Chapter 1
Introduction

1.1 Product Overview

This chapter introduces the architecture of the i.MX 8M Mini Applications Processor.

The i.MX 8M Mini is a family of products focused on delivering an excellent video and audio experience, combining media-specific features with high-performance processing optimized for low-power consumption.

1.2 Target Applications

The i.MX 8M Mini Media Applications Processor is built to achieve both high performance and low power consumption and relies on a powerful fully coherent core complex based on a quad Cortex-A53 cluster with video and graphics accelerators.

The i.MX 8M Family provides additional computing resources and peripherals:

- Advanced security modules for secure boot, cipher acceleration and DRM support
- General purpose Cortex-M4 processor for low power processing
- A wide range of audio interfaces including I2S, AC97, TDM and S/PDIF
- Large set of peripherals that are commonly used in consumer/industrial markets including USB 2.0, PCIe and Ethernet

1.3 Acronyms and Abbreviations

The table below contains acronyms and abbreviations used in this document.

Acronyms and Abbreviated Terms

Term	Meaning
ADC	Analog-to-Digital Converter
AHB	Advanced High-performance Bus
AIPS	Arm IP Bus
ALU	Arithmetic Logic Unit
AMBA	Advanced Microcontroller Bus Architecture
APB	Advanced Peripheral Bus
ASRC	Asynchronous Sample Rate Converter
AXI	Advanced eXtensible Interface
BIST	Built-In Self Test
CA/CM	Arm Cortex-A/Cortex-M
CAAM	Cryptographic Acceleration and Assurance Module
CAN	Controller Area Network
CPU	Central Processing Unit
CSI	CMOS Sensor Interface
CSU	Central Security Unit
CTI	Cross Trigger Interface
DAP	Debug Access Port
DDR	Double data rate
DMA	Direct memory access
DPLL	Digital phase-locked loop
DRAM	Dynamic random access memory
ECC	Error correcting codes
ECSPI	Enhanced Configurable SPI
LPSPI	Low-power SPI
EDMA	Enhanced Direct Memory Access
EIM	External Interface Module
ENET	Ethernet
EPIT	Enhanced Periodic Interrupt Timer
EPROM	Erasable Programmable Read-Only Memory
ETF	Embedded Trace FIFO
ETM	Embedded Trace Macrocell
FIFO	First-In-First-Out
GIC	General Interrupt Controller
GPC	General Power Controller
GPIO	General-Purpose I/O
GPR	General-Purpose Register
GPS	Global Positioning System
GPT	General-Purpose Timer
GPU	Graphics Processing Unit
GPV	Global Programmers View
HAB	High-Assurance Boot

Table continues on the next page...

Term	Meaning
I2C or I^2C	Inter-Integrated Circuit
IC	Integrated Circuit
IEEE	Institute of Electrical and Electronics Engineers
IOMUX	Input-Output Multiplexer
IP	Intellectual Property
IrDA	Infrared Data Association
JTAG	Joint Test Action Group (a serial bus protocol usually used for test purposes)
LCDIF	Liquid Crystal Display Interface
LDO	Low-Dropout
LIFO	Last-In-First-Out
LRU	Least-Recently Used
LSB	Least-Significant Byte
LUT	Look-Up Table
LVDS	Low Voltage Differential Signaling
MAC	Medium Access Control
MCM	Miscellaneous control Module
MMC	Multimedia Card
MSB	Most-Significant Byte
MT/s	Mega Transfers per second
OCRAM	On-Chip Random-Access Memory
OCOTP	On-Chip One-Time Programmable Controller
PCI	Peripheral Component Interconnect
PCIe	PCI enhanced
PCMCIA	Personal Computer Memory Card International Association
PGC	Power Gating Controller
PIC	Programmable Interrupt Controller
PMU	Power Management Unit
POR	Power-On Reset
PSRAM	Pseudo-Static Random Access Memory
PWM	Pulse Width Modulation
PXP	Pixel Pipeline
QoS	Quality of Service
R2D	Radians to Degrees
RISC	Reduced Instruction Set Computing
ROM	Read-Only Memory
ROMCP	ROM Controller with Patch
RTOS	Real-Time Operating System
Rx	Receive
SAI	Synchronous Audio Interface
SCU	Snoop Control Unit
SD	Secure Digital

Table continues on the next page...

