will be set. If the corresponding DE[i] bit was already set, the DSTART[i] bit will be set. • The next time the SDMA channel <i>i</i> attempts to clear the DE[i] bit by means of a <code>done</code> instruction, the bit in the DSTART[i] register will be cleared and the DE[i] bit will take the old value of the DSTART[i] bit. • Reading this register yields the current state of the DSTART[i] bits. This mechanism enables the BP to pipeline two DSTART commands per channel.

55.9.5 DMA Request Error Register (SDMABP_EVTERR)

Address: 20E_C000h base + 28h offset = 20E_C028h

SDMABP_EVTERR field descriptions

Field	Description
CHNERR	<p>This register is used by the SDMA to warn the BP when an incoming DMA request was detected; it then triggers a channel that is already pending or being serviced, which may mean there is an overflow of data for that channel. An interrupt is sent to the BP if the corresponding channel bit is set in the INTRMASK register.</p> <ul style="list-style-type: none"> • This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the BP or during an SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set. The EVTERR[i] bit is unaffected if the BP tries to set the EP[i] bit when that EP[i] bit is already set.

55.9.6 Channel DSP Interrupt Mask (SDMABP_INTRMASK)

Address: 20E_C000h base + 2Ch offset = 20E_C02Ch

SDMABP_INTRMASK field descriptions

Field	Description
DIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit DIMASK[i] is set, the DI[i] bit is set and an interrupt is sent to the BP when a DMA request error is detected on channel <i>i</i> (for example, EVTERR[i] is set).

55.9.7 DMA Request Error Register (SDMABP_EVTERRDBG)

Address: 20E_C000h base + 34h offset = 20E_C034h

SDMABP_EVTERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVTERR except reading it does not clear its contents. This address is meant to be used in debug mode. The BP OnCE may check this register value without modifying it.

55.10 SDMA Internal (Core) Memory Map and Internal Register Definitions

The actual SDMA memory mapped registers are summarized in the following sections; for peripherals' memory maps, refer to the respective chapters.

The following definitions serve as a key for the SDMA internal register summary.

SDMACORE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20E_C000	ARM platform Channel 0 Pointer (SDMACORE_MC0PTR)	32	R	0000_0000h	55.10.1/3777
20E_C002	Current Channel Pointer (SDMACORE_CCPtr)	32	R	0000_0000h	55.10.2/3777
20E_C003	Current Channel Register (SDMACORE_CCR)	32	R	0000_0000h	55.10.3/3777
20E_C004	Highest Pending Channel Register (SDMACORE_NCR)	32	R	0000_0000h	55.10.4/3778
20E_C005	External DMA Requests Mirror (SDMACORE_EVENTS)	32	R	0000_0000h	55.10.5/3779
20E_C006	Current Channel Priority (SDMACORE_CCPRI)	32	R	0000_0000h	55.10.6/3780
20E_C007	Next Channel Priority (SDMACORE_NCPRI)	32	R	0000_0000h	55.10.7/3780
20E_C009	OnCE Event Cell Counter (SDMACORE_ECOUNT)	32	R/W	0000_0000h	55.10.8/3781
20E_C00A	OnCE Event Cell Control Register (SDMACORE_ECTL)	32	R/W	0000_0000h	55.10.9/3781
20E_C00B	OnCE Event Address Register A (SDMACORE_EAA)	32	R/W	0000_0000h	55.10.10/3783
20E_C00C	OnCE Event Cell Address Register B (SDMACORE_EAB)	32	R/W	0000_0000h	55.10.11/3783
20E_C00D	OnCE Event Cell Address Mask (SDMACORE_EAM)	32	R/W	0000_0000h	55.10.12/3783
20E_C00E	OnCE Event Cell Data Register (SDMACORE_ED)	32	R/W	0000_0000h	55.10.13/3784
20E_C00F	OnCE Event Cell Data Mask (SDMACORE_EDM)	32	R/W	0000_0000h	55.10.14/3784
20E_C018	OnCE Real-Time Buffer (SDMACORE_RTb)	32	R/W	0000_0000h	55.10.15/3785
20E_C019	OnCE Trace Buffer (SDMACORE_TB)	32	R	0000_0000h	55.10.16/3785
20E_C01A	OnCE Status (SDMACORE_OSTAT)	32	R	0000_0000h	55.10.17/3786
20E_C01C	Channel 0 Boot Address (SDMACORE_MCHN0ADDR)	32	R	0000_0000h	55.10.18/3788
20E_C01D	ENDIAN Status Register (SDMACORE_ENDIANNESs)	32	R	0000_0001h	55.10.19/3789
20E_C01E	Lock Status Register (SDMACORE_SDMA_LOCK)	32	R	0000_0000h	55.10.20/3790
20E_C01F	External DMA Requests Mirror #2 (SDMACORE_EVENTS2)	32	R	0000_0000h	55.10.21/3791

55.10.1 ARM platform Channel 0 Pointer (SDMACORE_MC0PTR)

Address: 20E_C000h base + 0h offset = 20E_C000h

SDMACORE_MC0PTR field descriptions

Field	Description
MC0PTR	Contains the address-in the ARM platform memory space-of the initial SDMA context and scripts that are loaded by the SDMA boot script running on channel 0.

55.10.2 Current Channel Pointer (SDMACORE_CCPtr)

Address: 20E_C000h base + 2h offset = 20E_C002h

SDMACORE_CCPtr field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
CCPtr	Contains the start address of the context data for the current channel: Its value is $CONTEXT_BASE + 24 * CCR$ or $CONTEXT_BASE + 32 * CCR$ where $CONTEXT_BASE = 0x0800$. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in Channel 0 Boot Address (SDMAARM_CHN0ADDR) .

55.10.3 Current Channel Register (SDMACORE_CCR)

Address: 20E_C000h base + 3h offset = 20E_C003h

SDMACORE_CCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
CCR	Contains the number of the current running channel whose context is installed. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel. The PST bits in the OSTAT register indicate when the SDMA is in sleep state.

55.10.4 Highest Pending Channel Register (SDMACORE_NCR)

Address: 20E_C000h base + 4h offset = 20E_C004h

SDMACORE_NCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
NCR	Contains the number of the pending channel that the scheduler has selected to run next.

55.10.5 External DMA Requests Mirror (SDMACORE_EVENTS)

NOTE

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words).

If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.

The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the ARM platform programmed.

Address: 20E_C000h base + 5h offset = 20E_C005h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_EVENTS field descriptions

Field	Description
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 0-31. The EVENTS2 register displays events 32-47.

55.10.6 Current Channel Priority (SDMACORE_CCPRI)

Address: 20E_C000h base + 6h offset = 20E_C006h

SDMACORE_CCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
CCPRI	Contains the 3-bit priority of the channel whose context is installed. It is 0 when no channel is running. NOTE: 1-7 current channel priority 0 no running channel

55.10.7 Next Channel Priority (SDMACORE_NCPRI)

Address: 20E_C000h base + 7h offset = 20E_C007h

SDMACORE_NCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
NCPRI	Contains the 3-bit priority of the channel the scheduler has selected to run next. It is 0 when no other channel is pending.

55.10.8 OnCE Event Cell Counter (SDMACORE_ECOUNTER)

Address: 20E_C000h base + 9h offset = 20E_C009h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_OSTAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	<p>The Processor Status bits reflect the state of the SDMA RISC engine.</p> <ul style="list-style-type: none"> The "Program" state is the usual instruction execution cycle. The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel-switching instructions). The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. The "Debug" state means the SDMA is in debug mode. The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). The "in Sleep" states are the same as above except they do not have any corresponding channel. They are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow Loop Sleep 12 Debug in Sleep 13 Functional Unit in Sleep</p>

Table continues on the next page...

SDMACORE_OSTAT field descriptions (continued)

Field	Description
	14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the ARM platform peripheral interface. 0 JTAG interface controls the OnCE. 1 ARM platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value 0.
ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows: 0 1 matched addressA condition 1 1 matched addressB condition 2 1 matched data condition

55.10.18 Channel 0 Boot Address (SDMACORE_MCHN0ADDR)

Address: 20E_C000h base + 1Ch offset = 20E_C01Ch

SDMACORE_MCHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context
CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the ARM platform; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

55.10.19 ENDIAN Status Register (SDMACORE_ENDIANNES)

Address: 20E_C000h base + 1Dh offset = 20E_C01Dh

SDMACORE_ENDIANNES field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 APEND	APEND indicates the endian mode of the Peripheral and Burst DMA interfaces. This bit is tied to logic '1' indicating little-endian mode. 0 - ARM platform is in big-endian mode 1 - ARM platform is in little-endian mode

55.10.20 Lock Status Register (SDMACORE_SDMA_LOCK)

Address: 20E_C000h base + 1Eh offset = 20E_C01Eh

SDMACORE_SDMA_LOCK field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 LOCK	The LOCK bit reports the value of the LOCK bit in the SDMA_LOCK status register. SDMA software may use this value to determine if certain operations such as loading of new scripts is allowed. 0 - LOCK bit clear 1 - LOCK bit set

55.10.21 External DMA Requests Mirror #2 (SDMACORE_EVENTS2)

Address: 20E_C000h base + 1Fh offset = 20E_C01Fh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE_EVENTS2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 32-47. The separate EVENTS register displays events 0-31.

55.11 SDMA Peripheral Registers

Refer to the respective peripherals' chapters for more information.

Chapter 56

Semaphore (SEMA4)

56.1 Overview

The IPS_Semaphores module provides a platform IPS slave device which implements 16 hardware-enforced gates with the following features:

- Module definition supports 16 hardware-enforced gates in a dual-processor configuration, where cp0 is core processor 0 and cp1 is core processor 1
 - Hardware gates appear as a 16-entry byte-size array with read and write accesses
 - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful
 - Once locked, the gate is unlocked by a write of zeroes from the locking processor
 - Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
 - Secure reset mechanisms are supported to clear the contents of individual semaphore gates or notification logic, as well as a clear_all capability
 - Programming model allocates memory space to support up to 8 processors and up to 64 gates

A simplified block diagram of the Semaphores module is shown in [Figure 56-1](#). In the diagram, the register blocks named gate0, gate1, ..., gate 15 include the finite state machines implementing the semaphore gates plus the interrupt notification logic.

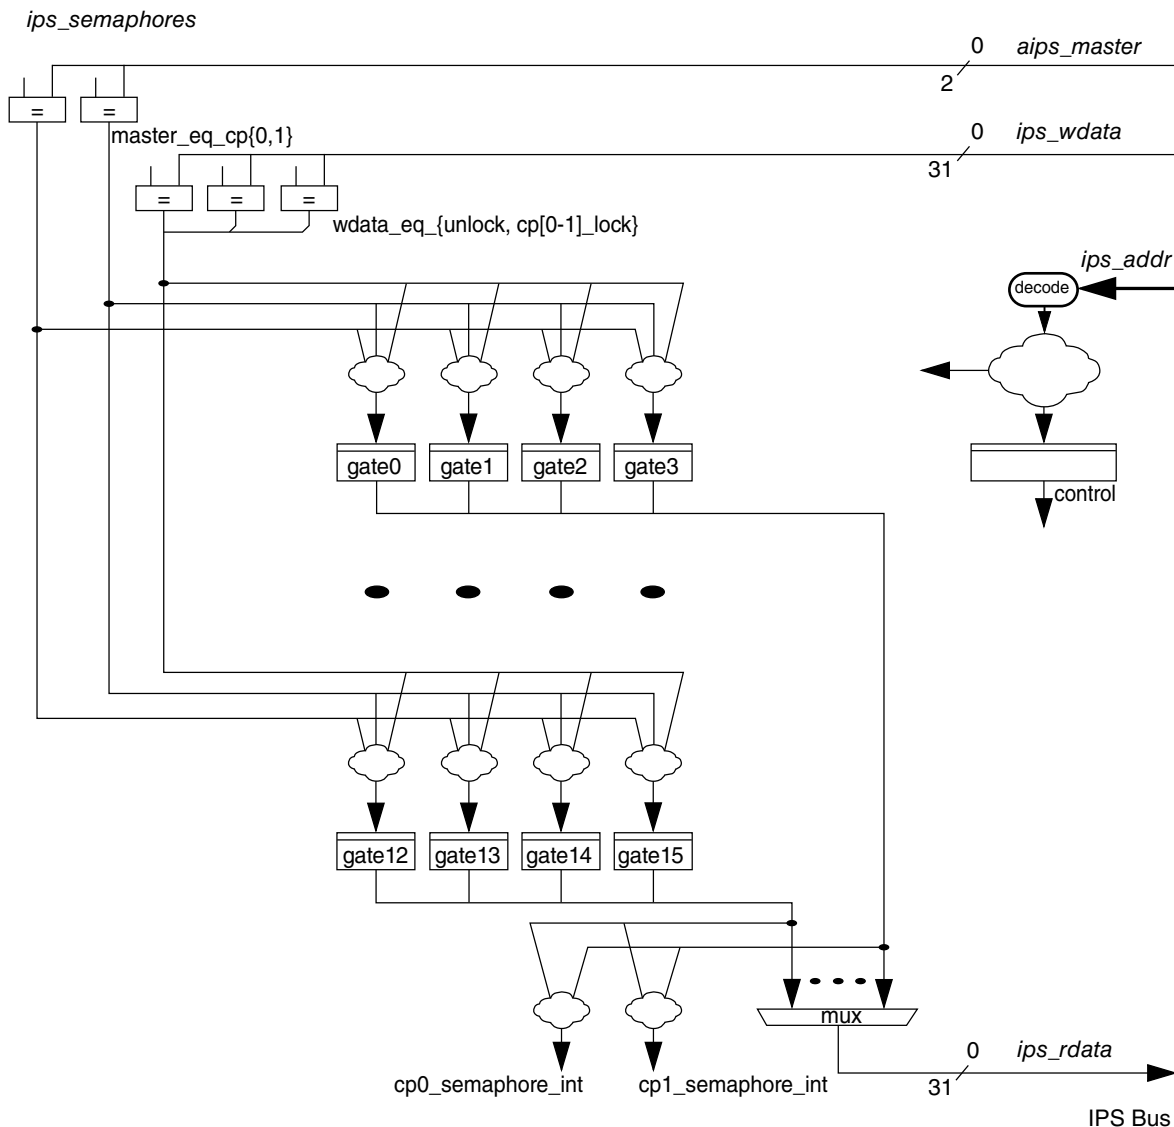

Figure 56-1. IPS_Semaphores Block Diagram

56.1.1 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a dual-processor configuration
 - Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array
 - 3-state implementation
 - if gate = 0b00, then state = unlocked
 - if gate = 0b01, then state = locked by processor 0

- if gate = 0b10, then state = locked by processor 1
- Uses the bus master number as a reference attribute plus the specified data patterns to validate all write operations
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor
- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
- Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear_all capability
- Memory-mapped IPS slave peripheral platform module
 - Interface to the IPS bus for programming-model accesses
 - Two outputs (one per processor) for interrupt notification of failed lock writes

56.1.2 Modes of Operation

The Semaphores module does not support any special modes of operation. As a slave peripheral memory-mapped device located on the platform's IPS slave bus, it responds based strictly on the memory addresses of the connected bus. The IPS bus is used to access the Semaphores ' programming model.

56.2 External Signal Description

The Semaphores module does not include any external interfaces.

56.3 Functional Description

In this section, the functional operation of the Semaphores module, specifically the state machines of the SEMA4_GATE_n and SEMA4_CP_nNTF registers are detailed.

56.3.1 SEMA4_GATE_n Operation

Recall each of the SEMA4_GATE_n registers implements a 2-bit, 3-state machine. The state transitions for each gate are shown in the following figure.

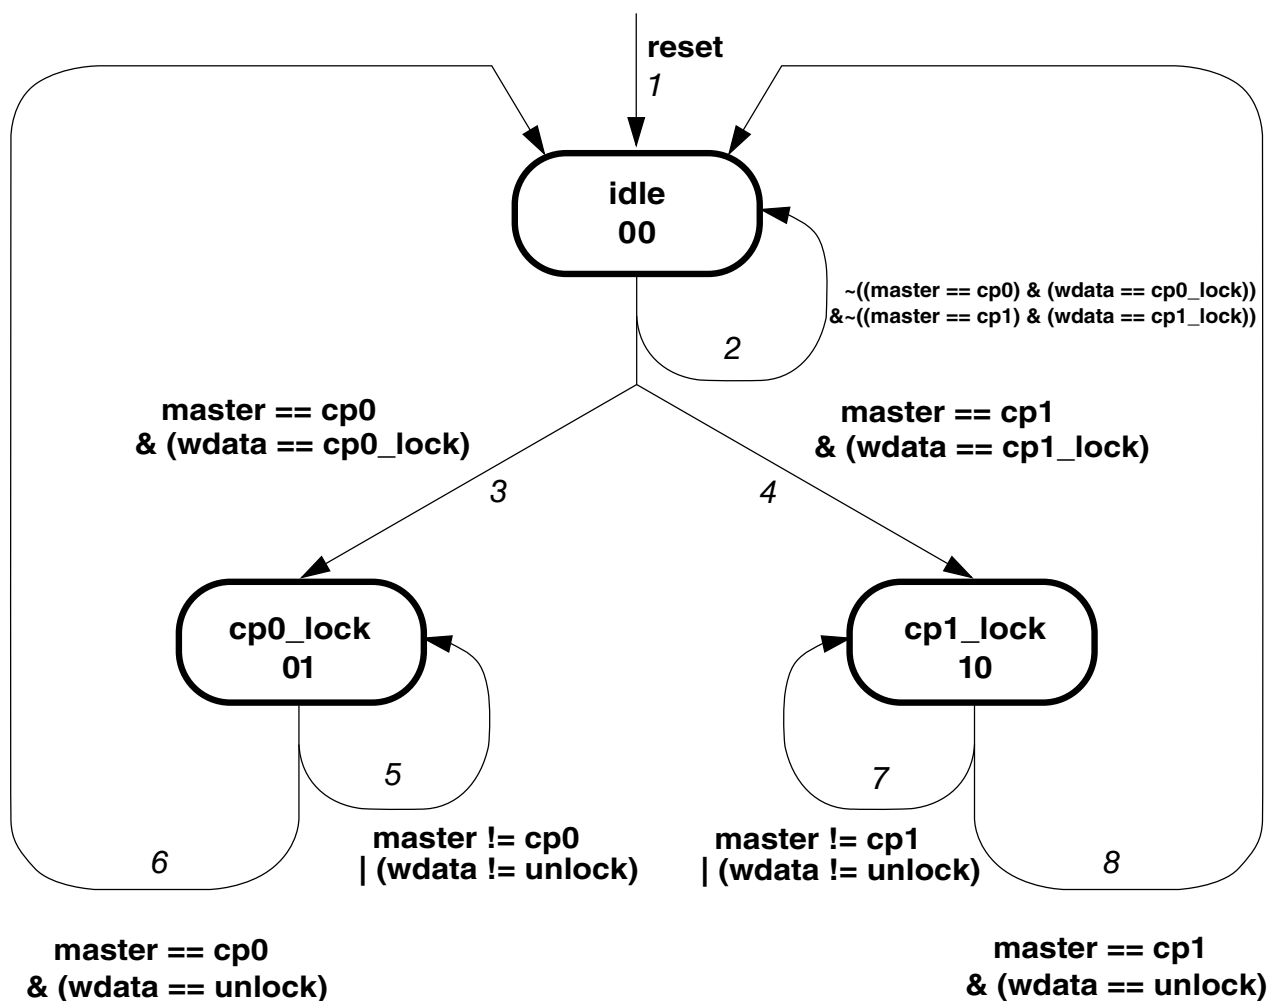

Figure 56-2. SEMA4_GATEn State Machine

The bus master number is used to identify core processor 0 (cp0) or core processor 1 (cp1). The Standard (or Reduced) Product Platform passes the AHB bus master number (`hmaster[2:0]`) through the AIPS (or AIPS-Lite) controller and drives an `aips_master[2:0]` output to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4_GATEn are defined in the following table.

Table 56-1. SEMA4_GATEn State Transitions

Current State	Next State	Transition	Description
-	idle	1	Any reset, whether a system reset or an individual gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.

Table continues on the next page...

**Table 56-1. SEMA4_GATEn State Transitions
(continued)**

Current State	Next State	Transition	Description
idle	cp1_lock	4	When a write of the "cp1_lock" value is initiated by processor 1, the gate transitions into the cp1_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cp1_lock	cp1_lock	7	Once in this state, the gate remains here if any attempted write is not from cp1 with the unlock data value.
cp1_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cp1 with the unlock data value occurs.

56.3.2 SEMA4_CPnNTF Operation

The failed lock write notification interrupt request is implemented in a 3-bit, 5-state machine which records failed lock attempts and transitions based on gate locking and unlocking. Two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn]. See the following figure.

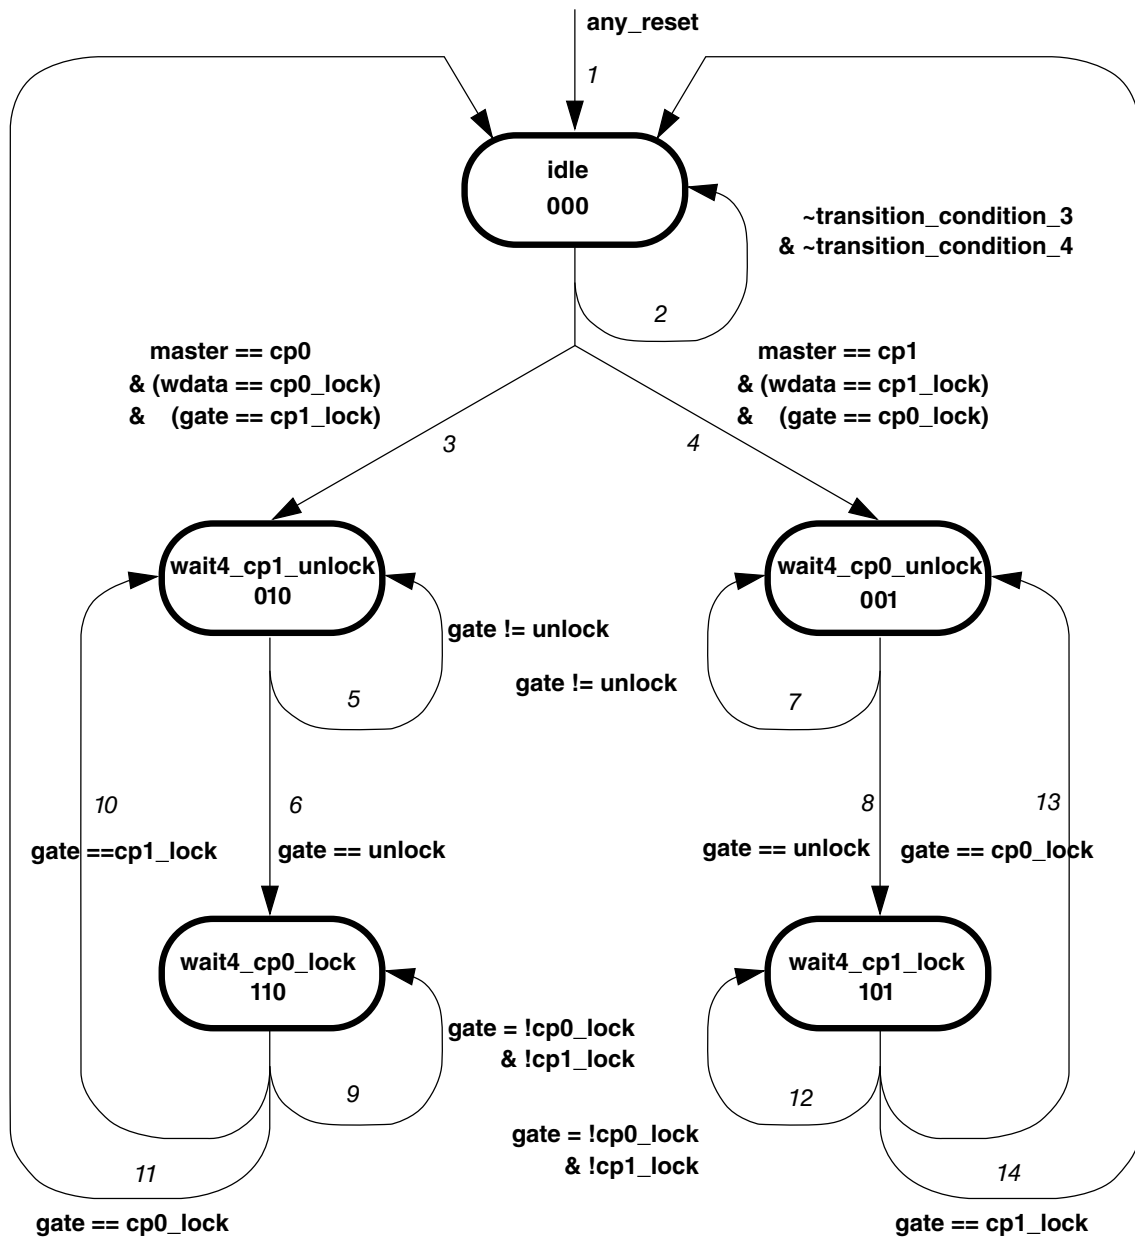

Figure 56-3. IRQ Notification State Machine

The state transitions of the IRQ notification function are defined in the following. Specific states of this machine are program-visible as the SEMA4_CPnNTF registers. In particular, two states are program-visible:

```

if state = wait4_cp0_lock (0b110) // generate cp0_semaphore_int if properly enabled
    then SEMA4_CP0NTF[Gn] = 1; else SEMA4_CP0NTF[Gn] = 0
if state = wait4_cp1_lock (0b101) // generate cp1_semaphore_int if properly enabled
    then SEMA4_CP1NTF[Gn] = 1; else SEMA4_CP1NTF[Gn] = 0
    
```

Table 56-2. IRQ Notification State Transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, including a system reset or an individual notification or secure gate reset, unconditionally forces the machine into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor to an already-locked gate occurs, the machine remains in the idle state.
idle	wait4_cp1_unlock	3	When a write of the "cp0_lock" data value is initiated by processor 0 but the gate is already locked by cp1, the machine transitions into this state, where it waits for cp1 to unlock the gate.
idle	wait4_cp0_unlock	4	When a write of the "cp1_lock" data value is initiated by processor 1 but the gate is already locked by cp0, the machine transitions into this state, where it waits for cp0 to unlock the gate.
wait4_cp1_unlock	wait4_cp1_unlock	5	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp1_unlock	wait4_cp0_lock	6	From this state, the machine transitions into the next state, waiting for cp0 to lock the gate, once it has been unlocked.
wait4_cp0_unlock	wait4_cp0_unlock	7	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp0_unlock	wait4_cp1_lock	8	From this state, the machine transitions into the next state, waiting for cp1 to lock the gate, once it has been unlocked.
wait4_cp0_lock	wait4_cp0_lock	9	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 0 or the gate is again locked by processor 1.
wait4_cp0_lock	wait4_cp1_unlock	10	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 1. With this transition, the notification interrupt request is negated.
wait4_cp0_lock	idle	11	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	wait4_cp1_lock	12	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 1 or the gate is again locked by processor 0.
wait4_cp1_lock	wait4_cp0_unlock	13	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	idle	14	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 1. With this transition, the notification interrupt request is negated.

The Semaphores module generates two interrupt request output signals, one per processor, combining the SEMA4_CPnINE and SEMA4_CPnNTF registers, where the boolean equations are:

```

cp0_semaphore_int
=   sema4_cp0ine[ine0]   &   sema4_cp0ntf[gn0]
  |   sema4_cp0ine[ine1]   &   sema4_cp0ntf[gn1]
  |   sema4_cp0ine[ine2]   &   sema4_cp0ntf[gn2]
  |   ...

56.4 Initialization Information

The reset state of the IPS_Semaphores module allows it to begin operation without the need for any further initialization. All the internal state machines are cleared by any reset event, allowing the module to immediately begin operation.

56.5 Application Information

In an operational multi-core system, most interactions involving the Semaphores module involves reads and writes to the SEMA4_GATE_n registers for implementation of the hardware-enforced software gate functions. Typical code segments for gate functions perform the following operations:

- To lock (close) a gate
 - The processor performs a byte write of "logical_processor_number + 1" to gate[i]
 - The processor reads back gate[i] and checks for a value of "logical_processor_number + 1"

If the compare indicates the expected value, then the gate is locked; proceed with the protected code segment. If the compare does not indicate the expected value, the lock operation failed; repeat the process beginning with byte write to gate[i] in spin-wait loop, or proceed with another execution path and wait for failed lock interrupt notification.

A simple C-language example of a `gateLock` function is shown in the following figure. This function follows the Hennessy/Patterson example described in [Multi-Core Programming 101: Software Gates](#).

```

#define UNLOCK    0
#define CP0_LOCK  1
#define CP2_LOCK  2

void gateLock (n)
int  n;                /* gate number to lock */
{
    int i;
    int current_value;
    int locked_value;

    i = processor_number(); /* obtain logical CPU number */

    if (i == 0)
        locked_value = CP0_LOCK;
    else
        locked_value = CP1_LOCK;

    /* read the current value of the gate and wait until the state == UNLOCK */
    do {
        current_value = gate[n];
    } while (current_value != UNLOCK);

