

Hello World!

i.MX PDK Linux Application Note

Document Number: 926-77204

Revision 2009.12

Contents

Installation and Setup.....	3
Creating a New Application.....	3
Building the Application	5
Adding the Application to the Package Directory Tree.....	6
Running the Application	7
Files for the Application Note	8

This document shows you how to create and load a simple Hello World application into the tree directory for the packages used in the Linux distribution and then run the application. Note that the distribution contains a Hello World application; however, this procedure explains how to create a new Hello World application.

Installation and Setup

Pre-requisites:

- SDK installed, as explained in the *i.MX PDK Linux User's Guide*
- NFS file system set to work with the PC host, using a serial interface between the target and the host PC (minicom for Linux or HyperTerminal for windows) at 115200

NOTE

For additional information, see the instructions for the building process and NFS procedures in the *i.MX PDK Linux User's Guide*.

Creating a New Application

In order to create the application at least three files are needed: the source file (c file), the Makefile, and the spec file. In some circumstances only the source file is needed and the information provided by the Makefile is included in another file with the extension `.spec`, which is also created when making a new application.

- **Source file** (c file): The application in C, and also the headers if the application requires them.
- **Makefile**: Each piece of code in Linux that requires a build process has a Makefile. The Makefile provides the rules, flags, includes and other elements that determine how the sources will be built.
- **.spec file**: A file with the extension `.spec`: File specification from the LTIB package that determines the instructions that the builder and installer should take when building (usually calls the make function that uses the Makefiles from each Package), installing, unpacking and even patching the package.

NOTE

To view source for the Hello World application spec file and the Makefile, see pages 8 and 9.

The first step is to obtain the sources, clean them, and then create a package. The tarball format can be `gz` or `bz2`. The example below uses `gz`. It is important to provide a version to the folder name and to the tarball as well. For the sources, see pages 8 and 9 in this document, which provides all of the source information.

```
cd hello-1.0
make clean
cd ..
tar zcvf hello-1.0.tar.gz hello-1.0
```

The next step is to copy the created package in the location where all the ltib packages are stored. By default the packages are stored in /opt/Freescale/pkgs:

```
mv hello-1.0.tar.gz /opt/freescale/pkgs/
```

The following step is to create the spec file for this package. All the packages have a spec file and they are stored in <ltib location>/dist/lfs-5.1. There is a special folder where a template of the spec file is stored (see pages 8 and 9 for the full source of the hello.spec):

```
cd <ltib location>/  
mkdir dist/lfs-5.1/hello  
cp dist/lfs-5.1/template/template.spec dist/lfs-5.1/hello/hello.spec
```

After the hello.spec file is created, some editing should be made in order to make it work properly. You can use any text editor to make the changes.

Field	Description
Summary	Enter a summary of what the package is/does.
Name	Enter the name of the package (usually from the tarball name) .
Version	Enter the version (usually from the tarball/directory).
Release	Begin at 1 and add a revision each time you change the spec file.
License	For example, GPL/LGPL/BSD. Find this in the package's files.
Group	If this exists on an rpm-based machine, copy from rpm -qi. If not, select something from /usr/share/doc/rpm-/GROUPS.
%Build	Just apply a Make.
%Install	Copy the executable to the usr/bin directory.

Building the Application

Now that the `.spec` file is created and ready, you can build and test the package.

To build the application, follow these steps:

1. Unpack the package that is stored in `/opt/Freescale/pkgs`, using the following command. This command unpacks the `hello -1.0.tar.gz` inside the `<ltib location>/rpm/Build/`:

```
cd <ltib location>/  
./ltib -m prep -p hello.spec
```

2. Build the package, using the following command:

```
./ltib -m sbuild -p hello.spec
```

3. Once the package is built without problems, install the package. (Within the `hello.spec` file, these are the `%install` section commands):

```
./ltib -m scinstall -p hello.spec
```

Now the package (executable) is installed as the test package in the NFS root filesystem area (`rootfs`). We specified in the spec file that it needs to be installed in `rootfs/usr/bin`.

```
./ltib -m sdeploy -p hello.spec
```

You will find the Hello World application file in the `rootfs/usr/bin` directory. The application is ready to be tested.

Adding the Application to the Package Directory Tree

Add the package to allow it to be visible when selecting the packages with `./ltib -c`.