Term	Meaning
SDIO	Secure Digital Input/Output
SDLC	Synchronous Data Link Control
SDMA	Smart DMA
SIM	Subscriber Identification Module
SNVS	Secure Non-Volatile Storage
SoC	System-on-Chip
SPBA	Shared Peripheral Bus Arbiter
SPDIF	Sony Phillips Digital Interface
SPI	Serial Peripheral Interface
SRAM	Static Random-Access Memory
SRC	System Reset Controller
TFT	Thin-Film Transistor
TPIU	Trace Port Interface
TSGEN	Time Stamp Generator
Tx	Transmit
TZASC	TrustZone Address Space Controller
UART	Universal Asynchronous Receiver/Transmitter
USB	Universal Serial Bus
USDHC	Ultra Secured Digital Host Controller
WDOG	Watchdog
WLAN	Wireless Local Area Network
WXGA	Wide Extended Graphics Array

1.4 Features

1.4.1 Arm Cortex-A53 MPCore™ Platform

The i.MX 8M Family Applications Processors are based on the Arm Cortex-A53 MPCore™ Platform, which has the following features:

- Quad symmetric Cortex-A53 processors, including:
  - 32 KB L1 Instruction Cache
  - 32 KB L1 Data Cache
  - Media Processing Engine (MPE) with NEON technology supporting the Advanced Single Instruction Multiple Data architecture
  - Floating Point Unit (FPU) with support of the VFPv4-D16 architecture
- Support of 64-bit Armv8-A architecture

- 512 KB unified L2 cache
- Target frequency of 1.8GHz

1.4.2 Arm Cortex-M4 Platform

Cortex-M4 Core Platform include the following:

- Low power microcontroller available for customer application:
  - Low power standby mode
  - IoT features including Weave
  - Manage IR or wireless remote
- Arm Cortex M4 CPU Processor, including:
  - 16 KB L1 Instruction Cache
  - 16 KB L1 Data Cache
  - 256 KB TCM

1.4.3 System Bus and Interconnect

System bus and interconnect include the following:

- Network interconnect (NoC) AXI arbiter
- Quality of service controller (QoSC) to configure priorities and limits of AXI transcations
- Performance monitor (PERFMON) to monitor AXI bus activity
- Debug monitor (DBGMON) to record AXI transactions preceding a system reset

1.4.4 Clocking and Resets

Clocking and resets include:

- Clock control module (CCM) provides centralized clock generation and control
  - Simplified clock tree structure
  - Unified clock programming model for each clock root
  - Multicore awareness for resource domains
- System reset controller (SRC) provides reset generation and distribution

1.4.5 Interrupts and DMA

Interrupts and DMA include:

- 128 shared peripheral interrupts routed to Cortex-A53 Global Interrupt Controller (GIC) and Cortex-M4 nested vector interrupt controller (NVIC) for flexible interrupt handling
- Three Smart direct memory access (SDMA) engines. Although these three engines are identical to each other, they are integrated into the processor to serve different peripherals.
  - SDMA-1 is a general-purpose DMA engine which can be used by low speed peripherals including UART, SPI and also others peripherals.
  - SDMA-2 and SMDA-3 is used for audio interface, including SAI-1/2/3/5/6, SPDIF and PDM audio input.