    /* the current value of the gate == UNLOCK. attempt to lock the gate for this
       processor. spin-wait in this loop until gate ownership is obtained */
    do {
        gate[n] = locked_value; /* write gate with processor_number + 1 */
        current_value = gate[n]; /* read gate to verify ownership was obtained */
    } while (current_value != locked_value);
}

```

Figure 56-4. Sample gateLock Function

- To unlock (open) a gate
 - After completing the protected code segment, the locking processor performs a byte write of zeroes to gate[i], opening (unlocking) the gate

A few comments on the logical CPU number are appropriate. In this example, a reference to `processor_number()` is used to retrieve this hardware configuration value. Typically, the logical processor numbers are defined by a hardwired input vector to the individual cores. The exact method for accessing the logical processor number varies by architecture. For PowerPC cores, there is a processor ID register (PIR) which is SPR 286 and contains this value. A single instruction can be used to move the contents of the PIR into a general-purpose register: `mf spr rx,286` where `rx` is the destination GPRn. Other architectures may support a specific instruction to move the contents of the logical processor number into a general-purpose register, e.g., `rdcpn rx` for a "read CPU number" instruction.

If the optional failed lock IRQ notification mechanisms are used, then accesses to the related registers (`SEMA4_CPnINE`, `SEMA4_CPnNTF`) are required. Note that there is no required negation of the failed lock write notification interrupt as the request is automatically negated by the Semaphores module once the gate has been successfully locked by the "failing" processor.

Finally, in the event a system state requires a software-controlled reset of a gate or IRQ notification register(s), accesses to the secure reset control registers (SEMA4_RSTGT, SEMA4_RSTNTF) are required. For these situations, it is recommended that the appropriate IRQ notification enable(s) (SEMA4_CPnINE) bits be disabled *before* initiating the secure reset 2-write sequence to avoid any race conditions involving spurious notification interrupt requests.

56.6 Memory map and register definition

The Semaphores module provides an IPS programming model mapped to an SPP-standard on-platform 16 KB space. The description here specifies a dual-core configuration with 16 semaphore gates. All the register names are prefixed with "Sema4" as an abbreviation for the full module name.

The programming model is referenced using 8-, 16- and 32-bit accesses. Reads can use any reference size, while writes are generally restricted to the size of the register. Exceptions to the write size restrictions are detailed in the individual register descriptions. Attempted references using inappropriate access sizes, to undefined (reserved) addresses, or with a non-supported access type (for example, a write to a read-only register) generate an IPS error termination.

Finally, the programming model allocates space for a definition with up to 64 gates and up to 8 processor cores, even though this definition is considerably larger than any currently-planned module implementations. The number of gates and supported processor cores are independent; there is no relationship between these two system variables.

The 16 KB Semaphores programming model map is shown in the following table.

SEMA4 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

56.6.1 Semaphores Gate 0 Register (SEMA4_Gate00)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate

Memory map and register definition

register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

6–7 GTFSM	Gate Finite State Machine. Gate Finite State Machine. The hardware gate is maintained in a 3-state implementation-unlocked, locked by processor 0 or locked by processor 1. For more details, see SEMA4_GATEn Operation . NOTE: The state of the gate reflects the last processor that locked it, which can be useful during system debug. 00 The gate is unlocked (free). 01 The gate has been locked by processor 0. 10 The gate has been locked by processor 1. 11 This state encoding is never used and therefore reserved. Attempted writes of 0x03 are treated as "no operation" and do not affect the gate state machine.

56.6.12 Semaphores Gate 11 Register (SEMA4_Gate11)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

56.6.17 Semaphores Processor n IRQ Notification Enable (SEMA4_CPnINE)

The application of a hardware semaphore module provides an opportunity for implementation of helpful system-level features. An example is an optional mechanism to generate a processor interrupt after a failed lock attempt. Recall traditional software gate functions execute a spin-wait loop in an effort to obtain and lock the referenced gate. With this module, the processor that fails in the lock attempt could continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function.

The optional notification interrupt function consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnINE registers, unimplemented bits read as zeroes, and writes are ignored.

56.6.18 Semaphores Processor n IRQ Notification (SEMA4_CPnNTF)

The Semaphores module optionally allows the processor that fails in the lock attempt to continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function rather than simply execute in a spin-wait loop.

The optional notification interrupt mechanism consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the read-only notification interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnNTF registers, unimplemented bits read as zeroes.

The notification interrupt is generated via a unique finite state machine, one per hardware gate. This machine operates in the following manner:

1. When an attempted lock fails, the FSM enters a first state where it waits until the gate is unlocked.
2. Once unlocked, the FSM enters a second state where it generates an interrupt request to the “failed lock” processor.
3. When the “failed lock” processor succeeds in locking the gate, the IRQ is automatically negated and the FSM returns to the idle state. However, if the other processor again locks the gate, the FSM returns to the first state, negates the interrupt request, and then waits for the gate to be unlocked (again).

The notification interrupt request is implemented in a 3-bit, 5-state machine, where two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn].

56.6.19 Semaphores (Secure) Reset Gate n (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism which allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The most significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xe2; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the upper byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1d) and the lower byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are cleared.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) which implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]) and the gate number(s) last cleared (SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 229_0000h base + 100h offset = 229_0100h

Field	Description		
	write access are valid only for write operations. Bit numbering in the descriptions begins with the most significant bit numbered 0. See the following table for details.		
	Access	Sub-Field	Description
	Read-Only	7-6 Reserved	Reserved. Always reads 0.
		5-4 RSTGSM	Reset Gate Finite State Machine. Reads of the SEMA4_RSTGT register return the encoded state machine value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. Note that the RSTGSM = 0b10 state is valid for only a single machine cycle, so it is impossible for a read to return this value 11 This state encoding is never used and therefore reserved.
		3 Reserved	Reserved. Always reads 0.
		2-0 RSTGMS	Reset Gate Bus Master. This 3-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device and the logical processor number is SoC-specific. See the chip configuration chapter for this information.
	Write-Only	7-0 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xe2 while the second write requires RSTGDP = 0x1d.

56.6.20 Semaphores (Secure) Reset IRQ Notification (SEMA4_RSTNTF)

As with the case of the secure reset function and the hardware gates, it is recognized that system operation may require a reset function to re-initialize the state of the IRQ notification logic without requiring a system-level reset.

To support this special notification reset requirement, the Semaphores module implements a "secure" reset mechanism which allows an IRQ notification (or all the notifications) to be initialized by following a specific dual-write access pattern. When successful, the specified IRQ notification state machine(s) are reset. Using a technique

similar to that required for the servicing of a software watchdog timer, the secure reset mechanism requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the IRQ notification(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTNTF memory location. The most significant byte (SEMA4_RSTNTF[RSTNDP]) must be 0x47; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTNTF location. For this write, the upper byte (SEMA4_RSTNTF[RSTNDP]) is the logical complement of the first data pattern (0xb8) and the lower byte (SEMA4_RSTNTF[RSTNTN]) specifies the notification(s) to be reset. This field can specify a single notification be cleared, or that all notifications are cleared.
3. Reads of the SEMA4_RSTNTF location return information on the 2-bit state machine (SEMA4_RSTNTF[RSTNSM]) which implements this function, the bus master performing the reset (SEMA4_RSTNTF[RSTNMS]) and the notification number(s) last cleared (SEMA4_RSTNTF[RSTNTN]). Reads of the SEMA4_RSTNTF register do not affect the secure reset finite state machine in any manner.

The reset function requires that the two consecutive writes to this register be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device and the logical processor number is SoC-specific. See the chip configuration chapter for this information.	
Write-Only	7-0 RSTNDP	Reset Notification Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the notification reset mechanism. For the first write, RSTNDP = 0x47 while the second write requires RSTNDP = 0xb8.	

Chapter 57

System JTAG Controller (SJC)

57.1 Overview

The System JTAG Controller (SJC) provides debug and test control with the maximum security.

The test access port (TAP) is designed to support features compatible with the IEEE Standard 1149.1 v2001 (JTAG).

The figure below shows an overview of the JTAG architecture.

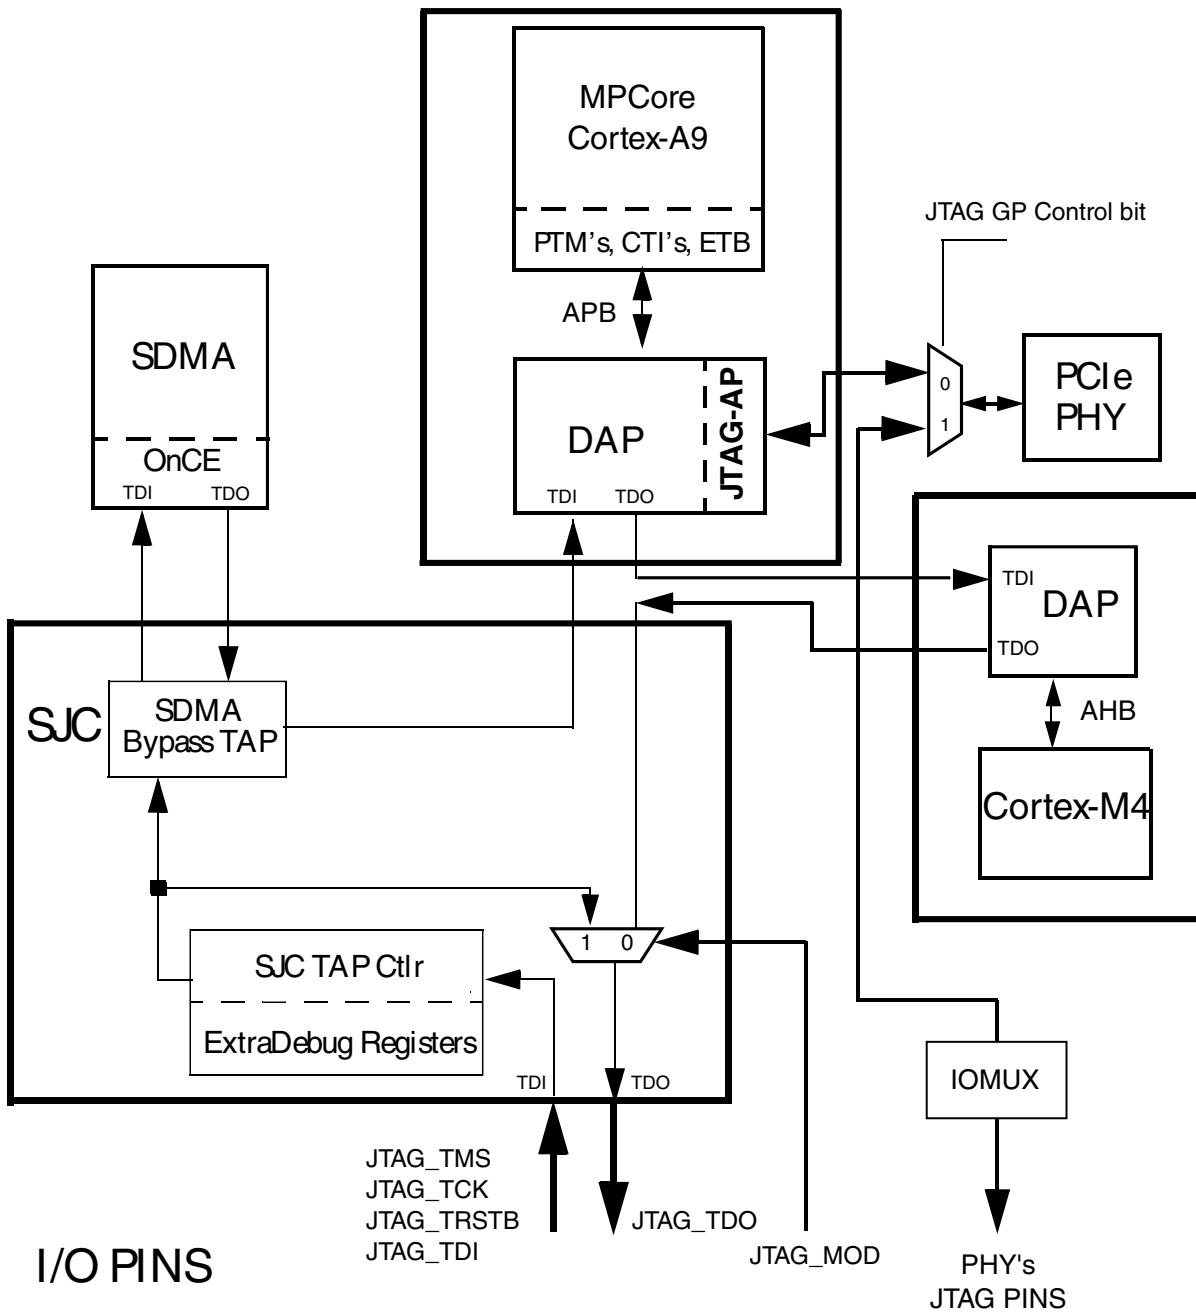

Figure 57-1. System JTAG Controller (SJC) Block Diagram

57.1.1 Features

The System JTAG Controller (SJC) provides the following capabilities:

- JTAG IEEE1149.1 mandatory instructions, see [EXTEST Instruction](#), [SAMPLE/PRELOAD Instruction](#), and [BYPASS Instruction](#).

- JTAG IEEE1149.1 optional instructions, see [ID_CODE Instruction \(IDCODE\)](#), and [HIGHZ Instruction](#).
- JTAG IEEE P1149.1 (standard JTAG) interface to off-chip test and development equipment including an SJC-only mode for true IEEE 1149.1 compliance, used primarily for board-level implementation of boundary scan.
- Debug-related control and status, such as putting selected cores into reset and/or debug mode and the ability to monitor individual core status signals via JTAG.
- Provides means for accessing each OnCE/ICE TAP controller independently to control a target system (see [Modes of Operation](#)).
- ExtraDebug logic (see [ENABLE_ExtraDebug Instruction](#)).
- The maximum clock speed of the SJC is one-eighth of the lowest frequency of the accessed OnCE/ICE. For example in normal operation (no core in low-power mode), this frequency is one-eighth of the SDMA frequency if this core is present in the TDI-TDO chain (serially connected with other cores or standalone). The user must also consider the 25 MHz frequency limitation on the CE bus.
- Core compliant modes to support standalone core debuggers (see [Modes of Operation](#)).
- Multi-cores daisy chained mode (default one) to support multi-core debuggers (see [Modes of Operation](#)).

Detailed information about the SJC is provided in the Security Reference Manual. Contact your Freescale representative for information about obtaining this document.

57.1.2 Modes of Operation

The SJC modes are controlled through both the TAP select register (SJC_TSR) and the MOD input port.

The MOD port (typically connected to pad of the same name) selects between two possible topologies of TAP connections, as seen at SoC level:

- Negating it (this should be the default state) selects all the TAPs (SJC, SDMA and DAP) to be connected in the TDI-TDO chain, which is referred to as "daisy chain" mode, throughout this chapter.
- Asserting it only selects the SJC TAP to be connected in the TDI-TDO chain.

IEEE1149.1 standard features are enabled by configuring the SJC input pin: MOD. Refer to the following table for MOD settings details:

Table 57-1. SJC Modes

MOD	Name	Description
0	Daisy chain ALL	For common SW debug (High speed and production)
1	SJC only	IEEE 1149.1 JTAG compliant mode

The following figure shows the SJC mode selection flow. The numbers shown in parenthesis below each block name indicates the TAP's IR length.

MOD = 0**MOD = 1**

(number in brackets lists IR length of given TAP)

Figure 57-2. SJC Mode Selection Using MOD Pin Sampling

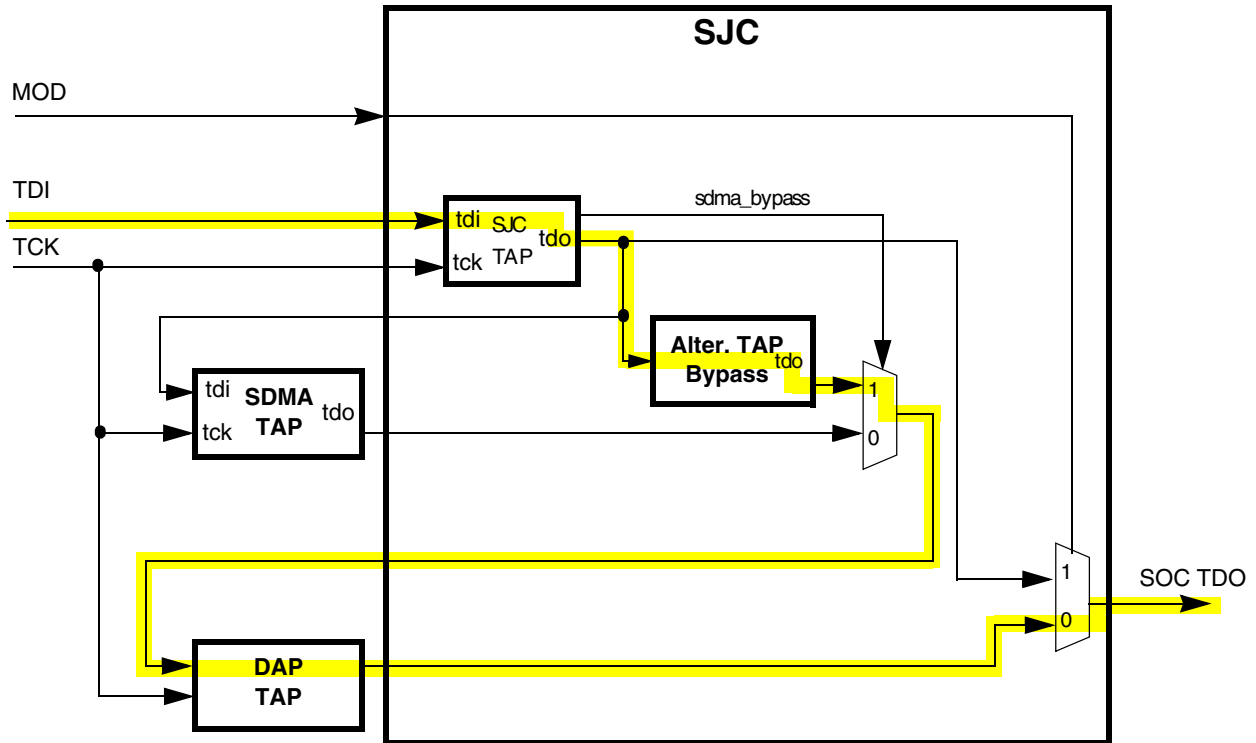

The Connect SDMA bit inside TAP select register controls the SDMA TAP bypass.

- When negated (should be the default state), the SDMA TAP is bypassed with a single D-FF (Flip-flop) during Shift-Dr path
- When asserted SDMA TAP is connected inside the chain
- When taking the SDMA into bypass or out of bypass (by writing to tapsel reg), additional cycle with TMS '0' should be given

The TAP selection block (TSB) provides a simple method of integrating various pieces of IP that have embedded TAPs.

- Provides a way to connect up multiple TAPs within a single SoC
- Identify the SJC TAP as the master TAP which controls the boundary chain (for IEEE 1149.1 standard compliance)
- Follow the state of SJC TAP, and when the Test-Logic-Reset (TLR) state is reached, reset all TAPs

The figure below shows the TAP Selection Block and SOC TAP Chain Scheme.

Note: The default daisy chain connectivity is highlighted in yellow

Figure 57-3. TAP Selection Block and SoC TAP Chain Scheme

NOTE

It is the responsibility of the user to ensure that in any configuration of the TAP controllers chosen, all of the TAPs in the chain comply with the demands of TCK clock frequency as well as the required ratio between TCK clock frequency and that of the core's to which the TAP refers.

57.2 External Signals

The table found here describes the external signals of SJC.

Table 57-2. SJC External Signals

Signal	Description	Pad	Mode	Direction
JTAG_DE_B	SoC debug request/acknowledge pin. The DE_IN_B pin is used to propagate an external debug request event to the core(s). This functionality must be enabled first, by set of DE_to_ARM /	RGMI2_TX_CTL	ALT7	IO

Table continues on the next page...

**Table 57-2. SJC External Signals
(continued)**

Signal	Description	Pad	Mode	Direction
	DE_to_SDMA bits in SJC's DCR register. It is SoC implementation dependent, whether this pin can also be used to reflect the debug acknowledge event back from the cores (in the case where an Open-Drain scheme is used externally).			
JTAG_MOD	SJC mode selection. This pin is sampled at TRST reset to determine two possible modes for the TAP connection configuration.	JTAG_MOD	No muxing	I
JTAG_TCK	Test Clock (TCK). This is used to synchronize the test logic and includes an internal pull-up resistor	JTAG_TCK	No muxing	I
JTAG_TDI	Test Data Input (TDI). Serial test instruction and data are received through the test data input (TDI) pin. TDI is sampled on the rising edge of TCK and includes an internal pullup resistor	JTAG_TDI	No muxing	I
JTAG_TDO	Test Data Output (TDO). The serial output for test instructions and data. TDO is tri-statable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK	JTAG_TDO	No muxing	O
JTAG_TMS	Test Mode Select (TMS). This is used to sequence the test controller's state machine. TMS is sampled on the rising edge of TCK and includes an internal pullup resistor	JTAG_TMS	No muxing	I
JTAG_TRSTB	Test Reset (TRST). This is used to asynchronously initialize the test controller. The TRST pin has an internal pullup resistor	JTAG_TRST_B	No muxing	I

57.2.1 External Signal Overview

The SJC provides test and debug control with a minimum number of contacts.

The figure below shows SJC connections to external contacts and other chip blocks.

57.2.2 TAP Controller

The TAP controller is responsible for interpreting the sequence of logical values on the TMS signal. It is a synchronous state machine that controls the operation of the JTAG logic. The value shown adjacent to each arc represents the value of the TMS signal sampled on the rising edge of TCK signal. For a description of the TAP controller states, refer to the appropriate IEEE 1149.1 document.

The state machine is shown in the following figure.

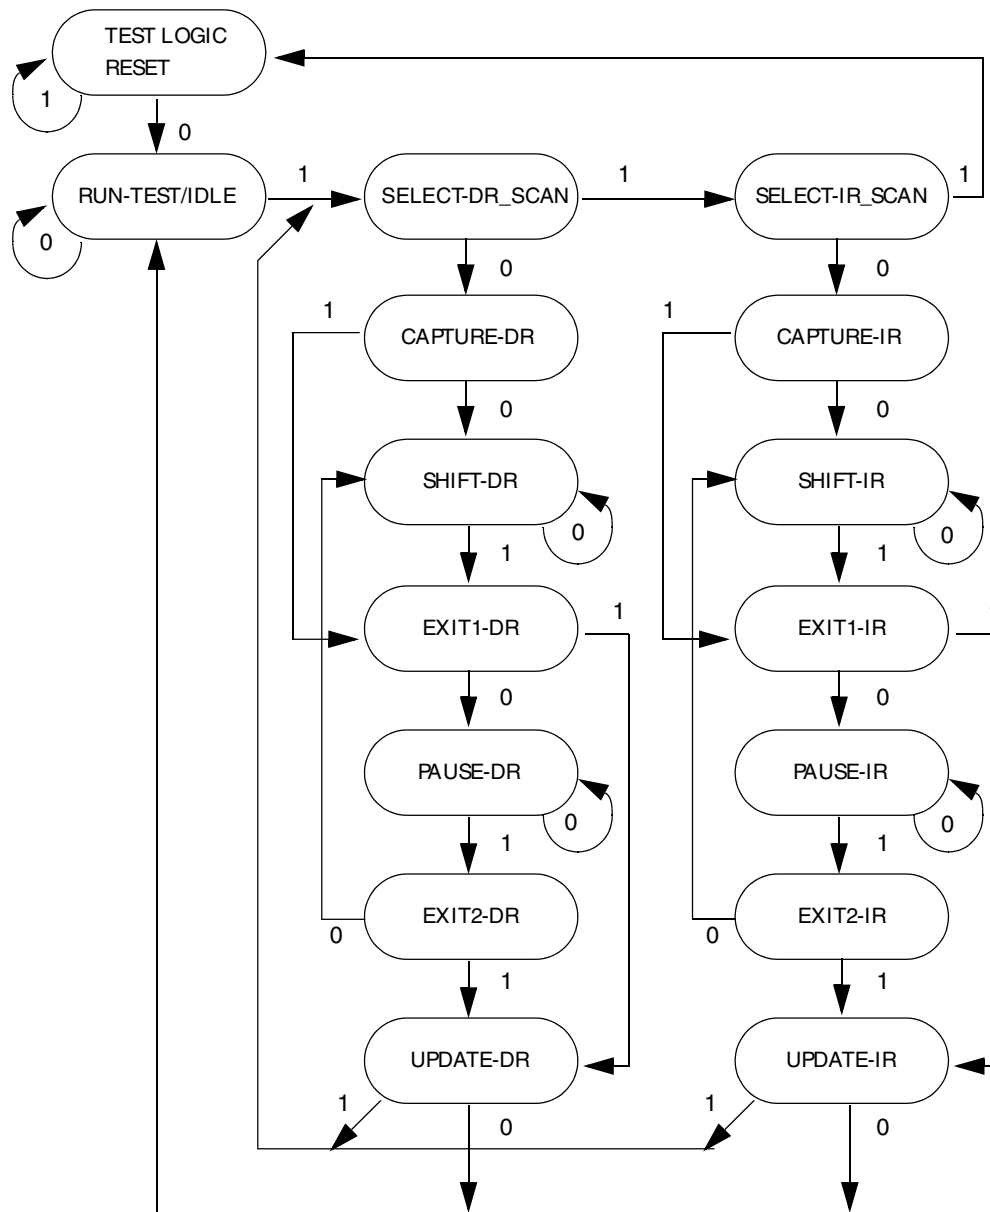

Figure 57-4. TAP Controller State Machine

The change of the JTAG state machine occurs on the rising edge of TCK. TMS and TDI change on the falling edge of TCK. TDO also changes on the falling edge of TCK following entry into the Shift_DR or Shift_IR states (TDO_EN is the enable of the tristate buffer driving the TDO output).

The figure below shows the timings of the SJC signals.

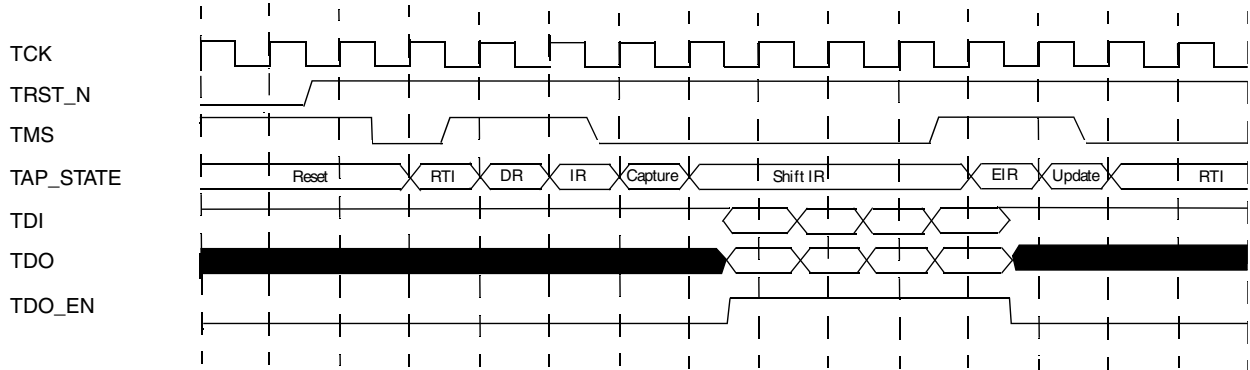

Figure 57-5. SJC Signals Timing Diagram

57.2.3 Accessing ExtraDebug Registers

Accessed through the Select-DR-Scan path, the ExtraDebug shift register consists of 38 bits (maximum) comprising a 32-bit data field (max length, see extradebug register description), a 5 bit address field and read/write bit.

The write actually takes place when the JTAG TAP controller enters the Update-DR state. On a read, the data field is ignored (the user should shift only 5 times to enter Read=1 and the address), the read takes place on the next path through DR at the Capture-DR state, the data is shifted-out during the Shift-DR state.

On the second path for a read access, simultaneous write access is not supported: command converter software shifts in zeros so the TAP decodes a write to the CSR (read-only register) which does not have any effect on the circuit.

The number of shift depends on the width of the accessed register as explained in the following diagrams.

First a write access (one path through Select-DR-Scan):

Figure 57-6. TDI/TDO on write access

Then a read access (requires two paths through Jtag DR Scan path):

First path

Second path

Figure 57-7. TDI/TDO on Read Access

For example, write value 0b1010_1100 to Debug Control Register (address = 0b00110).

Figure 57-8. Example: Write Access to DCR

External Signals

The SJC registers have different levels of security (refer to [JTAG Security Modes](#)):

- Secured- accessible only in mode 2 (supposed correct response entered), mode 3 and mode 4.
- Unsecured- accessible in all modes

The level of security of each register is indicated in its name or description, in "Programmable Registers" section.

A single DE_B pin is dedicated for debug request input/output in bidirectional open drain functionality (including an internal pull-up device).

Bits 6:5 in DCR register serve as mask bits, controlling the propagation of external debug request to each recipients (ARM Platform, SDMA).

The bits 1:0 define the propagation enable of IR debug request to recipient cores.

The following figure shows the \overline{DE} Pin Select Logic.

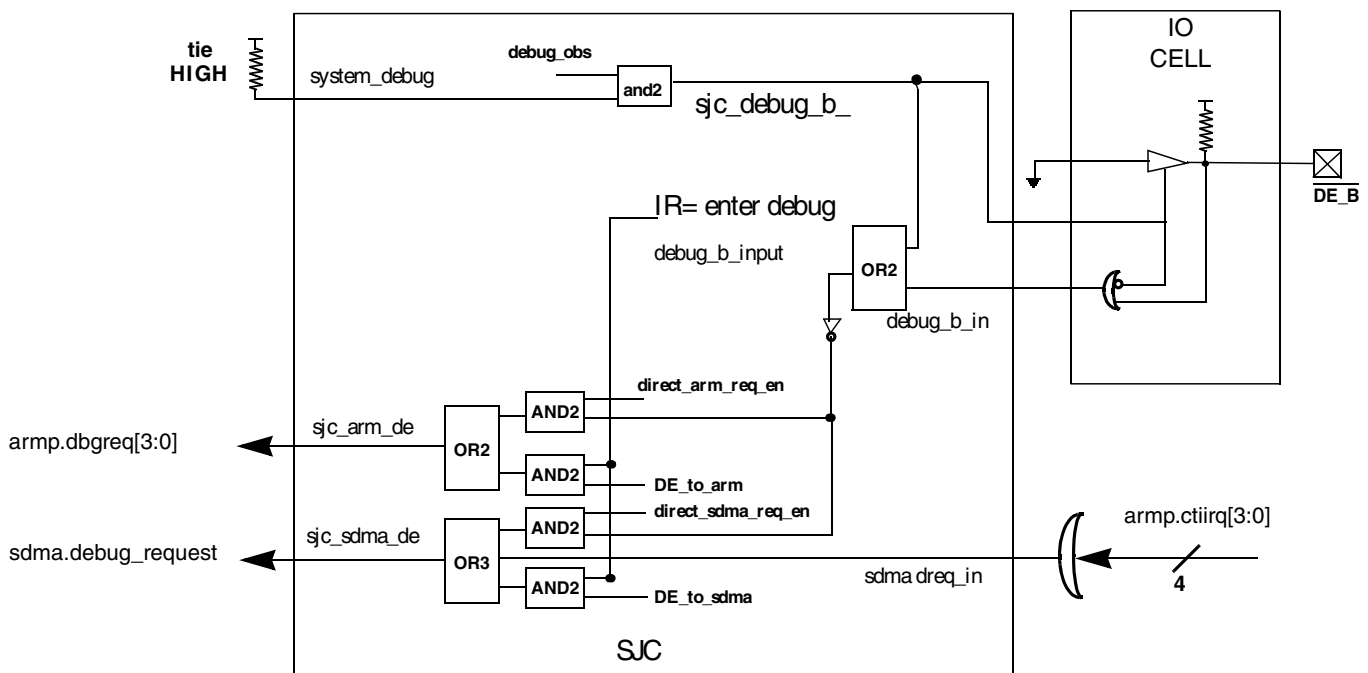

Figure 57-9. \overline{DE} Pin Select Logic

For security reasons, bits for output and input propagation control are at their negated values after reset. A user cannot put the cores in debug mode through \overline{DE} without any Jtag access.

The configuration after reset prevents propagation of debug requests / acknowledges to or from the cores.

57.3 TAP Selection Block (TSB)

As described in [Modes of Operation](#), the SJC can access cores in different modes selected through a TSB.

57.3.1 Select Mode Using Software

Conceptually, the SJC_TSR is a data register which is accessed through Access TSR IR instruction of SJC TAP.

The following figure shows the process of using reserved IR to access the SJC_TSR.

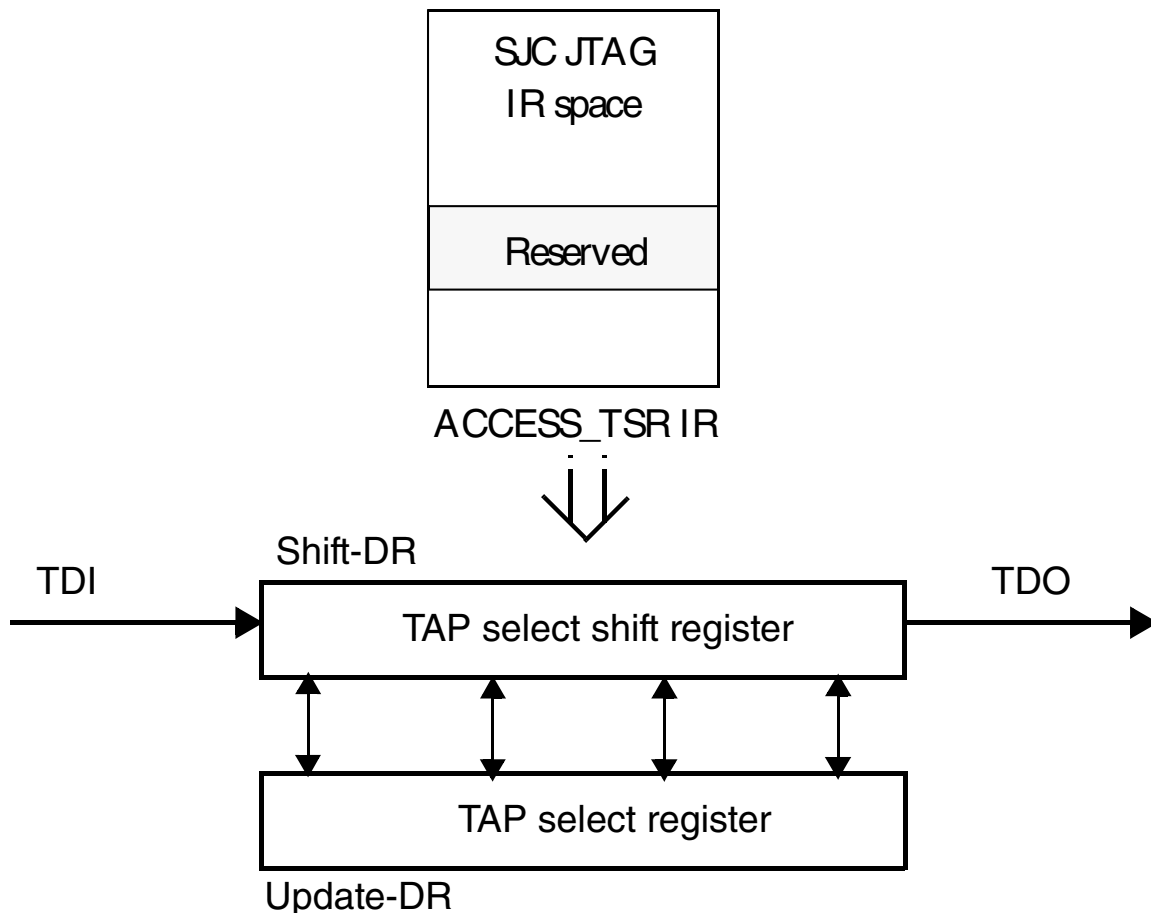

Figure 57-10. Using Reserved IR to Access the TAP Select Register (SJC_TSR)

Boundary Scan Register (BSR)

The SJC_TSR can only be changed during the update-DR state of the TSB JTAG state machine. This is necessary to prevent a TAP that is being selected from losing synchronization with the TSB state machine when the TSB state machine returns to run-test-idle. Therefore, an associated shift register for the SJC_TSR is loaded into the SJC_TSR during the update-DR state (see the figure above). The shift register must also capture the state of the SJC_TSR when in the Capture-DR state for visibility of the contents of the SJC_TSR. See [TAP Select Instruction](#), for more information.

57.4 Boundary Scan Register (BSR)

The Boundary Scan Register (BSR) in the JTAG implementation contains bits for all device signal and clock pins and associated control signals.

All SoC bidirectional pins have a single register bit in the boundary scan register for pin data, and are controlled by an associated control bit in the boundary scan register.

57.5 SoC JTAG Instruction Register (SJIR)

The SoC JTAG Instruction register is 5 bits wide.

Table 57-3. SoC JTAG Instruction Register (SJIR)

Code					SJC IR
B4	B3	B2	B1	B0	
0	0	0	0	0	IDCODE
0	0	0	0	1	SAMPLE/PRELOAD
0	0	0	1	0	EXTEST
0	0	0	1	1	HI-Z
0	0	1	0	0	ENABLE_ExtraDebug
0	0	1	0	1	ENTER_DEBUG (secured)
0	0	1	1	0	Reserved
0	0	1	1	1	TAP select
0	1	0	0	0	EXTEST_PULSE
0	1	0	0	1	EXTEST_TRAIN
0	1	0	1	0	Reserved
0	1	0	1	1	Reserved
0	1	1	0	0	Security Output challenge
0	1	1	0	1	Security Enter response
-	-	-	-	-	Reserved
1	1	1	1	1	BYPASS

The instruction register is reset to 0b00000 in the test-logic-reset controller state which is equivalent to the IDCODE instruction.

During the capture-IR controller state, the parallel inputs to the instruction register are loaded with the code 01 in the least significant bits as required by the standard; the most significant bits are loaded with the values 00, leading to a capture value of 0b000001.

57.5.1 ID_CODE Instruction (IDCODE)

Selects the ID register, and the system logic controls the I/O pins. This instruction is provided as a public instruction to allow the manufacturer, part number and version of a component to be determined through the TAP.

The table below shows the ID register configuration.

Table 57-4. ID Configuration Register (IDCODE)

IDCODE				ID Configuration Register												
	BIT 31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	BIT 16
	Version Information[3:0]			Part Number (Bits 27-16)												
TYPE	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
RESET	0	0	0	0	x	x	x	x	x	x	x	x	x	x	x	x
Note:																
	BIT 15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	BIT 0
	Part Number (Bits 15-12)				Manufacturer Identity											1
TYPE	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
RESET	x	x	x	x	0	0	0	0	0	0	0	0	1	1	1	0
Note:																

Table 57-5. ID Configuration Register Description (IDCODE)

Field	Description
31-28 Version Information	IC/SoC Version information number. Initial value: '0000' This number is subject to changes, for new IC/SoC (System On A Chip) revision releases.
27-12 Part Number	Customer Part Number The 16-bit Part Number value is unique for every Freescale's SoC / IC. See "System Debug" chapter for exact register value for a specific SoC.
11-1 Manufacturer Identity	Manufacturer Identity Freescale's Manufacturer Identity code.

Table continues on the next page...

Table 57-5. ID Configuration Register Description (IDCODE) (continued)

	Bits [11:1] - 00000001110
0	Tied to logic 1.

One application of the ID register is to distinguish the manufacturer(s) of components on a board when multiple sourcing is used. As more components emerge which conform to the IEEE 1149.1 standard, it is desirable to allow for a system diagnostic controller unit to blindly interrogate a board design to determine the type of each component in each location. This information is also available for factory process monitoring and for failure mode analysis of assembled boards.

Once the IDCODE instruction is decoded, it selects the ID register which is a 32 Bit data register. Because the bypass register loads a logic 0 at the start of a scan cycle, whereas the ID register loads a logic 1 into its least significant bit, examination of the first bit of data shifted out of a component during a test data scan sequence immediate following exit from Test-Logic-Reset controller state shows whether such a register is included in the design. When the IDCODE instruction is selected, the operation of the test logic has no effect on the operation of the on-chip system logic as required by the IEEE 1149.1 standard.

57.5.2 SAMPLE/PRELOAD Instruction

Selects the boundary scan register and the system logic controls the I/O pins.

The SAMPLE/PRELOAD instruction provides two separate functions:

- First, it provides a means to obtain a snapshot of system data and control signals. The snapshot occurs on the rising edge of TCK in the capture-DR controller state. The data can be observed by shifting it transparently through the boundary scan register.
- The second function of SAMPLE/PRELOAD is to initialize the boundary scan register output cells prior to selection of EXTEST. This initialization ensures that known data appears on the outputs when entering the EXTEST instruction.

NOTE

Because there is no internal synchronization between the JTAG clock (TCK) and the system clock (CLK), the user must provide some form of external synchronization to achieve meaningful results.

For more details on the function and use of SAMPLE/PRELOAD, refer to the appropriate IEEE 1149.1 document.

57.5.3 EXTEST Instruction

Selects the boundary scan register, and the 1149.1 test logic has control of the I/O pins.

By using the TAP controller, the register is capable of:

- Scanning user-defined values into the output buffers,
- Capturing values presented to input pins
- Controlling the direction of bidirectional pins,
- Controlling the output drive of tri-statable output pins.

For more details on the function and use of EXTEST, refer to the appropriate IEEE 1149.1 document.

The EXTEST instruction also asserts internal reset for the cores (through CCM, refer to [Figure 57-13](#)) to force a predictable internal state while performing external boundary scan operations.

57.5.4 HIGHZ Instruction

All output drivers, including the two-state drivers, are turned off (that is, high impedance). The instruction selects the bypass register.

In this mode, all internal pullup resistors on all the pins (except for the TMS, TDI, TCK, TRSTB pins) are disabled. This disabling functionality is not built into SJC, but should be implemented by some logic in the SOC/IO Pads.

For more details on the function and use of HIGHZ, refer to the IEEE 1149.1 document.

The HIGHZ instruction also asserts internal reset for the cores (through CCM, refer to [Figure 57-13](#)) to force a predictable internal state while performing external boundary scan operations.

57.5.5 BYPASS Instruction

Selects the single Bit bypass register and the system logic controls the I/O pins.

This creates a shift-register path from TDI to the bypass register and, finally, to TDO, circumventing the boundary scan register. This instruction is used to enhance test efficiency when a component other than the SoC Core based device becomes the device under test.

When the bypass register is selected by the current instruction, the shift-register stage is set to a logic zero on the rising edge of TCK in the capture-DR controller state. Therefore, the first bit to be shifted out after selecting the bypass register is always a logic zero.

For more details on the function and use of BYPASS, refer to the appropriate IEEE 1149.1 document.

57.5.6 ENABLE_ExtraDebug Instruction

The TDI and TDO pins are connected directly to the ExtraDebug registers, the SJC TAP controller remaining connected to TDI and TMS.

The ExtraDebug shift register consists of 38 bits (maximum) comprising a 32-bits data field (maximum length, see [Accessing ExtraDebug Registers](#)), a 5 bits address field and read/write bit. On a register read, the data field does not need to be filled in. The particular ExtraDebug register connected between TDI and TDO at a given time is selected by the ExtraDebug controller depending on the ExtraDebug Address being currently decoded. All communication with the ExtraDebug controller is done through the Select-DR-Scan path of the JTAG TAP Controller.

57.5.7 ENTER_DEBUG instruction

The ENTER_DEBUG instruction is used to generate a debug request event to SDMA and the ARM MPCore Platform simultaneously (practically, inherited minimal skew is expected, due to difference in event signal propagation in the different modules).

The TDI and TDO are connected to the Instruction Register (IR). After the acknowledgment of the Debug Mode is received (can be checked by reading the Core Status Register part of the ExtraDebug logic), the user can perform system debug functions on the cores.

NOTE

The ENTER_DEBUG event issue to the cores, can be masked, by bits in DCR register.

It is user's responsibility to shift-in another IR value (like IDCODE) before trying to bring the cores out of debug mode, as the debug request signals to the cores remains asserted as long as ENTER_DEBUG IR is in place.

The user need to check that cores are in debug mode (watching debug acknowledge signal) before leaving ENTER_DEBUG instruction, otherwise debug request might not take affect.

57.5.8 TAP Select Instruction

By means of TAP select instruction a user can access TAP select register and by controlling its only bit SDMA Bypass, control whether SDMA TAP is bypassed or not.

Table 57-6. TAP Select Register (TSR)

	TAP Select Register
	BIT 0
	Connect SDMA
TYPE	rw
RESET	0
Note:	

Table 57-7. TAP Select Register Description

Field	Description
0 SDMA Bypass	Connect SDMA Control whether SDMA TAP is bypassed or not: <ul style="list-style-type: none"> • 0 - SDMA TAP is bypassed by the alternate TAP inside SJC (emulating 4-bit IR and 1-bit bypass path). • 1 - SDMA TAP is connected to the TDI-TDO chain. <p>NOTE: Additional cycle with TMS '0' should be inserted, after writing to this register, to allow the SDMA tap be sync before SDMA get into / out of bypass.</p>

57.6 Security

JTAG manipulation is one of the known hackers' ways of executing unauthorized program code, getting control over the OS and run code in privileged modes.

The SJC provides a debug access to several H/W blocks including the ARM processor and the system bus. This allows for program control and manipulation as well as visibility into system peripherals and memory. The PTM interface allow bus transactions to be traced. Together these tools provide the hacker all the access needed to completely comprise the system. Means must be provided to block any malicious JTAG access.

The SJC provides a way of regulating the JTAG access.

The following are the different JTAG security modes:

- Mode #1: No Debug-Maximum Security. All security sensitive JTAG features are permanently blocked.
- Mode #2: Secure JTAG-High security. JTAG use is regulated by secret key based authentication mechanism.
- Mode #3: JTAG Enabled-Low security. JTAG always enabled.

The JTAG security modes are configured using eFUSES which can be burned after packaging by applying electrical signals. The fuse burning is an irreversible process, once a fuse is burned (e-fuse or laser fuse) it is impossible to change the fuse back to the unburned state.

57.6.1 JTAG Security Modes

JTAG can be in one of JTAG security modes which is selected by setting the SJC eFUSE configuration. The physical location of the fuses is not in the SJC.

57.6.1.1 Mode 1: No Debug - Maximum Security

No Debug JTAG security mode provides the highest security level.

In this mode, all JTAG features are disabled except for:

- ScanBoundary Scan
- MBIST, all modes except for debug modes which enable controlled memory contents output
- PLL BIST
- BIST monitor mode, allowing routing to external pins BIST pass/fail/invoke information
- PLL bypass- Bypass ARM or/and USB PLL.
- Visibility of the following status bits: power mode - normal, standby, stop, shutdown, and so on

These features do not reduce the security level of the product, and they allow to perform important tests and board connectivity checks.

57.6.1.2 Mode 2: Secure JTAG - High Security

The Secure JTAG mode limits the JTAG access by using challenge/response based authentication mechanism. Any access to JTAG port is being checked. Only authorized debug devices (that is, devices having the right response) can access the JTAG, unauthorized JTAG access attempts are denied.