To add the Hello World package, follow these steps:

1. Make sure that the package that was unpacked in `<ltib location>/rpm/BUILD/` is erased.

```
cd <ltib location>/  
cd /rpm/BUILD/  
rm -r hello-1.0/
```

2. Go to `<ltib directory>/config/userspace/`:

```
cd <ltib location>/  
cd config/userspace/
```

3. Use a text editor (such as vi, emacs, or gedit) to open the file `packages.lkc`.

This file is ordered alphabetically, so look for the “H” section. In front of the section `PKG_HELLOWORD` add the following:

```
config PKG_HELLO  
bool "hello"
```

4. Save the changes.
5. Go to `pkg_map` file that is located in the same directory (`config/userspace`).
6. Open `pkg_map` with a text editor.
7. Add the following entry anywhere (it does not need to be in alphabetical order).

```
PKG_HELLO      =  hello
```

Now we are ready to add the application from the directory tree.

Running the Application

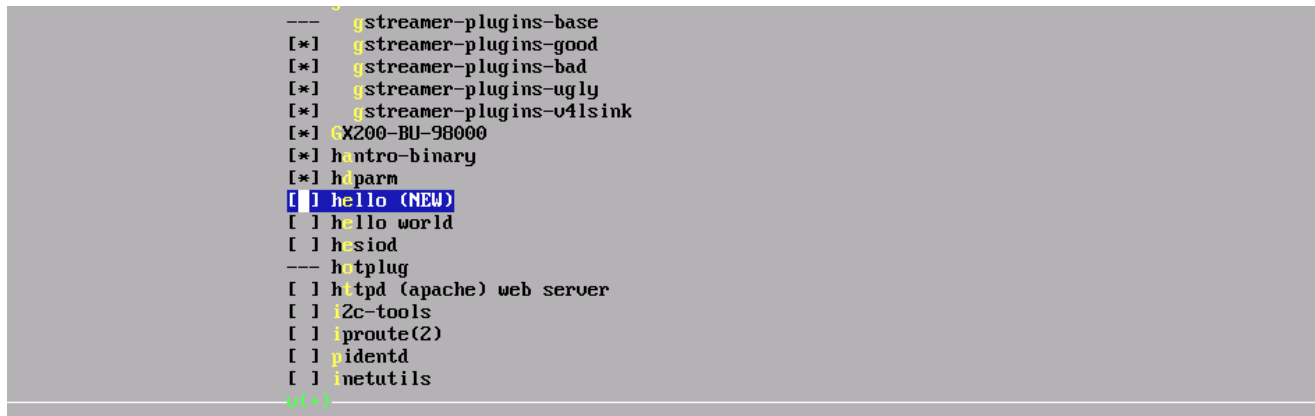

To run the application, follow these steps:

1. In the location where the ltib is installed on the host PC <ltib directory>. Type the following command:

```
cd <ltib location>/
./ltib -c
```

The configuration prompt is displayed (Figure 1).

Figure 1 Package List

```

---
[*] streamer-plugins-base
[*] streamer-plugins-good
[*] streamer-plugins-bad
[*] streamer-plugins-ugly
[*] streamer-plugins-u4lsink
[*] X200-BU-98000
[*] hantro-binary
[*] htparm
[ ] hello (NEW)
[ ] hello world
[ ] hsiod
---
[ ] httpd (apache) web server
[ ] lib2c-tools
[ ] libproute2
[ ] libidentd
[ ] libnetutils
u(+)

```

2. In the Package List, find 'hello', select it, and exit, saving the changes.

The `hello` package will build automatically and save the binary in `rootfs/usr/bin/`.

3. Run the file in the target using the following commands (nfs must be working and there must be a serial terminal at 115200).

```
mx#cd /usr/bin
mx#./hello
```

The application runs, and messages are displayed in the serial console.

All of the applications will follow this procedure. The differences are in the complexity of the Makefile, sources, or spec file.

Files for the Application Note

hello.c

```
#include <stdio.h>

int main()
{
    int i;

    printf("hello world\n");

    for ( i = 0; i < 10 ; i++ ) {
        printf("loop count = %d\n", i);
    }

    printf("hello this is the end\n");

    return 0;
}
```

hello.spec

```
%define pfx /opt/freescale/rootfs/{_target_cpu}
```

```
Summary      : hello application for appnote