1.4.6 On-Chip Memory

The on-chip memory system consists of the following:

- Boot ROM (256KB)
- On-chip RAM (256KB + 32KB)

1.4.7 External Memory Interface

The external memory interfaces supported on this chip include:

- 16/32-bit DRAM Interface:
  - LPDDR4-3000
  - DDR4-2400
  - DDR3L-1600
- 8-bit NAND FLASH, including support for Raw MLC/SLC devices, BCH ECC up to 62-bit, and ONFi3.2 compliance (clock rates up to 100 MHz and data rates up to 200 MB/sec)
- eMMC 5.0 FLASH (2 interfaces)
- SPI NOR FLASH (3 interfaces)
- FlexSPI FLASH with support for XIP (for M4 in low-power mode) and parallel read mode of two identical FLASH devices

1.4.8 Timers

The timers on this chip include:

- One local generic timer integrated into each Cortex-A53 CPU
- Global system counter with timer bus interface to Cortex-A53 MPCore generic timers
- One local system timer (SysTick) integrated into the Cortex-M4 CPU
- Six general purpose timer (GPT) modules
- Three watchdog timer (WDOG) modules
- Four pulse width modulation (PWM) modules

1.4.9 Graphics Processing Unit (GPU)

The chip incorporates the following Graphics Processing Unit (GPU) features:

- 2D/3D acceleration
- Target frequency of 800 MHz
- Support OpenGL ES 1.1, 2.0, OpenVG 1.1
- TrustZone support using a local MMU to manage secure regions
- Support multi-source composition
- Support one-pass filter
- Support tile format

1.4.10 Video Processing Unit (VPU)

The chip incorporates the following Video Processing Unit (VPU) features:

- VP9 Profile 0, 2 (10 bit) decoder (VPU G2)
- HEVC/H.265 decoder (VPU G2)
- AVC/H.264 Baseline, Main, High decoder (VPU G1)
- VP8 decoder (VPU G1)
- AVC/H.264 encoder (VPU H1)
- VP8 encoder (VPU H1)
- TrustZone support

1.4.11 Display Interfaces

The chip has the following display support:

- LCDIF Display Controller:
  - Supports up to 2 layers of overlay
  - Support up to 1080p60 display through MIPI DSI
- MIPI Interface:
  - 4-lane MIPI CSI interface
  - 4-lane MIPI DSI interface
- CSI Interface:
  - CSI is a simple camera interface which is used to capture the MIPI CSI input and save the pixels into memory

1.4.12 Audio

Audio include the following:

- S/PDIF Input and Output, including a new Raw Capture input mode
- Five external SAI (synchronous audio interface) modules supporting I2S, AC97, TDM, codec/DSP and DSD interfaces, including one SAI with 8 TX and 8 RX lanes, one SAI with 4 TX and 4 RX lanes, two SAI with 2 TX and 2 RX lanes, and one SAI with 1 TX and 1 RX lanes. Supports over 20 channels of audio subject to I/O limitations.

1.4.13 General Connectivity Interfaces

The chip contains a rich set of general connectivity interfaces, including:

- One PCI Express (PCIe):
  - Single lane supporting PCIe Gen 2
  - Dual mode operation to function as root complex or endpoint
  - Integrated PHY interface
  - Supports L1 low power substate
- Two USB 2.0 OTG controllers with integrated PHY interface
  - Spread spectrum clock support
- Three Ultra Secure Digital Host Controller (uSDHC) interfaces
  - MMC 5.0 compliance with HS400 DDR signaling to support up to 400 MB/sec
  - SD/SDIO 3.01 compliance with 200 MHZ SDR signaling to support up to 100 MB/sec
  - Support for SDXC (extended capacity)
- One Gigabit Ethernet controller with support for EEE, Ethernet AVB and IEEE1588
- Four universal asynchronous receiver/transmitter (UART) modules

- Four I2C modules
- Three SPI modules

1.4.14 Security

Security functions are enabled and accelerated by the following hardware:

- RDC – Resource Domain Controller:
  - Supports 4 domains and up to 8 regions
- Arm TrustZone including the TZ architecture:
  - ARM Cortex-A53 MPCore TrustZone support
- On-chip RAM (OCRAM) secure region protection using OCRAM controller
- High Assurance Boot (HAB)
- Cryptographic Acceleration and Assurance Module (CAAM)
  - Support Widevine and PlayReady content protection
  - Public Key Cryptography (PKHA) with RSA and Elliptic Curve (ECC) algorithms
  - Real-time integrity checker (RTIC)
  - DRM support for RSA, AES, 3DES, DES
  - Side channel attack resistance
  - True random number generation (RNG)
  - Manufacturing protection support
- Secure Non-Volatile Storage (SNVS), including
  - Secure Real Time Clock (SRTC)
- Secure JTAG Controller (SJC)

1.4.15 Multicore Support

Multicore support contains:

- Resource domain controller (RDC) to support isolation and safe sharing of system resources
- Messaging unit (MU)
- Hardware Semaphore (SEMA42)
- Shared bus topology

1.4.16 GPIO and Pin Multiplexing

- General-purpose input/output (GPIO) modules with interrupt capability
- Input/output multiplexing controller (IOMUXC) to provide centralized pad control

1.4.17 Power Management

The power management unit consists of:

- Temperature sensor with programmable trip points
- Flexible power domain partitioning with internal power switches to support efficient power management

1.4.18 System Debug

The system debug features are:

- ARM CoreSight debug and trace architecture
- Trace Port Interface Unit (TPIU) to support off-chip real-time trace
- Embedded Trace FIFO (ETF) with 4 KB internal storage to provide trace buffering
- Unified trace capability for Quad Cortex-A53 and Cortex-M4 CPUs
- Cross Triggering Interface (CTI)
- Support for 5-pin (JTAG) debug interfaces

1.5 Architectural Overview

This section contains the i.MX 8M Mini architectural details.

1.5.1 Block Diagram

The high-level block diagram is shown in the figure below.