The intent of this mode is to allow return field testing. When a secured JTAG device is being returned for debugging, this mode allows authorized re-activation of the JTAG.

57.6.1.2.1 Challenge/Response Mechanism in System JTAG Mode

When SJC is in System JTAG mode the authentication process is as follows:

1. Shift Output Challenge instruction to IR.
2. Passing through Capture-DR state of the SJC and by performing Shift-DR operations Challenge code can be accessed from TDO.
3. Shift Enter Response instruction to IR. By performing Shift-DR, operations enter Response code value through TDI. As Update-DR state is entered, Response code is compared with the correct one.

In Fixed challenge-response pair mode, each part has its individual challenge - response pair which is determined at manufacturing time, and does not change later on. The SJC compares the user's response to the expected response.

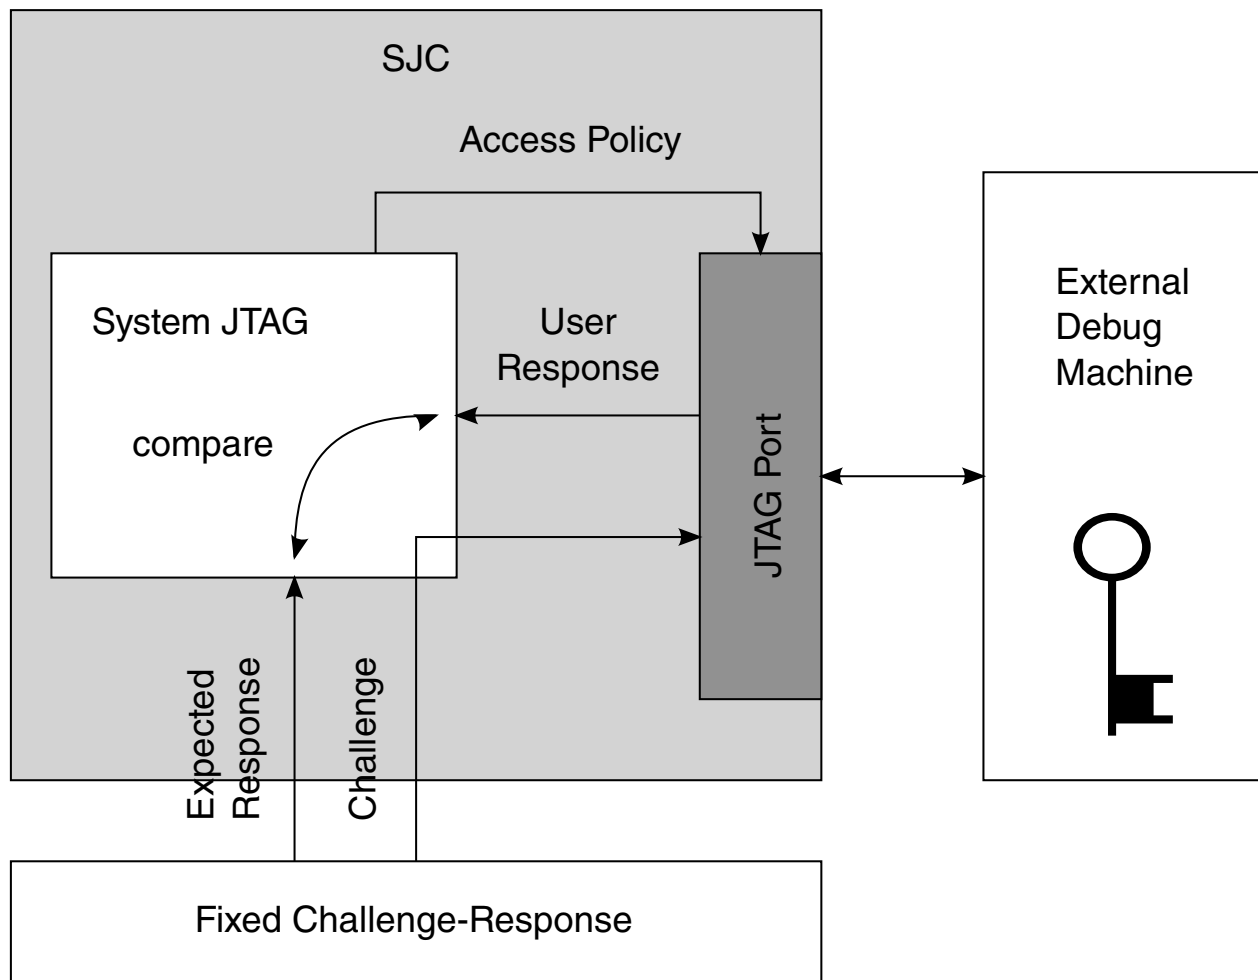

Figure 57-11. Mode #2 - Secure JTAG with Fixed Challenge-response Pair

57.6.1.3 Mode 3: JTAG Enabled - Low Security

In the JTAG Enabled JTAG security mode, all JTAG features are enabled.

57.6.2 Software Enabled JTAG

To increase the flexibility of the SJC, an option to enable the JTAG via software is added and is available only in Secure JTAG mode. By writing '1' to HAB_JDE (HAB JTAG DEBUG ENABLE) bit in the e-fuse controller module (OCOTP_CTRL), the JTAG is opened, regardless of its security mode. It is the responsibility of software to assert or negate this bit.

Additionally, a corresponding lock bit is available (in the e-fuse control module) to ensure that only trusted software is able to set the JDE bit. When the LOCK bit is set, no future change of JDE is possible, until the next POR (power-on-reset) cycle.

The platform initialization software should set the LOCK bit for JDE bit before transferring control to the application code.

The S/W JTAG enable allows JTAG enabling without activating the challenge-Response mechanism (which requires JTAG access tool enhancement or special H/W). The JTAG S/W enable does not allow debug in case of boot or memory fault as it requires reset before entering debug.

This feature can be permanently blocked by burning the dedicated e-fuse.

NOTE

The S/W enabled JTAG feature reduces the overall security level of the system as it relies on S/W protections. If this feature is not required, it is strongly recommended to burn the JTAG_HEO e-fuse which disables this feature.

57.6.3 Kill Trace

The kill trace signal disables any output of the PTM block. The PTM can be accessed either via JTAG port and/or by direct software code. Blocking the JTAG port also yields assertion of the kill trace signal. This resulted in blocking of trace port. The intention of this action is to block any attempt to break into the system via software manipulation of the debug modules. The kill trace, when active, prevents trace output even in case where it can be activated via chip pin.

The kill trace feature needs to be activated by burning a dedicated e-fuse. If the fuse is left intact, kill trace is never activated as seen in [Figure 57-12](#).

Figure 57-12. Kill Trace eFUSE

The kill trace is asserted when "kill trace enable" fuse is burned and "ipt_secur_block" signal in SJC is asserted, which happens when at least one of the following is true:

- Mode #2 (Secure JTAG) and no code has been entered
- Mode #2 (Secure JTAG) with incorrect response entered
- Mode #1 (No debug)
- TRST_B signal is active
- POR has not ever been asserted

57.6.4 SJC Disable Fuse

In addition to the different JTAG security modes that are implemented internally in the System JTAG Controller (SJC), there is an option to disable the SJC functionality by eFUSE configuration. This creates additional JTAG mode that is, JTAG Disabled with highest level of JTAG protection. In this mode all JTAG features are disabled.

Specifically, the following debug features are disabled in addition to the features that were already disabled in No Debug JTAG mode:

- Memory BIST
- Boundary scan register (SJC_BSR)
- Non-Secure JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secure JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

57.7 Functional Description

This section provides a complete functional description of the block.

57.7.1 Static Core Debug

The SJC JTAG TAP controller is fully compatible with the IEEE 1149.1a-2001 Standard Test Access Port and Boundary Scan Architecture specifications.

The ARM MPCore platform debug system (named CoreSight) including the real-time Program Trace Macrocell (PTM), are controlled via the Debug Access Port (DAP) module. Refer to ARM MPCore and PTM Technical reference manuals for more details.

The SDMA has a TAP controller to manage its own OnCE, see SDMA OnCE specifications for more details.

The OnCE and ICE provide a mean of interacting with the cores and their peripherals non-intrusively so that a user may examine registers, memories to facilitate hardware and software development. Refer to [TAP Selection Block \(TSB\)](#), for more information.

57.7.2 Reset Mechanism

The following figure shows the SJC reset logic

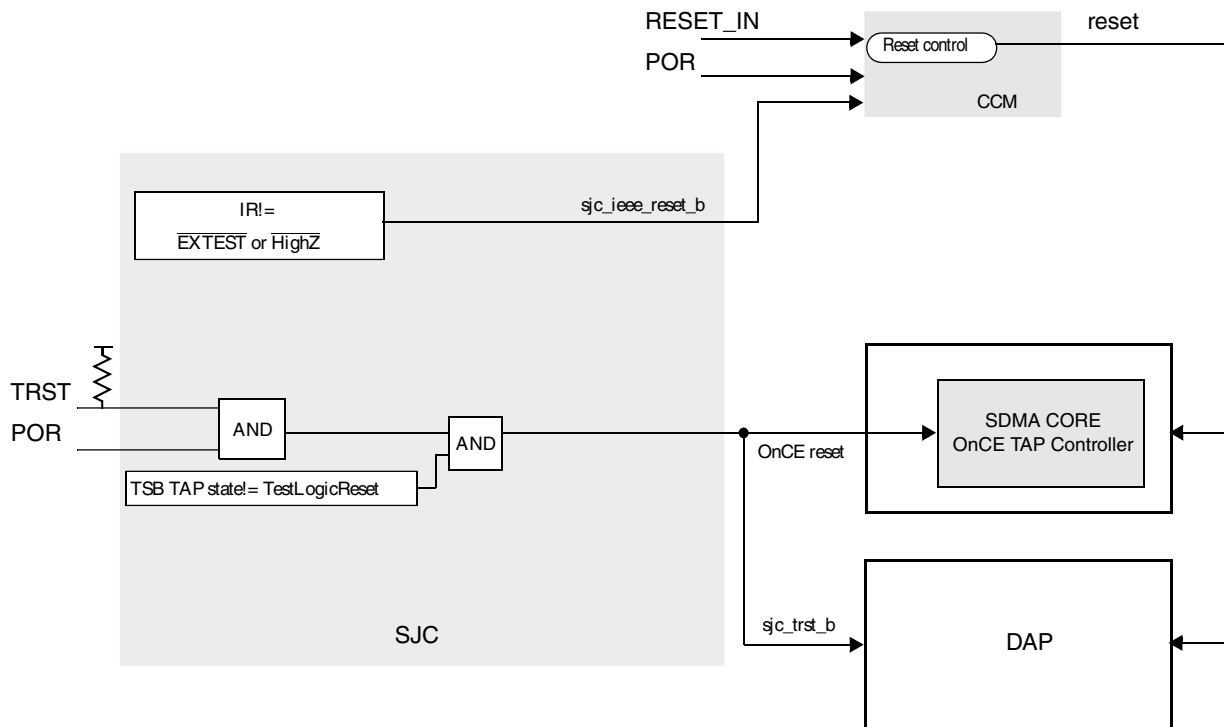

Figure 57-13. SJC Reset Logic

NOTE

- Asserting TRSTB in any scan mode resets the TCR losing the testmode configuration and selects default TAP.
- SJC generates an IEEE reset signal to the CCM when in one of the IEEE modes HIGHZ or EXTEST. This signal generates a system reset to the cores until exit from one of these modes.
- The TSB generates Once/ICE reset (either TRSTB if implemented or other) when its TAP state reaches Test-Logic-Reset (meaning that TAP accessed is also reaching Test-Logic-Reset).

57.8 Initialization/Application Information

The control afforded by the output enable signals using the boundary scan register and the EXTEST instruction requires a compatible circuit-board test environment to avoid device-destructive configurations. The user must avoid situations in which the SJC output drivers are enabled into actively driven networks.

There are two constraints related to the JTAG interface:

- Ensure that the JTAG test logic is kept transparent to the system logic by forcing TAP into the Test-Logic-Reset controller state. During power-up, SJC's internal TRSTB is asserted as IC's POR_B is asserted which forces the TAP controller into this state. After that, if TMS either remains unconnected or is connected to VCC, then the TAP controller cannot leave the Test-Logic-Reset state, regardless of the state of TCK.
- DE_B is an IO pin with pullup and care must be taken of the direction when driving this signal.

57.9 SJC Memory Map/Register Definition

In addition to the standard accessible JTAG registers (per IEEE1149.1 standard) listed in [SoC JTAG Instruction Register \(SJIR\)](#) , the chip contains the following registers accessed using the ExtraDebug mechanism, controlled via "ENABLE_ExtraDebug" IR instruction.

NOTE

SJC registers are only accessible by JTAG interface. They are not memory mapped to processor address space, so the absolute addresses provided by default in the SJC memory map are not valid.

This section assumes the JTAG controller is accessed in standalone mode or daisy chained (defined by TAP Selection Block) using the appropriate TSB configuration.

See "System Debug" chapter for more details about the general purpose register descriptions that are unique to this chip.

SJC memory map

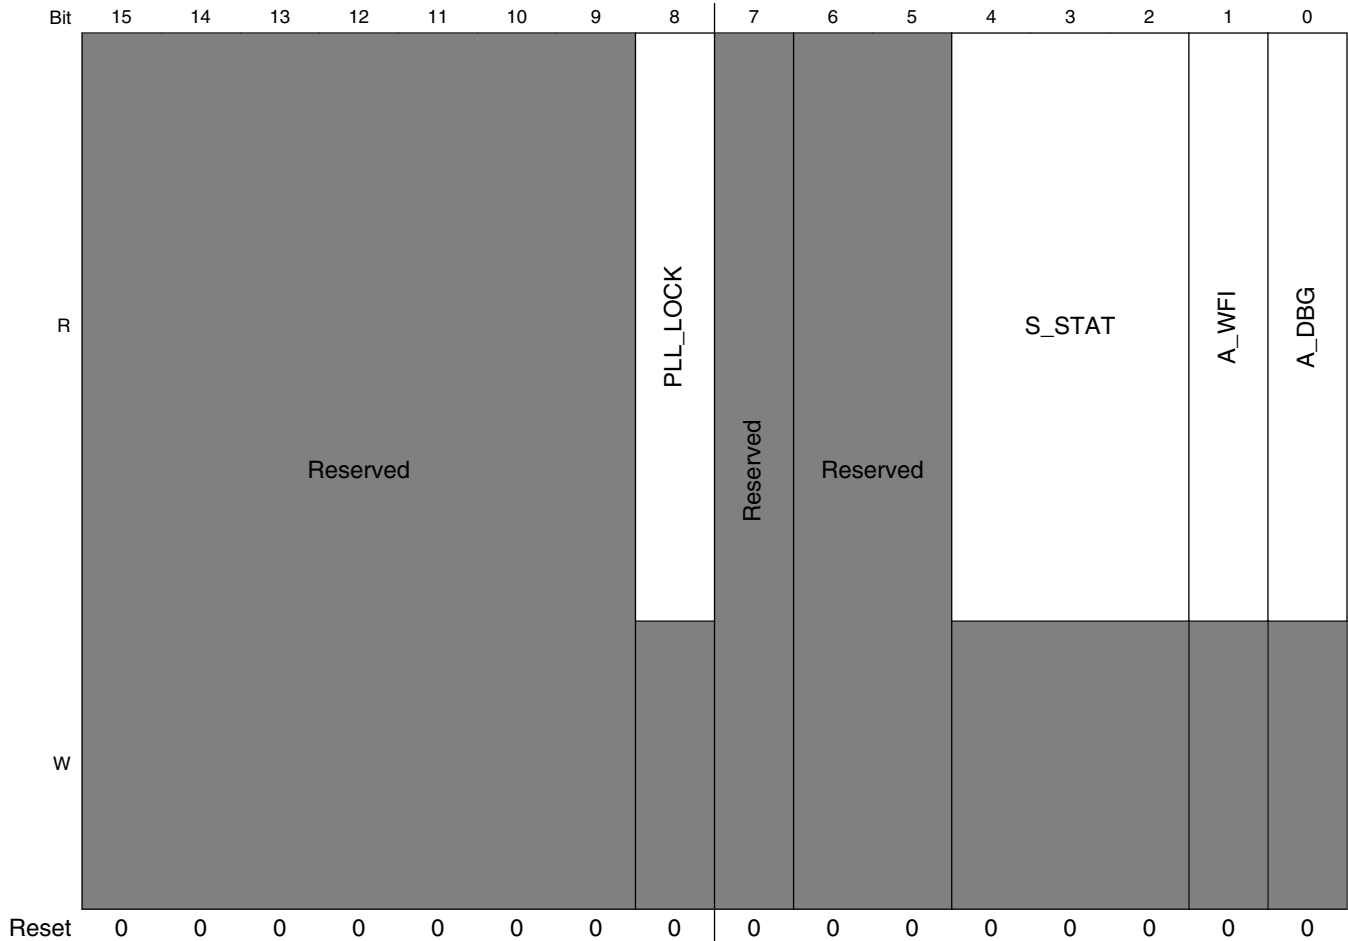

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	General Purpose Unsecured Status Register 1 (SJC_GPUSR1)	32	R	0000_0000h	57.9.1/3852

57.9.1 General Purpose Unsecured Status Register 1 (SJC_GPUSR1)

The General Purpose Unsecured Status Register 1 is a read only registers used to check the status of the different Cores and of the PLL. The rest of its bits are for general purpose use.

Address: 0h base + 0h offset = 0h

SJC_GPUSR1 field descriptions

Field	Description
31–9 -	This field is reserved. Reserved.
8 PLL_LOCK	PLL_LOCK A Combined PLL-Lock flag indicator, for all the PLL's.
7 -	This field is reserved. Reserved
6–5 -	This field is reserved. Reserved.
4–2 S_STAT	3 LSBits of SDMA core statusH.
1 A_WFI	ARM core wait-for interrupt bit Bit 1 is the ARM core standbywfi (stand by wait-for interrupt). When this bit is HIGH, ARM core is in wait for interrupt mode.
0 A_DBG	ARM core debug status bit Bit 0 is the ARM core DBGACK (debug acknowledge) DBGACK can be overwritten in the ARM core DCR to force a particular DBGACK value. Consequently interpretation of the DBGACK value is highly dependent on the debug sequence. When this bit is HIGH, ARM core is in debug.

57.9.2 General Purpose Unsecured Status Register 2 (SJC_GPUSR2)

Address: 0h base + 1h offset = 1h

0 KTF	Kill Trace Enable fuse value 0 (intact) - kill trace is never active 1 (burned) - kill trace functionality enabled

57.9.7 General Purpose Clocks Control Register (SJC_GPCCR)

This register is used to configure clock related modes in SOC, see System Configuration chapter for more information. Those bits are directly connected to JTAG outputs. Bit 0 of GPCCR controls SDMA clocks invocation. When out of reset, the SDMA is in sleep mode with no SDMA clock running. Unlike events, debug requests does not wake SDMA if it is in sleep mode. The debug request is recognized by the SDMA only when it exits sleep mode upon reception of an event. To be able to enter debug mode even if no event is triggered, the SDMA clock on bit needs to be set prior to sending the debug request (clear at reset).

Address: 0h base + 7h offset = 7h

Bit	31	30	29	28	27	26	25	24		23	22	21	20	19	18	17	16

1 ACLKOFFDIS	Disable/prevent ARM platform clock/power shutdown
0 SCLKR	SDMA Clock ON Register - This bit forces the clock on of the SDMA

Chapter 58

Secure Non-Volatile Storage (SNVS)

58.1 SNVS overview

The low-power (battery-backed) section incorporates a secure real time counter, a monotonic counter, and a general purpose register. This portion of the block is powered by a battery that maintains the state of the SNVS_LP registers when the chip is powered off.

Figure 58-1. Example SNVS Connectivity

NOTE

For the security features of SNVS, see the *Security Reference Manual for i.MX 6SoloX (IMX6SXS RM)*.

58.1.1 SNVS features

The following table summarizes the features:

Table 58-1. SNVS feature summary

Feature	What it does
Real time counter (RTC)	<ul style="list-style-type: none">• The counter is driven by a dedicated clock, which is off when the system power is down• Programmable time alarm interrupt• Periodic interrupt can be generated with different frequencies
Monotonic counter	<ul style="list-style-type: none">• The monotonic counter state is nonvolatile.• The counter can only increment.• The counter is a non-rollover counter• The counter value is invalidated in case of security violation.
General-purpose register	<ul style="list-style-type: none">• The general-purpose register state is nonvolatile.
Register access protection	<ul style="list-style-type: none">• Privileged software access policy• Registers can be programmed only when the system security monitor is in functional state.• Some registers/values can only be programmable once per boot cycle.

58.1.2 Modes of operation

The SNVS operates in either the system power-down or system power-up mode of operation.

During system power-down, SNVS_HP is powered-down. SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode, SNVS_LP retains the state of its registers .

During system power-up, SNVS_HP and SNVS_LP are both powered-up and all SNVS functions are operational.

58.2 External Signals

The table found here describes the external signals of SNVS.

Table 58-2. SNVS External Signals

Signal	Description	Pad	Mode	Direction
SNVS_PMIC_ON_REQ	Wake-up signal	SNVS_PMIC_ON_REQ	No muxing	O
SNVS_TAMPER	Tamper signal	SNVS_TAMPER	No muxing	I
SNVS_VIO_5	Security violation input signal	GPIO1_IO00	ALT6	I
SNVS_VIO_5_CTL	Security violation output indicator signal for SNVS_VIO_5	GPIO1_IO01	ALT6	O

58.3 Clocks

The table found here describes the clock sources for SNVS.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 58-3. SNVS Clocks

Clock name	Clock Root	Description
hp_ipg_clk	ipg_clk_root	HP peripheral clock
hp_ipg_clk_s	ipg_clk_root	HP peripheral access clock used for clocking the registers on bus R/W accesses
ipg_hp_rtc_clk	ckil_sync_clk_root	HP RTC clock advances the RTC, doesn't have to be synchronous with any module clock.

Table continues on the next page...

Table 58-3. SNVS Clocks (continued)

Clock name	Clock Root	Description
lp_ipg_clk	ipg_clk_root	LP peripheral clock
lp_ipg_clk_s	ipg_clk_root	LP peripheral access clock used for register R/W accesses

58.4 SNVS structure

The SNVS block is divided into two major submodules based on power supply: the high power domain (SNVS_HP) and the low power domain (SNVS_LP). They are powered as follows:

- SNVS_LP - dedicated always-powered-on domain
- SNVS_HP - system (chip) power domain

The following figure illustrates the low power and chip power domains of SNVS.

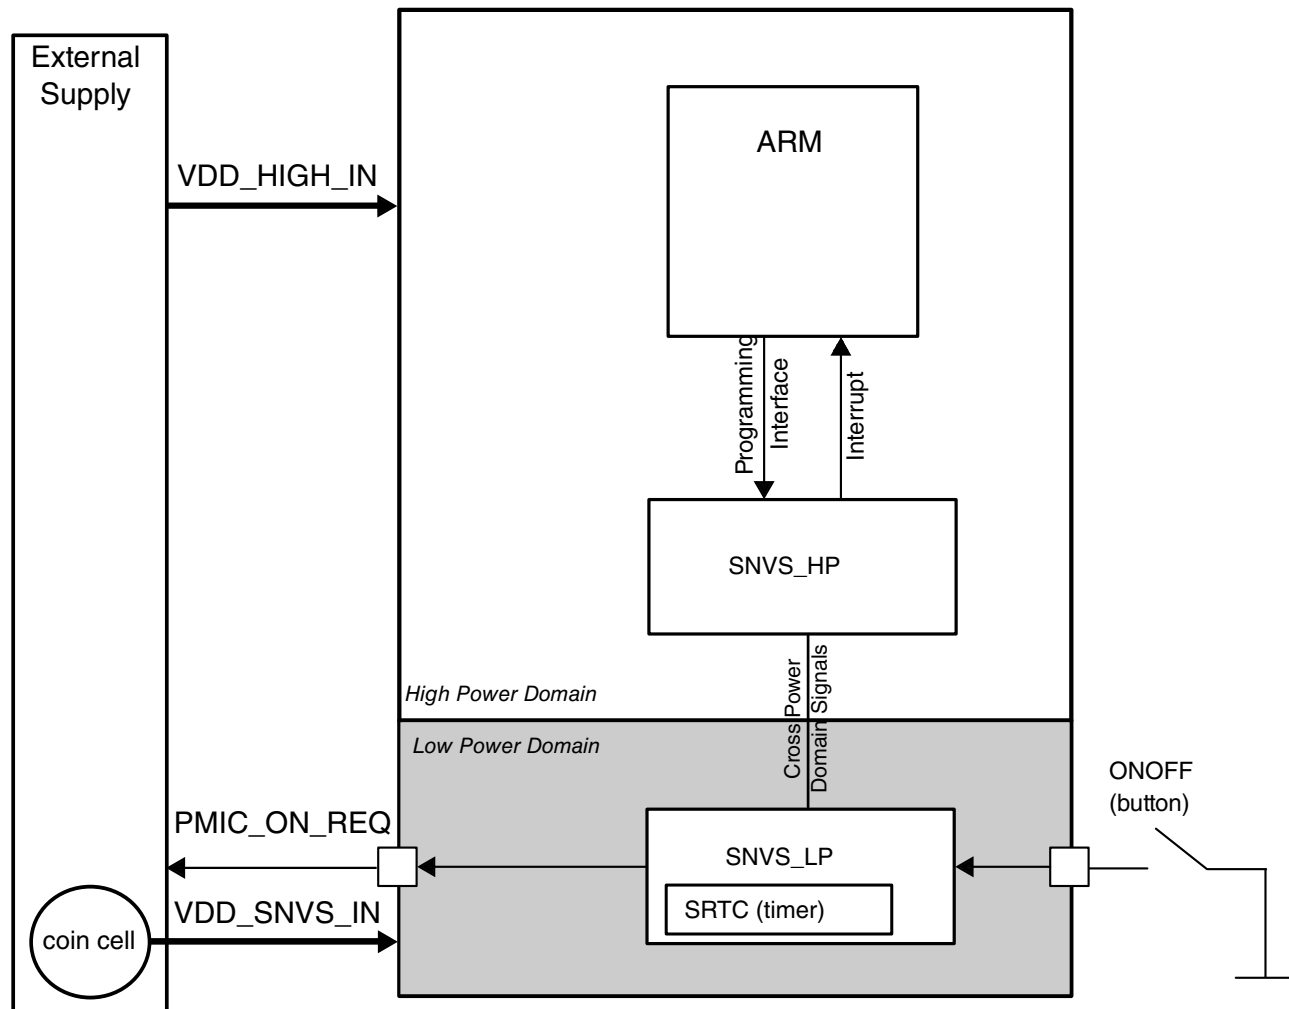

Figure 58-2. SNVS Power Domains

The SNVS_HP section implements all features that enable system communication and provisioning of the SNVS_LP section.

The SNVS_LP section provides hardware that enables secure storage and protection of sensitive data.

58.4.1 SNVS_HP (high power domain)

SNVS_HP is partitioned into the following functional units:

- IP bus interface
- SNVS_LP interface
- Real time counter with alarm
- Control and status registers

SNVS_HP is in the chip's power supply domain and thus receives power along with the rest of the chip. SNVS_HP provides an interface between SNVS_LP and the rest of the system; there is no way to access the SNVS_LP registers except through the SNVS_HP. For access to the SNVS_LP registers, SNVS_HP must be powered up. It uses a register access permission policy to determine whether access to particular registers is permitted.

58.4.2 Non-secure real time counter

SNVS_HP has an autonomous non-secure real time counter. The counter is not active and is reset when the system is powered down. The HP RTC can be used by any application; it has no privileged software access restrictions. The counter can be synchronized with the SNVS_LP SRTC by writing to a specific bit in the SNVS_HP Control Register.

58.4.2.1 Calibrating the time counter

The RTC accuracy may suffer from a drift in the clock, which is used to increment the RTC register. To compensate for this drift, a clock calibration mechanism can adjust the RTC value. It is up to the system processor to decide whether calibration is required or not. If RTC correction is required, enable the mechanism and set the calibration value in the control register. The calibration value is a 5 bit value including the sign bit, which is implemented in 2's complement.

If the calibration mechanism is enabled, the calibration value is added or subtracted from the RTC on a periodic basis, once per 32768 cycles of the RTC clock.

The following table shows the available correction range.

Table 58-4. Time counter calibration settings

Calibration value setting	Correction in counts per 32768 cycles of the counter clock
01111	+15
:	:
00010	+2
00001	+1
00000	0
11111	-1
11110	-2
:	:
10001	-15
10000	-16

58.4.2.2 Time counter alarm

The SNVS_HP non-secure RTC has its own time alarm register. Any application can update this register. The SNVS_HP time alarm can generate interrupts to alert the host processor and can wake up the host processor from one of its low-power modes. Note that this alarm cannot wake up the entire system if it is powered off because this alarm would also be powered off.

58.4.2.3 Periodic interrupt

The SNVS_HP non-secure RTC incorporates a periodic interrupt. The periodic interrupt is generated when a zero-to-one or one-to-zero transition occurs on the selected bit of the RTC. The periodic interrupt source is chosen from 16 bits of the HP RTC according to the PI_FREQ field setting in the HP Control Register. This bit selection also defines the frequency of the periodic interrupt.

The following figure shows the SNVS_HP RTC and its interrupts.

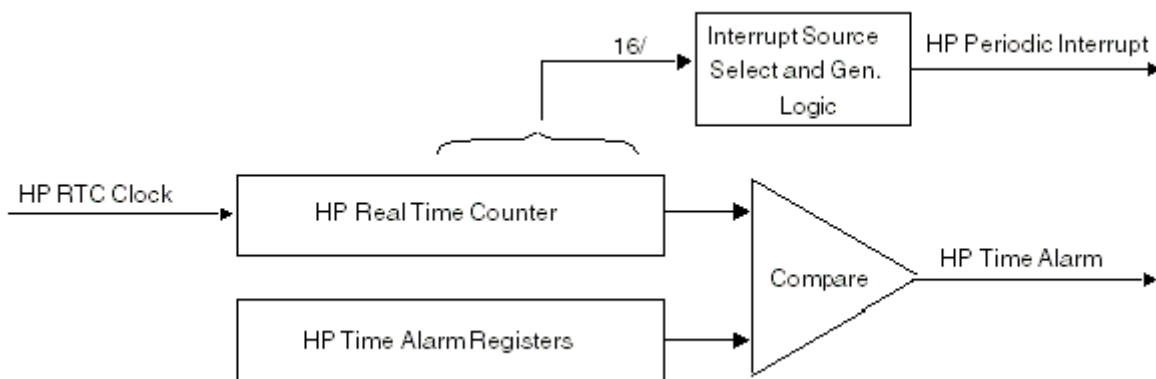

Figure 58-3. SNVS_HP RTC, alarm, and interrupts

58.5 SNVS_LP (low power domain)

SNVS_LP has the following functional units:

- Non-rollover monotonic counter
- General purpose register
- Control and status registers

The SNVS_LP is a data storage subsystem. Its purpose is to store and protect system data, regardless of the main system power state.

SNVS_LP is in the always-powered-up domain, which is a separate power domain with its own power supply.

58.5.1 Behavior during system power down

When the chip power supply domain loses power, SNVS_LP continues to operate normally, and it ignores all inputs from SNVS_HP.

58.5.2 Monotonic counter (MC)

The following figure shows the MC and its rollover security violation.

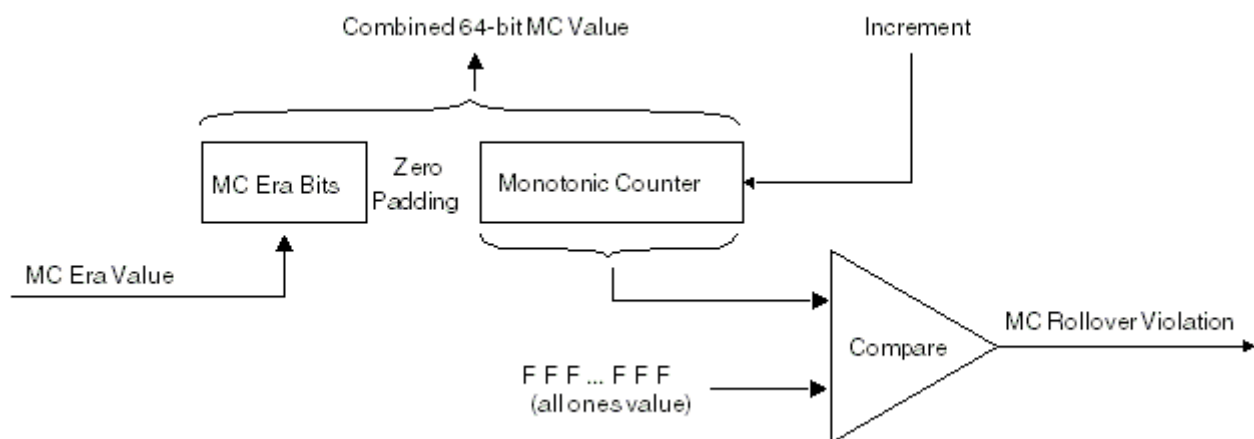

Figure 58-4. SNVS_LP monotonic counter

Some security applications require a monotonic counter (MC) that cannot be exhausted or returned to any previous value during the product's lifetime. Because the MC can never repeat a number, it cannot be reset or cycled back to its starting count. If it reaches its maximum value, it does not rollover. Instead, a monotonic counter rollover indication is generated to the SNVS_LP tamper monitor. This generates an interrupt to the host processor.

The SNVS uses an ERA value derived from the OTP elements as a mechanism for recovery from an MC failure (for example, due to a failure of LP power) where the MC value was compromised or cleared. The ERA value is prepended to the MC to form its

most significant bits. Once any of the ERA value bits are set, the MC can count up from any value, including zero. This guarantees that any future value of the combined monotonic counter will be greater than any of its past values.

58.6 SNVS reset and system power up

This table describes reset actions for SNVS.

Table 58-5. Reset summary

Reset	Source	Characteristics	Internally resets
HP Hard	ipg_hard_async_reset_b	active-low, asynchronous	All SNVS_HPSNVS_LP registers and flops.
LP Power On Reset (POR)	lp_por_b	active-low, asynchronous	All SNVS_LP registers and flops
LP software Reset	software	active-high, synchronous, 1 cycle	All SNVS_LP registers and flops. LP software Reset can be asserted if not disabled.

58.6.1 PMIC Interface

The On/Off logic inside of SNVS_LP allows for connecting directly to a PMIC or other voltage regulator device. The logic takes a button input signal and then outputs a PMIC "ON" Request and a "Power Off" Interrupt. PMIC logic also supports the SNVS_LP tamper logic which will allow waking the system up when a tamper event has happened while in the OFF state. The logic has two different modes of operation (Dumb and Smart mode).

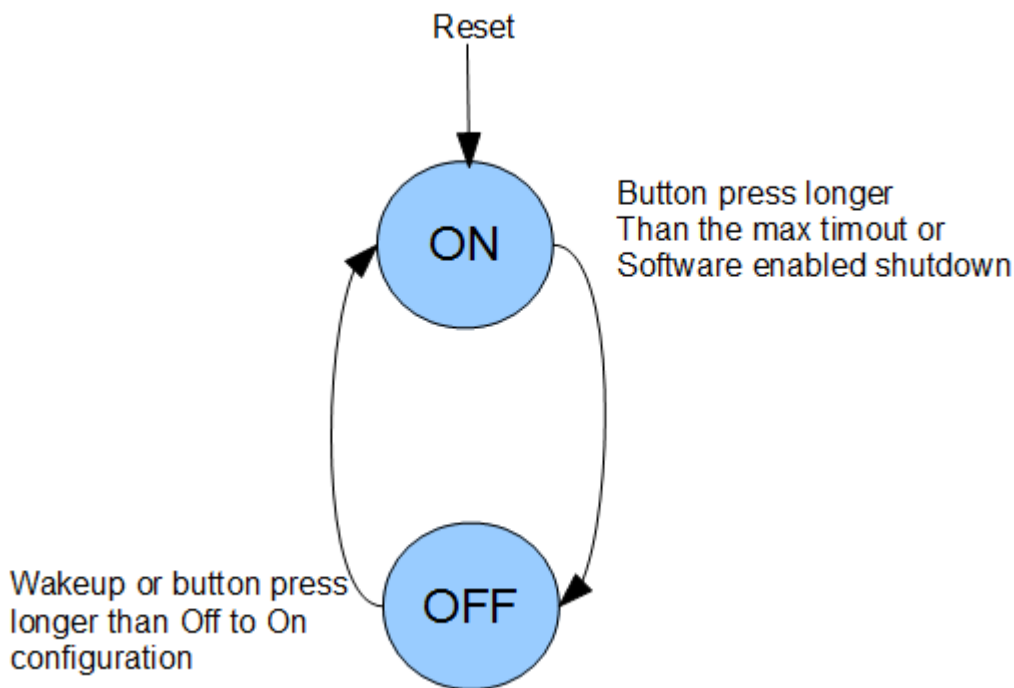

Dumb PMIC Mode:

The dumb pmic mode uses PMIC "ON" Request to issue a level signal for on and off. Dumb pmic mode has many different configuration options which include (debounce, off to on time, and max time out).

- **Debounce:** The debounce configuration supports 0 msec, 50 msec, 100 msec and 500 msec. The debounce is used to generate the set_pwr_off_irq interrupt. While in the ON state and the button is pressed longer than the debounce time the set_pwr_off_irq is generated.

- **Off to On Time:** The Off to On configuration supports 0 msec, 50 msec, 100 msec, and 500 msec. This configuration supports the time it takes to request power on after the configured button press time has been reached. Once the button is pressed longer than the configuration time, the state machine will transition from the OFF to the ON state.
- **Max Timeout:** The max timeout configuration supports 5 secs, 10 secs, 15 secs and disable. This configuration supports the time it takes to request power down after the button has been pressed for the defined time.

The dumb PMIC mode uses a 2 state state machine, as shown below. The output of the pmic_en_b is generated by the state of the state machine.

Smart PMIC Mode:

The smart PMIC mode is meant to connect to another PMIC. The PMIC "ON" Request signal issues a pulse instead of a level signal. The only configuration option available for this mode is the Debounce configuration that is used for the "Power Off" Interrupt.

58.7 SNVS interrupts and alarms

SNVS provides the following interrupt and alarm lines:

Programming Guidelines

- Functional interrupt (active low)
- Real-time clock period interrupt
- Power off (button) interrupt

The following table summarizes all SNVS interrupts and alarm sources.

Table 58-6. Interrupts and alarms summary

Interrupt	Source	Default configuration ¹	Configuration options
SNVS functional interrupt	RTC time alarm	Disable	Enable/Disable
	RTC periodic interrupt	Disable	Enable/Disable
SNVS power off (button) interrupt	BTN input signal	50msec debounce	Debounce time

1. Default behavior refers to the setting after LP/HP reset.

58.8 Programming Guidelines

This section provides initialization and application information for the SNVS module.

58.8.1 RTC control bits setting

All SNVS registers are programmed from the register bus. Therefore, any changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC clock after they are programmed. To avoid IP clock and RTC clock synchronization issues, these values can only be programmed when the corresponding function is disabled. The following table presents the list of these values with the control bit setting required for programming.

Table 58-7. RTC synchronized values list

Function	Value/register	Control bit setting
HP section		
HP Real Time Counter	HPRTC MR and HPRTCLR Registers	RTC_EN = 0 - HPRTC MR/HPRTCLR can be programmed RTC_EN = 1 - HPRTC MR/HPRTCLR cannot be programmed
HP Time Alarm	HPTAMR and HPTALR Registers	HPTA_EN = 0 - HPTAMR/HPTALR can be programmed HPTA_EN = 1 - HPTAMR/HPTALR cannot be programmed
HP Time Calibration Value	HPCALB_VAL Value	HPCALB_EN = 0 - HPCALB_VAL can be programmed HPCALB_EN = 1 - HPCALB_VAL cannot be programmed

Use the following step to program synchronized values:

1. Check the enable bit value. If set, clear it.
2. Verify that the enable bit is cleared.

There are two reasons to verify the enable bit's setting:

- Enable bit clearing does not happen immediately; it takes three IPclock cycles and two RTC clock cycles to change the enable bit's value.
 - If the enable bit is locked for programming, it cannot be cleared.
3. Program the desired value.
 4. Set the enable bit; it takes three IP clock cycles and two RTC clock cycles for the bit to set.

NOTE

Incrementing the value programmed into RTC registers by two compensates for the two RTC clock cycle delay that is required to enable the counter.

58.8.2 RTC value read

There are two scenarios when software can read corrupted values from the RTC (HPRTCMR and HPRTCLR) registers:

- The RTC counters are incremented by the slow 32 kHz clock, which is asynchronous to the system clock. The counter value is synchronized to the system clock before software reads that. The synchronization register may capture the counter value in the middle of the counter update. In this case, it is not guaranteed that all bits are properly sampled by the synchronization register; the value read by software can be wrong.
- The RTC value is longer than the single bus read transaction of 32-bits. Therefore, software reads two registers, each holding a portion of the counter value. After reading one of these registers but before reading the second register, both registers may update their values. In this case, the value combined by software will be incorrect.

To avoid these issues, it is strongly recommended that software perform two consecutive reads of the RTC value:

- If two consecutive reads are similar, the value is correct.
- If two consecutive reads are different, perform two more reads.

The worst case scenario may require three sessions of two consecutive reads.

58.8.3 General initialization guidelines

Complete the following steps in order to properly initialize the module:

1. Enable interrupts in SNVScntrol and configuration registers.
2. Program SNVS general functions/configurations.
3. User Specific: Set lock bits.

NOTE

58.9 SNVS Memory Map/Register Definition

This section contains detailed register descriptions for the SNVS registers. Each description includes a standard register diagram and register table. The register table provides detailed descriptions of the register bit and field functions, in bit order.

SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

Privileged read/write accessible registers can only be accessed for read/write by privileged software. Unauthorized write accesses are ignored, and unauthorized read accesses return zero. Non-privileged software can access privileged access registers when the non-privileged software access enable bit is set in the SNVS_HP Command Register.

- Non-Secure
- Trusted
- Secure

Non-privileged read/write accessible registers are read/write accessible by any software.

The following table shows the SNVS memory map. The LP register values are set only on LP POR and are unaffected by System (HP) POR. The HP registers are set only on System POR and are unaffected by LP POR.

NOTE

For more information on security-related bitfields, see the *Security Reference Manual for i.MX 6SoloX (IMX6SXSRM)*.

SNVS_LPSMCMR field descriptions

Field	Description
31–16 MC_ERA_BITS	Monotonic Counter Era Bits These bits are inputs to the module and typically connect to fuses.
MON_COUNTER	Monotonic Counter Most Significant 16 Bits The MC is incremented by one when: <ul style="list-style-type: none"> • A write transaction to the LPSMCMR or LPSMCLR register is detected. • The MC_ENV bit is set. • MC_SL and MC_HL bits are not set.

58.9.13 SNVS_LP Secure Monotonic Counter LSB Register (SNVS_LPSMCLR)

The SNVS_LP Secure Monotonic Counter LSB Register contains the 32 least significant bits of the monotonic counter. The MC is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register.

Address: 20C_C000h base + 60h offset = 20C_C060h

SNVS_LPSMCLR field descriptions

Field	Description
MON_COUNTER	Monotonic Counter bits The MC is incremented by one when: <ul style="list-style-type: none"> • A write transaction to the LPSMCMR or LPSMCLR Register is detected. • The MC_ENV bit is set. • MC_SL and MC_HL bits are not set.

58.9.14 SNVS_LP General Purpose Register (SNVS_LPGPR)

The SNVS_LP General Purpose Register is a 32-bit read/write register located in the low power domain. Since LPGPR is located in the battery-backed power domain, LPGPR can be used by any application for retaining data during an SoC power-down mode. LPGPR will be automatically zeroized when a tamper event occurs, unless GPR zeroization is disabled via the GPR_Z_DIS bit in the LP Control Register.

Address: 20C_C000h base + 68h offset = 20C_C068h

SNVS_LPGPR field descriptions

Field	Description
GPR	General Purpose Register When GPR_SL or GPR_HL bit is set, the register cannot be programmed.

58.9.15 SNVS_HP Version ID Register 1 (SNVS_HPVIDR1)

The SNVS_HP Version ID Register 1 is a read-only register that contains the current version of the SNVS. The version consists of a module ID, a major version number, and a minor version number.

Address: 20C_C000h base + BF8h offset = 20C_CBF8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CONFIG_OPT	SNVS Configuration Option

Chapter 59

Shared Peripheral Bus Arbiter (SPBA)

59.1 Overview

The Shared Peripheral Bus Arbiter (SPBA) is a three-to-one IP Bus interface arbiter. Three masters arbitrate for shared peripheral access through the SPBA.

The SPBA has three primary functions:

- The IP Bus Line switches a master to one peripheral
- The Masters arbiter arbitrates between the three masters to solve concurrent access or restricted access to peripherals
- The Control Registers and Ownership Control includes a set of registers which are reachable through software and permit the access scheme to be defined for each peripheral (Resource Ownership and Access Control). It generates signals for the external steering logic of interrupts and DMA signals.

The figure below shows the SPBA block diagram

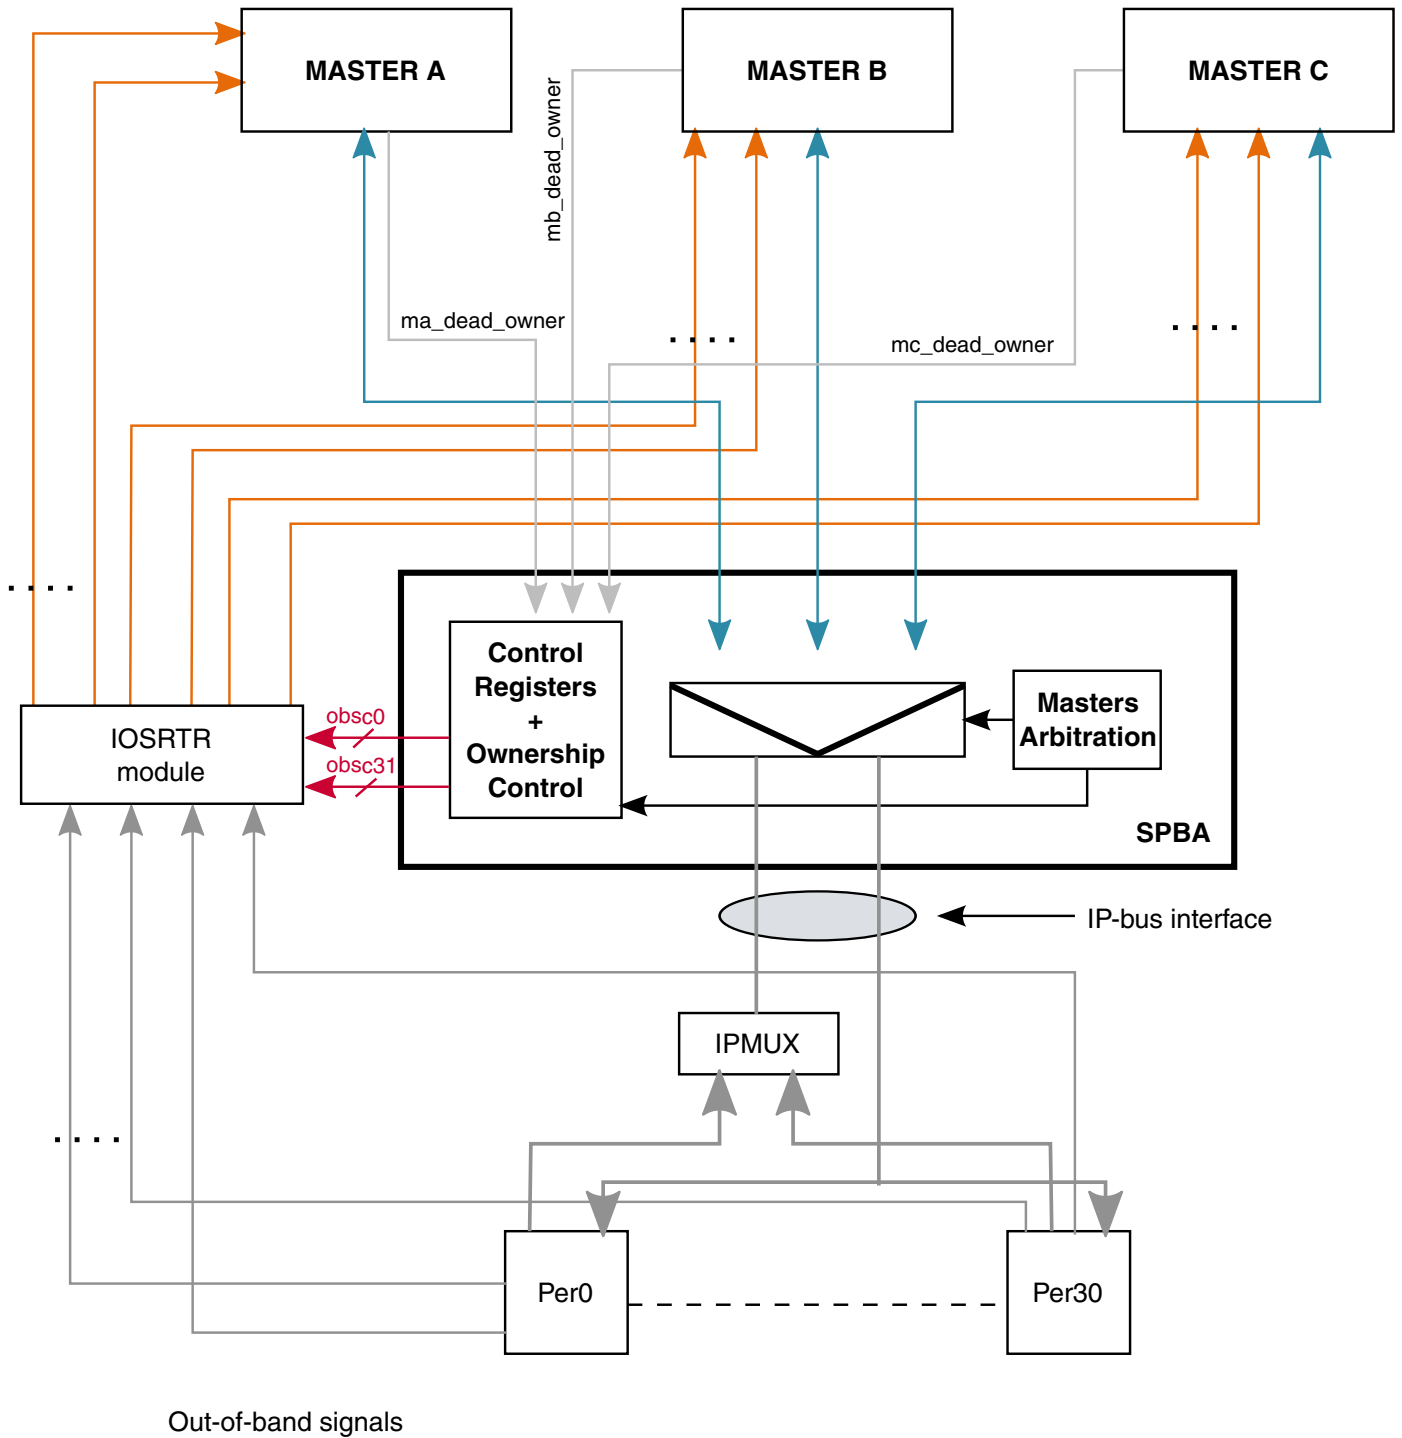

Figure 59-1. SPBA Block Diagram

59.1.1 Features

The SPBA includes the following features:

- Three IP Bus masters arbitration: Master A, B and C
- Support for DMA masters
- 32-bit data
- Supports up to 31 shared peripherals, each consuming 16 kilobytes of address space
- SPBA can be considered the 32nd peripheral, used for resource ownership and access control of the 31 peripherals
- Provides 31 sets of out of band steering control (OBSC) signals to the off-block steering logic
- Operating frequency up to 67 MHz
- Supports TrustZone
- RDC resource domain access controls
- Clocks: ipg_clk, ipg_clk_s

59.1.2 Modes of operation

SPBA behavior is transparent when accessing a peripheral, though it has these distinct modes of operation.

Reset/Abort

The SPBA has a hardware reset which initializes all registers, arbitration and peripherals rights registers (PRRs).

An abort signal input is provided allowing each master to abort its current access and release ownership (in case of master reset sequence).

Functional

Once a master request is granted, its IP Bus signals are steered to the requested peripheral.

Standby

No clock needed. The SPBA needs clocks only during access to the PRRs, arbitration, and abort phases. It generates two clock enable signals indicating when the clocks must be provided.

Configuration

During this phase, a master accesses the SPBA PRRs. The SPBA memory-mapped registers are seen as a shared peripheral.

59.2 Clocks

The table found here describes the clock sources for SPBA.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 59-1. SPBA Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

59.3 Functional description

59.3.1 Masters arbitration

The arbitration mechanism determines which port will control the master port, based on a simple round-robin arbitration scheme.

There are several use cases to consider.

- Only one master request per access. The master is switched to the shared peripheral bus, without arbitration. [Figure 59-2](#) shows the MB request on the global module enable signal, served without wait state.
- If two masters simultaneously access SPBA, the last granted master is held off using the <master>_ips_xfr_wait output signal (default value is high). When the master is granted sips_xfr_wait, shared IP Bus peripheral is connected to <master>_ips_xfr_wait outputs.
- If three masters simultaneously access SPBA, then the last two granted masters are held off using <master>_ips_xfr_wait. [Figure 59-3](#) shows a case in which the last two accesses granted are MA and MB. The requests are used even if they are in the same cycle.
- If after reset, at the first multiple access, no master has been granted, the priority is static: Master A (MA), Master B (MB) and last Master C (MC) port.
- No master request. No master switch to shared peripherals.

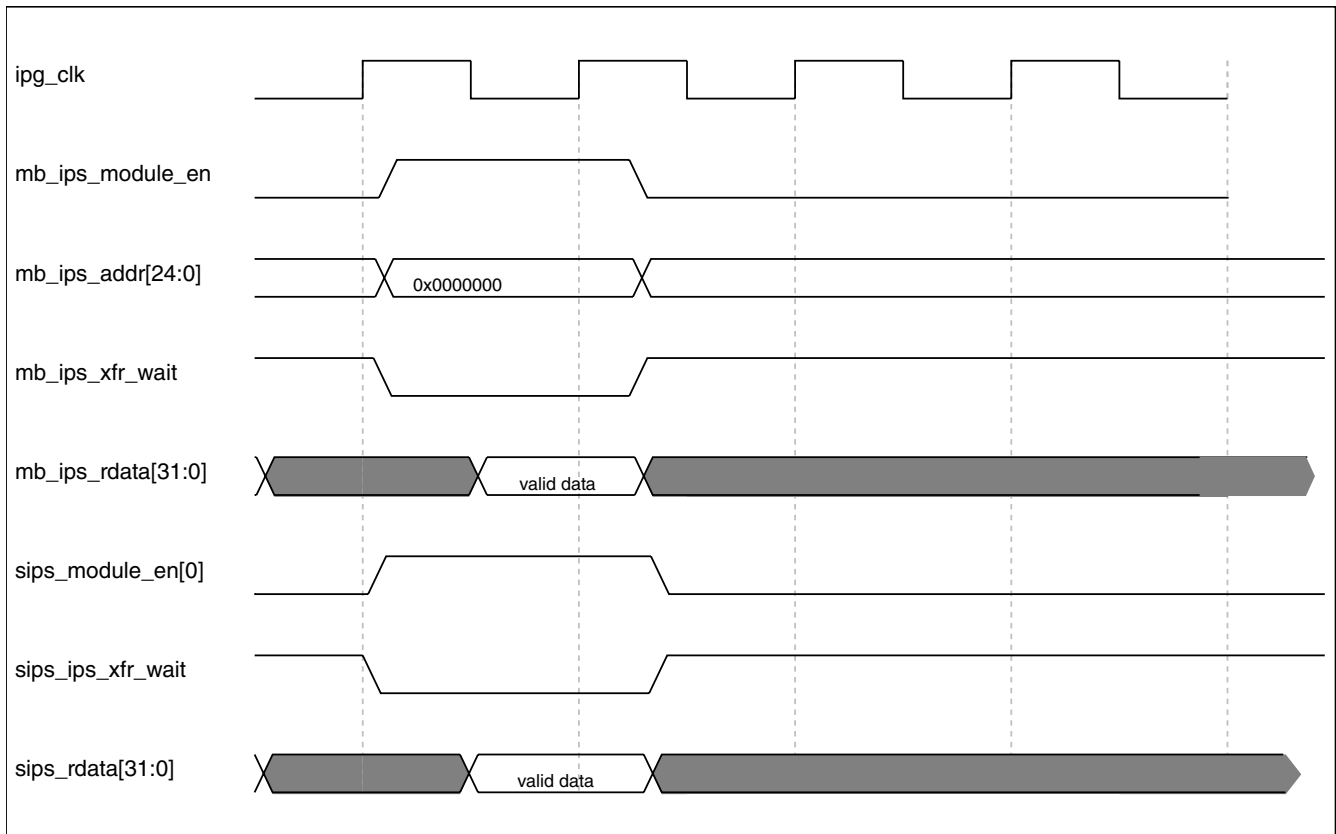

Figure 59-2. Example of one master request, no SPBA arbitration

The following figure assumes MA and MB have been the last two masters granted in the previous transfers (MA then MB).

Functional description

Figure 59-3. Example of three master requests: Masters already granted are "waited";

59.4 Resource ownership control

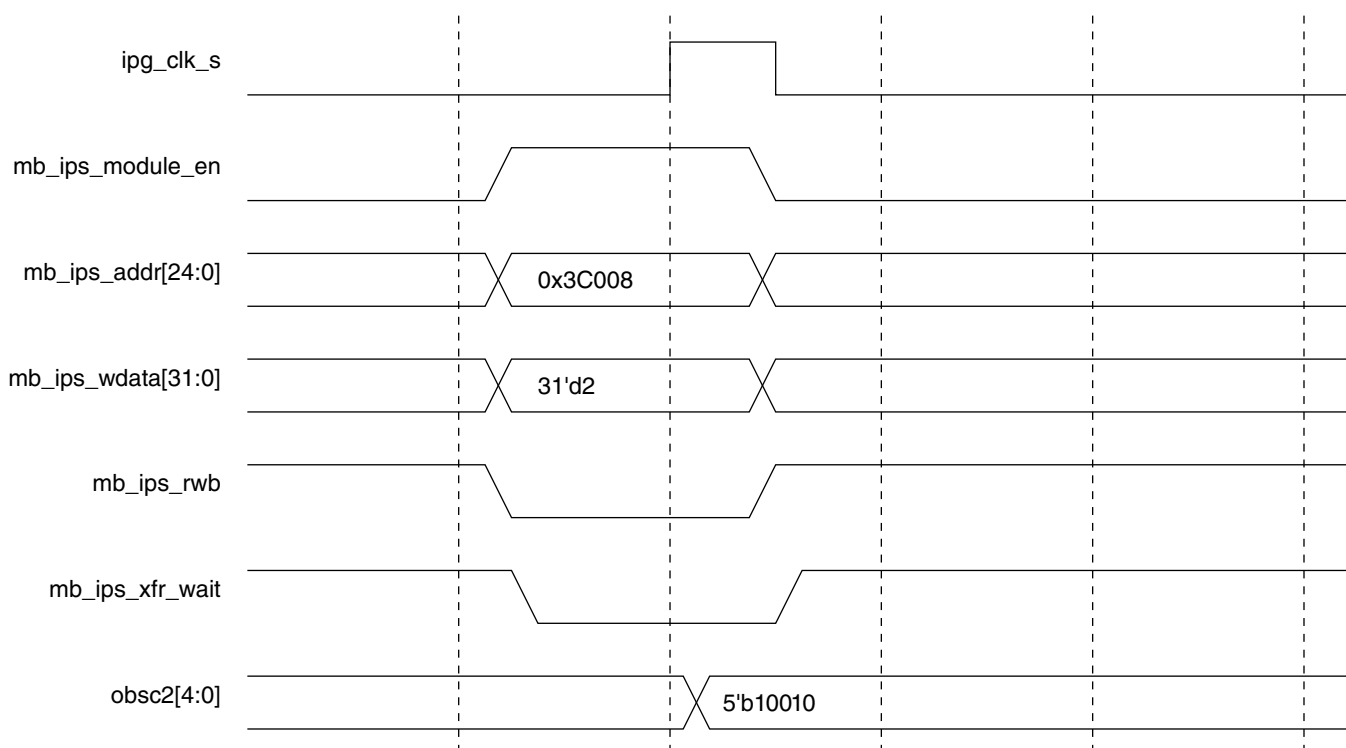

The resource ownership control regulates access to the shared peripherals and determines the steering of out-of-band signals. SPBA supports both master and domain ownerships.

59.4.1 Access control

59.4.1.1 Peripheral access

The peripheral access (resource access) of the requesting master is given by the corresponding RAR bit of the Peripheral Right Register. It determines if the master has access privilege to the resource.

Any attempt at access made by a requesting master whose access privilege bit is not set (in the PRR) is terminated with a bus error (<master>_ips_xfr_err is asserted by SPBA logic). The master that owns the resource can lock the peripheral for itself and/or grant other masters access to the peripheral by setting the appropriate bit(s) in the RAR field.

Master B is taking ownership of peripheral 2 by writing 3'b010 in the SPBA peripheral 2 right register (rarfield)
 This ownership can be checked on obsc2 output as roi2[1:0] = 2'b10 and rar2[2:0] = 3'b010
 (obsc[4:0] = {roi2[1], roi2[0], rar2[2], rar2[1], rar2[0]})

Figure 59-4. Example of one master B gaining ownership of peripheral 2

59.4.1.2 Peripheral Right Register access

The ROI bits of the Peripheral Right Register (PRR) determine which master is allowed to make write access to PRR. The identification of the requesting master is compared to the ROI bits of the PRR to determine if the master has ownership of the corresponding register.

Any attempted write access to a PRR already owned by another master will be ignored.

59.4.2 Owner election

When the peripheral is not owned by any master (ROI="00", after coming out of reset for instance), the first master to perform successfully a write to the RAR bits of the PRR is granted ownership of the peripheral and its associated PRR.