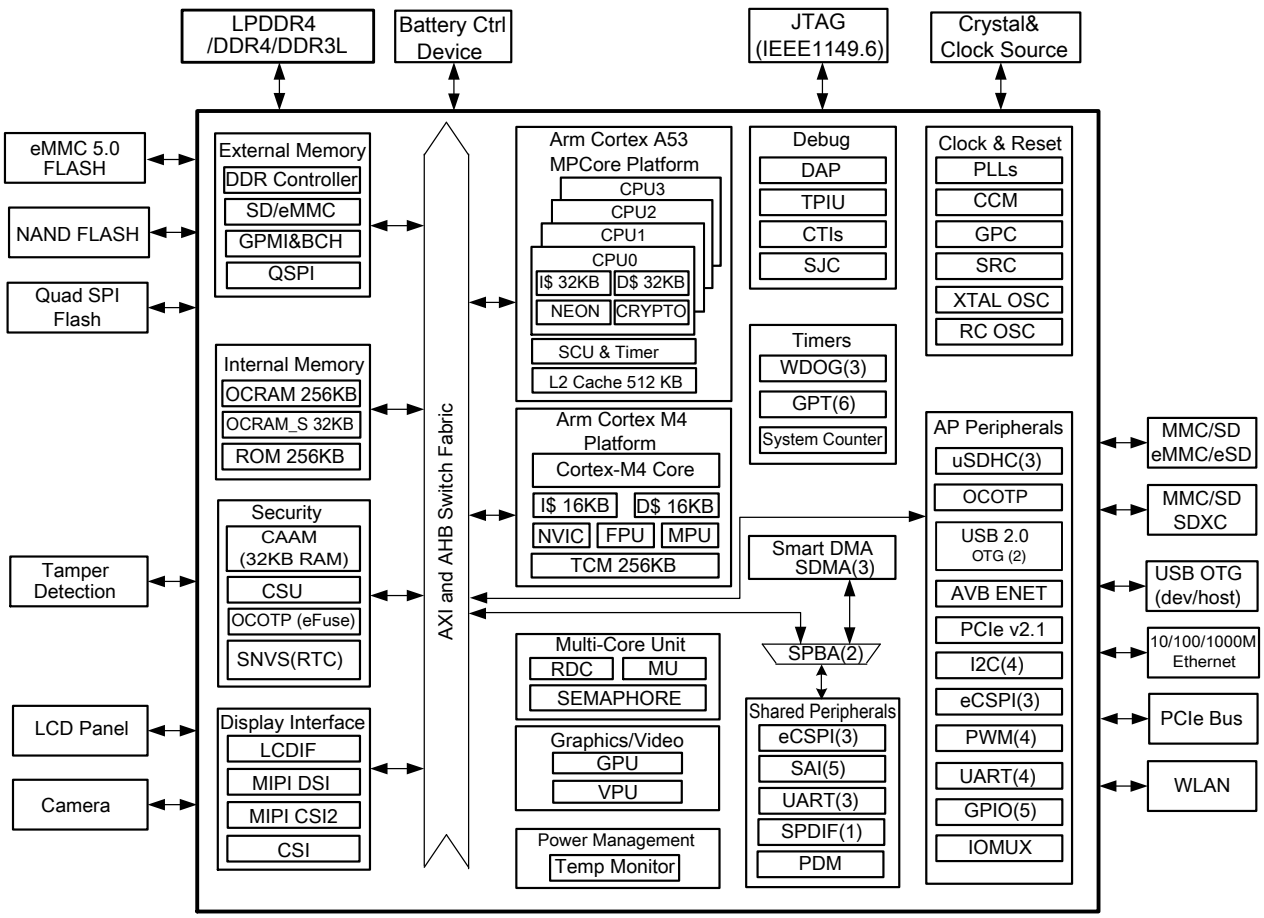

Figure 1-1. Block Diagram

1.6 Primary Boot Options

The i.MX 8M Mini supports the following boot devices:

- NAND FLASH (including SLC and MLC)
- SDIO / MMC / SDXC
- eSD 3.0/eMMC 5.0 (fast boot)
- SPI (serial FLASH)
- USB
- QSPI
- Ethernet (via plug-in mode)

The Quad-A53 core on i.MX 8M Mini is enabled during boot as the primary core to handle the entire secure boot flow. The chip will always boot from A53 core first, the M4 core will be held in reset during the A53 boot and won't run until it is enabled by the A53 core. The image for M4 cores will be loaded into memory and authenticated by the A53 core.

1.7 Endianness Support

This chip supports Little Endian mode only.

Chapter 2
Memory Map

2.1 Memory

This chapter introduces the memory architecture of the chip. The system memory high-level partition is defined below:

2.1.1 Memory system overview

2.1.1.1 On-chip L1, L2 caches, TCM

Cortex-A53 MPcore Platform

- Level 1 Cache (4x per Cortex-A53 Core)
  - Instruction (32 KB)
  - Data (32 KB)
- Level 2 Cache, shared by the four Cortex-A53 cores:
  - Unified instruction and data (512 KB)

Cortex M4 Platform

- Cache
  - Instruction (16 KB)
  - Data (16 KB)
- Tightly-Coupled-Memory
  - TCML on Code Bus (128KB)
  - TCMH on System Bus (128KB)

2.1.1.2 On-chip memories

- Boot ROM (256 KB)

- On-Chip RAM - OCRAM (256 KB)
- On-Chip RAM for State Retention - OCRAM_S (32 KB)

2.1.1.3 External L3 memories

The chip supports external memories, via the following memory interfaces / controllers:

- 16/32-bit DRAM Interface:
  - LPDDR4-3000, DDR4-2400, DDR3L-1600
- 8-bit NAND FLASH, including support for Raw MLC/SLC devices, BCH ECC up to 62-bit, and ONFi 2.x compliance (clock rates up to 100 MHz and data rates up to 200 MB/sec)
- eMMC 5.0 FLASH
- SPI NOR FLASH
- Quad SPI FLASH with support for XIP (for M4 in low-power mode) and parallel read mode of two identical FLASH devices

2.1.2 Cortex-A53 Memory Map

Start Address	End Address	Region	Size	Description
1_0000_0000	2_3FFF_FFFF	DDR Address	5120MB	DDR Memory (Quad-A53 only)
4000_0000	FFFF_FFFF	DDR Address	3072MB	DDR Memory (All modules)

2.1.4 DMA memory maps

The Smart DMA memory maps are defined in the following tables.