After writing to the PRR (RAR bit(s)), the master must read it back to make sure that it was granted ownership. If the RMO field is 2'b11, then the ownership claim is successful. If RMO is 2'b10, another master claimed ownership before this master was able to complete its write. This resolves the case in which two or more masters attempt to write the PRR at the same time; only the first master will be granted ownership. However all masters must read the PRR to determine if this case occurred, and if so, whether they were the first master which was granted ownership.

NOTE

A master that has been granted ownership of the PRR does not automatically have the right access to the peripheral; it must still set its own RAR bits in the PRR to access the peripheral.

59.4.3 Ending ownership

Ownership may be voluntarily ended by the owning master, or automatically upon assertion of a master-specific dead_owner signal.

The former is appropriate for software-controlled yielding of ownership. The latter is appropriate for automatic yielding of ownership when the owner has gone into reset.

When a master is reset, it clears the ROI bits of the PRRs owned by the corresponding master. When the owner is dead (in reset), all peripherals previously owned by that master must be changed to the un-owned state.

NOTE

It is the programmer's responsibility to make sure the peripherals are placed in an appropriate state before ending ownership.

59.4.3.1 Software Controlled Ownership Ending

The ROI bits will be automatically cleared when the master that owns the PRR access right clears (write) the RAR bits ([Table 2](#)).

It will then end the ownership of the PRR.

59.4.4 The Un-owned State

During the time when the peripheral is un-owned (i.e the ROI field contains all 0's), all masters have full access to it (RAR bits can then be modified by a master if ROI[1:0] = 2'b0).

In such cases it is necessary for software to ensure any necessary coherency in the resource, there is no hardware protection.

59.5 SPBA Memory Map/Register Definition

The SPBA control registers (Peripheral Right Registers) are mapped as a virtual shared peripheral.

SPBA can support up to 31 shared peripherals. Each of them has its own Peripheral Right Register (PRR) accessible within the SPBA memory-mapped registers, and consists of the Requesting Master Owner, the Resource Owner ID and the Resource Access Right fields.

SPBA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
0	Peripheral Rights Register (SPBA_PRR0)	32	R/W	0000_0007h	59.5.1/3910

59.5.1 Peripheral Rights Register (SPBA_PRRn)

This register controls master ownership and access for a peripheral.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

SPBA_PRRn field descriptions

Field	Description
31–30 RMO	Requesting Master Owner. This 2-bit register field indicates if the corresponding resource is owned by the requesting master or not. This register is reset to 2'b0 if ROI = 2'b0. 00 UNOWNED — The resource is unowned. 01 Reserved. 10 ANOTHER_MASTER — The resource is owned by another master. 11 REQUESTING_MASTER — The resource is owned by the requesting master.
29–18 -	This field is reserved. Reserved
17–16 ROI	Resource Owner ID. This field indicates which master (one at a time) can access to the PRR for rights modification. This is a read-only register. After reset, ROI bits are cleared ("00" -> un-owned resource).

Table continues on the next page...

SPBA_PRR_n field descriptions (continued)

Field	Description
	<p>A master performing a write access to the an un-owned PRR will get its ID automatically written into ROI, while modifying RARx bits. It can then read back the RMO, RAR, ROI bits to make sure RMO returns the right value, ROI bits contain its ID and RARx bits are correctly asserted. Then no other master (whom ID is different from the one stored in ROI) will be able to modify RAR fields.</p> <p>Owner master of a peripheral can assert its dead_owner signal, or write 1'b0 in the RARx to release the ownership (ROI[1:0] reset to 2'b0).</p> <p>00 UNOWNED — Unowned resource. 01 MASTER_A — The resource is owned by master A port. 10 MASTER_B — The resource is owned by master B port. 11 MASTER_C — The resource is owned by master C port.</p>
15–3 -	This field is reserved. Reserved
2 RARC	<p>Resource Access Right. Control and Status bit for master C.</p> <p>This field indicates whether master C can access the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA).</p> <p>0 PROHIBITED — Access to peripheral is not allowed. 1 ALLOWED — Access to peripheral is granted.</p>
1 RARB	<p>Resource Access Right. Control and Status bit for master B.</p> <p>This field indicates whether master B can access the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA).</p> <p>0 PROHIBITED — Access to peripheral is not allowed. 1 ALLOWED — Access to peripheral is granted.</p>
0 RARA	<p>Resource Access Right. Control and Status bit for master A.</p> <p>This field indicates whether master A can access the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA).</p> <p>0 PROHIBITED — Access to peripheral is not allowed. 1 ALLOWED — Access to peripheral is granted.</p>

Chapter 60

Sony/Philips Digital Interface (SPDIF)

60.1 Introduction

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal and external components in the system such as ESAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

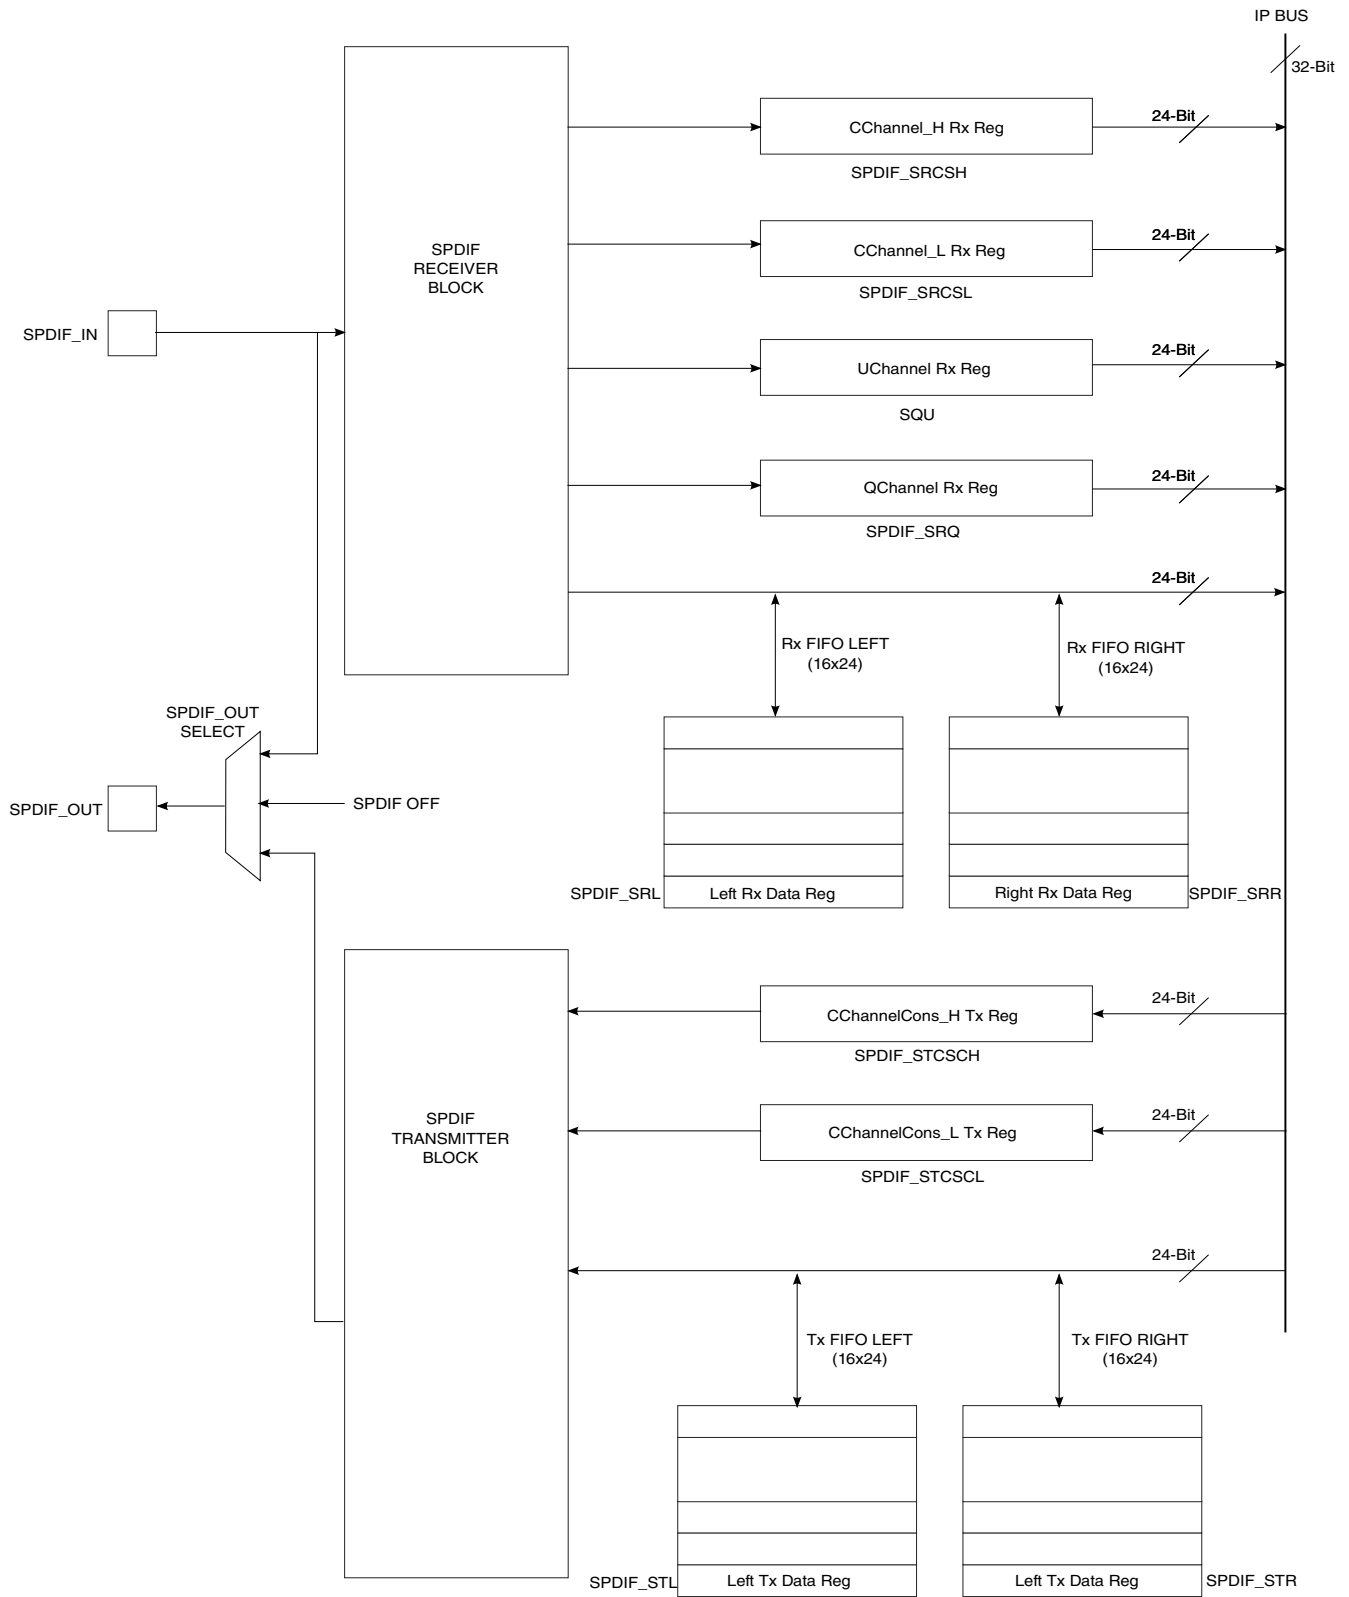

Figure 60-1. SPDIF Transceiver Data Interface Block Diagram

60.1.1 Overview

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphasemark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphasemark bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. Both the Rx clock and Tx clock are sent to the ASRC. [Figure 60-2](#) shows the clock structure of the SPDIF transceiver.

Figure 60-2. SPDIF Transceiver Clock Diagram

60.2 External Signals

60.3 Clocks

The table found here describes the clock sources for SPDIF.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 60-2. SPDIF Clocks

Clock name	Clock Root	Description
gclkw_t0	ipg_clk_root	Global clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
tx_clk	spdif0_clk_root	Module Tx clock

60.4 Functional Description

60.4.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception see [Audio Data Reception](#)
- Channel Status bits Reception see [Channel Status Reception](#)
- U Channel bits Reception see [User Bit Reception](#)
- Validity Flag Reception see [Validity Flag Reception](#)
- SPDIF Receiver Exception support see [SPDIF Receiver](#)
- SPDIF Lock Detection

60.4.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

Figure 60-3. FIFO Auto-resync Controller State Machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right

sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

60.4.1.1.1 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules: 1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 KHz, approximately 10 micro-seconds. For 88 KHz, approximately 5 micro-seconds.) 2. Write/read data to FIFO s at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

- **SPDIF receiver - Additional features**

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

Rx FIFO on and Rx FIFO reset.

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

60.4.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCChannel_l.

60.4.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

60.4.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver.**

This mode is selected if USyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 60-3. Sync Control Bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated. Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q

channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.

- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.
- **Behavior of U Channel receive interface on incoming non-CD data.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set '0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

60.4.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

60.4.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxCChannel_1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.¹
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

1. The SPDIF input is a biphas/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

60.4.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 KHz up to 96 KHz. (fully compliant) and 96 KHz up to 176 KHz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

60.4.1.7 SPDIF PLOCK Detection and RxcIk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency. (For a 44.1 KHz input sampling frequency, the average pulse rate = 128 x 44.1 KHz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

60.4.1.8 Measuring Frequency of SPDIF_RxCIk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

$\text{FreqMeas}[23:0] = \text{FreqMeas_CLK} / \text{BUS_CLK} * 2^{10} * \text{GAIN}$.

For example, if the GAIN is selected as $8 * (2^{10})$ ($\text{PhaseConfig}[5:3] = 3'b011$), the actual result

$\text{FreqMeas_CLK} / \text{BUS_CLK}$ is equal to $\text{FreqMeas}[23:0] / 2^{23}$.

60.4.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is selected through a multiplexer from several clock sources (see [TxClk_Source](#) for clock source inputs). The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphasic mark format, consisting of audio data, channel status.

60.4.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See [Audio Data Reception](#).

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

60.4.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCCchannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCCchannelCons_l.

60.4.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF_SCR register.

60.5 SPDIF Memory Map/Register Definition

SPDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

7 QRxOv	Q Channel receive register overrun
6 UQSync	U/Q Channel sync found
5 UQErr	U/Q Channel framing error
4 RxFIFOUnOv	Rx FIFO underrun/overrun
3 RxFIFOResyn	Rx FIFO resync
2 LockLoss	SPDIF receiver loss of lock
-	This field is reserved. Reserved.

60.5.7 SPDIFRxLeft Register (SPDIF_SRL)

SPDIFRxLeft register is an audio data reception register.

Address: 200_4000h base + 14h offset = 200_4014h

SPDIF_SRL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataLeft	Processor receive SPDIF data left

60.5.8 SPDIFRxRight Register (SPDIF_SRR)

SPDIFRxRight register is an audio data reception register.

Address: 200_4000h base + 18h offset = 200_4018h

SPDIF_SRR field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxDataRight	Processor receive SPDIF data right

60.5.9 SPDIFRxChannel_h Register (SPDIF_SRC SH)

SPDIFRxChannel_h register is a channel status reception register.

Address: 200_4000h base + 1Ch offset = 200_401Ch

SPDIF_SRCSH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxCChannel_h	SPDIF receive C channel register, contains first 24 bits of C channel without interpretation

60.5.10 SPDIFRxChannel_I Register (SPDIF_SRCSL)

SPDIFRxChannel_I register is a channel status reception register.

Address: 200_4000h base + 20h offset = 200_4020h

SPDIF_SRCSL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxCChannel_I	SPDIF receive C channel register, contains next 24 bits of C channel without interpretation

60.5.11 UchannelRx Register (SPDIF_SRU)

UchannelRx register is a user bits reception register.

Address: 200_4000h base + 24h offset = 200_4024h

SPDIF_SRU field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
RxUChannel	SPDIF receive U channel register, contains next 3 U channel bytes

60.5.12 QchannelRx Register (SPDIF_SRQ)

QChannelRx register is a user bits reception register.

Address: 200_4000h base + 28h offset = 200_4028h

SPDIF_SRQ field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
RxQChannel	SPDIF receive Q channel register, contains next 3 Q channel bytes

60.5.13 SPDIFTxLeft Register (SPDIF_STL)

SPDIFTxLeft register is an audio data transmission register.

Address: 200_4000h base + 2Ch offset = 200_402Ch

SPDIF_STL field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataLeft	SPDIF transmit left channel data. It is write-only, and always returns zeros when read

60.5.14 SPDIFTxRight Register (SPDIF_STR)

SPDIFTxRight register is an audio data transmission register.

Address: 200_4000h base + 30h offset = 200_4030h

SPDIF_STR field descriptions

Field	Description
31–24 [unimplemented]	This field is reserved. This is a 24-bit register the upper byte is unimplemented.
TxDataRight	SPDIF transmit right channel data. It is write-only, and always returns zeros when read

60.5.15 SPDIFTxCChannelCons_h Register (SPDIF_STCSCH)

SPDIFTxCChannelCons_h register is a channel status transmission register.

Address: 200_4000h base + 34h offset = 200_4034h

SPDIF_STCSCH field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.

Table continues on the next page...

SPDIF_STCSCH field descriptions (continued)

Field	Description
TxCChannelCons_h	SPDIF transmit Cons. C channel data, contains first 24 bits without interpretation. When read, it returns the latest data written by the processor

60.5.16 SPDIFTxChannelCons_I Register (SPDIF_STCSCL)

SPDIFTxChannelCons_I register is a channel status transmission register.

Address: 200_4000h base + 38h offset = 200_4038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved									TxChannelCons_I																						
W	Reserved									TxChannelCons_I																						
Reset	0 0 0 0 0 0 0 0 0									0 0																						

SPDIF_STCSCL field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
TxCChannelCons_I	SPDIF transmit Cons. C channel data, contains next 24 bits without interpretation. When read, it returns the latest data written by the processor

60.5.17 FreqMeas Register (SPDIF_SRFM)

Address: 200_4000h base + 44h offset = 200_4044h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved									FreqMeas																						
W	Reserved									FreqMeas																						
Reset	0 0 0 0 0 0 0 0 0									0 0																						

SPDIF_SRFM field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
FreqMeas	Frequency measurement data

60.5.18 SPDIFTxClk Register (SPDIF_STC)

The SPDIFTxClk Control register includes the means to select the transmit clock and frequency division.

Address: 200_4000h base + 50h offset = 200_4050h

SPDIF_STC field descriptions

Field	Description
31–24 [unimplemented]	This is a 24-bit register the upper byte is unimplemented. This field is reserved.
23–20 Reserved	This read-only field is reserved and always has the value 0.
19–11 SYSCLK_DF	system clock divider factor, 2~512. 0 no clock signal 1 divider factor is 2 511 divider factor is 512
10–8 TxClk_Source	000 REF_CLK_32K input (XTALOSC 32kHz clock) 001 tx_clk input (from SPDIF0_CLK_ROOT. See CCM.) 010 ASRC_EXT_CLK input 011 SPDIF_EXT_CLK, from pads 100 ESAI_HCKT input 101 ipg_clk input (frequency divided) 110 MLB clock input 111 MLB PHY clock input
7 tx_all_clk_en	Spdif transfer clock enable. When data is going to be transferred, this bit should be set to 1.

Table continues on the next page...

SPDIF_STC field descriptions (continued)

Field	Description
	0 disable transfer clock. 1 enable transfer clock.
TxClk_DF	Divider factor (1-128) 0 divider factor is 1 1 divider factor is 2 127 divider factor is 128

Chapter 61

System Reset Controller (SRC)

61.1 SRC Overview

The System Reset Controller (SRC) controls the reset and boot operation of the SoC.

It is responsible for the generation of all reset signals and boot decoding.

The reset controller determines the source and the type of reset, such as POR, WARM, COLD, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire IC. Whenever the chip is powered on, the reset is issued through SRC_ONOFF signal and the entire chip is reset.

61.1.1 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Resets the appropriate domains based upon the resets sources and the nature of the reset
- Latches the SRC_BOOT_MODE pins and common configuration signals from the internal fuse

61.2 External Signals

The table found here describes the external signals of SRC.

The following table describes the external signals of SRC:

Table 61-1. SRC External Signals

Signal	Description	Pad	Mode	Direction
SRC_BOOT_CFG00	Boot configuration signal	LCD1_DATA00	ALT6	IO
SRC_BOOT_CFG01	Boot configuration signal	LCD1_DATA01	ALT6	IO
SRC_BOOT_CFG02	Boot configuration signal	LCD1_DATA02	ALT6	IO
SRC_BOOT_CFG03	Boot configuration signal	LCD1_DATA03	ALT6	IO
SRC_BOOT_CFG04	Boot configuration signal	LCD1_DATA04	ALT6	IO
SRC_BOOT_CFG05	Boot configuration signal	LCD1_DATA05	ALT6	IO
SRC_BOOT_CFG06	Boot configuration signal	LCD1_DATA06	ALT6	IO
SRC_BOOT_CFG07	Boot configuration signal	LCD1_DATA07	ALT6	IO
SRC_BOOT_CFG08	Boot configuration signal	LCD1_DATA08	ALT6	IO
SRC_BOOT_CFG09	Boot configuration signal	LCD1_DATA09	ALT6	IO
SRC_BOOT_CFG10	Boot configuration signal	LCD1_DATA10	ALT6	IO
SRC_BOOT_CFG11	Boot configuration signal	LCD1_DATA11	ALT6	IO

Alarm timer is set up by software routine and started.

Table continues on the next page...

Table 61-3. Power mode transitions (continued)

Power mode	Configuration with external PMIC	Configuration with internal PMIC
	<ol style="list-style-type: none"> SoC is programming PMIC for power off when standby is asserted. In CCM STOP mode, Standby is asserted, PMIC gates SoC supplies. 	<ol style="list-style-type: none"> Upon alarm_in assertion to '1', PMIC_ON_REQ goes '0'. External regulator goes OFF.
Emergency ON to OFF, by button	<ol style="list-style-type: none"> Button is pressed for an extended time on the external PMIC. PMIC is powering off. 	<ol style="list-style-type: none"> Button is pressed for longer than 5 seconds on the SoC. FSM validates button pressed for 5 seconds. Emergency power off is logged, PMIC_ON_REQ goes '0', alarm_mask goes '1'. External regulator goes OFF.
OFF to ON, by button	<ol style="list-style-type: none"> Button is pressed on the external PMIC. PMIC powers ON. 	<ol style="list-style-type: none"> Button is pressed on the SoC. PMIC_ON_REQ goes '1', alarm_mask goes '0'. External regulator powers ON.
OFF to ON, by timer alarm	<ol style="list-style-type: none"> Timer alarm in SNVS is programmed by software before SoC goes OFF. SoC enters OFF mode. Upon timer limit, wake up alarm goes '0'. PMIC_ON_REQ goes '1'. PMIC receives assertion of PMIC_ON_REQ and wakes up. 	<ol style="list-style-type: none"> Timer alarm in SNVS is programmed by software before SoC goes OFF. SoC enters OFF mode. Upon timer limit, wake up alarm goes '0'. PMIC_ON_REQ goes '1'. External regulator is enabled by PMIC_ON_REQ = 1.

61.5 Power-On Reset and power sequencing

This module generates an internal POR_B signal that is logically AND'ed with any externally applied SRC_POR_B signal. The internal POR_B signal will be held low until all of the following conditions are met:

- 4ms after the external power supply VDDHIGH_IN is valid
- 1ms after the VDD_SOC_CAP supply is valid

The 4ms and 1ms delays are derived from counting the 32kHz RTC clock cycles; the accuracy depends on the accuracy of the RTC. When the RTC crystal is either absent or in the process of powering up, an internal ring oscillator will be the source of RTC, which is not as accurate as the crystal.

61.5.1 External POR using SRC_POR_B

If the external SRC_POR_B signal is used to control the processor POR, SRC_POR_B must remain low (asserted) until the VDD_ARM_CAP and VDD_SOC_CAP supplies are stable.

61.5.2 Internal POR

If the external SRC_POR_B signal is not used (always held high or left unconnected), the processor defaults to the internal POR function (PMU controls generation of the POR based on the power supplies).

If the internal POR function is used, the following power supply requirements must be met:

- VDD_ARM_IN and VDD_SOC_IN may be supplied from the same source, or
- VDD_SOC_IN can be supplied before VDD_ARM_IN with a maximum delay of 1 ms.

61.6 Functional Description

61.6.1 Reset Control

This section details the reset control of this device.

61.6.1.1 Reset inputs and outputs

The reset control logic receives reset requests from all potential reset sources. All the immediate sources of reset are directly passed to the reset stretching block, whereas the resets requiring qualification are passed on to the reset qualification logic before they are sent to the reset stretching block.

All reset inputs and outputs are described in the following figure:

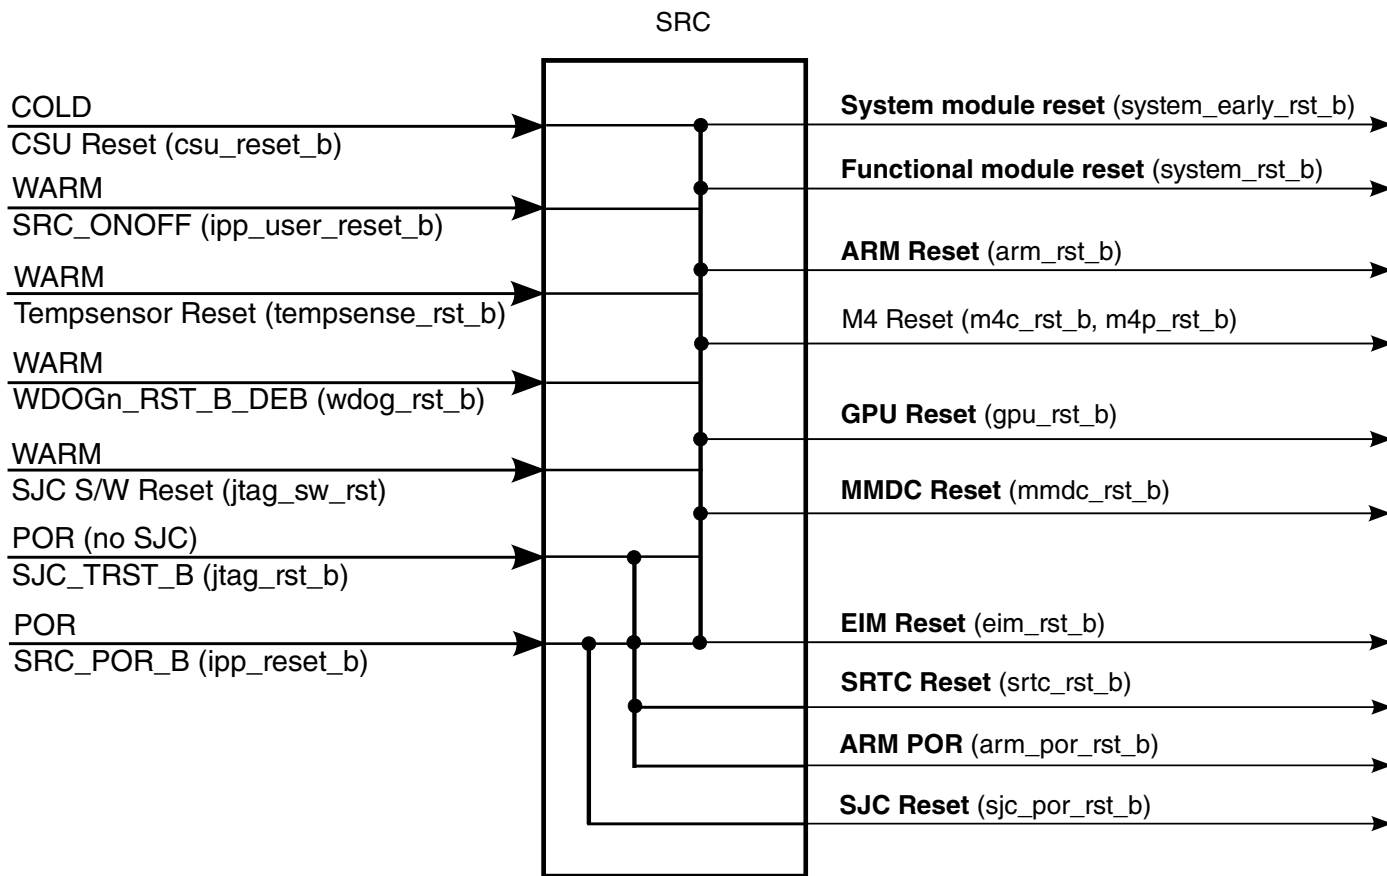

Figure 61-5. SRC inputs and outputs

The reset types and modules they affect are shown in Table 61-4. As there is no chip POR, the POR_B is used to reset the entire chip including test logic and JTAG modules.

NOTE

All resets are expected to be active low except jtag_sw_rst.

Table 61-4. SRC reset functionality

SoC Modules	POR	COLD	WARM
System modules (PLLs, fuses, etc)	yes	yes	yes
Functional modules	yes	yes	yes
ARM	yes	yes	yes
ARM SoC	yes	yes	yes
M4 Core	yes	yes	yes
M4 Platform	yes	yes	yes
GPU	yes	yes	yes
MMDC	yes	yes	yes
ARM POR	yes	no	no
ARM debug	yes	no	no

Table continues on the next page...

Table 61-4. SRC reset functionality (continued)

SoC Modules	POR	COLD	WARM
SJC	yes	no	no
SRTC	yes	no	no

The reset priorities are POR (strongest), COLD and WARM (weakest). If a stronger reset is asserted during the sequence of a weaker reset, then the weaker sequence will be overridden, and the stronger reset sequence will commence. There is no priority within a reset type (POR, etc). If a reset is asserted during the reset sequence of the same type, the reset sequence will be interrupted and restarted.

The following lists the functionality of each of these reset outputs:

- `system_early_rst_b` - Resets the system modules that need to start first as CCM, OCOTP_CTRL, FUSEBOX, MMDC, etc.
- `system_rst_b` - Resets functional modules
- `arm_rst_b` - Resets ARM module (on regular system reset)
- `gpu_rst_b` - Resets GPU module (on regular system reset)
- `mmdc_rst_b` - Resets MMDC
- `arm_por_rst_b` - Resets ARM por input
- `arm_soc_rst_b` - Reset for ARM SOC
- `m4c_rst_b` - Reset for M4 core
- `m4p_rst_b` - Reset for M4 platform
- `arm_dbg_rst_b` - Reset debug logic of ARM
- `test_logic_rst_b` - Reset test logic (IOMUXC, DAP)
- `sjc_por_rst_b` - Reset to SJC
- `srtc_rst_b` - Resets SRTC

NOTE

It is assumed that each reset source will deassert after its assertion, either due to reset generated to the system from SRC, or by negation of the reset source (if it came from an external source to the chip). In the latter case, the reset source is assumed to be held for at least 2 XTALI clocks so it can be sampled by SRC.

61.6.1.2 Reset Handling

61.6.1.2.1 Reset Qualification

The reset qualification logic qualifies the reset source before sending it out to the chip as a valid reset. WARM resets are in this category. All remaining reset sources are immediate resets and are acknowledged by the reset circuitry the moment they are asserted.

WARM resets are not immediate resets. WARM resets do reset the CCM, the source of MMDC clock. So, if a WARM reset were to immediately reset the CCM, then the MMDC clock would be shut off and this may cause the MMDC data to be lost. During normal mode of operation of the chip, the protocol that is followed before shutting off the MMDC clock is that an `mmdc_dvfs_req` signal is sent to MMDC and only after the MMDC sends an acknowledge signal, `mmdc_dvfs_ack`, is the clock to the MMDC gated off.

However, the implication here is that a valid WARM reset source condition will not be able to cause a chip reset until the MMDC sends the acknowledge signal (`mmdc_dvfs_ack`). For example, a JTAG reset event has occurred but the JTAG reset will not be serviced until the `mmdc_dvfs_ack` signal is received. So, essentially all WARM reset sources depend on the MMDC providing the `mmdc_dvfs_ack` acknowledge signal before the reset is performed. When the MMDC is not used, `mmdc_dvfs_ack` is defaulted high.

The occurrence of WARM reset results in the assertion of `warm_reset` signal before the system resets are asserted to indicate to the MMDC that the reset occurred is a WARM reset.

A reset source is updated in the Reset Status Register (`SRC_SRSR`) when it becomes valid, provided it is asserted for the minimum amount of time after asserting. So, all immediate resets are immediately updated in the Status Register (`SRC_SRSR`). WARM resets would be updated when the `mmdc_dvfs_ack` signal is received from the MMDC.

Once the reset is qualified, depending on the source of the reset, internal resets are asserted appropriately.

61.6.1.2.2 Reset Sequence and De-Assertion

The `SRC_ONOFF` will assert immediately after any reset source is recognized (except for the case of WARM reset when MMDC needs to answer `mmdc_dvfs_ack` first). After all of the reset sources are released, the SRC will start the following set of events depending on the type of reset that occurred.

61.6.1.2.3 POR (SRC_POR_B)

SRC_POR_B is an external reset signal. When the chip is powered up, the reset signal is passed through the POR_B pin indicating power-up sequence. The SRC resets the entire chip including the JTAG (SJC) module. All SRC registers will be reset during the POR sequence.

As soon as SRC_POR_B occurs, all resets are asserted and the entire chip is reset by SRC. The SRC_POR_B is stretched for 2 XTALI cycles and the stretching sequence takes place after 2 XTALI clocks of POR_B pin deassertion.

The sjc_por_rst_b and src_rst_b signals are deasserted together with SRC_POR_B signal. Those outputs are also deasserted after the stretching of SRC_POR_B has deasserted.

Once the above resets deassert, system_early_rst_b reset is deasserted after 2 XTALI clocks. The system_early_rst_b is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

When the system root clocks are ready, the CCM will assert system_clk_ready signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation.

SRC then enables OCOTP_CTRL and fusebox clocks, so that fuses can be loaded to OCOTP_CTRL.

- SRC will prepare the boot information and then deassert mmdc_rst_b.
- SRC will wait 8 ipg clock cycles, and then SRC will enable MMDC clocks.
- SRC will wait 8 XTALI clocks to allow MMDC to generate fixed external clock to external memory SDRAM.
- SRC will enable GPU clocks.
- After 8 ipg cycles, SRC will disable GPU clocks.
- After 8 ipg cycles, resets to all modules will be de-asserted (system_rst_b, gpu_rst_b).
- After 8 ipg cycles, system clocks will be enabled (en_system_clk).

61.6.1.2.4 COLD RESET

The sequence is similar to SRC_POR_B except the memory repair operation is not performed.

Once the reset source deasserts, system_early_rst_b reset is deasserted after at least 2 XTALI clocks. The system_early_rst_b is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

Once the system root clocks are ready, the CCM will assert `system_clk_ready` signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation. See CCM for more information.

Once `system_clk_ready` arrives at the SRC, it will enable `OCOTP_CTRL` and fusebox clocks, so that fuses can be loaded to `OCOTP_CTRL`. `OCOTP_CTRL` will notify with `iim_ready_flag` once the fusebox loading finishes.

- SRC will prepare the boot information and then deassert `mmdc_rst_b`.
- SRC will wait 8 ipg clock cycles, and then SRC will enable MMDC clocks.
- SRC will wait 8 XTALI clocks to allow MMDC to generate fixed external clock to external memory SDRAM.
- SRC will enable GPU clocks so that reset will penetrate this module.
- After 8 ipg cycles, SRC will disable GPU clocks.
- After 8 ipg cycles resets to all modules will be deasserted (`system_rst_b`, `gpu_rst_b`).
- After 8 ipg cycles, system clocks will be enabled (`en_system_clk`).

61.6.1.2.5 WARM RESET

WARM reset will be enabled only if `SRC_SCR[warm_reset_enable]` bit is programmed. Otherwise, all WARM reset sources will generate a COLD reset. This bit will be reset only by a POR.

A WARM reset is similar to a COLD reset except that before the reset is sent, a signal to MMDC is asserted `mmdc_dvfs_req` (generates DVFS assertion to MMDC) to request to prepare MMDC to a WARM reset, finishing the transactions placing MMDC in self-refresh. Another signal will be asserted to MMDC (`warm_reset`) that will wrap the WARM reset sequence and will notify MMDC that a WARM reset is in process.

One of the sources of the WARM reset is `SRC_ONOFF`. If this is the case, it is qualified for 4 XTALI edges. The WARM reset is initiated immediately after 4 XTALI edges. The system does not come out of reset until the the `SRC_ONOFF` is released.

In case the handshake mechanism with MMDC is stuck, meaning that no `mmdc_dvfs_ack` is received, COLD reset will be generated after a number of XTALI clocks. The number of XTALI clocks is defined in register the `SRC_SCR[warm_rst_bypass_count]` bitfield (default of this bitfield is 16 XTALI counts.)

The following is a basic description of the WARM reset sequence:

1. ARM sets `SRC_SCR[warm_reset_enable]` bit to enable the WARM Reset functionality. If this bit is not set, all WARM reset sources will result in COLD reset.
2. Assertion of one of the WARM reset sources.
3. The reset source is qualified in the SRC.

4. If `mmdc_dvfs_ack` signal is low, then SRC triggers the MMDC to switch to self-refresh mode using `mmdc_dvfs_req` signal. This is done through the CCM to combine with the DVFS sent from the CCM in case of frequency change of MMDC.
5. Wait for `mmdc_dvfs_ack` signal from the MMDC. If no ack is received during `warm_rst_bypass_count` number of XTALI clocks, COLD reset will be generated.
6. Assert `warm_reset` signal to MMDC.
7. SRC asserts system resets

The deassertion sequence is exactly the same as in the Cold Reset except waiting for 8 XTALIs for MMDC to generate fixed external clock to external memory MMDC. This stage is not needed in WARM reset since MMDC is held in self-refresh in WARM reset and there is no need to reconfigure it when exiting WARM reset.

WARM BOOT

Software can save any needed information in the memory before initiating a WARM reset. In this case, software will set `SRC_SRSR[warm_boot]` bit before initiating WARM reset. After the system returns to run mode, the `warm_boot` bit will still be set, indicating the software that data was saved in memory and can be reused.

NOTE

`mmdc_dvfs_req` and acknowledge during WARM reset can be masked in the CCM by configuration of register `CCDR[17:16]`.

61.6.2 Parallel Reset Requests

SRC will follow the following rules in the case of parallel reset requests:

1. The order of strength of resets is POR - strongest, cold - medium, warm - weakest.
2. If a stronger reset is asserted during weaker reset sequence, then the stronger reset will take over and the stronger reset process will commence. The following cases fall into this category:
 - POR reset request in the middle of cold or warm reset process - the cold or warm reset process will be stopped and the POR sequence will start.
 - COLD reset request in the middle of warm reset process - the warm reset process will be stopped and the cold sequence will start.
3. If a weaker reset is asserted during stronger reset sequence, then the stronger reset sequence will continue without interference. If at the end of the stronger reset process the weaker request is still asserted then the weaker sequence will commence. The following cases fall into this category:

- COLD or WARM reset requests in the middle of POR reset process - the POR process will continue without interference.
 - WARM reset request in the middle of COLD reset process - the COLD process will continue without interference.
4. If a similar reset request is asserted during the process of reset handling, then the process of reset handling will start over (with the same process). The following cases fall into this category:
- POR reset request in the middle of POR reset process - the POR process will start over.
 - COLD reset request in the middle of COLD reset process - the COLD process will start over.

There is one exception to this category: WARM reset request in the middle of WARM reset process. In this case, the new WARM reset process cannot restart because MMDC is reset and there can't be a handshake with MMDC if it is reset. In this case the first WARM reset will continue, and only if the second WARM reset is still asserted after the first one has finished, the WARM sequence will start again.

61.6.3 Boot Mode Control

61.6.3.1 BOOT_MODE Pin Latching

The exact boot sequence is controlled by the values of the BOOT_MODE pins on this device.

The value of the BOOT_MODE pins will be latched after the OCOTP_CTRL asserts the fuse read completion flag. After latching, the values of the BOOT_MODE pins are used to determine the booting options of the core as described in the SRC_SBMRx registers.

The boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals. The gpio_bt_sel e-fuse defines the source to be used to derive the boot information. When gpio_bt_sel is set, e-fuses are used. When cleared, GPIO signals are used.

The boot information is provided in SRC_SBMR1 register. The figure below shows the selection of boot mode information.

NOTE

BOOT_MODE[1:0] inputs of SRC are connected to BOOT_MODE[1:0] pins.

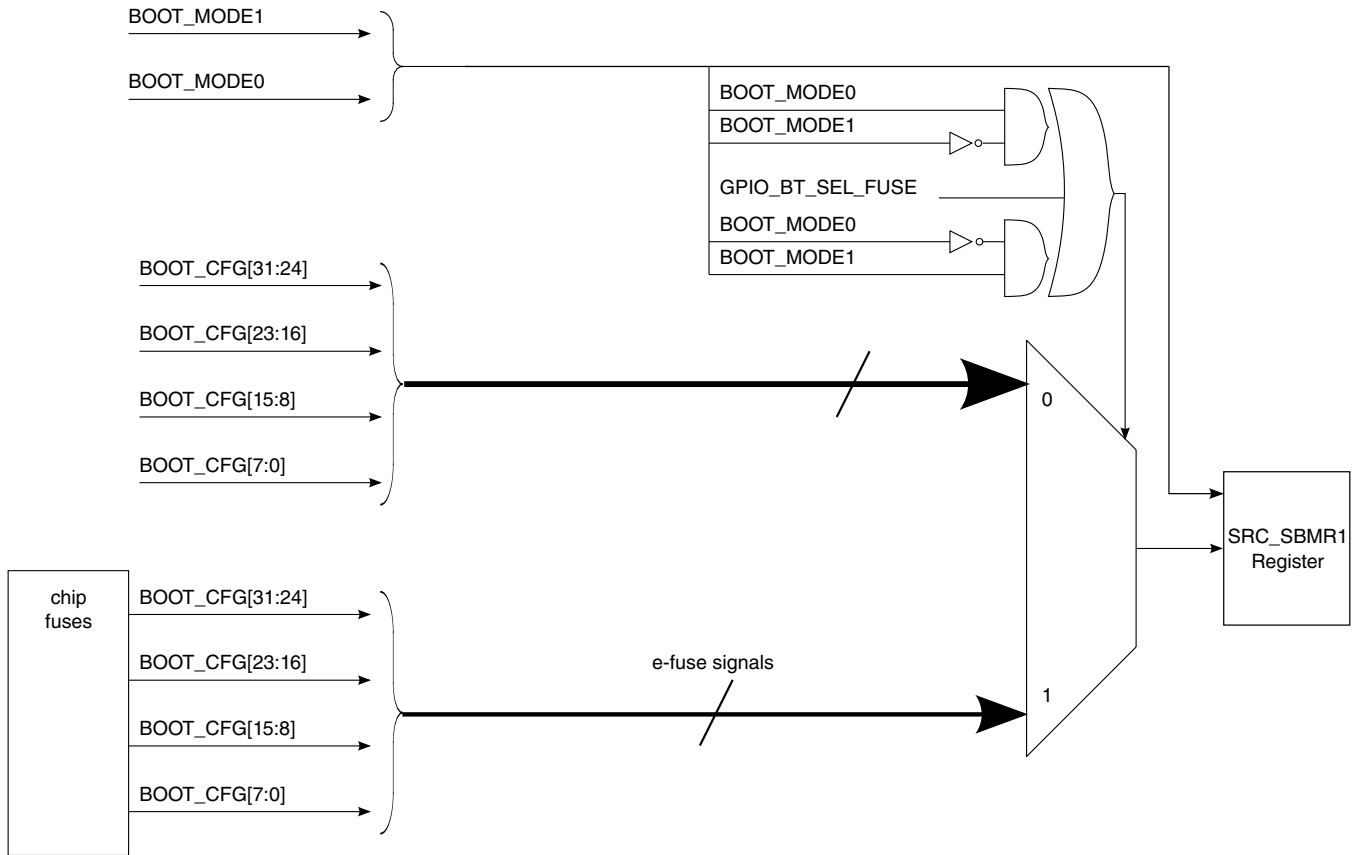

Figure 61-6. Boot mode information

SRC_SCR field descriptions

Field	Description
31–28 mask_wdog3_rst	<p>Mask wdog3_rst_b source. If these 4 bits are coded from A to 5 then, the wdog3_rst_b input to SRC will be masked and the wdog3_rst_b will not create a reset to the chip.</p> <p>NOTE: During the time the WDOG3 event is masked using SRC logic, it is likely that the WDOG3 Reset Status Register (WRSR) bit 1 (which indicates a WDOG3 timeout event) will get asserted. Software / OS developer must prepare for this case. Re-enabling the WDOG3 is possible, by unmasking it in SRC, though it must be preceded by servicing the WDOG3. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG3 module.</p> <p>NOTE: Hardware reset is the only way to cause the de-assertion of that bit. Any other code than 0101 will be coded to 1010 i.e. wdog3_rst_b is not masked</p> <p>0101 wdog3_rst_b is masked 1010 wdog3_rst_b is not masked</p>

Table continues on the next page...

SRC_SCR field descriptions (continued)

Field	Description
27–26 mix_rst_strch	SoC mix (Audio, ENET, uSDHC, EIM, QSPI, OCRAM, MMDC, etc) power up reset stretch mix reset width = (mix_rst_strch +1)* 88 ipg_clk cycles 00 mix reset width is 88 ipg_cycle cycles 01 mix reset width is 2 * 88 ipg_cycle cycles 10 mix reset width is 3 * 88 ipg_cycle cycles 11 mix reset width is 4 * 88 ipg_cycle cycles
25 dbg_rst_msk_pg	Do not assert debug resets after power gating event of core 0 do not mask core debug resets (debug resets will be asserted after power gating event) 1 mask core debug resets (debug resets won't be asserted after power gating event)
24 wdog3_rst_optn	Wdog3_rst_b option 0 Wdog3_rst_b asserts M4 reset (default) 1 Wdog3_rst_b asserts global reset
23 wdog3_rst_optn_m4	wdog3_rst_b option for M4. This bit is only effective when wdog3_rst_option is set to 1. 0 wdgo3_rst_b Reset M4 core only (default) 1 Reset both M4 core and platform
22 m4_enable	Enable M4 core 0 M4 is disabled 1 M4 is enabled
21 cores_dbg_rst	Software reset for debug of arm platform only. NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. 0 do not assert arm platform debug reset 1 assert arm platform debug reset
20–18 mask_tempsense_reset	Mask tempsense_reset source. If these 3 bits are coded from 1 to 5 then, the tempsense_reset input to SRC will be masked and the tempsense_reset will not create a reset to the chip. NOTE: Hardware reset is the only way to cause the de-assertion of that bit. Any other code than 101 will be coded to 010 (i.e. tempsense_reset is not masked) 010 tempsense_reset is not masked (default) 101 tempsense_reset is masked
17 core0_dbg_rst	Software reset for core0 debug only. NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. 0 do not assert core0 debug reset 1 assert core0 debug reset
16–15 Reserved	This read-only field is reserved and always has the value 0.
14 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SRC_SCR field descriptions (continued)

Field	Description
13 core0_rst	Software reset for core0 only. NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. 0 do not assert core0 reset 1 assert core0 reset
12 m4p_rst	Self-clearing SW reset for M4 platform NOTE: This bit is a self-clearing reset. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self-cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SRC_SISR register for details. 0 Do not assert M4 platform reset 1 Assert M4 platform reset
11 eim_rst	EIM reset is needed in order to reconfigure the eim chip select. The software reset bit must de-asserted. The eim chip select configuration should be updated. The software bit must be re-asserted since this is not self-refresh.
10–7 mask_wdog_rst	Mask wdog_rst_b source. If these 4 bits are coded from A to 5 then, the wdog_rst_b input to SRC will be masked and the wdog_rst_b will not create a reset to the chip. NOTE: During the time the WDOG event is masked using SRC logic, it is likely that the WDOG Reset Status Register (WRSR) bit 1 (which indicates a WDOG timeout event) will get asserted. software / OS developer must prepare for this case. Re-enabling the WDOG is possible, by unmasking it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module. (Hardware reset is the only way to cause the de-assertion of that bit). any other code will be coded to 1010 i.e. wdog_rst_b is not masked 0101 wdog_rst_b is masked 1010 wdog_rst_b is not masked (default)
6–5 warm_rst_bypass_count	Defines the XTALI cycles to count before bypassing the MMDC acknowledge for WARM reset. If the MMDC acknowledge will not be asserted before this counter has elapsed, then a COLD reset will be initiated. 00 Counter not to be used - system will wait until MMDC acknowledge until it is asserted. 01 Wait 16 XTALI cycles before changing WARM reset to a COLD reset. 10 Wait 32 XTALI cycles before changing WARM reset to a COLD reset. 11 Wait 64 XTALI cycles before changing WARM reset to a COLD reset
4 m4c_non_sclr_rst	Non-self-clearing SW reset for M4 core 0 do not assert M4 core reset 1 assert M4 core reset
3 m4c_rst	Self-clearing SW reset for M4 core

Table continues on the next page...

SRC_SCR field descriptions (continued)

Field	Description
	<p>NOTE: This bit is a self-clearing reset. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SRC_SISR register for details.</p> <p>0 Do not assert M4 core reset 1 Assert M4 core reset</p>
2 -	This field is reserved. Reserved
1 sw_gpu_rst	<p>Software reset for GPU</p> <p>NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SRC_SISR register for details.</p> <p>NOTE: The reset process will involve 8 GPU cycles before negating the GPU reset, to allow reset assertion to propagate into GPU.</p> <p>0 do not assert GPU reset 1 assert GPU reset</p>
0 warm_reset_enable	<p>WARM reset enable bit. WARM reset will be enabled only if warm_reset_enable bit is set. Otherwise all WARM reset sources will generate COLD reset.</p> <p>0 WARM reset disabled 1 WARM reset enabled</p>

61.7.2 SRC Boot Mode Register 1 (SRC_SBMR1)

The Boot Mode register (SBMR) contains bits that reflect the status of Boot Mode Pins of the chip. The reset value is configuration dependent (depending on boot/fuses/IO pads).

Address: 20D_8000h base + 4h offset = 20D_8004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SRC_SBMR1 field descriptions

Field	Description
31–24 BOOT_ CFG4[7:0]	Refer to fusemap.
23–16 BOOT_ CFG3[7:0]	Refer to fusemap.
15–8 BOOT_ CFG2[7:0]	Refer to fusemap.
BOOT_ CFG1[7:0]	Refer to fusemap.

61.7.3 SRC Reset Status Register (SRC_SRSR)

The SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred. This register is reset on ipp_reset_b. This is a read-write register.

For bit[6-0] - writing zero does not have any effect. Writing one will clear the corresponding bit. The individual bits can be cleared by writing one to that bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

Address: 20D_8000h base + 8h offset = 20D_8008h

SRC_SRSR field descriptions

Field	Description
31–17 Reserved	This read-only field is reserved and always has the value 0.
16 warm_boot	<p>WARM boot indication shows that WARM boot was initiated by software. This indicates to the software that it saved the needed information in the memory before initiating the WARM reset. In this case, software will set this bit to '1', before initiating the WARM reset. The warm_boot bit should be used as indication only after a warm_reset sequence. Software should clear this bit after warm_reset to indicate that the next warm_reset is not performed with warm_boot. Please refer to Reset Sequence and De-Assertion for details on warm_reset.</p> <p>0 WARM boot process not initiated by software. 1 WARM boot initiated by software.</p>
15–9 Reserved	This read-only field is reserved and always has the value 0.
8 tempense_rst_b	<p>Temper Sensor software reset. Indicates whether the reset was the result of software reset from on-chip Temperature Sensor.</p> <p>0 Reset is not a result of software reset from Temperature Sensor. 1 Reset is a result of software reset from Temperature Sensor.</p>
7 wdog3_rst_b	<p>IC Watchdog3 Time-out reset. Indicates whether the reset was the result of the watchdog3 time-out event.</p> <p>0 Reset is not a result of the watchdog3 time-out event. 1 Reset is a result of the watchdog3 time-out event.</p>
6 jtag_sw_rst	<p>JTAG software reset. Indicates whether the reset was the result of software reset from JTAG.</p> <p>0 Reset is not a result of software reset from JTAG. 1 Reset is a result of software reset from JTAG.</p>
5 jtag_rst_b	<p>HIGH - Z JTAG reset. Indicates whether the reset was the result of HIGH-Z reset from JTAG.</p> <p>0 Reset is not a result of HIGH-Z reset from JTAG. 1 Reset is a result of HIGH-Z reset from JTAG.</p>
4 wdog_rst_b	<p>IC Watchdog Time-out reset. Indicates whether the reset was the result of the watchdog time-out event.</p>

Table continues on the next page...

SRC_SRSR field descriptions (continued)

Field	Description
	0 Reset is not a result of the watchdog time-out event. 1 Reset is a result of the watchdog time-out event.
3 ipp_user_reset_b	Indicates whether the reset was the result of the ipp_user_reset_b qualified reset. 0 Reset is not a result of the ipp_user_reset_b qualified as COLD reset event. 1 Reset is a result of the ipp_user_reset_b qualified as COLD reset event.
2 csu_reset_b	Indicates whether the reset was the result of the csu_reset_b input. NOTE: If case the csu_reset_b occurred during a WARM reset process, during the phase that ipg_clk is not available yet, then the occurrence of CSU reset will not be reflected in this bit. 0 Reset is not a result of the csu_reset_b event. 1 Reset is a result of the csu_reset_b event.
1 Reserved	This read-only field is reserved and always has the value 0.
0 ipp_reset_b	Indicates whether reset was the result of ipp_reset_b pin (Power-up sequence) 0 Reset is not a result of ipp_reset_b pin. 1 Reset is a result of ipp_reset_b pin.

61.7.4 SRC Interrupt Status Register (SRC_SISR)

Address: 20D_8000h base + 14h offset = 20D_8014h

SRC_SISR field descriptions

Field	Description
31–9 Reserved	This read-only field is reserved and always has the value 0.
8–6 Reserved	This read-only field is reserved and always has the value 0.
5 core0_wdog_rst_ req	WDOG reset request from core0. Read-only status bit.
4 m4p_passed_ reset	Interrupt generated to indicate that M4 platform passed software reset and is ready to be used 0 Interrupt generated not due to M4 platform passed reset 1 Interrupt generated due to M4 platform passed reset
3 open_vg_ passed_reset	Interrupt generated to indicate that open_vg passed software reset and is ready to be used 0 interrupt generated not due to open_vg passed reset 1 interrupt generated due to open_vg passed reset
2 m4c_passed_ reset	Interrupt generated to indicate that M4 core passed software reset and is ready to be used 0 Interrupt generated not due to M4 core passed reset 1 Interrupt generated due to M4 core passed reset
1 Reserved	This read-only field is reserved and always has the value 0.
0 gpu_passed_ reset	Interrupt generated to indicate that GPU passed software reset and is ready to be used 0 interrupt generated not due to GPU passed reset 1 interrupt generated due to GPU passed reset

61.7.5 SRC Interrupt Mask Register (SRC_SIMR)

Address: 20D_8000h base + 18h offset = 20D_8018h

SRC_SIMR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 -	This field is reserved. Reserved
3 mask_open_vg_ passed_reset	mask interrupt generation due to open_vg passed reset 0 do not mask interrupt due to open_vg passed reset - interrupt will be created 1 mask interrupt due to open_vg passed reset

61.7.16 SRC General Purpose Register 10 (SRC_GPR10)

Address: 20D_8000h base + 44h offset = 20D_8044h

SRC_GPR10 field descriptions

Field	Description
31–26 -	Read/write bits, for general purpose NOTE: Reset only by POR
25 -	This field is reserved. Reserved.
-	Read/write bits, for general purpose NOTE: Reset only by POR

Chapter 62

Synchronous Serial Interface (SSI)

62.1 Overview

This block guide presents the Synchronous Serial Interface (SSI), and discusses the architecture, the programming model, the operating modes, and initialization of SSI.

The SSI is a full-duplex, serial port that allows the chip to communicate with a variety of serial devices. These serial devices can be standard CODer-DECoder (CODECs), Digital Signal Processors (DSPs), microprocessors, peripherals, and popular industry audio codecs that implement the inter-IC sound bus standard (I2S) and Intel AC97 standard.

SSI is typically used to transfer samples in a periodic manner. The SSI consists of independent transmitter and receiver sections with independent clock generation and frame synchronization.

The [Figure 62-1](#) illustrates the organization of the SSI. It consists of control registers to set up the port, status register, separate transmit and receive circuits with FIFO registers, and separate serial clock and frame sync generation for the transmit and receive sections. The second set of Tx and Rx FIFOs, replicates the logic used for the first set of FIFOs.

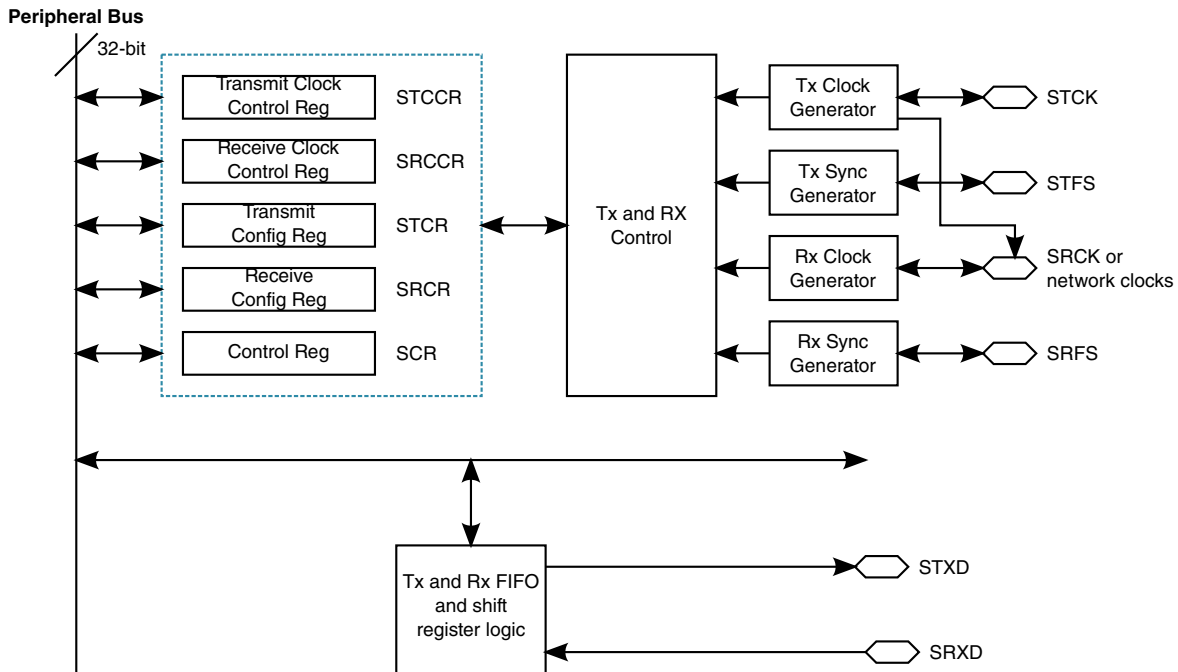

Figure 62-1. SSI Block Diagram

62.1.1 Features

The SSI includes the following features:

- Independent (asynchronous) or shared (synchronous) transmit and receive sections with separate or shared internal/external clocks and frame syncs, operating in Master or Slave mode.
- Normal mode operation using frame sync
- Network mode operation allowing multiple devices to share the port with as many as thirty-two time slots
- Gated Clock mode operation requiring no frame sync
- 2 sets of Transmit and Receive FIFOs. Each of the four FIFOs is 15x32 bits. The two sets of Tx/Rx FIFOs can be used in Network mode to provide 2 independent channels for transmission and reception (this mode is named as two-channel mode in the following descriptions)
- Programmable data interface modes such as I2S, LSB, MSB aligned
- Programmable word length (8, 10, 12, 16, 18, 20, 22 or 24 bits)
- Program options for frame sync and clock generation
- Programmable I2S modes (Master, Slave or Normal). Maximum audio sampling rate is 196kHz. (Note that maximum sampling rate depends on IPG frequency.) Minimum audio sampling rate is 8kHz. Network clock (as an oversampling clock to external device) available as output from SRCK in I2S Master mode

- AC97 support. Max frame rate is 48kHz. Min frame rate is 8kHz.
- Completely separate clock and frame sync selections for the receive and transmit sections. In AC97 standard, the clock is taken from an external source and frame sync is generated internally.
- SSI's system clock (generated inside CCM) can be used in I2S Transmitter Master mode. This system clock is also available as source clock for output SRCK in master mode, when operated in sync mode.
- Programmable internal clock divider
- Time Slot Mask Registers for reduced ARM platform overhead (for both Tx and Rx)
- SSI power-down feature

62.1.2 Modes of Operation

SSI has the following basic operating modes.

- **Normal Mode** : Asynchronous protocol, Synchronous protocol
 - Normal Mode Transmit
 - Normal Mode Receive
- **Network Mode** : Asynchronous protocol, Synchronous protocol
 - Network Mode Transmit
 - Network Mode Receive
- **Gated Clock Mode** : Synchronous protocol only
- **I2S Mode**
- **AC97 Mode**
 - AC97 Fixed Mode (SSI.SACNT[1]=0)
 - AC97 Variable Mode (SSI.SACNT[1]=1)

62.2 External Signal Description

62.2.1 Signals Overview

The Synchronous Serial Interface (SSI) can be connected directly to the external pins or through the Digital Audio Multiplexer (AUDMUX). Refer to the AUDMUX chapter for programming details of the various multiplexing options.

Table 62-1. Off-Chip Block Signals

Name	I/O	Function	Reset State	Pull up
SRCK	I/O	Serial Receive Clock. SRCK can be used as either an input or an output. This clock signal is used by the receiver in asynchronous mode and is always continuous. During synchronous mode, the STCK port is used instead for clocking in data. In SSI synchronous modes, this port can be used as an output for the network clock (oversampling clock) . In I2S master mode, this signal can be used to output the network clock to an external CODEC.	0	Passive
SRFS	I/O	Serial Receive Frame Sync. The SRFS port can be used as either an input or an output. The frame sync is used by the receiver to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur one bit before the transfer of data or right at the transfer of data. If SRFS is configured as an input, the external device should drive SRFS during the rising edge of STCK or SRCK.	0	Passive
SRXD	I	Serial Receive Data. The SRXD port is an input and is used to bring serial data into the Receive Data Shift Register.	-	-
STCK	I/O	Serial Transmit Clock. The STCK port can be used as either an input or an output. This clock signal is used by the transmitter and can be either continuous or gated. During Gated Clock mode, data on the STCK port is valid only during the transmission of data, otherwise it is pulled to the inactive state. In Synchronous mode, this port is used by both the transmit and receive sections.	0	Passive
STFS	I/O	Serial Transmit Frame Sync. The STFS port can be used as either an input or an output. The frame sync is used by the transmitter to synchronize the transfer of data. The frame sync signal can be one bit or one word in length and can occur one bit before the transfer of data or right at the transfer of data. In Synchronous mode, this port is used by both the transmit and receive sections. In Gated Clock mode, frame sync signals are not used. If STFS is configured as an input, the external device should drive STFS during the rising edge of STCK if TSCKP is positive edge triggered. The external device should drive STFS during the falling edge of STCK if TSCKP is negative edge triggered.	0	Passive
STXD	O	Serial Transmit Data. The STXD port is an output and transmits data from the Serial Transmit Shift Register. The STXD port is an output port when data is being transmitted and is disabled between data word transmissions and on the trailing edge of the bit clock after the last bit of a word is transmitted.	0	Passive

The following figure shows the main SSI configurations. These ports support all transmit and receive functions with continuous or gated clock as shown.

NOTE

Gated clock implementations do not require the use of the frame sync ports (STFS and SRFS).

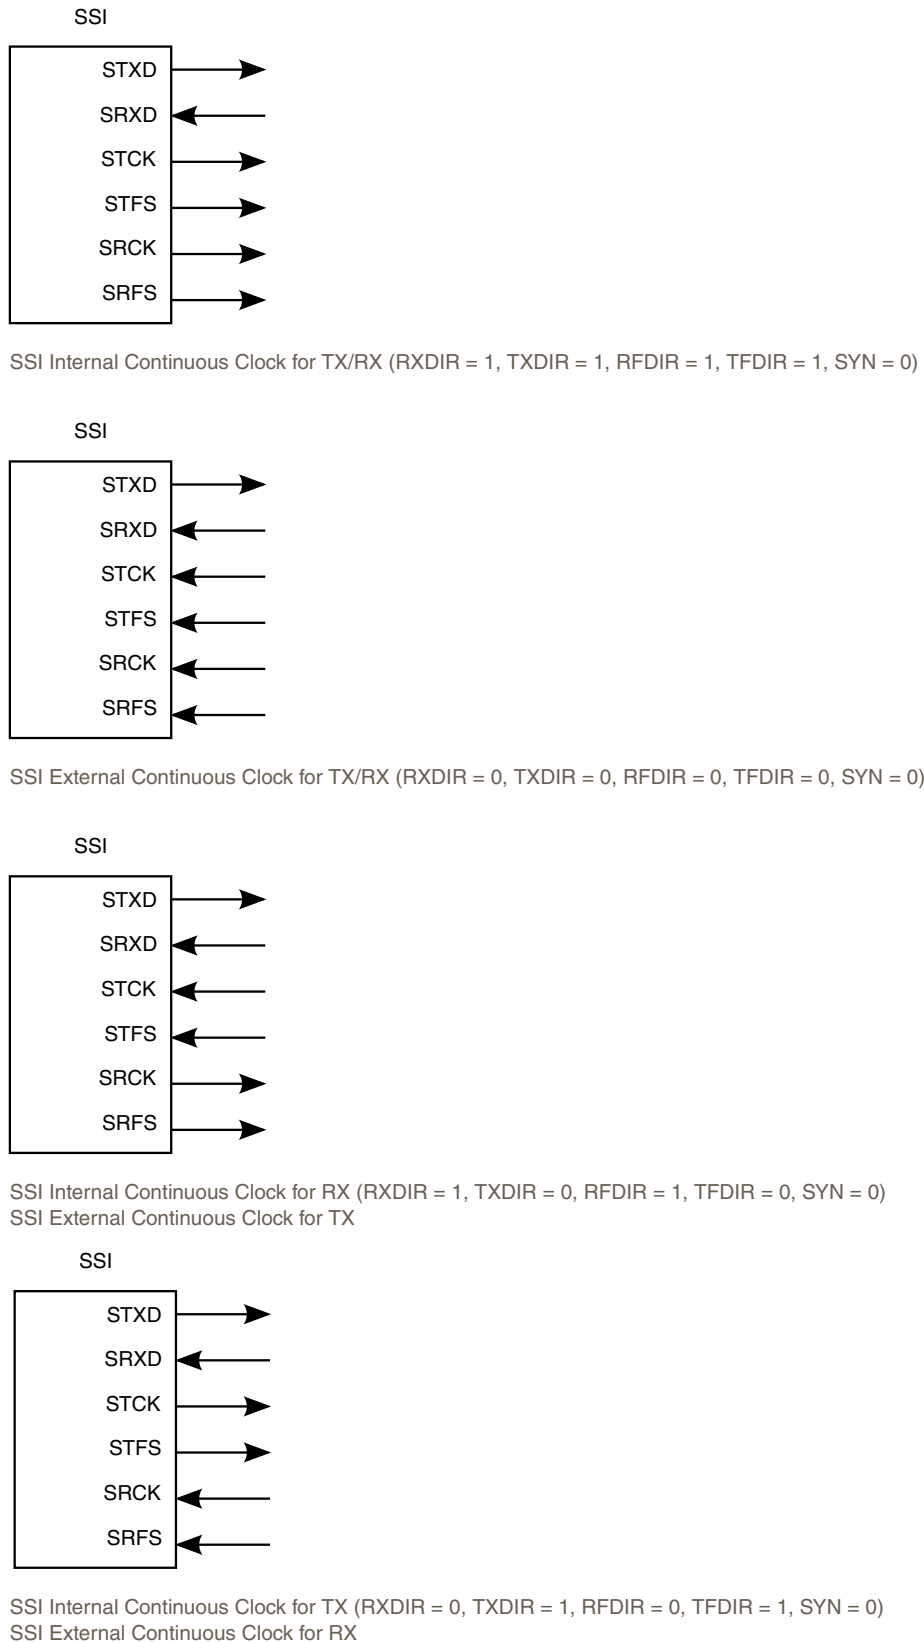

Figure 62-2. Asynchronous (SYN=0) SSI Configurations-Continuous Clock

External Signal Description

See the following figure for an example of the port signals for an 8-bit data transfer. Continuous and gated clock signals are shown, as well as the bit-length frame sync signal and the word-length frame sync signal.

Figure 62-3. Serial Clock and Frame Sync Timing

62.3 Clocks

The table found here describes the clock sources for SSI.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 62-3. SSI Clocks

Clock name	Clock Root	Description
ccm_ssi_clk	ssi_clk_root	Module / system clock for bit clock generation
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

62.4 SSI Transmit FIFO 0 & 1 Registers

The SSI Transmit FIFO registers are 15x32-bit registers. These registers are not directly accessible by the end user. Transmit Shift Register (TXSR) receives its values from these FIFO registers. Transmitted data is first-in-first-out.

When the Transmit Interrupt Enable (TIE) bit in the SIER and either of the Transmit FIFO Empty Enable (TFE0 or 1) bits in the SIER are set, an interrupt is asserted whenever the number of empty slots exceed or are equal to the selected threshold value of corresponding Tx-FIFO. The threshold value is contained in the corresponding Transmit FIFO Watermark (TFWM0 or 1) field in the SSI FIFO Control/Status Register (SFCSR).

62.5 SSI Transmit Shift Register (TXSR)

The SSI Transmit Shift Register (TXSR) is a 24-bit shift register that contains the data being transmitted.

This register is not directly accessible by the end user. When a continuous clock is used, data is shifted out to the Serial Transmit Data (STXD) port by the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted out to the STXD port by the selected (internal/external) gated clock. The Word Length control bits (WL[3:0]) in the SSI Transmit and Receive Clock Control Register (STCCR) determine the number of bits to be shifted out of the TXSR before it is considered empty and can be written to again. This word length can be 8, 10, 12, 16, 18, 20, 22 or 24 bits. The data to be transmitted occupies the most significant portion of the shift register if TXBIT0 is '0', otherwise it occupies the least significant portion. The unused portion of the register is ignored. Data is always shifted out of this register with the Most Significant Bit (MSB) first when the SHFD bit of the STCR is cleared. If this bit is set, the Least Significant Bit (LSB) is shifted out first. The figures below show the transmitter loading and shifting operation. The figures show the working for some WL values, the same can be extended for other values.

Figure 62-4. Transmit Data Path (TXBIT0=0, TSHFD=0) (MSB Alignment)

Figure 62-5. Transmit Data Path (TXBIT0=0, TSHFD=1) (MSB Alignment)

Figure 62-6. Transmit Data Path (TXBIT0=1, TSHFD=0) (LSB Alignment)

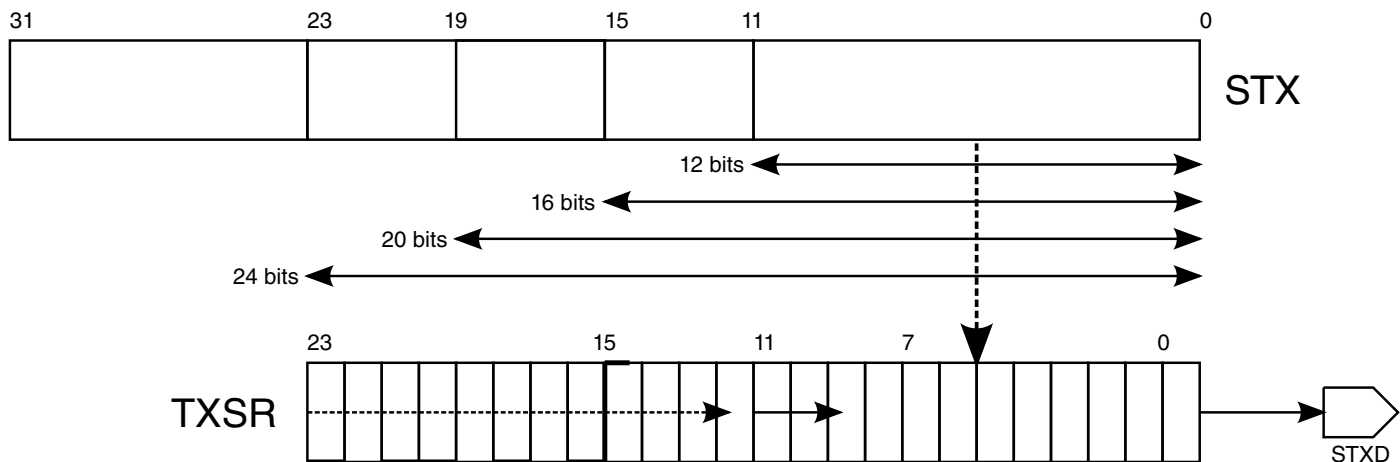

Figure 62-7. Transmit Data Path (TXBIT0=1, TSHFD=1) (LSB Alignment)

62.6 SSI Receive FIFO 0 and 1 Registers

The SSI Receive FIFO registers are 15x32-bit registers. These registers are not directly accessible by the end user. These FIFO registers receive data from the Receive Shift Register (RXSR). Received data is first-in-first-out.

When the Receive Interrupt Enable (RIE) bit in the SIER and either of the Receive FIFO Full Enable (RFF0_EN or RFF1_EN) bits in the SIER are set, an interrupt is asserted whenever the number of full slots exceeds or is equal to the selected threshold value of corresponding Rx-FIFO. The threshold value is contained in the corresponding Receive FIFO Watermark (RFWM0 or 1) field in the SSI FIFO Control/Status Register (SFCSR).

62.7 SSI Receive Shift Register (RXSR)

The SSI Receive Shift Register (RXSR) is a 24-bit, shift register that receives incoming data from the serial receive data SRXD port.

This register is not directly accessible by the end user. When a continuous clock is used, data is shifted in by the selected (internal/external) bit clock when the associated (internal/external) frame sync is asserted. When a gated clock is used, data is shifted in by the selected (internal/external) gated clock. Data is assumed to be received MSB first if the SHFD bit of the SSI.SRCR is cleared. If this bit is set, the data is received LSB first. Data is transferred to the appropriate SSI Receive Data Register (SRX0/1) or Receive FIFOs (if the receive FIFO is enabled and the corresponding SRX is full) after 8, 10, 12, 16, 18, 20, 22 or 24 bits have been shifted in depending on the WL[3:0] control bits. For receiving less than 24 bits of data, LSB bits are appended with zero. The figures below show the receiver loading and shifting operation. These figures show the operation for several values of WL and the same can be extended for other values.

62.8 Functional Description

This section provides a complete functional description of the block.

62.8.1 Operating Modes

Different modes can be programmed by several bits in the SSI control registers.

See the table below for the list of SSI operating modes and some of the typical applications in which they can be used:

Table 62-4. SSI Operating Modes

TX, RX Sections	Serial Clock	Mode	Typical Application
Asynchronous	Continuous	Normal	Multiple synchronous CODECs
Asynchronous	Continuous	Network	TDM CODEC or DSP networks
Synchronous	Continuous	Normal	Multiple synchronous CODECs
Synchronous	Continuous	Network	TDM CODEC or DSP network
Synchronous	Gated	Normal	SPI-type devices; DSP to ARM platform

The transmit and receive sections of the SSI can be synchronous or asynchronous. In Synchronous mode, the transmitter and the receiver use a common clock and frame synchronization signal. Masking of slots for Transmit and Receive section can differ in

synchronous mode. Also the shifting of data is independent and for receive section depends on RXBIT0 and RSHFD bits in SSI.SRCR register. In Asynchronous mode, the transmitter and receiver each has its own clock and frame synchronization signals.

Normal or Network mode can be selected. In Normal mode, the SSI functions with one data word of I/O per frame. In Network mode, any number from two to thirty-two data words of I/O per frame can be used. Network mode is typically used in time division multiplex networks with other processors or CODECs, allowing interface to time division multiplexed networks without additional logic. Gated clock mode option can be selected in Normal synchronous mode only. During Gated clock mode the clock is not-continuous and runs only during data-transmission. These distinctions result in the basic operating modes that allow the SSI to communicate with a wide variety of devices.

The SSI supports both Normal and Network modes, and these can be selected independently of whether the transmitter and receiver are synchronous or asynchronous. Typically these protocols are used in a periodic manner, where data is transferred at regular intervals, such as at the sampling rate of an external CODEC. Both modes use the concept of a frame. The beginning of the frame is marked with a frame sync when programmed with continuous clock. The frame sync occurs at a periodic interval. The length of the frame is determined by the DC[4:0] bits in either the SSI.SRCCR or SSI.STCCR register, depending on whether data is being transmitted or received. The number of words transferred per frame depends on the mode of the SSI.

In Normal mode, one data word is transferred per frame. In Network mode, the frame is divided into anywhere between two and thirty-two time slots, where in each time slot one data word can optionally be transferred.

Apart from the above basic modes of operation, SSI supports the following modes which require some specific programming.

- I2S mode
- AC97 mode
 - AC97 Fixed mode
 - AC97 Variable mode

In (non-I2S) slave modes (external frame sync), the programmed word length setting of the SSI should be equal to the word length setting of the master. In I2S slave mode, the programmed word length setting of the SSI can be lesser than or equal to the word length setting of the I2S master (external CODEC).

In slave modes, the programmed frame length setting (DC bits) of the SSI can be lesser than or equal to the frame length setting of the master (external CODEC).

The following sections provide detailed descriptions of the above modes.

62.8.1.1 Normal Mode

Normal mode is the simplest mode of the SSI. It is used to transfer data in one time slot per frame.

A time slot is a unit of data and the WL[3:0] bits define the number of bits in a time slot. In Continuous Clock mode, a frame sync occurs at the beginning of each frame. The length of the frame is determined by the following factors:

- The period of the Serial Bit Clock (DIV2, PSR, PM[7:0] bits for internal clock or the frequency of the external clock on the STCK port)
- The number of bits per time slot (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

If Normal mode is configured with more than one time slot per frame, data is transferred only in the first time slot. No data is transferred in subsequent time slots. In Normal mode, DC[4:0] values corresponding to more than a single time slot in a frame, only results in lengthening of the frame.

62.8.1.1.1 Normal Mode Transmit

The conditions for data transmission from the SSI in Normal mode are:

- SSI Enabled (SSIEN = 1)
- Write data to Transmit Data Register (STX)
- Transmitter Enabled (TE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

When the above conditions occur in Normal mode, the next data word is transferred into the Transmit Shift Register (SSI.TXSR) from the Transmit Data Register 0 (SSI.STX0), or from the Transmit FIFO 0 Register, if transmit FIFO 0 is enabled. The new data word is transmitted on arrival of frame-sync preceded by clocks in continuous clock mode. In gated-external mode, data word is transmitted on arrival of frame-sync. In gated-internal mode, data word is transmitted whenever data is available in Tx-FIFO.

If Transmit FIFO 0 is not enabled and the transmit data register empty enable (TDE0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the word in SSI_STX0 is shifted to Transmit Shift (SSI.TXSR) register for shifting.

If Transmit FIFO 0 is enabled and the transmit fifo empty enable (TFE0_EN) and transmit interrupt enable (TIE) bits are set, transmit interrupt occurs when the number of empty slots in Transmit Fifo 0 exceed or are equal to the selected threshold value i.e.

Transmit Fifo 0 Watermark (TFWM0) value. If transmit FIFO 0 is enabled and filled with data, 15 data words can be transferred before the core must write new data to the SSI.STX0 register.

The STXD port is disabled except during the data transmission period. For a continuous clock, the optional frame sync output and clock outputs are not disabled, even if both receiver and transmitter are disabled.

62.8.1.1.2 Normal Mode Receive

The conditions for data reception from the SSI are:

- SSI enabled (SSIEN = 1)
- Receiver enabled (RE = 1)
- Frame sync active (for continuous clock case)
- Bit clock begins

With the above conditions in Normal mode with a continuous clock, each time the frame sync signal is generated (or detected) a data word is clocked in. With the above conditions and a gated clock, each time the clock begins, a data word is clocked in.

If Receive FIFO 0 is not enabled and Receive Interrupt enable (RIE) and Received Data 0 Ready enable (RDR0_EN) bits are set, receive interrupt occurs when received data word is transferred from the Receive Shift Register (SSI.RXSR) to the Receive Data Register 0 (SSI.SRX0), thus setting the Receive Data Ready 0 (RDR0) flag.

If Receive FIFO 0 is enabled, and Receive Interrupt enable (RIE) and Received Fifo 0 full enable (RFF0_EN) bits are set, receive interrupt occurs when the received data word is transferred to the Receive FIFO 0 and Receive FIFO 0 reaches the selected threshold and results in Receive FIFO Full 0 (RFF0) flag to get set.

The core program has to read the data from the Receive Data Register 0 (SSI.SRX0) (in case Receive FIFO0 is disabled) before a new data word is transferred from the Receive Shift Register (SSI.RXSR), otherwise the Receive Overrun Error 0 (ROE0) bit is set. If receive FIFO 0 is enabled, the Receive Overrun Error 0 (ROE0) bit is set when the Receive FIFO 0 data level reaches the selected threshold and a new data word is ready to be transferred to the Receive FIFO 0.

See the following figure for an illustration of transmitter and receiver timing for an 8-bit word in the first time slot in Normal mode, continuous clock with a late word length frame sync. The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the Transmit Shift Register, which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the Receive Shift Register shifts in the received data available on the SRXD input and, at the end of the time slot, this data is transferred to the Rx Data Register.

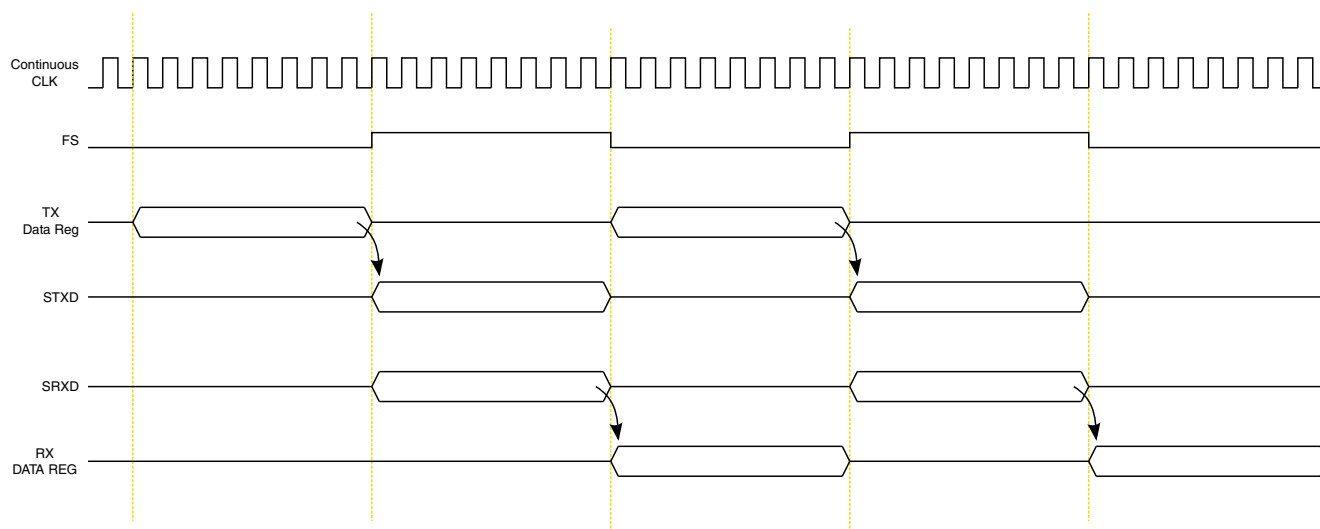

Figure 62-12. Normal Mode Timing - Continuous Clock

The following figure shows a similar case for internal (SSI generates clock) gated clock mode and [Figure 62-14](#) shows a case for external (SSI receives clock) gated clock mode.

NOTE

A pull-down resistor is required in the gated clock case because the clock port is disabled between transmissions.

The Tx Data register is loaded with the data to be transmitted. On arrival of the clock, this data is transferred to the Transmit Shift Register, which gets transmitted on arrival of the frame-sync on the STXD output. Simultaneously, the Receive Shift Register shifts in the received data available on the SRXD input and, at the end of the time slot, this data is transferred to the Rx Data Register. In case of Internal Gated clock mode, the Tx Data line and clock output port are put in the high-impedance state at the end of transmission of the last bit (at the completion of the complete clock cycle), whereas, in External Gated clock mode, the Tx Data line is tri-stated at the last inactive edge of the incoming bit clock (during the last bit in a data word).

Functional Description

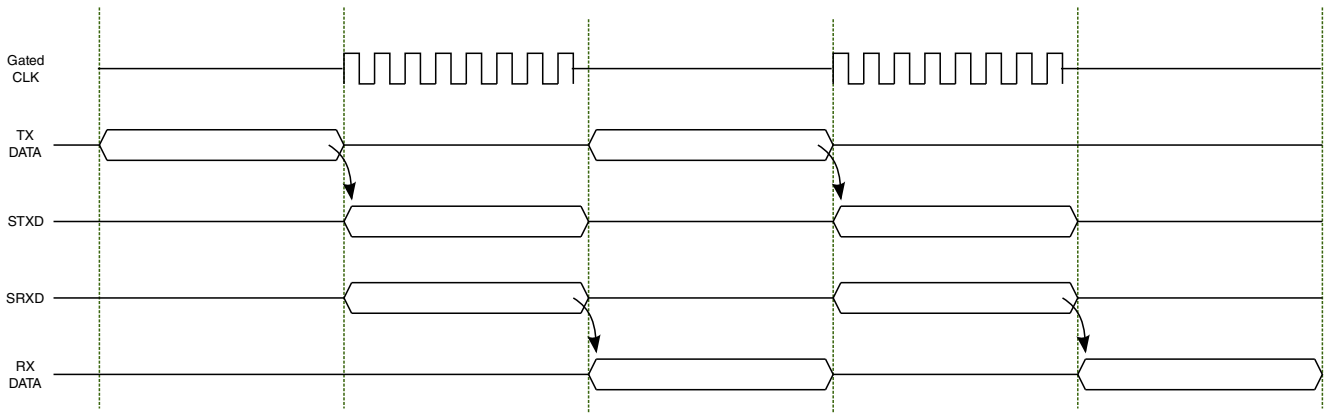

Figure 62-13. Normal Mode Timing - Internal Gated Clock

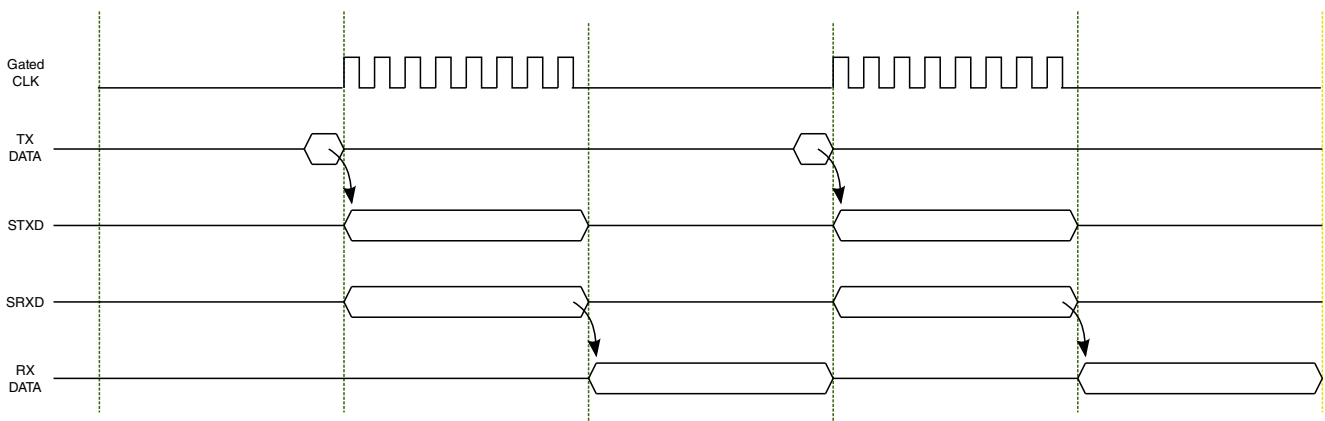

Figure 62-14. Normal Mode Timing - External Gated Clock

62.8.1.2 Network Mode

Network mode is used for creating a Time Division Multiplexed (TDM) network, such as a TDM CODEC network or a network of DSPs.

In Continuous Clock mode, a frame sync occurs at the beginning of each frame. In this mode, the frame is divided into more than one time slot. During each time slot, one data word can be transferred. Each time slot is then assigned to an appropriate CODEC or DSP on the network. The DSP can be a master device that controls its own private network, or a slave device that is connected to an existing TDM network and occupies a few time slots.