Table 2-1. SDMA1 Peripheral Memory Map

Address	Peripheral
0xF000	SPBA
0xE000	Reserved for SDMA internal registers
0xD000	Reserved
0xC000	Reserved
0xB000	Reserved
0xA000	Reserved
0x9000	UART2
0x8000	UART3
0x7000	Reserved for SDMA internal registers
0x6000	UART1
0x5000	Reserved
0x4000	eCSPI3
0x3000	eCSPI2
0x2000	eCSPI1
0x1000	Reserved
0x0000	Reserved for SDMA internal memory

Table 2-2. SDMA2/3 Peripheral Memory Map

Address	Peripheral
0xF000	SPBA
0xE000	Reserved for SDMA internal registers
0xD000	Reserved
0xC000	Reserved
0xB000	Reserved
0xA000	Reserved
0x9000	SPDIF1
0x8000	MICFIL
0x7000	Reserved for SDMA internal registers
0x6000	SAI6
0x5000	SAI5
0x4000	Reserved
0x3000	SAI3
0x2000	SAI2

Table continues on the next page...

Table 2-2. SDMA2/3 Peripheral Memory Map (continued)

Address	Peripheral
0x1000	SAI1
0x0000	Reserved for SDMA internal memory

2.1.5 AIPS Memory Maps

Table 2-3. AIPS1 Memory Map

Chapter 3
Security

3.1 System Security

3.1.1 Overview

The security system modules are described in the sections below.

3.1.2 Central Security Unit (CSU)

The chip uses the CSU to manage security for all masters/slaves that don’t directly support security like the CPU core.

3.1.3 Cryptographic Acceleration and Assurance Module (CAAM)

CAAM is the chip's cryptographic acceleration and assurance module, which serves as NXP's latest cryptographic acceleration and offloading hardware. It combines functions previously implemented in separate modules to create a modular and scalable acceleration and assurance engine. It also implements block encryption algorithms, stream cipher algorithms, hashing algorithms, public key algorithms, run-time integrity checking, a secure memory controller, and a hardware random number generator.

CAAM supports the following key features:

- PKHA block to support Public Key Cryptography with RSA 4096 and ECC algorithms
- 3 Job Rings
- RTIC (real time integrity checking)
- AES, DES, 3DES with Side channel attack resistance
- Widevine cipher text stealing (AES-CBC-CTS mode)
- PlayReady content protection

In order to provide better video content protection, CAAM also supports the domain based resource protection.

3.1.4 Secure Non-Volatile Storage (SNVS)

Secure Non-Volatile Storage (SNVS) is a companion logic block to the Cryptographic Acceleration and Assurance Module (CAAM). This block is the chip's central reporting point for security-relevant events, such as the success or failure of boot software validation and the detection of potential security compromises. This security event information allows the SNVS to determine whether the chip is in a trustworthy state.

3.1.5 On-Chip OTP Controller (OCOTP_CTRL)

The OCOPT_CTRL is used to control the 8K bit OTP fuse in the chip. It supports:

- Load fuse into shadow registers after power-on reset;
- Register interface to allow SW to read, override or program the fuse
- Flexible permission control to the fuse, including read-protect, override-protect, program-protect, lock and etc
- Programming sequence to allow single bit to be programmed individually, and also allow the non-programmed bit to be programmed later

For the 8K bits fuse, following bits are reserved for various IP requirements:

- Fuse control to disable each of the four Cortex A53 cores.
- Fuse control to disable individual IP modules such as MIPI, ENET, USB, PCIe and etc.
- Fuse control to disable the Dolby Vision logic inside the display controller block.
- Fuse for ROM patch, with a dedicated fuse lock bit for security purpose.