The frame sync signal indicates the beginning of a new data frame. Each data frame is divided into time slots and transmission and/or reception of one data word can occur in each time slot (rather than in just the frame sync time slot as in Normal mode). The frame rate dividers, controlled by the DC[4:0] bits, select two to thirty-two time slots per frame. The length of the frame is determined by the following factors:

- The period of the serial bit clock (PSR, PM[7:0] bits for internal clock, or the frequency of the external clock on the STCK port)
- The number of bits per sample (WL[3:0] bits)
- The number of time slots per frame (DC[4:0] bits)

In Network mode, data can be transmitted in any time slot. The distinction of the Network mode is that each time slot is identified with respect to the frame sync (data word time). This time slot identification allows the option of transmitting data during the time slot by writing to the STX registers or ignoring the time slot as determined by SSI.STMSK register bits. The receiver is treated in the same manner and received data is only transferred to the receive data register/fifo if the corresponding time slot is enabled (through SSI.SRMSK).

By utilizing the SSI.STMSK and SSI.SRMSK registers, software only has to service the SSI during valid time slots. This eliminates any overhead associated with unused time slots. See [SSI Memory Map/Register Definition](#) for more information on SSI.STMSK and SSI.SRMSK.

In the Two-Channel mode of operation, the second set of Transmit and Receive FIFOs and Data Registers are used to create two separate channels. These channels are completely independent, with a their own set of Core interrupts and DMA requests, which are identical to the ones available for the default channel. In this mode, data is transmitted/received in enabled time slots alternately from/to FIFO 0 and FIFO 1, starting from FIFO 0. The first data word is taken from FIFO 0 and transmitted in the first enabled time slot and subsequently, data is loaded from FIFO 1 and FIFO 0 alternately and transmitted. Similarly, the first received data is sent to FIFO 0 and subsequent data is sent to FIFO 1 and FIFO 0 alternately. Time slots can be selected through the Transmit and Receive Time Slot Mask registers (SSI.STMSK and SSI.SRMSK). For using this mode of operation, the TCH_EN bit (SCR[8]) needs to be set.

62.8.1.2.1 Network Mode Transmit

The transmit portion of SSI is enabled when the SSIEN and the TE bits in the SSI.SCR are both set. However, for continuous clock, when the TE bit is set, the transmitter is enabled only after detection of a new frame sync (transmission starts from the next frame boundary).

Normal start-up sequence for transmission is to perform the following:

Functional Description

1. Enable Network Mode.
2. Enable SSI
3. Write the data to be transmitted to the SSI.STX register. This clears the TDE flag
4. Set the TE bit to enable the transmitter on the next frame boundary (for continuous clock case).
5. Enable transmit interrupts.

(Alternatively, the programmer may decide not to transmit in a time slot by configuring the STMSK.) TDE flag is set as data is shifted from SSI.STX register to TXSR, but the STXD port remains disabled during the time slots. When the next frame sync is detected or generated (continuous clock), the data word in TXSR and is shifted out (transmitted). When the SSI.STX register is empty, the TDE bit is set, which causes a transmitter interrupt (in case the FIFO is disabled) to be sent if the TIE bit is set. Software can poll the TDE bit or use interrupts to reload the STX register with new data for the next time slot. Failing to reload the SSI.STX register before the TXSR is finished shifting (empty) causes a transmitter underrun and the TUE error bit is set. In case the FIFO is enabled, the TFE flag is set in accordance with the watermark setting and this flag causes the transmitter interrupt to occur.

The operation of clearing the TE bit disables the transmitter after completion of transmission of the current frame. Setting the TE bit enables transmission from the next frame. During that time the STXD port is disabled. The TE bit should be cleared after the TDE bit is set to ensure that all pending data is transmitted.

To summarize, the Network mode transmitter generates interrupts every enabled time slot (when FIFO is disabled) and requires the core program to respond to each enabled time slot. These responses from the core are one of the following:

- Write data in data register to enable transmission in the next time slot.
- Configure the time slot register to disable transmission in the next time slot (unless time slot is already masked by SSI.STMSK register bit).
- Do nothing-transmit underrun occurs at the beginning of the next time slot and the previous data is re-transmitted.

In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected (TDE1 is low by default).

62.8.1.2.2 Network Mode Receive

The receiver portion of the SSI is enabled when both the SSIEN and the RE bits in the SSI.SCR are set. However, the receive enable only takes place during that time slot if RE is enabled before the second to last bit of the word. If the RE bit is cleared, the receiver is disabled at the end of the current frame.

SSI is capable of finding the start of the next frame automatically. When the word is completely received, it is transferred to the SRX register, which sets the RDR bit (Receive Data Ready). Setting the RDR bit causes a receive interrupt to occur if the receiver interrupt is enabled (the RIE bit is set) and (Receive data ready enable) RDR_EN bit is set. The second data word (second time slot in the frame), begins shifting in immediately after the transfer of the first data word to the SSI.SRX register. The core program has to read the data from the Receive Data Register (which clears RDR) before the second data word is completely received (ready to transfer to RX data register) or a receive overrun error occurs (the ROE bit is set).

An interrupt can occur after the reception of each enabled data word or the programmer can poll the RDR flag. The core program response can be one of the following:

- Read RX and use the data.
- Read RX and ignore the data.
- Do nothing-the receiver overrun exception occurs at the end of the current time slot.

NOTE

For a continuous clock, the optional frame sync output and clock output signals are not affected, even if the transmitter or receiver is disabled. TE and RE do not disable the bit clock or the frame sync generation. To disable the bit clock and the frame sync generation, the SSIEN bit in the SSI.SCR can be cleared or TFR_CLK_DIS/RFR_CLK_DIS bits can be set, or the port control logic external to the SSI (for example, in the IOMUXC) can be re configured.

In the Two-Channel mode of operation, both the channels (Data Registers, FIFOs, Interrupts and DMA requests) operate in the same manner, as described above. The only difference in case of the second channel is that the Interrupts related to this channel are generated only in case this mode of operation is selected.

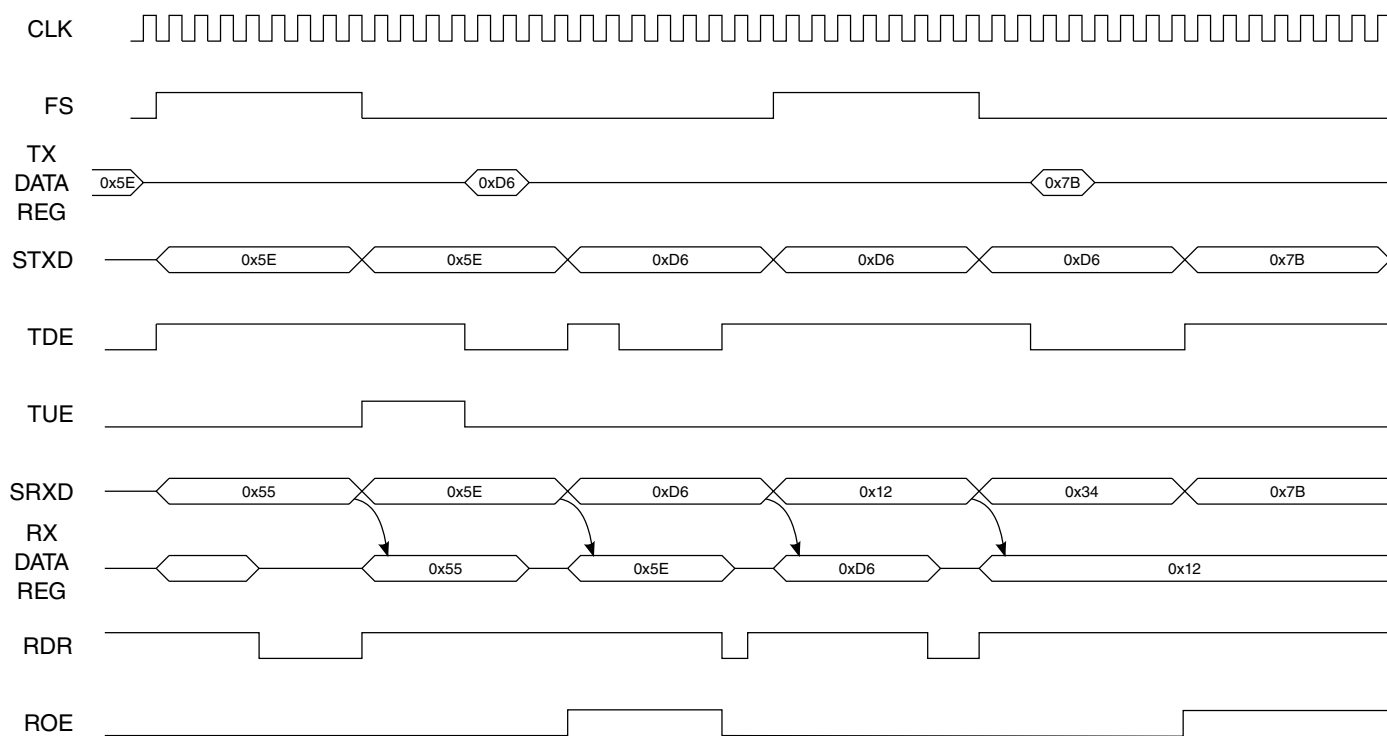

The transmitter and receiver timing for an 8-bit word with continuous clock, FIFO disabled, three words per frame sync in Network mode is shown in the figure below).

NOTE

The transmitter repeats the value 0x5E because of an underrun condition

Functional Description

For the receive section, data received on the SRXD pin gets transferred to the Rx Data register at the end of each time slot. If the FIFO is disabled, the RDR flag gets set and causes a receiver interrupt if RE, RIE and RDR_EN bits are set. If the FIFO is enabled, then the RFF flag is used for interrupt generation (this flag is set in accordance with the watermark settings). Here all time slots are enabled. The receive data ready flag is set after reception of the first data (0x55). Since the flag is not cleared (Rx Data Register is not read by core), the Receive Overrun Error (ROE) flag is set on reception of the next data (0x5E). ROE flag is cleared on writing '1' to the corresponding interrupt status bit in SSI Status Register.

Note: Processor must write to '1' to the corresponding TUE/ROE Interrupt status bit in SISR to clear TUE/ROE Interrupt.

Figure 62-15. Network Mode Timing - Continuous Clock

62.8.1.3 Gated Clock Mode

Gated Clock mode is often used to connect to SPI-type interfaces on Micro controller Units (MCUs) or external peripheral chips. In Gated Clock mode, the presence of the clock indicates that valid data is on the STXD or SRXD ports.

For this reason, no frame sync is needed in this mode. Once transmission of data has completed, the clock is pulled to the inactive state. Gated clocks are allowed for both the transmit and receive sections with either internal or external clock in Normal mode. Gated clocks are not allowed in Network mode. See [Table 62-2](#) ("Clock Pin Configurations") for SSI configuration for gated-mode operation.

The clock runs when the TE bit and/or the RE bit are appropriately enabled. For the case of internally generated clock, all internal bit clocks, word clocks, and frame clocks continue to operate. When a valid time slot occurs (such as the first time slot in Normal mode), the internal bit clock is enabled onto the appropriate clock port. This allows data to be transferred out in periodic intervals in Gated Clock mode. With an external clock, the SSI waits for a clock signal to be received. Once the clock begins, valid data is shifted in. Care should be taken to clear all DC bits (0x00000) when SSI is used in Gated mode. In gated mode of operation the TFS, RFS, TLS, RLS, TFRC and RFRC bits of SSI.AISR register are not generated.

For Gated clock operated in external clock mode, a proper clock signalling must be applied to the SSI STCK in order for it to function properly. When TSCKP is 0, CLK_IST value should be 1. When TSCKP is 1, CLK_IST value should be 0. If the SSI uses rising edge transition to clock data (TSCKP=0) and the falling edge transition to latch data (RSCKP=0), the clock must be in an active low state when idle. If the SSI uses falling edge transition to clock data (TSCKP=1) and the rising edge transition to latch data (RSCKP=1), the clock must be in a active high state when idle. The figures below illustrate the different edge clocking/latching.

Figure 62-16. Internal Gated Mode Timing - Rising Edge Clocking / Falling Edge Latching

Functional Description

Figure 62-17. Internal Gated Mode Timing - Falling Edge Clocking / Rising Edge Latching

Figure 62-18. External Gated Mode Timing - Rising Edge Clocking / Falling Edge Latching

Figure 62-19. External Gated Mode Timing - Falling Edge clocking / Rising Edge Latching

The bit clock ports must be kept free of timing glitches. If a single glitch occurs, all ensuing transfers will be out of synchronization.

In case of External Gated Mode, even though the Tx Data line is put in the high-impedance state at the last non-active edge of the bit clock, the round trip delay should be sufficient to take care of hold time requirements at the external receiver.

62.8.1.4 I2S Mode

The SSI is compliant to the Inter-IC Sound (I2S) bus specification from Philips Semiconductors (February 1986, Revised June 5, 1996). For more information on I2S, refer to the latest version of NXP Semiconductor's I2S specification.

See the following figure for an illustration of the basic I2S protocol timing.

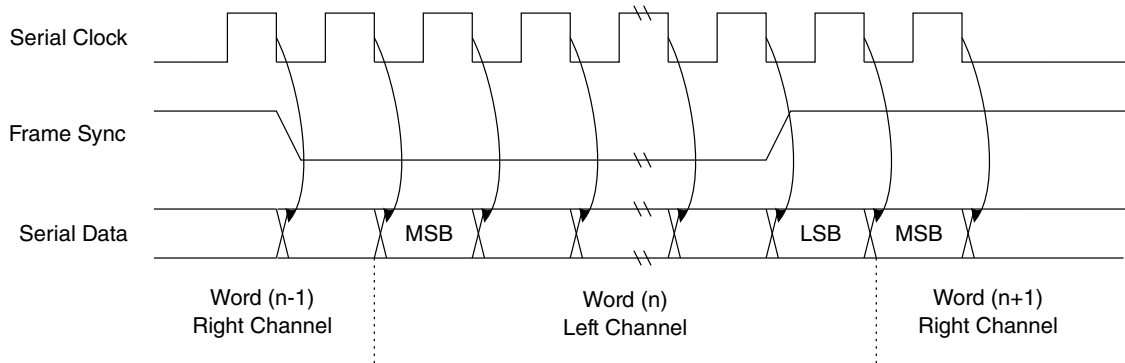

Figure 62-20. I2S Mode Timing - Serial Clock, Frame Sync and Serial Data

Select I2S mode using the options listed in the table below.

Table 62-5. I2S Mode Selection

I2S_MODE[1]	I2S_MODE[0]	Mode Type
0	0	Normal mode
0	1	I2S master mode
1	0	I2S slave mode
1	1	Normal mode

In normal mode operation, no register bits are forced to any particular state internally and the user can program the SSI to work in any operating condition.

When I2S modes are entered (I2S master (01) or I2S slave (10)), the following settings are recommended:

- Sync mode (SSI_SCR[4] =1)
- Tx shift direction: MSB transmitted first (SSI_STCR[4]=0)
- Rx shift direction: MSB received first (SSI_SRCR[4]=0)
- Tx data clocked at falling edge of the clock (SSI_STCR[3]=1)
- Rx data latched at rising edge of the clock (SSI_SRCR[3]=1)
- Tx frame sync active low (SSI_STCR[2]=1)
- Rx frame sync active low (SSI_SRCR[2]=1)

Functional Description

- Tx frame sync initiated one bit before data is transmitted (SSI_STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SSI_SRCR[0]=1)
- TX Frame Rate should be 2 (SSI_STCCR[12:8] = 1)
- RX Frame Rate should be 2 (SSI_SRCCR[12:8] = 1)

In I2S master mode (SSI_SCR[6:5]=01), the following additional settings are recommended:

- TXDIR bit (SSI_STCR[5]) set to 1 to select internal generated bit clock
- TFDIR bit (SSI_STCR[6]) set to 1 to select internal generated frame sync

In I2S master mode (SSI_SCR[6:5]=01), the following settings are internally overridden by the hardware:

- Network mode is selected (SSI_SCR[3]=1)
- Tx frame sync length set to one-word-long-frame (SSI_STCR[1]=0)
- Rx frame sync length set to one-word-long-frame (SSI_SRCR[1]=0)
- Tx shifting with respect to bit 0 of TXSR (SSI_STCR[9]=1)
- Rx shifting with respect to bit 0 of RXSR (SSI_SRCR[9]=1)

The user needs to set the following control bits to configure the bit clock and frame sync:

- PM (SSI_STCCR[7:0])
- PSR (SSI_STCCR[17])
- DIV2 (SSI_STCCR[18])
- WL (SSI_STCCR[16:13])
- DC (SSI_STCCR[12:8])

The word length is fixed to 32 in I2S Master mode and the WL bits determine the number of bits that will contain valid data (out of the 32 transmitted/received bits in each channel).

In I2S slave mode (SSI_SCR[6:5]=10), the following additional settings are recommended:

- TXDIR bit (SSI_STCR[5]) set to 0 to select external generated bit clock
- TFDIR bit (SSI_STCR[6]) set to 0 to select external generated frame sync

In I2S slave mode (SSI_SCR[6:5]=10), the following settings are internally overridden by the hardware:

- Normal mode is selected (SSI_SCR[3]=0)
- Tx frame sync length set to one-bit-long-frame (SSI_STCR[1]=1)
- Rx frame sync length set to one-bit-long-frame (SSI_SRCR[1]=1)
- Tx shifting with respect to bit 0 of TXSR (SSI_STCR[9]=1)
- Rx shifting with respect to bit 0 of RXSR (SSI_SRCR[9]=1)

The user needs to set the following control bits to configure the data transmission:

- WL (SSI_STCCR[16:13])
- DC (SSI_STCCR[12:8])

The word length is variable in I2S slave mode and the WL bits determine the number of bits that will contain valid data. The actual word length is determined by the external CODEC. The external I2S Master still sends frame sync according to the I2S protocol (early, word wide and active low), the SSI internally operates so that each frame sync transition is the start of a new frame (the WL bits determine the number of bits to be transmitted/received). After one data word has been transferred, the SSI waits for the next frame sync transition to start operation in the next time slot. Transmit (STMSK) and receive (SRMSK) mask bits should not be used in I2S Slave mode of operation. Masking is supported only for network mode of operation.

62.8.1.5 AC97 Mode

In AC97 mode of operation, the SSI transmits a 16-bit Tag Slot at the start of a frame and the rest of the slots (in that frame) are all 20-bits wide.

The same sequence is followed while receiving data. Refer to the AC97 specification for details regarding transmit and receive sequences and data formats.

NOTE

The Audio Codec specification released in 1997 [AC '97] defines the Architecture and Digital Interface, specifically designed for implementing audio and modem I/O functionality in personal computers. Companion specifications include the Modem Codec [MC '97], and the combined Audio/Modem Codec standard [AMC '97]. The current version of AC '97 was produced in 2002. The AC-97 specification defines a recommended 48-pin QFP IC package.

Note that the SSI only has one RxDATA pin so the SSI can only support one codec. Secondary codecs are not supported.

When AC97 mode is enabled, the following settings are internally overridden by the hardware. The programmed register values are not changed by entering AC97 mode but they no longer apply to the block's operation. Writing to the programmed register fields will update their values; these updates can be seen by reading back the register fields. However, these settings will not take effect until AC97 mode is turned off.

The register bits within the bracket are the equivalent settings:

Functional Description

- Sync mode is entered (SSI.SCR[4]=1)
- Network mode is selected (SSI.SCR[3]=1)
- Tx shift direction is MSB transmitted first (SSI.STCR[4]=0)
- Rx shift direction is MSB received first (SSI.SRCR[4]=0)
- Tx data is clocked at rising edge of the clock (SSI.STCR[3]=0)
- Rx data is latched at falling edge of the clock (SSI.SRCR[3]=0)
- Tx frame sync is active high (SSI.STCR[2]=0)
- Rx frame sync is active high (SSI.SRCR[2]=0)
- Tx frame sync length is one-word-long-frame (SSI.STCR[1]=0)
- Rx frame sync length is one-word-long-frame (SSI.SRCR[1]=0)
- Tx frame sync initiated one bit before data is transmitted (SSI.STCR[0]=1)
- Rx frame sync initiated one bit before data is received (SSI.SRCR[0]=1)
- Tx shifting with respect to bit 0 of TXSR (SSI.STCR[9]=1)
- Rx shifting with respect to bit 0 of RXSR (SSI.SRCR[9]=1)
- Tx FIFO is enabled (SSI.STCR[7]=1)
- Rx FIFO is enabled (SSI.SRCR[7]=1)
- TFDIR bit (SSI.STCR[6]) is forced to 1 internally to select internal generated frame sync
- TXDIR bit (SSI.STCR[5]) is forced to 0 internally to select external generated bit clock

Any alteration of these bits individually will not affect the operational conditions of the SSI unless AC97 mode is deselected.

Hence, the only control bits needed to be set by the user to configure the data transmission/reception are the WL (SSI.STCCR[16:13]) and DC (SSI.STCCR[12:8]) bits. In AC97 mode, the WL bits can only legally take the values corresponding to 16-bit (truncated data) or 20-bit time slots. In case WL bits are set to select 16-bit time slots, the SSI pads the transmit data (four least significant bits) with zeros and while receiving, stores only the most significant 16 bits in the Rx FIFO.

Follow the sequence for programming the SSI to work in AC97 mode:

1. Program the WL bits to a value corresponding to either 16 or 20 bits. The WL bit setting is only for the data portion of the AC97 frame (Slots #3 through #12). The Tag slot (Slot #0) is always 16 bits wide and the Command Address and Command Data slots (Slots #1 and #2) are always 20 bits wide.
2. Select the number of time slots by programming the DC bits. For AC97 operation, DC bits should be set to a value of '0xC', resulting in 13 time slots per frame.
3. Write data to be transmitted, in Tx FIFO 0 (through Tx Data Register 0) and Tx FIFO 1 while using Two-Channel Mode (TCH_EN = 1).
4. Program the FV, TIF, RD, WR and FRDIV bits in SSI.SACNT register

5. Update the contents of SSI.SACADD, SSI.SACDAT and SSI.SATAG (for Fixed mode only) registers
6. Enable the AC97 mode of operation (AC97EN bit in SSI.SACNT register)

Once the SSI starts transmitting and receiving data (after being configured in AC97 mode), the programmer needs to service the interrupts, as and when they are raised (updates to command address/data or tag registers, reading of received data and writing more data for transmission). Further details regarding fixed and variable mode implementation are provided in the following sections.

While using AC97 in Two-Channel Mode (TCH_EN=1), it is recommended that the received tag is not stored in the Rx FIFO (TIF=0). In case the programmer needs to update the SSI.SATAG register and also issue a RD/WR command (in a single frame), it is recommended that the SSI.SATAG register be updated prior to issuing a RD/WR command.

62.8.1.5.1 AC97 Fixed Mode (SSI.SACNT[1]=0)

In fixed mode of operation, SSI transmits in accordance with the AC97 Frame Rate Divider bits (i.e. FRDIV in SACNT) which decides the number of frames for which the SSI should be idle, after operating for one frame.

In a valid frame, TAG Value (written by Core) will be transmitted in Slot #0, Command Address will be transmitted in Slot #1 in case of RD/WR Command, and Command Data will be transmitted in Slot #2 in case of a WR Command. The data from TX-FIFO is transmitted in Slot #3 - Slot #12 depending on the valid slots indicated by the TAG value.

While receiving, bit 15 of the TAG Value (Slot #0) is checked to see if the CODEC is ready. If this bit is set, the frame is received. The received TAG provides the information about Slots containing valid data. The the corresponding TAG bit is valid, the Command Address (Slot #1) and Command Data (Slot #2) values are stored in the corresponding registers. The received data (Slot #3 - Slot #12) is then stored in the Rx-FIFO (for valid slots).

62.8.1.5.2 AC97 Variable Mode (SSI.SACNT[1]=1)

In Variable Mode, the transmit slots which should contain data in the current frame are determined by SLOTREQ bits received in the previous frame. While receiving, if the CODEC is ready, the frame is received and the SLOTREQ bits (contained in Slot #1) are stored for scheduling transmission in the next frame.

The SSI.SACCST, SSI.SACCEN and SSI.SACCDIS registers helps in determining which transmit slots are active. This information is used to ensure that SSI does not transmit data for powered-down/inactive channels.

Table 62-6. Data Alignment (continued)

12-bit LSB Aligned																			1	1	9	8	7	6	5	4	3	2	1	0								
																			1	1	9	8	7	6	5	4	3	2	1	0

	9	8	7	6	5	4	3	2	1	0																												
22-bit LSB Aligned																			2	2	1	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0		
																			1	0	9	8	7	6	5	4	3	2	1	0								
22-bit MSB Aligned	2	2	1	1	1	1	1	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0																
	1	0	9	8	7	6	5	4	3	2	1	0																										
24-bit LSB Aligned																			2	2	2	2	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0	
																			3	2	1	0	9	8	7	6	5	4	3	2	1	0						
24-bit MSB Aligned	2	2	2	2	1	1	1	1	1	1	1	1	1	1	9	8	7	6	5	4	3	2	1	0														
	3	2	1	0	9	8	7	6	5	4	3	2	1	0																								

In addition, receive data can either be zero-extended or sign-extended if LSB alignment is selected. With zero-extension, all bits above the most significant bit are 0's. This format is useful when data is stored in a pure integer format. With sign-extension, all bits above the most significant bit are equal to the most significant bit. This format is useful when data is stored in a fixed-point integer format (which implies fractional values). Receive data extension is controlled by the RXEXT bit in the SSI.SRCR. Transmit data used with LSB alignment has no concept of sign/zero-extension. Unused bits above the most significant bit are simply ignored.

When configured in I2S or AC97 mode, the SSI forces the selection of LSB alignment. However, RXEXT still permits a choice between zero-extension and sign-extension.

See [SSI](#) for more details on the relevant bits in the SSI.STCR and SSI.SRCR registers.

62.8.3 SSI Architecture

The Synchronous Serial Interface (SSI) is connected to chip pads through the Digital Audio Mux (AUDMUX) block. The AUDMUX can be configured to connect the SSI to the chip pads in various ways.

Refer to [Figure 62-1](#) for a block diagram of the SSI.

62.8.4 SSI Clocking

The SSI uses the following clocks:

- Bit clock - Used to serially clock the data bits in and out of the SSI port. This clock is either generated internally (from SSI's sys clock) or taken from external clock source (through the Tx/Rx clock ports).
- Word clock - Used to count the number of data bits per word (8, 10, 12, 16, 18, 20, 22 or 24 bits). This clock is generated internally from the bit clock.
- Frame clock (Frame Sync) - Used to count the number of words in a frame. This signal can be generated internally from the bit clock, or taken from external source (from the Tx/Rx frame sync ports).
- Network clock - In master mode, this is an integer multiple of frame clock. This is oversampling clock. It is used in cases when SSI has to provide the clock.

Care should be taken to ensure that the bit clock frequency (either internally generated by dividing the SSI's sys clock or sourced from external device through Tx/Rx clock ports) is never greater than 1/5 of the ipg_clk (from CCM) frequency.

In Normal mode (SCR[6:5]=00), the bit clock, used to serially clock the data, is visible on the Serial Transmit Clock (STCK) and Serial Receive Clock (SRCK) ports. The word clock is an internal clock used to determine when transmission of an 8, 10, 12, 16, 18, 20, 22 or 24 bit word has completed. The word clock in turn then clocks the frame clock, which counts the number of words in the frame. The frame clock can be viewed on the STFS and SRFS frame sync ports, because a frame sync is generated after the correct number of words in the frame have passed. In master and synchronous mode, the unused port SRCK is used as network clock (oversampling clock) enabled by the SCR register bit 15, SYS_CLK_EN. This network clock is an oversampling clock of the frame sync clock (STFS). In this mode, the word length (WL), Prescaler Range (PSR), Prescaler Modulus (PM) and Frame rate (DC) selects the ratio of network clock to sampling clock STFS. In case of I2S mode, the network clock (oversampling clock) can be made available on this port if the SYS_CLK_EN bit is set. The relationship between the clocks and the dividers is shown in the figure below ("SSI Clocking"). The bit clock can be received from an SSI clock port or can be generated from the network clock through a divider, as shown in [Figure 62-22](#) ("SSI Transmit Clock Generator Block Diagram").

Figure 62-21. SSI Clocking

62.8.4.1 SSI Clock and Frame Sync Generation

Data clock and frame sync signals can be generated internally, or can be obtained from external sources. If internally generated, the SSI clock generator is used to derive bit clock and frame sync signals from the SSI's sys clock. The SSI clock generator consists of a selectable, fixed prescaler and a programmable prescaler for bit rate clock generation.

In Gated Clock mode, the data clock is valid only when data is being transmitted. Otherwise the clock port is pulled to the inactive state. A programmable frame rate divider and a word length divider are used for frame rate sync signal generation.

The following figure shows a block diagram of the clock generator for the transmit section. The serial bit clock can be internal or external, depending on the Transmit Direction (TXDIR) bit in the SSI Transmit Configuration Register (SSI.STCR). The receive section contains an equivalent clock generator circuit.

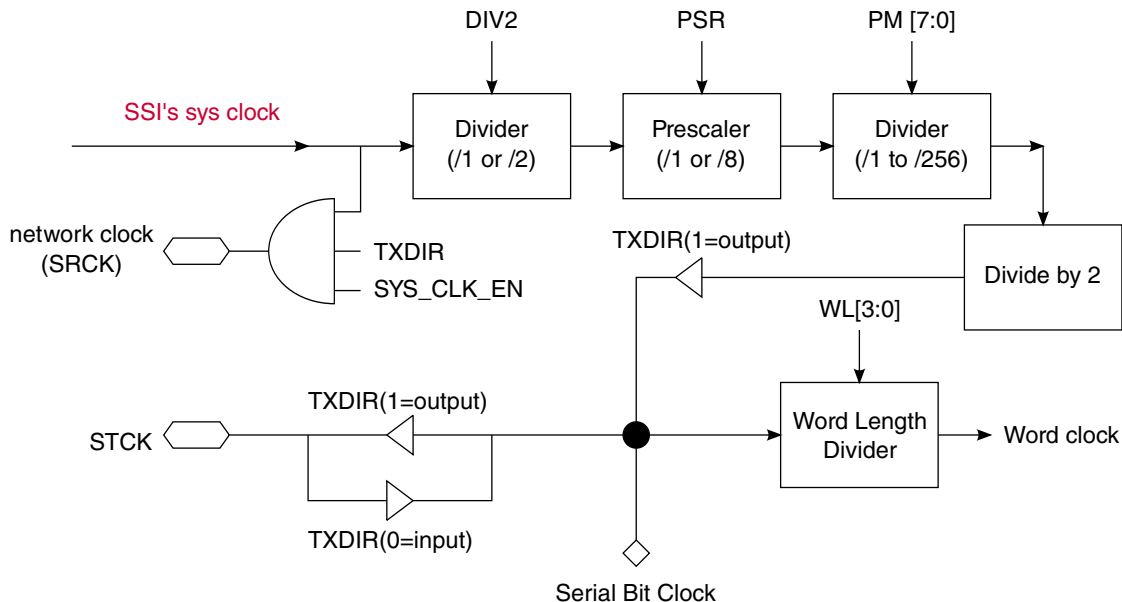

Figure 62-22. SSI Transmit Clock Generator Block Diagram

Functional Description

The figure below shows the Frame Sync Generator block for the transmit section. When internally generated, both receive and transmit frame sync are generated from the word clock and are defined by the Frame Rate Divider (DC[4:0]) bits and the Word Length (WL[3:0]) bits of the SSI Transmit Clock Control Register (SSI.STCCR). The receive section contains an equivalent circuit for the Frame Sync Generator.

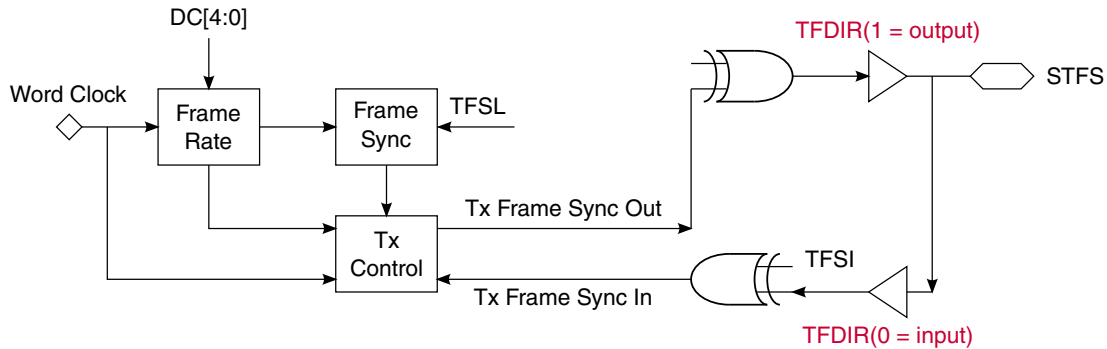

Figure 62-23. SSI Transmit Frame Sync Generator Block Diagram

62.8.4.2 DIV2, PSR and PM Bit Description

The bit clock frequency can be calculated from the SSI's sys clock using the equation in the following figure.

NOTE

You must ensure that the bit-clock frequency must be never greater than 1/5 of the peripheral clock frequency. The oversampling clock frequency can go up to peripheral clock frequency. Bits DIV2, PSR and PM should not be all set to zero at the same time.

$$f_{\text{INT_BIT_CLK}} = f_{\text{SSI's sys clock}} / [(DIV2 + 1) \times (7 \times PSR + 1) \times (PM + 1) \times 2]$$

where PM = PM[7:0]

$$f_{\text{FRAME_SYN_CLK}} = (f_{\text{INT_BIT_CLK}}) / [(DC + 1) \times WL]$$

where DC = DC[4:0] and WL = 8, 10, 12, 16, 18, 20, 22, 24

Figure 62-24. SSI Bit Clock Equation

For example, if the SSI's sys clock is 12.288 MHz, in 8-bit word Normal mode with DC[4:0] set to 0(00000), PM[7:0] set to 47 (0010 1111), the PSR bit cleared, DIV2 bit set to 1, a bit clock rate of $12.288 \text{ Mhz} / [1 \times 4 \times 48] = 64 \text{ kHz}$ is generated. Since the 8-bit word rate is equal to one (i.e. normal mode), the sampling rate (FS rate) would then be $64 \text{ kHz} / [1 * 8] = 8 \text{ kHz}$.

In the next example, SSI's sys clock is 11.2896 Mhz. A 16-bit word Network mode with DC[4:0] set to 1 (00001), PM[7:0] set to 3 (0000 0011), the PSR bit is set to 0, DIV2 bit set to 0, and a 11.2896 MHz oversampling clock, a bit clock rate of $11.2896 \text{ Mhz} / [1 \times 2 \times 4] = 1.4112 \text{ MHz}$ is generated. Since the 16-bit word rate is equal to two, the sampling rate (FS rate) would be $1.4112 \text{ MHz} / [2 * 16] = 44.1 \text{ kHz}$.

The table below shows programming examples for the clock dividers in the CCM and the SSI to support various bit clock (STCK) frequencies.

Table 62-7. SSI Bit Clock and Frame Rate as a Function of PSR, PM, and DIV2

Bits/ Word	Words / Frame	Ideal Frame Rate (kHz)	PLL Freq (Mhz)	SSIDIV (in CCM)	SSI's sys clock Freq (Mhz)	DIV2	PSR	PM	WL	DC	Actual Serial bit clock Freq (kHz) STCK	Target Serial bit clock Freq (kHz) STCK	Error (Hz)

16	2	44.1	632.217 6	56	11.2896	0	0	3	7	1	1411.2	1411.2	0
16	4	44.1	632.217 6	56	11.2896	0	0	1	7	3	2822.4	2822.4	0

NOTE

The table above describes how various frame rates can be achieved with the PLLs supplying a frequency of 688.128 MHz and 633.2176 MHz (with WL and DC settings as shown).

These clocks are recommended as convenient starting points but the system allows for other input clock frequencies as well.

[Table 62-7](#) shows programming of the CCM and SSI dividers in order to generate the appropriate network clock and serial bit clock frequencies for various sampling rates. In these examples, the master mode is selected either by setting I2S master bit (SCR[6:5]=01) or individually programming the SSI in network, synchronous, transmit internal mode (the table specifically illustrates the I2S mode frequencies/sample rates). The network clock is oversampling clock.

Note that the I2S master mode requires that a word length of 32 bits be used (regardless of the actual data type). Consequently, the fixed I2S frame rate of 64 bits per frame (word length (WL) can be any value) and DC of 1 are assumed.

62.8.5 Receive Interrupt Enable Bit Description

When the RIE and RE bit are set, the processor is interrupted when either of the SSI Receive FIFO Full (RFF0/1) bits in SSI.SISR is set (if the corresponding Receive FIFO is enabled).

If the Receive FIFO is not enabled, the interrupt is generated when the corresponding SSI Receive Data Ready (RDR0/1) bit in the SSI.SISR is set. When the receive FIFO is enabled, a maximum of 15 values are available to be read (15 values per channel in Two-Channel mode). If not enabled, then one value can be read from the SRX register (one each in case of Two-Channel mode). If the RIE bit is cleared, these interrupts are disabled. However, the RFF0/1 and RDR0/1 bits still indicate the receive data register full condition. Reading the SSI.SRX registers clears the RDR bits, thus clearing the pending interrupt. Two receive data interrupts (two per channel in case of Two-Channel mode) are available: receive data with exception status and receive data without exception. The tables below show the conditions under which these interrupts are generated.

Table 62-8. SSI Receive Data 1 Interrupts

Interrupt	RIE	ROE0	RFF0/RDR0
Receive Data 1(with Exception Status)	1	1	1
Receive Data 1(without exception)	1	0	1

Table 62-9. SSI Receive Data 0 Interrupts

Interrupt	RIE	ROE1	RFF1/RDR1
Receive Data 0 (with Exception Status)	1	1	1
Receive Data 0 (without exception)	1	0	1

62.8.6 Transmit Interrupt Enable Bit Description

The SSI Transmit Interrupt Enable (TIE) control bit determines whether the processor is interrupted when the SSI transmitter needs to be serviced.

When the TIE and TE bits are set, the program controller is interrupted when either of the SSI Transmit FIFO Empty (TFE0/1) flags in SISR are set (if corresponding Transmit FIFO is enabled). If the corresponding Transmit FIFO is not enabled, an interrupt is generated when the corresponding SSI Transmit Data Register Empty (TDE0/1) flag in the SISR is set and Transmit Enable (TE) bit is set.

When Transmit FIFO 0 is enabled, a maximum of 15 values can be written to the SSI (15 per channel in case of Two-Channel mode, using Tx FIFO 1). If not enabled, then one value can be written to the SSI.STX0 register (one per channel in case of Two-Channel mode using SSI.STX1). When the TIE bit is cleared, all transmit interrupts are disabled. However, the TDE0/1 bits always indicate the corresponding SSI.STX register empty condition, even when the transmitter is disabled by the Transmit Enable (TE) bit (in the SSI.SCR). Writing data to the STX clears the corresponding TDE bit, thus clearing the interrupt. Two transmit data interrupts are available (four in case of Two-Channel mode, two per channel): transmit data with exception status and transmit data without exceptions. The tables below show the conditions under which these interrupts are generated.

Table 62-10. SSI Transmit Data 1 Interrupts

Interrupt	TIE	TUE1	TFE1/TDE1
Transmit Data 1 (with Exception Status)	1	1	1
Transmit Data 1 (without exception)	1	0	1

Table 62-11. SSI Transmit Data 0 Interrupts

Interrupt	TIE	TUE0	TFE0/TDE0
Transmit Data 0 (with Exception Status)	1	1	1
Transmit Data 0 (without exception)	1	0	1

62.8.7 Internal Frame and Clock Shutdown

During transmit/receive operation, disabling TE/RE will ensure that data transmission/reception stops after current frame ends following which TFRC/RFRC Status bits will get set to indicate the Frame Completion State.

If TE is disabled 4 clock cycles before the next frame, extra frame generated are invalid frames. TFR_CLK_DIS/RFR_CLK_DIS bit is set in the current or any of the previous frames, SSI will stop driving the STFS/SRFS and STCK/SRCK signals after the current frame ends.

If TFR_CLK_DIS/RFR_CLK_DIS bit is not set, SSI will continue generating STFS/SRFS and STCK/SRCK signals (in case direction is from SSI), which then can be disabled by writing '1' to TFR_CLK_DIS/RFR_CLK_DIS bit. SSI will then stop driving these signals after end of frame is reached following which TFRC/RFRC status bits will get set to indicate the Frame Completion State.

The following figure is an illustration of transmission case where TXDIR and TFDIR are both set to '1'. In this case TE is disabled with TFR_CLK_DIS bit set in current or any of the previous frames.

Figure 62-25. TFR_CLK_DIS assertion in current or previous frame as TE disable

The figure below is an illustration of transmission case where TXDIR and TFDIR are both set to '1'. In this case TFR_CLK_DIS bit is set after few frames of disabling TE. TFRC (Transmit Frame Complete) is set at frame boundary after TE is cleared. Once software services this interrupt and sets TFR_CLK_DIS bit later, TFRC bit is again set at next frame boundary.

Functional Description

Figure 62-26. TFR_CLK_DIS assertion in subsequent frame after disabling TE

62.8.8 Peripheral Bus Interface

The SSI has a Peripheral Bus interface to provide a control and data interface. This interface is used by both the processor and DMA controller.

62.8.8.1 Transfer Lengths Supported

The Peripheral Bus interface of the SSI only supports 32-bit transfers with all SSI registers other than SSI.STX0, SSI.STX1, SSI.SRX0, and SSI.SRX1 (that is, the data registers).

With the exception of the data registers, using 8-bit and 16-bit transactions could result in undesired behavior but will not result in a transfer bus error. The data registers (SSI.STX0, SSI.STX1, SSI.SRX0, and SSI.SRX1) support 8-bit, 16-bit, and 32-bit transfer lengths without restrictions.

62.8.8.2 Transfer Bus Errors

Transfer bus errors are generated upon response to the following:

- Write transfer to a read-only register.
- Read or write access to a register space beyond the last populated register of the SSI in its memory map (up until the end of the allocated memory address range of the SSI).

62.8.8.3 Clock Rate

The Peripheral Bus clock frequency must be at least five times the serial bit clock frequency.

62.8.9 Reset

The SSI is affected by the following types of reset:

- Power-on Reset-The Power-on reset clears the SSIEN bit in SSI.SCR, which disables the SSI. All other status and control bits in the SSI are affected as described in SSI Programming Model in the "Memory Map and Register Definition section".
- SSI Reset-The SSI reset is generated when the SSIEN bit in the SSI.SCR is cleared. The SSI status bits are preset to the same state produced by the Power-on reset. The SSI control bits are unaffected. The control bits in the SSI.SCR are also unaffected. The SSI reset is useful for selective reset of the SSI without changing the present SSI control bits and without affecting the other peripherals.

62.9 SSI Memory Map/Register Definition

SSI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page

62.9.1 SSI Transmit Data Register n (SSIx_STXn)

NOTE

Enable SSI (SSIEN=1) before writing to SSI Transmit Data Registers.

Address: Base address + 0h offset + (4d × i), where i=0d to 1d

SSIx_STXn field descriptions

Field	Description
STXn	<p>SSI Transmit Data. These bits store the data to be transmitted by the SSI. These are implemented as the first word of their respective Tx FIFOs. Data written to these registers is transferred to the Transmit Shift Register (TXSR), when shifting of the previous data is complete. If both FIFOs are in use, data is alternately transferred from STX0 and STX1, to TXSR. Multiple writes to the STX registers will not result in the previous data being over-written by the subsequent data. STX1 can only be used in Two-Channel mode of operation. Protection from over-writing is present irrespective of whether the transmitter is enabled or not.</p> <p>Example 1: If Tx FIFO0 is in use and user writes Data1...Data16 to STX0, Data16 will not over-write Data1. Data1...Data15 are stored in the FIFO while Data16 is discarded.</p> <p>Example 2: If Tx FIFO0 is not in use and user writes Data1, Data2 to STX0, then Data2 will not over-write Data1 and will be discarded.</p>

62.9.2 SSI Receive Data Register n (SSIx_SRXn)

Address: Base address + 8h offset + (4d × i), where i=0d to 1d

SSIx_SRXn field descriptions

Field	Description
SRXn	<p>SSI Receive Data. These bits store the data received by the SSI. These are implemented as the first word of their respective Rx FIFOs. These bits receive data from the RXSR depending on the mode of operation. In case both FIFOs are in use, data is transferred to each data register alternately. SRX1 can only be used in Two-Channel mode of operation.</p>

62.9.3 SSI Control Register (SSIx_SCR)

The SSI Control Register (SSIx_SCR) sets up the SSI reset is controlled by bit 0 in the SSI_SCR. SSI operating modes are also selected in this register (except AC97 mode which is selected in the SSI_SACNT register).

Address: Base address + 10h offset

SSIx_SCR field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 SYNC_TX_FS	<p>SYNC_FS_TX bit provides a safe window for TE to be visible to the internal circuit which is just after FS occurrence. When SYNC_TX_FS is set, TE(SCR[1]) gets latched on FS occurrence & latched TE is used to enable/disable SSI transmitter. TE needs setup of 2 bit-clock cycles before occurrence of FS. If TE is changed within 2 bit-clock cycles of FS occurrence, there is high probability that TE will be latched on next FS.</p> <p>Note: With TFR_CLK_DIS feature on, TE is used directly to enable transmitter in following cases (i) Sync mode & Rx disabled (ii) Async Mode. Latched-TE is used to disable the transmitter.</p> <p>This bit has no relevance in gated mode and AC97 mode.</p> <p>0 TE_NOT_LATCHED — TE not latched with FS occurrence & used directly for transmitter enable/disable.</p> <p>1 TE_LATCHED — TE latched with FS occurrence & latched-TE used for transmitter enable/disable.</p>
11 RFR_CLK_DIS	<p>Receive Frame Clock Disable.</p> <p>This bit provides the option to keep the Frame-sync and Clock enabled or to disable them after the receive frame in which the receiver is disabled. Writing to this bit has effect only when RE is disabled. The receiver is disabled by clearing the RE bit.</p>

Table continues on the next page...

SSIx_SCR field descriptions (continued)

Field	Description
	<p>0 CONTINUE — Continue Frame-sync/Clock generation after current frame during which RE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received.</p> <p>1 STOP — Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where receiver is already disabled in current or previous frames.</p>
10 TFR_CLK_DIS	<p>Transmit Frame Clock Disable.</p> <p>This bit provide option to keep the Frame-sync and Clock enabled or disabled after current transmit frame, in which transmitter is disabled by clearing TE bit. Writing to this bit has effect only when SSI is enabled TE is disabled.</p> <p>0 CONTINUE — Continue Frame-sync/Clock generation after current frame during which TE is cleared. This may be required when Frame-sync and Clocks are required from SSI, even when no data is to be received.</p> <p>1 STOP — Stop Frame-sync/Clock generation at next frame boundary. This will be effective also in case where transmitter is already disabled in current or previous frames.</p>
9 CLK_IST	<p>Clock Idle State. This bit controls the idle state of the transmit clock port during SSI internal gated mode.</p> <p>Note: When Clock idle state is '1' the clock polarity should always be negedge triggered and when Clock idle = '0' the clock polarity should always be positive edge triggered.</p> <p>0 IDLE_0 — Clock idle state is '0'.</p> <p>1 IDLE_1 — Clock idle state is '1'.</p>
8 TCH_EN	<p>Two-Channel Operation Enable. This bit allows SSI to operate in the two-channel mode. In this mode while receiving, the RXSR transfers data to SRX0 and SRX1 alternately and while transmitting, data is alternately transferred from STX0 and STX1 to TXSR. For an even number of slots, Two-Channel Operation can be enabled to optimize usage of both FIFOs or disabled as in the case of odd number of active slots. This feature is especially useful in I2S mode, where data for Left Speaker can be placed in Tx-FIFO0 and for Right speaker in Tx-FIFO1.</p> <p>0 DISABLED — Two-channel mode disabled.</p> <p>1 ENABLED — Two-channel mode enabled.</p>
7 SYS_CLK_EN	<p>Network Clock (Oversampling Clock) Enable. When set, this bit allows the SSI to output the network clock at the SRCK port, provided that synchronous mode, and transmit internal clock mode are set. The relationship between bit clock and network clock is determined by DIV2, PSR, and PM bits. This feature is especially useful in I2S Master mode to output network clock (oversampling clock) on SRCK port.</p> <p>0 NOT_OUTPUT — network clock not output on SRCK port.</p> <p>1 OUTPUT — network clock output on SRCK port.</p>
6-5 I2S_MODE	<p>I2S Mode Select. These bits allow the SSI to operate in Normal, I2S Master or I2S Slave mode. Refer to I2S Mode for a detailed description of I2S Mode of operation. Refer to Table 62-5 for details regarding settings.</p>
4 SYN	<p>Synchronous Mode. This bit controls whether SSI is in synchronous mode or not. In synchronous mode, the transmit and receive sections of SSI share a common clock port (STCK) and frame sync port (STFS).</p> <p>0 ASYNC_MODE — Asynchronous mode selected.</p> <p>1 SYNC_MODE — Synchronous mode selected.</p>
3 NET	<p>Network Mode. This bit controls whether SSI is in network mode or not.</p> <p>0 DISABLED — Network mode not selected.</p> <p>1 ENABLED — Network mode selected.</p>

Table continues on the next page...

SSIx_SCR field descriptions (continued)

Field	Description
2 RE	<p>Receive Enable. This control bit enables the receive section of the SSI. When this bit is enabled, data reception starts with the arrival of the next frame sync. If data is being received when this bit is cleared, data reception continues until the end of the current frame and then stops. If this bit is set again before the second to last bit of the last time slot in the current frame, then reception continues without interruption. RE should not be toggled in the same frame.</p> <p>0 DISABLED — Receive section disabled. 1 ENABLED — Receive section enabled.</p>
1 TE	<p>Transmit Enable. This control bit enables the transmit section of the SSI. It enables the transfer of the contents of the STX registers to the TXSR and also enables the internal transmit clock. The transmit section is enabled when this bit is set and a frame boundary is detected. When this bit is cleared, the transmitter continues to send data until the end of the current frame and then stops. Data can be written to the STX registers with the TE bit cleared (the corresponding TDE bit will be cleared). If the TE bit is cleared and then set again before the second to last bit of the last time slot in the current frame, data transmission continues without interruption. The normal transmit enable sequence is to write data to the STX register(s) and then set the TE bit. The normal disable sequence is to clear the TE and TIE bits after the TDE bit is set.</p> <p>In gated clock mode, clearing the TE bit results in the clock stopping after the data currently in TXSR has shifted out. When the TE bit is set, the clock starts immediately (for internal gated clock mode). TE should not be toggled in the same frame.</p> <p>After enabling/disabling transmission, SSI expects 4 setup clock cycles before arrival of frame-sync for frame-sync to be accepted/rejected by In case of fewer clock cycles, there is high probability of the frame-sync to get missed.</p> <p>Note: If continuous clock is not provided, SSI expects 6 clock cycles before arrival of frame-sync for frame-sync to be accepted by the SSI.</p> <p>0 DISABLED — Transmit section disabled. 1 ENABLED — Transmit section enabled.</p>
0 SSIEN	<p>SSIEN - SSI Enable</p> <p>This bit is used to enable/disable the SSI. When disabled, all SSI status bits are preset to the same state produced by the power-on reset, all control bits are unaffected, the contents of Tx and Rx FIFOs are cleared. When SSI is disabled, all internal clocks are disabled (except register access clock).</p> <p>0 DISABLED — SSI is disabled. 1 ENABLED — SSI is enabled.</p>

62.9.4 SSI Interrupt Status Register (SSIx_SISR)

The SSI Interrupt Status Register (SSI_SISR) is used to monitor the SSI. This register is used by the core to interrogate the status of the SSI. In gated mode of operation the TFS, RFS, TLS, RLS, TFRC and RFRC bits of AISR register are not generated. The status bits are described in the following table.

- SSI Status flags are valid when SSI is enabled.

SSI Memory Map/Register Definition

- See [Receive Interrupt Enable Bit Description](#) and [Transmit Interrupt Enable Bit Description](#) for interrupt source mapping.
- All the flags in the SSI_SISR are updated after the first bit of the next SSI word has completed transmission or reception. Certain status bits (ROE0/1 and TUE0/1) are cleared by writing 1 to the corresponding interrupt status bit in SSI_SISR.

Address: Base address + 14h offset

SSIx_SISR field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 RFRC	Receive Frame Complete. This flag is set at the end of the frame during which Receiver is disabled. If Receive Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Receive Frame & Clock are disabled. See the description of RFR_CLK_DIS bit for more details on how to disable Receiver Frame & Clock or keep them enabled after receiver is disabled.

Table continues on the next page...

SSIx_SISR field descriptions (continued)

Field	Description
	0 End of Frame not reached 1 End of frame reached after disabling RE or disabling RFR_CLK_DIS, when receiver is already disabled.
23 TFRC	Transmit Frame Complete. This flag is set at the end of the frame during which Transmitter is disabled. If Transmit Frame & Clock are not disabled in the same frame, this flag is also set at the end of the frame in which Transmit Frame & Clock are disabled. See description of TFR_CLK_DIS bit for more details on how to disable Transmit Frame & Clock or keep them enabled after transmitter is disabled. 0 End of Frame not reached 1 End of frame reached after disabling TE or disabling TFR_CLK_DIS, when transmitter is already disabled.
22–19 Reserved	This read-only field is reserved and always has the value 0.
18 CMDAU	Command Address Register Updated. This bit causes the Command Address Updated interrupt (when CMDAU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Address. This bit is cleared on reading the SACADD register. 0 No change in SACADD register. 1 SACADD register updated with different value.
17 CMDDU	Command Data Register Updated. This bit causes the Command Data Updated interrupt (when CMDDU_EN bit is set). This status bit is set each time there is a difference in the previous and current value of the received Command Data. This bit is cleared on reading the SACDAT register. 0 No change in SACDAT register. 1 SACDAT register updated with different value.
16 RXT	Receive Tag Updated. This status bit is set each time there is a difference in the previous and current value of the received tag. It causes the Receive Tag Interrupt (if RXT_EN bit is set). This bit is cleared on reading the SATAG register. 0 No change in SATAG register. 1 SATAG register updated with different value.
15 RDR1	Receive Data Ready 1. This flag bit is set when SRX1 or Rx FIFO 1 is loaded with a new value and Two-Channel mode is selected. RDR1 is cleared when the Core reads the SRX1 register. If Rx FIFO 1 is enabled, RDR1 is cleared when the FIFO is empty. If RIE and RDR1_EN are set, a Receive Data 1 interrupt request is issued on setting of RDR1 bit in case Rx FIFO1 is disabled, if the FIFO is enabled, the interrupt is issued on RFF1 assertion. The RDR1 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.
14 RDR0	Receive Data Ready 0. This flag bit is set when SRX0 or Rx FIFO 0 is loaded with a new value. RDR0 is cleared when the Core reads the SRX0 register. If Rx FIFO 0 is enabled, RDR0 is cleared when the FIFO is empty. If RIE and RDR0_EN are set, a Receive Data 0 interrupt request is issued on setting of RDR0 bit in case Rx FIFO0 is disabled, if the FIFO is enabled, the interrupt is issued on RFF0 assertion. The RDR0 bit is cleared by POR and SSI reset. 0 No new data for Core to read. 1 New data for Core to read.

Table continues on the next page...

SSIx_SISR field descriptions (continued)

Field	Description
13 TDE1	<p>Transmit Data Register Empty 1. This flag is set whenever data is transferred to TXSR from STX1 register and Two-Channel mode is selected.</p> <p>If Tx FIFO1 is enabled, this occurs when there is at least one empty slot in STX1 or Tx FIFO1. If Tx FIFO1 is not enabled, this occurs when the contents of STX1 are transferred to TXSR.</p> <p>The TDE1 bit is cleared when the Core writes to STX1. If TIE and TDE1_EN are set, an SSI Transmit Data 1 interrupt request is issued on setting of TDE1 bit. The TDE1 bit is cleared by POR and SSI reset.</p> <p>0 Data available for transmission. 1 Data needs to be written by the Core for transmission.</p>
12 TDE0	<p>Transmit Data Register Empty 0. This flag is set whenever data is transferred to TXSR from STX0 register.</p> <p>If Tx FIFO 0 is enabled, this occurs when there is at least one empty slot in STX0 or Tx FIFO 0. If Tx FIFO 0 is not enabled, this occurs when the contents of STX0 are transferred to TXSR.</p> <p>The TDE0 bit is cleared when the Core writes to STX0. If TIE and TDE0_EN are set, an SSI Transmit Data 0 interrupt request is issued on setting of TDE0 bit. The TDE0 bit is cleared by POR and SSI reset.</p> <p>0 Data available for transmission. 1 Data needs to be written by the Core for transmission.</p>
11 ROE1	<p>Receiver Overrun Error 1. This flag is set when the RXSR is filled and ready to transfer to SRX1 register or to Rx FIFO 1 (when enabled) and these are already full and Two-Channel mode is selected. If Rx FIFO 1 is enabled, this is indicated by RFF1 flag, else this is indicated by the RDR1 flag. The RXSR is not transferred in this case.</p> <p>The ROE1 flag causes an interrupt if RIE and ROE1_EN are set.</p> <p>The ROE1 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. Clearing the RE bit does not affect the ROE1 bit.</p> <p>0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.</p>
10 ROE0	<p>Receiver Overrun Error 0. This flag is set when the RXSR is filled and ready to transfer to SRX0 register or to Rx FIFO 0 (when enabled) and these are already full. If Rx FIFO 0 is enabled, this is indicated by RFF0 flag, else this is indicated by the RDR0 flag. The RXSR is not transferred in this case.</p> <p>The ROE0 flag causes an interrupt if RIE and ROE0_EN are set.</p> <p>The ROE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit. Clearing the RE bit does not affect the ROE0 bit.</p> <p>0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.</p>
9 TUE1	<p>Transmitter Underrun Error 1. This flag is set when the TXSR is empty (no data to be transmitted), the TDE1 flag is set, a transmit time slot occurs and the SSI is in Two-Channel mode. When a transmit underrun error occurs, the previous data is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set).</p> <p>The TUE1 flag causes an interrupt if TIE and TUE1_EN are set.</p> <p>The TUE1 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit.</p> <p>0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.</p>
8 TUE0	<p>Transmitter Underrun Error 0. This flag is set when the TXSR is empty (no data to be transmitted), the TDE0 flag is set and a transmit time slot occurs. When a transmit underrun error occurs, the previous data</p>

Table continues on the next page...

SSIx_SISR field descriptions (continued)

Field	Description
	<p>is retransmitted. In Network mode, each time slot requires data transmission (unless masked through STMSK register), when the transmitter is enabled (TE is set).</p> <p>The TUE0 flag causes an interrupt if TIE and TUE0_EN are set.</p> <p>The TUE0 bit is cleared by POR and SSI reset. It is also cleared by writing '1' to this bit.</p> <p>0 Default interrupt issued to the Core. 1 Exception interrupt issued to the Core.</p>
7 TFS	<p>Transmit Frame Sync. This flag indicates the occurrence of transmit frame sync. Data written to the STX registers during the time slot when the TFS flag is set, is sent during the second time slot (in Network mode) or in the next first time slot (in Normal mode). In Network mode, the TFS bit is set during transmission of the first time slot of the frame and is then cleared when starting transmission of the next time slot. In Normal mode, this bit is high for the first time slot. This flag causes an interrupt if TIE and TFS_EN are set. The TFS bit is cleared by POR and SSI reset.</p> <p>0 No Occurrence of Transmit frame sync. 1 Transmit frame sync occurred during transmission of last word written to STX registers.</p>
6 RFS	<p>Receive Frame Sync. This flag indicates the occurrence of receive frame sync. In Network mode, the RFS bit is set when the first slot of the frame is being received. It is cleared when the next slot begins to be received. In Normal mode, this bit is always high (When DC = 0). This flag causes an interrupt if RIE and RFS_EN are set. The RFS bit is cleared by POR and SSI reset.</p> <p>0 No Occurrence of Receive frame sync. 1 Receive frame sync occurred during reception of next word in SRX registers.</p>
5 TLS	<p>Transmit Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last time slot of the frame. TLS is set at the start of the last transmit time slot and causes the SSI to issue an interrupt (if TIE and TLS_EN are set). TLS is not generated when frame rate is 1 in normal mode of operation. TLS is cleared when the SISR is read with this bit set. The TLS bit is cleared by POR and SSI reset.</p> <p>0 Current time slot is not last time slot of frame. 1 Current time slot is the last transmit time slot of frame.</p>
4 RLS	<p>Receive Last Time Slot. This flag indicates the last time slot in a frame. When set, it indicates that the current time slot is the last receive time slot of the frame. RLS is set at the end of the last time slot and causes the SSI to issue an interrupt (if RIE and RLS_EN are set). RLS is cleared when the SISR is read with this bit set. The RLS bit is cleared by POR and SSI reset.</p> <p>0 Current time slot is not last time slot of frame. 1 Current time slot is the last receive time slot of frame.</p>
3 RFF1	<p>Receive FIFO Full 1. This flag is set when Rx FIFO1 is enabled, the data level in Rx FIFO1 reaches the selected Rx FIFO WaterMark 1 (RFWM1) threshold and the SSI is in Two-Channel mode. The setting of RFF1 only causes an interrupt when RIE and RFF1_EN are set, Rx FIFO1 is enabled and the Two-Channel mode is selected. RFF1 is automatically cleared when the amount of data in Rx FIFO1 falls below the threshold. The RFF1 bit is cleared by POR and SSI reset.</p> <p>When Rx FIFO1 contains 15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read.</p> <p>0 NOT_FULL — Space available in Receive FIFO1. 1 FULL — Receive FIFO1 is full.</p>
2 RFF0	<p>Receive FIFO Full 0. This flag is set when Rx FIFO0 is enabled and the data level in Rx FIFO0 reaches the selected Rx FIFO WaterMark 0 (RFWM0) threshold. The setting of RFF0 only causes an interrupt</p>

Table continues on the next page...

SSIx_SISR field descriptions (continued)

Field	Description
	<p>when RIE and RFF0_EN are set and Rx FIFO0 is enabled. RFF0 is automatically cleared when the amount of data in Rx FIFO0 falls below the threshold. The RFF0 bit is cleared by POR and SSI reset.</p> <p>When Rx FIFO0 contains 15 words, the maximum it can hold, all further data received (for storage in this FIFO) is ignored until the FIFO contents are read.</p> <p>0 NOT_FULL — Space available in Receive FIFO0. 1 FULL — Receive FIFO0 is full.</p>
<p>1 TFE1</p>	<p>Transmit FIFO Empty 1. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 1 (TFWM1) threshold and the Two-Channel mode is selected. The setting of TFE1 only causes an interrupt when TIE and TFE1_EN are set, Tx FIFO1 is enabled and Two-Channel mode is selected. The TFE1 bit is automatically cleared when the data level in Tx FIFO1 becomes more than the amount specified by the watermark bits. The TFE1 bit is set by POR and SSI reset.</p> <p>0 HAS_DATA — Transmit FIFO1 has data for transmission. 1 EMPTY — Transmit FIFO1 is empty.</p>
<p>0 TFE0</p>	<p>Transmit FIFO Empty 0. This flag is set when the empty slots in Tx FIFO exceed or are equal to the selected Tx FIFO WaterMark 0 (TFWM0) threshold. The setting of TFE0 only causes an interrupt when TIE and TFE0_EN are set and Tx FIFO0 is enabled. The TFE0 bit is automatically cleared when the data level in Tx FIFO0 becomes more than the amount specified by the watermark bits. The TFE0 bit is set by POR and SSI reset.</p> <p>0 HAS_DATA — Transmit FIFO0 has data for transmission. 1 EMPTY — Transmit FIFO0 is empty.</p>

62.9.5 SSI Interrupt Enable Register (SSIx_SIER)

The SSI Interrupt Enable Register (SIER) is a 25-bit register used to set up the SSI interrupts and DMA requests.

Address: Base address + 18h offset

SSIx_SIER field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 RFRCIE	Receive Frame Complete Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
23 TFRFCIE	Transmit Frame Complete Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not.

Table continues on the next page...

SSIx_SIER field descriptions (continued)

Field	Description
	0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
22 RDMAE	Receive DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the RFF0/1 bits in the SISR are set and if the corresponding RFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding RDR bit is set. 0 SSI Receiver DMA requests disabled. 1 SSI Receiver DMA requests enabled.
21 RIE	Receive Interrupt Enable. This control bit allows the SSI to issue receiver related interrupts to the Core. Refer to Receive Interrupt Enable Bit Description for a detailed description of this bit. 0 SSI Receiver Interrupt requests disabled. 1 SSI Receiver Interrupt requests enabled.
20 TDMAE	Transmit DMA Enable. This bit allows SSI to request for DMA transfers. When enabled, DMA requests are generated when any of the TFE0/1 bits in the SISR are set and if the corresponding TFEN bit is also set. If the corresponding FIFO is disabled, a DMA request is generated when the corresponding TDE bit is set. 0 SSI Transmitter DMA requests disabled. 1 SSI Transmitter DMA requests enabled.
19 TIE	Transmit Interrupt Enable. This control bit allows the SSI to issue transmitter data related interrupts to the Core. Refer to Transmit Interrupt Enable Bit Description for a detailed description of this bit. 0 SSI Transmitter Interrupt requests disabled. 1 SSI Transmitter Interrupt requests enabled.
18 CMDAUIE	Command Address Register Updated Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
17 CMDDUIE	Command Data Register Updated Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
16 RXTIE	Receive Tag Updated Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
15 RDR1IE	Receive Data Ready 1 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
14 RDR0IE	Receive Data Ready 0 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not.

Table continues on the next page...

SSIx_SIER field descriptions (continued)

Field	Description
	0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
13 TDE1IE	Transmit Data Register Empty 1 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
12 TDE0IE	Transmit Data Register Empty 0 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
11 ROE1IE	Receiver Overrun Error 1 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
10 ROE0IE	Receiver Overrun Error 0 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
9 TUE1IE	Transmitter Underrun Error 1 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
8 TUE0IE	Transmitter Underrun Error 0 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
7 TFSIE	Transmit Frame Sync Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
6 RFSIE	Receive Frame Sync Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
5 TLSIE	Transmit Last Time Slot Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not.

Table continues on the next page...

SSIx_SIER field descriptions (continued)

Field	Description
	0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
4 RLSIE	Receive Last Time Slot Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
3 RFF1IE	Receive FIFO Full 1 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
2 RFF0IE	Receive FIFO Full 0 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
1 TFE1IE	Transmit FIFO Empty 1 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.
0 TFE0IE	Transmit FIFO Empty 0 Interrupt Enable. Enable Bit. Controls whether the corresponding status bit in SISR can issue an interrupt to the core or not. 0 Corresponding status bit cannot issue interrupt. 1 Corresponding status bit can issue interrupt.

62.9.6 SSI Transmit Configuration Register (SSIx_STCR)

The SSI Transmit Configuration Register (SSIx_STCR) is a read/write control register used to direct the transmit operation of the STCR controls the direction of the bit clock and frame sync ports, STCK and STFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all SSI_STCR bits. However, SSI reset does not affect the SSI_STCR bits. The SSI_STCR bits are described in the following paragraphs. See the Programmable Registers section for the programming model of the SSI. The SSI Control Register (SSIx_SCR) must first be set to enable interrupts. Next, the SSI interrupt bit in the Interrupt Enable Register (SSIx_SIER) must be set to enable the interrupt. Finally, the interrupt can be enabled from within the SSI.

Address: Base address + 1Ch offset

SSIx_STCR field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
9 TXBIT0	Transmit Bit 0. This control bit allows SSI to transmit the data word from bit position 0 or 15/31 in the transmit shift register. The shifting data direction can be MSB or LSB first, controlled by the TSHFD bit. 0 MSB_ALIGNED — Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of transmit shift register (MSB aligned). 1 LSB_ALIGNED — Shifting with respect to bit 0 of transmit shift register (LSB aligned).
8 TFEN1	Transmit FIFO Enable 1. This bit enables transmit FIFO 1. When enabled, the FIFO allows 15 samples to be transmitted by the SSI (per channel) (a 9th sample can be shifting out) before TDE1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled). 0 Transmit FIFO 1 disabled. 1 Transmit FIFO 1 enabled.

Table continues on the next page...

SSIx_STCR field descriptions (continued)

Field	Description
7 TFENO	<p>Transmit FIFO Enable 0. This bit enables transmit FIFO 0. When enabled, the FIFO allows 15 samples to be transmitted by the SSI per channel (a 9th sample can be shifting out) before TDE0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is transferred to the transmit shift register (provided the interrupt is enabled).</p> <p>0 Transmit FIFO 0 disabled. 1 Transmit FIFO 0 enabled.</p>
6 TFDIR	<p>Transmit Frame Direction. This bit controls the direction and source of the transmit frame sync signal. Internally generated frame sync signal is sent out through the STFS port and external frame sync is taken from the same port.</p> <p>0 EXTERNAL — Frame Sync is external. 1 INTERNAL — Frame Sync generated internally.</p>
5 TXDIR	<p>Transmit Clock Direction. This bit controls the direction and source of the clock signal used to clock the TXSR. Internally generated clock is output through the STCK port. External clock is taken from this port. Refer to Table 62-2 for details of clock pin configurations.</p> <p>0 EXTERNAL — Transmit Clock is external. 1 INTERNAL — Transmit Clock generated internally.</p>
4 TSHFD	<p>Transmit Shift Direction. This bit controls whether the MSB or LSB will be transmitted first in a sample.</p> <p>NOTE: The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (TSHFD cleared).</p> <p>0 MSB_FIRST — Data transmitted MSB first. 1 LSB_FIRST — Data transmitted LSB first.</p>