3.1.6 TrustZone

TrustZone security architecture is supported in the chip. For on-chip RAM, both OCRAM/OCRAM_S have TrustZone access control support through its TZ wrapper logic. One region with configurable address range of the OCRAM/OCRAM_S can be set to TZ access only. DRAM has a dedicated TZASC block that can support up to 16 configurable memory regions.

3.1.7 Resource Domain Controller (RDC)

The ichip uses domain based resource control architecture for the memory/peripheral resource sharing and isolation between the Quad-core Cortex A53 platform, Cortex M4 core, and other bus masters. RDC supports flexible configuration on IP's access permission, each individual IP can, for example, be configured as A-core only or M-core only. RDC also supports multiple regions with flexible access permission control for each memory space. The memory region access control is defined in the table below. The security and exclusive support for DRAM will be done by the TZASC and the DRAM controller itself.

NOTE

The RDC and TrustZone features are completely independent of each other but will be used together.

Table 3-1. Memory Region Access Control

Memory Space	Regions Supported	Granularity	Security Support	Exclusive Support
DRAM	8 regions	4K Bytes		
QSPI1	8 regions	4K Bytes		
PCIe1	8 regions	4K Bytes		
OCRAM	5 regions	128 Bytes		
OCRAM_S	5 regions	128 Bytes		
TCM	5 regions	128 Bytes		
GIC	4 regions	4K Bytes		
GPU	8 regions	4K Bytes		
VPU	4 regions	4K Bytes		
DEBUG(DAP)	4 regions	4K Bytes		
DDRC (REG)	5 regions	4K Bytes		

3.2 Resource Domain Controller (RDC)

3.2.1 Overview

The Resource Domain Controller (RDC) provides robust support for the isolation of destination memory mapped locations such as peripherals and memory to a single core, a bus master, or set of cores and bus masters.

Many of today's processors have multiple cores for increased performance and flexibility. In some cases, the cores serve different functions (e.g. user level applications versus real time machine control) and in such cases the software for each core may be developed by different providers.