3 TSCKP	<p>Transmit Clock Polarity. This bit controls which bit clock edge is used to clock out data for the transmit section. Note: TSCKP is 0 CLK_IST = 0; TSCKP is 1 CLK_IST = 1</p> <p>0 RISING_EDGE — Data clocked out on rising edge of bit clock. 1 FALLING_EDGE — Data clocked out on falling edge of bit clock.</p>
2 TFSI	<p>Transmit Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the transmit section of SSI.</p> <p>0 ACTIVE_HIGH — Transmit frame sync is active high. 1 ACTIVE_LOW — Transmit frame sync is active low.</p>
1 TFSL	<p>Transmit Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the transmit section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0].</p> <p>0 ONE_WORD — Transmit frame sync is one-word long. 1 ONE_CLOCK_BIT — Transmit frame sync is one-clock-bit long.</p>
0 TEFS	<p>Transmit Early Frame Sync. This bit controls when the frame sync is initiated for the transmit section. The frame sync signal is deasserted after one bit-for-bit length frame sync and after one word-for-word length frame sync. In case of synchronous operation, the frame sync can also be initiated on receiving the first bit of data.</p> <p>0 FIRST_BIT — Transmit frame sync initiated as the first bit of data is transmitted. 1 ONE_BIT_BEFORE — Transmit frame sync is initiated one bit before the data is transmitted.</p>

62.9.7 SSI Receive Configuration Register (SSIx_SRCR)

The SSI Receive Configuration Register (SSI_SRCR) is a read/write control register used to direct the receive operation of the SSI. SSI_SRCR controls the direction of the bit clock and frame sync ports, SRCK and SRFS. Interrupt enable bit for the transmit sections is provided in this control register. The Power-on reset clears all SSI_SRCR bits. However, SSI reset does not affect the SSI_SRCR bits.

SSIx_SRCR field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value 0.
10 RXEXT	Receive Data Extension. This control bit allows SSI to store the received data word in sign extended form. This bit affects data storage only in case received data is LSB aligned (SRCR[9]=1) 0 OFF — Sign extension turned off. 1 ON — Sign extension turned on.
9 RXBIT0	Receive Bit 0. This control bit allows SSI to receive the data word at bit position 0 or 15/31 in the receive shift register. The shifting data direction can be MSB or LSB first, controlled by the RSHFD bit. 0 MSB_ALIGNED — Shifting with respect to bit 31 (if word length = 16, 18, 20, 22 or 24) or bit 15 (if word length = 8, 10 or 12) of receive shift register (MSB aligned). 1 LSB_ALIGNED — Shifting with respect to bit 0 of receive shift register (LSB aligned).
8 RFEN1	Receive FIFO Enable 1. This bit enables receive FIFO 1. When enabled, the FIFO allows 15 samples to be received by the SSI per channel (a 16th sample can be shifting in) before RDR1 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled). 0 Receive FIFO 1 disabled. 1 Receive FIFO 1 enabled.

Table continues on the next page...

SSIx_SRCR field descriptions (continued)

Field	Description
7 RFEN0	<p>Receive FIFO Enable 0. This bit enables receive FIFO 0. When enabled, the FIFO allows 15 samples to be received by the SSI (per channel) (a 16th sample can be shifting in) before RDR0 bit is set. When the FIFO is disabled, an interrupt is generated when a single sample is received by the SSI (provided the interrupt is enabled).</p> <p>0 Receive FIFO 0 disabled. 1 Receive FIFO 0 enabled.</p>
6 RFDIR	<p>Receive Frame Direction. This bit controls the direction and source of the receive frame sync signal. Internally generated frame sync signal is sent out through the SRFS port and external frame sync is taken from the same port.</p> <p>0 EXTERNAL — Frame Sync is external. 1 INTERNAL — Frame Sync generated internally.</p>
5 RXDIR	<p>Receive Clock Direction. This bit controls the direction and source of the clock signal used to clock the RXSR. Internally generated clock is output through the SRCK port. External clock is taken from this port. Refer to Table 62-2 for details on clock pin configurations.</p> <p>0 EXTERNAL — Receive Clock is external. 1 INTERNAL — Receive Clock generated internally.</p>
4 RSHFD	<p>Receive Shift Direction. This bit controls whether the MSB or LSB will be received first in a sample.</p> <p>NOTE: The CODEC device labels the MSB as bit 0, whereas the Core labels the LSB as bit 0. Therefore, when using a standard CODEC, Core MSB (CODEC LSB) is shifted in first (RSHFD cleared).</p> <p>0 MSB_FIRST — Data received MSB first. 1 LSB_FIRST — Data received LSB first.</p>
3 RSCKP	<p>Receive Clock Polarity. This bit controls which bit clock edge is used to latch in data for the receive section.</p> <p>0 FALLING_EDGE — Data latched on falling edge of bit clock. 1 RISING_EDGE — Data latched on rising edge of bit clock.</p>
2 RFSI	<p>Receive Frame Sync Invert. This bit controls the active state of the frame sync I/O signal for the receive section of SSI.</p> <p>0 ACTIVE_HIGH — Receive frame sync is active high. 1 ACTIVE_LOW — Receive frame sync is active low.</p>
1 RFSL	<p>Receive Frame Sync Length. This bit controls the length of the frame sync signal to be generated or recognized for the receive section. The length of a word-long frame sync is same as the length of the data word selected by WL[3:0].</p> <p>0 ONE_WORD — Receive frame sync is one-word long. 1 ONE_CLOCK_BIT — Receive frame sync is one-clock-bit long.</p>
0 REFS	<p>Receive Early Frame Sync. This bit controls when the frame sync is initiated for the receive section. The frame sync is disabled after one bit-for-bit length frame sync and after one word-for-word length frame sync.</p> <p>0 FIRST_BIT — Receive frame sync initiated as the first bit of data is received. 1 ONE_BIT_BEFORE — Receive frame sync is initiated one bit before the data is received.</p>

62.9.8 SSI Transmit Clock Control Register (SSIx_STCCR)

The SSI Transmit and Receive Control (SSI_STCCR and SSI_SRCCR) registers are 19-bit, read/write control registers used to direct the operation of the SSI. The Clock Controller Module (CCM) can source the SSI clock (SSI's sys clock from CCM's ssi_clk_root) from multiple sources and perform fractional division to support commonly used audio bit rates. The CCM can maintain the SSI's sys clock frequency at a constant rate even in cases where the ipg_clk (from CCM) frequency changes. These registers control the SSI clock generator, bit and frame sync rates, word length, and number of words per frame for the serial data. The SSI_STCCR register is dedicated to the transmit section, and the SSI_SRCCR register is dedicated to the receive section except in Synchronous mode, in which the SSI_STCCR register controls both the receive and transmit sections. Power-on reset clears all SSI_STCCR and SSI_SRCCR bits. SSI reset does not affect the SSI_STCCR and SSI_SRCCR bits. The control bits are described in the following paragraphs. Although the bit patterns of the SSI_STCCR and SSI_SRCCR registers are the same, the contents of these two registers can be programmed differently.

SSIx_STCCR field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value 0.
18 DIV2	Divide By 2. This bit controls a divide-by-two divider in series with the rest of the prescalers. 0 Divider bypassed. 1 Divider used to divide clock by 2.
17 PSR	Prescaler Range. This bit controls a fixed divide-by-eight prescaler in series with the variable prescaler. It extends the range of the prescaler for those cases where a slower bit clock is required. 0 Prescaler bypassed. 1 Prescaler used to divide clock by 8.
16–13 WL3_WL0	Word Length Control. These bits are used to control the length of the data words being transferred by the SSI. These bits control the Word Length Divider in the Clock Generator. They also control the frame sync pulse length when the FSL bit is cleared. In I2S Master mode, the SSI works with a fixed word length of 32, and the WL bits are used to control the amount of valid data in those 32 bits. In AC97 Mode of operation, if word length is set to any value other than 16 bits, it will result in a word length of 20 bits.
12–8 DC4_DC0	Frame Rate Divider Control. These bits are used to control the divide ratio for the programmable frame rate dividers. The divide ratio works on the word clock. In Normal mode, this ratio determines the word transfer rate. In Network mode, this ratio sets the number of words per frame. The divide ratio ranges from 1 to 32 in Normal mode and from 2 to 32 in Network mode. In Normal mode, a divide ratio of 1 (DC=00000) provides continuous periodic data word transfer. A bit-length frame sync must be used in this case. These bits can be programmed with values ranging from "00000" to "11111" to control the number of words in a frame.
PM7_PM0	Prescaler Modulus Select. These bits control the prescale divider in the clock generator. This prescaler is used only in Internal Clock mode to divide the internal clock. The bit clock output is available at the clock port. A divide ratio from 1 to 256 (PM[7:0] = 0x00 to 0xFF) can be selected. Refer to DIV2 , PSR and PM Bit Description for details regarding settings.

62.9.9 SSI Receive Clock Control Register (SSIx_SRCCR)

The SSI Transmit and Receive Control (SSI_STCCR and SSI_SRCCR) registers are 19-bit, read/write control registers used to direct the operation of the SSI. The Clock Controller Module (CCM) can source the SSI clock (SSI's sys clock-from CCM's ssi_clk_root) from multiple sources and perform fractional division to support commonly used audio bit rates. The CCM can maintain the SSI's sys clock frequency at a constant rate even in cases where the ipg_clk from CCM frequency changes. These registers control the SSI clock generator, bit and frame sync rates, word length, and number of words per frame for the serial data. The SSI_STCCR register is dedicated to the transmit section, and the SSI_SRCCR register is dedicated to the receive section except in Synchronous mode, in which the SSI_STCCR register controls both the receive and transmit sections. Power-on reset clears all SSI_STCCR and SSI_SRCCR bits. SSI reset does not affect the SSI_STCCR and SSI_SRCCR bits. The control bits are described in the following paragraphs. Although the bit patterns of the SSI_STCCR and SSI_SRCCR registers are the same, the contents of these two registers can be programmed differently.

Transmit FIFO empty is set when TxFIFO <= 4 data.</p> <p>1100 TFE set when there are more than or equal to 12 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 3 data.</p> <p>1101 TFE set when there are more than or equal to 13 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 2 data.</p> <p>1110 TFE set when there are more than or equal to 14 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO <= 1 data.</p> <p>1111 TFE set when there are 15 empty slots in Transmit FIFO. Transmit FIFO empty is set when TxFIFO = 0 data.</p>
15–12 RFCNT0	<p>Receive FIFO Counter 0. These bits indicate the number of data words in Receive FIFO 0. See SSI_SFCSR[RFCNT1] for details regarding settings for receive FIFO counter bits.</p>
11–8 TFCNT0	<p>Transmit FIFO Counter 0. These bits indicate the number of data words in Transmit FIFO 0. See SSI_SFCSR[TFCNT1] for details regarding settings for transmit FIFO counter bits.</p>
7–4 RFWM0	<p>Receive FIFO Full WaterMark 0. These bits control the threshold at which the RFF0 flag will be set. The RFF0 flag is set whenever the data level in Rx FIFO 0 reaches the selected threshold. See SSI_SFCSR[RFWM1] for details regarding settings for receive FIFO watermark bits.</p>
TFWM0	<p>Transmit FIFO Empty WaterMark 0. These bits control the threshold at which the TFE0 flag will be set. The TFE0 flag is set whenever the empty slots in Tx FIFO exceed or are equal to the selected threshold. See SSI_SFCSR[TFWM0] for details regarding settings for transmit FIFO watermark bits.</p>

62.9.11 SSI AC97 Control Register (SSIx_SACNT)

Address: Base address + 38h offset

SSIx_SACNT field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value 0.
10–5 FRDIV	Frame Rate Divider. These bits control the frequency of AC97 data transmission/reception. They are programmed with the number of frames for which the SSI should be idle, after operating in one frame. Through these bits, AC97 frequency of operation, from 48 KHz (000000) to 1 KHz (101111) can be achieved. Sample Value: 001010 (10 Decimal) = SSI will operate once every 11 frames.
4 WR	Write Command. This bit specifies whether the next frame will carry an AC97 Write Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bits (corresponding to Command Address and Command Data slots of the next Tx frame) are automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Write Command. 1 Next frame will have a Write Command.
3 RD	Read Command. This bit specifies whether the next frame will carry an AC97 Read Command or not. The programmer should take care that only one of the bits (WR or RD) is set at a time. When this bit is set, the corresponding tag bit (corresponding to Command Address slot of the next Tx frame) is automatically set. This bit is automatically cleared by the SSI after completing transmission of a frame. 0 Next frame will not have a Read Command. 1 Next frame will have a Read Command.
2 TIF	Tag in FIFO. This bit controls the destination of the information received in AC97 tag slot (Slot #0). 0 SATAG_REGISTER — Tag info stored in SATAG register. 1 RX_FIFO0 — Tag info stored in Rx FIFO 0.
1 FV	Fixed/Variable Operation. This bit selects whether the SSI is in AC97 Fixed mode or AC97 Variable mode.

Table continues on the next page...

SSIx_SACNT field descriptions (continued)

Field	Description
	0 FIXED — AC97 Fixed Mode. 1 VARIABLE — AC97 Variable Mode.
0 AC97EN	AC97 Mode Enable. This bit is used to enable SSI AC97 operation. Refer to AC97 Mode for details of AC97 operation. 0 AC97 mode disabled. 1 SSI in AC97 mode.

62.9.12 SSI AC97 Command Address Register (SSIx_SACADD)

Address: Base address + 3Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SSIx_SACADD field descriptions

Field	Description
31–19 Reserved	This read-only field is reserved and always has the value 0.
SACADD	AC97 Command Address. These bits store the Command Address Slot information (bit 19 of the slot is sent in accordance with the Read and Write Command bits in SSI_SACNT register). These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Address Slot. If the contents of these bits change due to an update, the CMDAU bit in SISR is set.

62.9.13 SSI AC97 Command Data Register (SSIx_SACDAT)

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SSIx_SACDAT field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value 0.
SACDAT	AC97 Command Data. The outgoing Command Data Slot carries the information contained in these bits. These bits can be updated by a direct write from the Core. They are also updated with the information received in the incoming Command Data Slot. If the contents of these bits change due to an update, the

Table continues on the next page...

SSIx_SACDAT field descriptions (continued)

Field	Description
	CMDDU bit in SISR is set. These bits are transmitted only during AC97 Write Command. During AC97 Read Command, 0x00000 is transmitted in time slot #2.

62.9.14 SSI AC97 Tag Register (SSIx_SATAG)

Address: Base address + 44h offset

SSIx_SATAG field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
SATAG	AC97 Tag Value. Writing to this register (by the Core) sets the value of the Tx-Tag in AC97 fixed mode of operation. On a read, the Core gets the Rx-Tag Value received (in the last frame) from the Codec. If TIF bit in SSI_SACNT register is set, the TAG value is also stored in Rx-FIFO in addition to SATAG register. When the received Tag value changes, the RXT bit in SISR register is set. Bits SATAG[1:0] convey the Codec -ID. In current implementation only Primary Codecs are supported. Thus writing value 2'b00 to this field is mandatory.

62.9.15 SSI Transmit Time Slot Mask Register (SSIx_STMSK)

Address: Base address + 48h offset

SSIx_STMSK field descriptions

Field	Description
STMSK	Transmit Mask. These bits indicate which slot has been masked in the current frame. The Core can write to this register to control the time slots in which the SSI transmits data. Each bit has info corresponding to the respective time slot in the frame. Transmit mask bits should not be used in I2S Slave mode of operation. SSI_STMSK register value must be set before enabling Transmission. 0 Valid Time Slot. 1 Time Slot masked (no data transmitted in this time slot).

62.9.16 SSI Receive Time Slot Mask Register (SSIx_SRMSK)

Address: Base address + 4Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SSIx_SRMSK field descriptions

Field	Description
SRMSK	<p>Receive Mask. These bits indicate which slot has been masked in the current frame. The Core can write to this register to control the time slots in which the SSI receives data. Each bit has info corresponding to the respective time slot in the frame. SSI_SRMSK register value must be set before enabling Receiver. Receive mask bits should not be used in I2S Slave mode of operation.</p> <p>0 Valid Time Slot. 1 Time Slot masked (no data received in this time slot).</p>

62.9.17 SSI AC97 Channel Status Register (SSIx_SACCST)

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																SACCST															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SSIx_SACCST field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
SACCST	<p>AC97 Channel Status. These bits indicate which data slot has been enabled in AC97 variable mode operation. This register is updated in case the core enables/disables a channel through a write to SSI_SACCEN/SSI_SACCDIS register or the external codec enables a channel by sending a '1' in the corresponding SLOTREQ bit. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). The contents of this register only have relevance while the SSI is operating in AC97 variable mode. Writes to this register result in an error response on the block interface.</p> <p>0 Data channel disabled. 1 Data channel enabled.</p>

62.9.18 SSI AC97 Channel Enable Register (SSIx_SACCEN)

Address: Base address + 54h offset

SSIx_SACCEN field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
SACCEN	AC97 Channel Enable. The Core writes a '1' to these bits to enable an AC97 data channel. Writing a '0' has no effect. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). Writes to these bits only have effect in the AC97 Variable mode of operation. These bits are always read as '0' by the Core. 0 Write Has no effect. 1 Write Enables the corresponding data channel.

62.9.19 SSI AC97 Channel Disable Register (SSIx_SACCDIS)

Address: Base address + 58h offset

SSIx_SACCDIS field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
SACCDIS	AC97 Channel Disable. The Core writes a '1' to these bits to disable an AC97 data channel. Writing a '0' has no effect. Bit [0] corresponds to the first data slot in an AC97 frame (Slot #3) and Bit [9] corresponds to the tenth data slot (slot #12). Writes to these bits only have effect in the AC97 Variable mode of operation. These bits are always read as '0' by the Core. 0 Write Has no effect. 1 Write Disables the corresponding data channel.

Chapter 63

Temperature Monitor (TEMPMON)

63.1 Overview

The temperature sensor module implements a temperature sensor/conversion function based on a temperature-dependent voltage to time conversion.

The module features alarm functions that can raise independent interrupt signals if the temperature is above two high-temperature thresholds and below a low temperature threshold. These temperature thresholds are programmable and designated as low, high and panic temperature. The panic threshold is a special programmable threshold in that if the temperature increases above this value and the temperature-panic-reset interrupt is enabled in the System Reset Controller, the hardware will assume that software no longer has control over the thermal situation and will initiate a reset of the chip.

In order to avoid false panic temperature initiated resets, the panic alarm will not fire until the temperature panic condition has been met for four consecutive conversion cycles. A self-repeating mode can also be programmed which executes a temperature sensing operation based on a programmed delay.

Since the high and low temperature thresholds are programmable, they form a sliding temperature bracket that can be tailored to the application's needs. For example, at start-up software can set the low temperature threshold to the minimum temperature code and the high temperature threshold to a maximum operating temperature for the system.

The system can then use this module to monitor the on-die temperature and take appropriate actions such as throttling back the core frequency when a the high temperature interrupt is set. Once the high temperature interrupt is set then the system can program the low temperature threshold to a desired cool down temperature. The system would then switch to monitoring the low temperature alarm and wait for its interrupt to be set. With this scheme, once the low temperature interrupt is set then software could be assured that the temperature has cooled down to a safe level and the process could be repeated.

The high-level implementation of the temperature sensor is shown in the figure below.

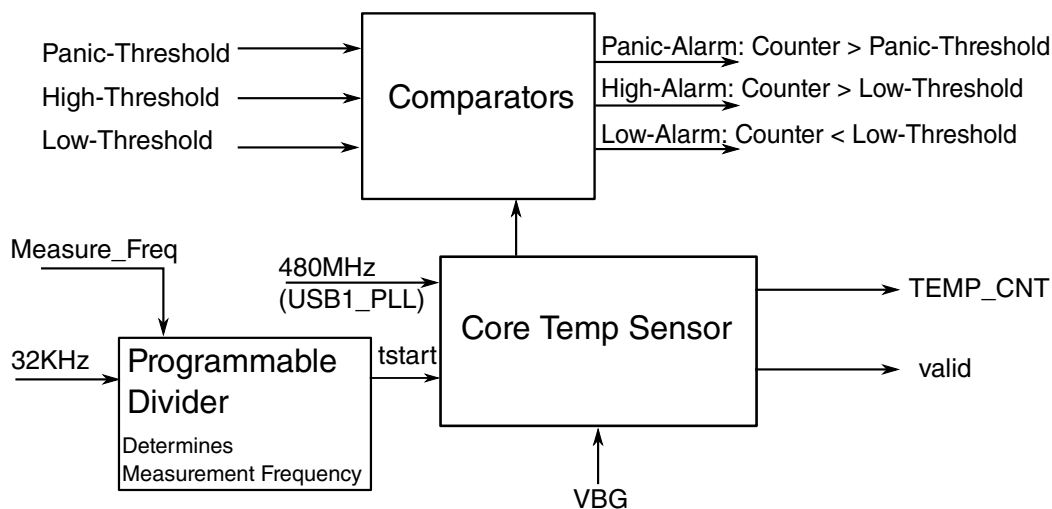

Figure 63-1. High Level Temp Sensor System Diagram

As shown in the figure above, the temperature sensor uses and assumes that the bandgap reference, 480MHz PLL and 32KHz RTC modules are properly programmed and fully settled for correct operation.

63.2 Software Usage Guidelines

During normal system operation software can use the temperature sensor counter output (TEMP_CNT) in conjunction with the fused temperature calibration data to determine the on-die operational temperature or to set an over-temperature interrupt alarm to within a couple of °C.

Based on calibration, two sets of temperature and counter values will be available via fuses on the device. These data points will correspond to the points (N₁, T₁) and (N₂, T₂) in the curve below.

Figure 63-2. Temperature Measurement Cycle

After a temperature measurement cycle, software should use the calibration points in conjunction with the temperature code value in the `TEMPMON_TEMPSENSE0[TEMP_CNT]` bitfield to calculate the temperature for the device using the following equation:

$$T_{\text{meas}} = T_2 - (N_{\text{meas}} - N_2) * ((T_2 - T_1) / (N_1 - N_2))$$

Likewise, to determine the alarm counter value to be written in the `TEMPMON_TEMPSENSE0` register for a temperature based interrupt, the above equation can be solved for the N_{meas} value that should be used based on the desired temperature trigger.

The temperature calibration point fuse values are available in the `OCOTP_ANA1` register. The temperature calibration values are fused individually for each part in the product testing process. The fields of this register are described in the following table.

Table 63-1. OCOTP_ANA1 Temperature Sensor Calibration Data

Bit Range	Bit Mask	Name	Description
[31:20]	FFF0_0000h	ROOM_COUNT	Value of <code>TEMPMON_TEMPSENSE0[TEMP_VALUE]</code> after a measurement cycle at room temperature (25.0 °C).
[19:8]	000F_FF00h	HOT_COUNT	Value of <code>TEMPMON_TEMPSENSE0[TEMP_VALUE]</code> after a measurement cycle at the hot temperature, i.e. <code>HOT_TEMP</code> .
[7:0]	0000_00FFh	HOT_TEMP	The hot temperature test point. Each LSB equals 1 °C.

The points on the calibration curve are as follows.

- $(N_1, T_1) = (\text{ROOM_COUNT}, 25.0)$

TEMPMON Memory Map/Register Definition

- $(N_2, T_2) = (\text{HOT_COUNT}, \text{HOT_TEMP})$
- $(N_{\text{meas}}, T_{\text{meas}}) = (\text{TEMP_CNT}, T_{\text{meas}})$

Substituting the fields from OCOTP_ANA1 into the earlier equation results in the following:

$$T_{\text{meas}} = \text{HOT_TEMP} - (N_{\text{meas}} - \text{HOT_COUNT}) * ((\text{HOT_TEMP} - 25.0) / (\text{ROOM_COUNT} - \text{HOT_COUNT}))$$

63.3.1 Tempensor Control Register 0 (TEMPMON_TEMPSENSE0n)

This register defines the basic controls for the temperature sensor minus the frequency of automatic sampling which is defined in the tempsensor.

Address: 20C_8000h base + 180h offset + (4d × i), where i=0d to 3d

TEMPMON Memory Map/Register Definition

TEMPMON_TEMPSENSE0n field descriptions

Field	Description
31–20 ALARM_VALUE	This bit field contains the temperature count (raw sensor output) that will generate an alarm interrupt.
19–8 TEMP_CNT	This bit field contains the last measured temperature count.
7 -	This field is reserved. Reserved.
6 -	This field is reserved. Reserved.
5–3 -	This field is reserved. Reserved
2 FINISHED	Indicates that the latest temp is valid. This bit should be cleared by the sensor after the start of each measurement. 0 INVALID — Last measurement is not ready yet. 1 VALID — Last measurement is valid.
1 MEASURE_TEMP	Starts the measurement process. If the measurement frequency is zero in the TEMPSSENSE1 register, this results in a single conversion.

Table continues on the next page...

TEMPMON_TEMPSENSE0n field descriptions (continued)

Field	Description
	0 STOP — Do not start the measurement process. 1 START — Start the measurement process.
0 POWER_DOWN	This bit powers down the temperature sensor. 0 POWER_UP — Enable power to the temperature sensor. 1 POWER_DOWN — Power down the temperature sensor.

63.3.2 Tempensor Control Register 1 (TEMPMON_TEMPSENSE1n)

This register defines the automatic repeat time of the temperature sensor.

Address: 20C_8000h base + 190h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TEMPMON_TEMPSENSE1n field descriptions

Field	Description
31–16 -	This field is reserved. Reserved.
MEASURE_ FREQ	This bits determines how many RTC clocks to wait before automatically repeating a temperature measurement. The pause time before remeasuring is the field value multiplied by the RTC period. 0x0000 Defines a single measurement with no repeat. 0x0001 Updates the temperature value at a RTC clock rate. 0x0002 Updates the temperature value at a RTC/2 clock rate. ... — 0xFFFF Determines a two second sample period with a 32.768KHz RTC clock. Exact timings depend on the accuracy of the RTC clock.

63.3.3 Tempensor Control Register 2 (TEMPMON_TEMPSENSE2n)

This register defines the automatic repeat time of the temperature sensor.

Address: 20C_8000h base + 290h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TEMPMON_TEMPSENSE2n field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–16 PANIC_ALARM_VALUE	This bit field contains the temperature that will generate a panic interrupt when exceeded by the temperature measurement.
15–12 -	This field is reserved. Reserved.
LOW_ALARM_VALUE	This bit field contains the temperature that will generate a low alarm interrupt when the field is greater than the temperature measurement.

Chapter 64

TrustZone Address Space Controller (TZASC)

64.1 Overview

The TrustZone Address Space Controller (TZASC) protects security-sensitive SW and data in a trusted execution environment against potentially compromised SW running on the platform.

The TZASC block diagram is shown in figure below.

Figure 64-1. TZASC Block Diagram

The TZASC is an IP by ARM ("CoreLink™ TrustZone Address Space Controller TZC-380"), designed to provide configurable protection over program (SW) memory space.

The main features of TZASC are:

- Supports 16 independent address regions
- Access controls are independently programmable for each address region
- Sensitive registers may be locked
- Host interrupt may be programmed to signal attempted access control violations

- AXI master/slave interfaces for transactions
- APB slave interface for configuration and status reporting

64.2 Clocks

The table found here describes the clock sources for TZASC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 64-1. TZASC Clocks

Clock name	Clock Root	Description
ackl	mmdc_axi_clk_root	Module clock

64.3 i.MX 6SoloX Specific Configuration

The i.MX 6SoloX uses a single TZASC instance, on the DDR controller (MMDC), to provide address protection based on access security level.

The i.MX 6SoloX utilizes bus muxing logic to route DDR memory traffic through or bypass the TZASC module. By default, the TZASC is bypassed, and its clocks are gated off.

Enabling TZASC is expected to have a slight impact on memory performance. Exact value cannot be stated, since varies, depending on specific application software.

The proper and preferred method of enabling the TZASC, is by burning the TZASC_ENABLE fuse

For every power-up cycle, with TZASC_ENABLE fuse burned, the Boot ROM code will seamlessly handle the enable and engage of the TZASC module and its clocks, leaving it in an active state, (i.e. enabled, and not bypassed). From this state on, it is the responsibility of OS image, to configure the memory regions protection, per a specific application / use-case needs.

A configuration lock bit ("TZASC_BOOT_LOCK" in GPR3 register of IOMUXC) once set, will block any attempts to change the security settings, past the OS image configuration code settings. The configuration locking is in place, until the next hardware reset cycle.

NOTE

Engaging the TZASC functionality (i.e. - not bypassed), has to be done while DDR bus is guaranteed to be idle, with no pending transactions.

Enabling TZASC, w/o use of the associated fuse, is possible, but not trivial, since has to be done while traffic to DDR is guaranteed to be stopped. A typical way of achieving this, is by:

- Ensuring no other master can issue accesses to DDR.
- Protect against program flow change, to DDR space, (Disable interrupts, ans such).
- Run switching code from internal RAM.

TZASC enabling code has to handle the data-path mux control (via TZASC_BYPASS bits in GPR9, in IOMUXC module) as well as clock enabling (in LPCG module), and configuration locking, if desired (via set of TZASC_BOOT_LOCK bit in GPR3, IOMUXC module).

The TZASC_BYPASS bit in GPR9 register, once set, preserve its value until the next power-up cycle ("Sticky" type), in order to protect against unauthorized 'disable' operation.

64.4 Address Mapping in various memory mapping modes

The address configured to the TZASC controller(s) must match the "local addresses" as being passed on to the DDR controller(s).

The DDR controller "local addresses" refer to the addresses seen by the DDR controller. In the single-channel single-controller scheme, the local addresses are in the 2-4GB range.

Memory "aliasing" implications on TZASC settings - in systems which does not utilize the maximal supported DDR space the controller is designed for, the whole DDR memory map becomes "aliased" (replicated) by the size of the physical memory used. In such cases, the TZASC must be configured to protect all aliased regions as well (i.e. effectively reducing the number of available TZASC regions, since all aliased regions must be handled, for each "real" space needing protection).

For complete details on TZASC functionality and the programming model, see the ARM document, "CoreLink™ TrustZone Address Space Controller TZC-380 Technical Reference Manual, (Rev r0p1 or newer)", available at <http://infocenter.arm.com>.

Chapter 65

Universal Asynchronous Receiver/Transmitter (UART)

65.1 Overview

Universal Asynchronous Receiver/Transmitter (UART) provides serial communication capability with external devices through a level converter and an RS-232 cable or through use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission) to provide low speed IrDA compatibility.

UART supports NRZ encoding format , RS485 compatible 9 bit data format and IrDA-compatible infrared slow data rate (SIR) format.

The following figure is the UART block diagram.

The "Module Clock" is the UART_CLK which comes from CCM. The "Peripheral Clock" is the IPG_CLK which comes from CCM.

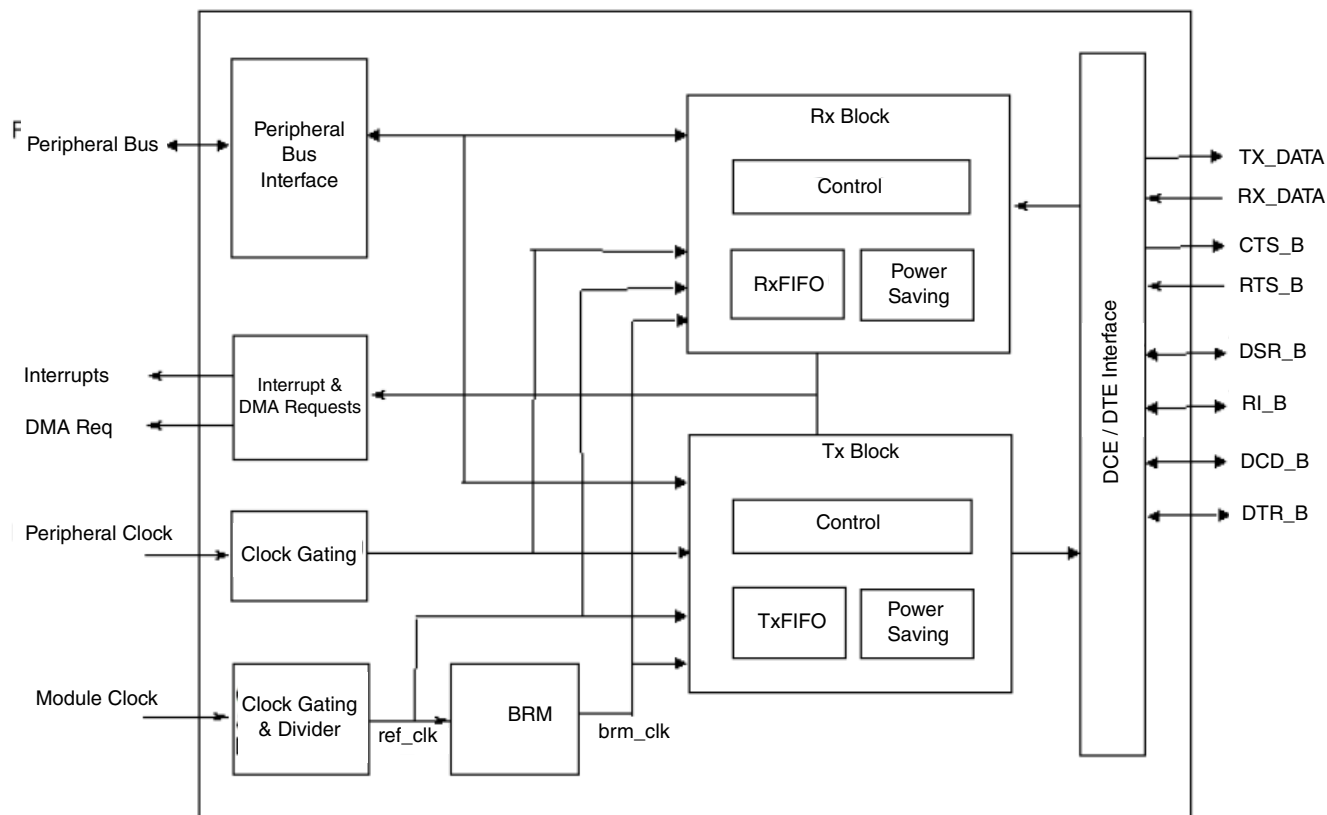

Figure 65-1. UART Block Diagram

65.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible, up to 5.0 Mbit/s
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s)
- 9-bit or Multidrop mode (RS-485) support (automatic slave address detection)
- 7 or 8 data bits for RS-232 characters, or 9 bit RS-485 format
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send (RTS_B) and clear to send (CTS_B) signals
- RS-485 driver direction control via CTS_B signal
- Edge-selectable RTS_B and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression
- UART internal clocks enable/disable

- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- RX_DATA input and TX_DATA output can be inverted respectively in RS-232/RS-485 mode
- DCE/DTE capability
- RTS_B, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE), RI_B (DTE only), DCD_B (DTE only), DTR_B (DCE only) and DSR_B (DTE only) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset (SRST_B)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

65.1.2 Modes of operation

- Serial RS-232NRZ mode
- 9-bit RS-485 mode
- IrDA mode

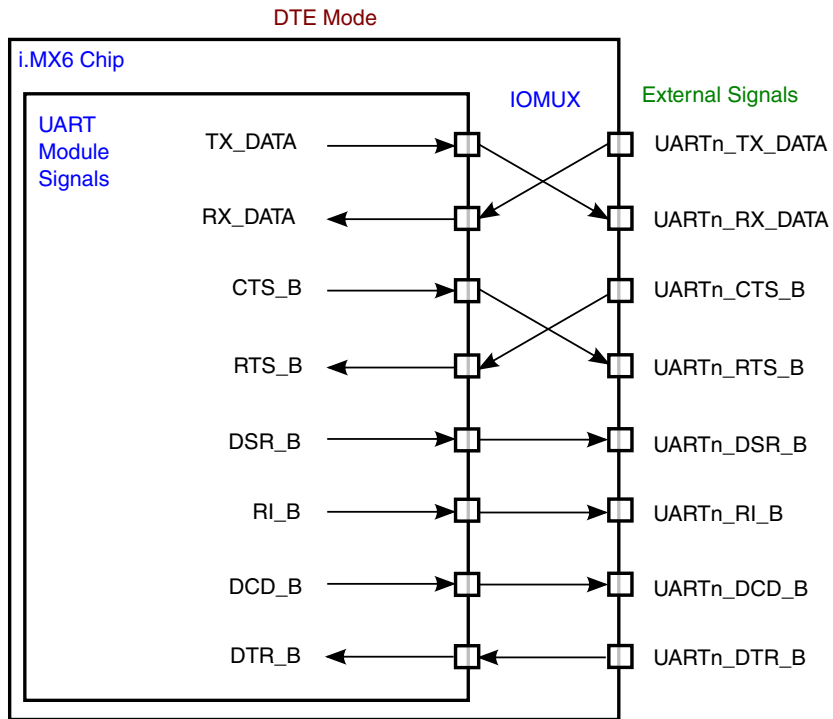

To set UART in different modes, see the table below.

Table 65-1. UART mode definition

MDEN (UMCR[0])	IREN (UCR1[7])	UART Mode	Description
0	0	RS-232	RXD/TXD data is serial RS-232 NRZ format
0	1	IrDA (Interface)	RXD/TXD data is IrDA-compatible infrared slow data rate (SIR) format
1	0	RS-485	RXD/TXD data is RS485 compatible 9 bit data format
1	1	Undefined	Undefined

65.2 External Signals