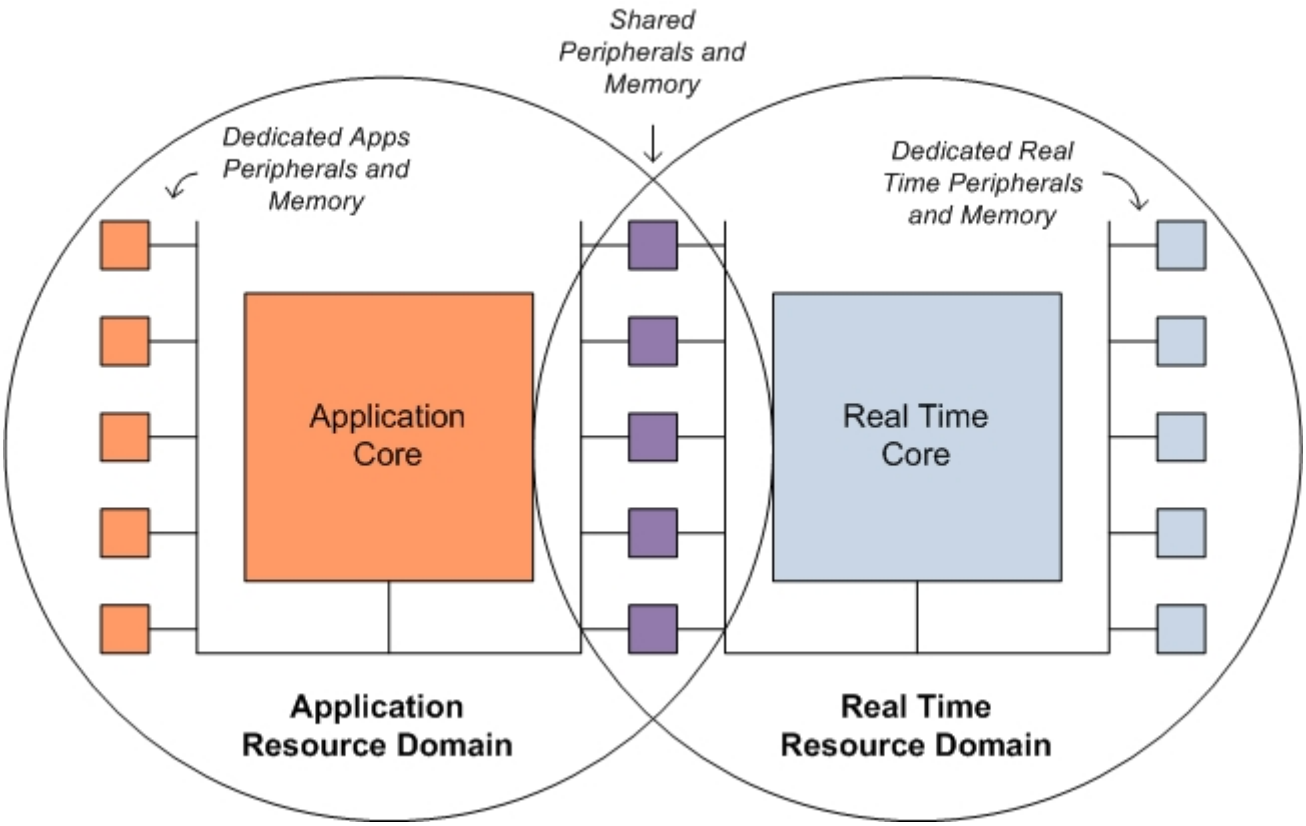

Figure 3-1. Dedicated and Shared Peripherals

For efficiency reasons the code on the cores may share chip resources such as peripherals and memory. The sharing of chip resources between the somewhat independent processing domains allows for the opportunity of data collisions where information stored in peripherals or memory by a process on one core is overwritten by software running on another core. Without careful collaboration between the two operating systems inadvertent malfunction or degradation in performance may result.

The RDC provides a mechanism to allow boot time configuration code to establish resource domains by assigning cores, bus masters, peripherals and memory regions to domain identifiers. Once configured, bus transactions are monitored to restrict accesses initiated by cores and bus masters to their respective peripherals and memory.

For shared peripherals, the RDC provides a semaphore-based locking mechanism to provide for temporary exclusivity while the domain software uses the peripheral. Once the software of one domain has finished the task and finished with the peripheral then it may release the semaphore making the peripheral available to the other domain.

3.2.1.1 Features

Resource domain subsystem has the following features:

- Assignment of cores, bus masters, peripherals, and memory regions to a resource domain
- Fixed memory resolution of 128 Bytes for small address spaces and 4 KB for large address spaces
- Four resource domain identifiers
- Memory read/write access controls for each resource domain and region
- Optional semaphore-based, hardware-enforced exclusive access of shared peripherals to a resource domain
- Prioritized access permissions for overlapping memory regions
- Automatic restoration of resource domain access permissions to memory regions in the power-down domain

3.2.2 Functional Description

The RDC is the central location for creation of isolated resource domains and for the enablement of semaphore-based access also known as “safe sharing”. Configuration software assigns one of four resource domain identifiers to each core and bus master, and allocates each memory region and peripheral to one or more resource domains.

Memory Read or Write access privileges for each resource domain are declared for each memory region. In addition, the software configuration determines which shared peripherals (those peripherals allocated to more than one domain) require safe sharing by setting the semaphore-required configuration for each peripheral.

The RDC configuration information is sent to the fabric ports, memories gaskets, semaphore controller, and peripherals to control access based on domain assignments. The fabric uses the domain identifier associated with each port to include this information along with the bus transaction. When the slave gasket encounters a bus transaction it makes a comparison of the transaction domain ID to the RDC-provided list of allowed domains. If the transaction domain ID is on the list then access may be permitted.

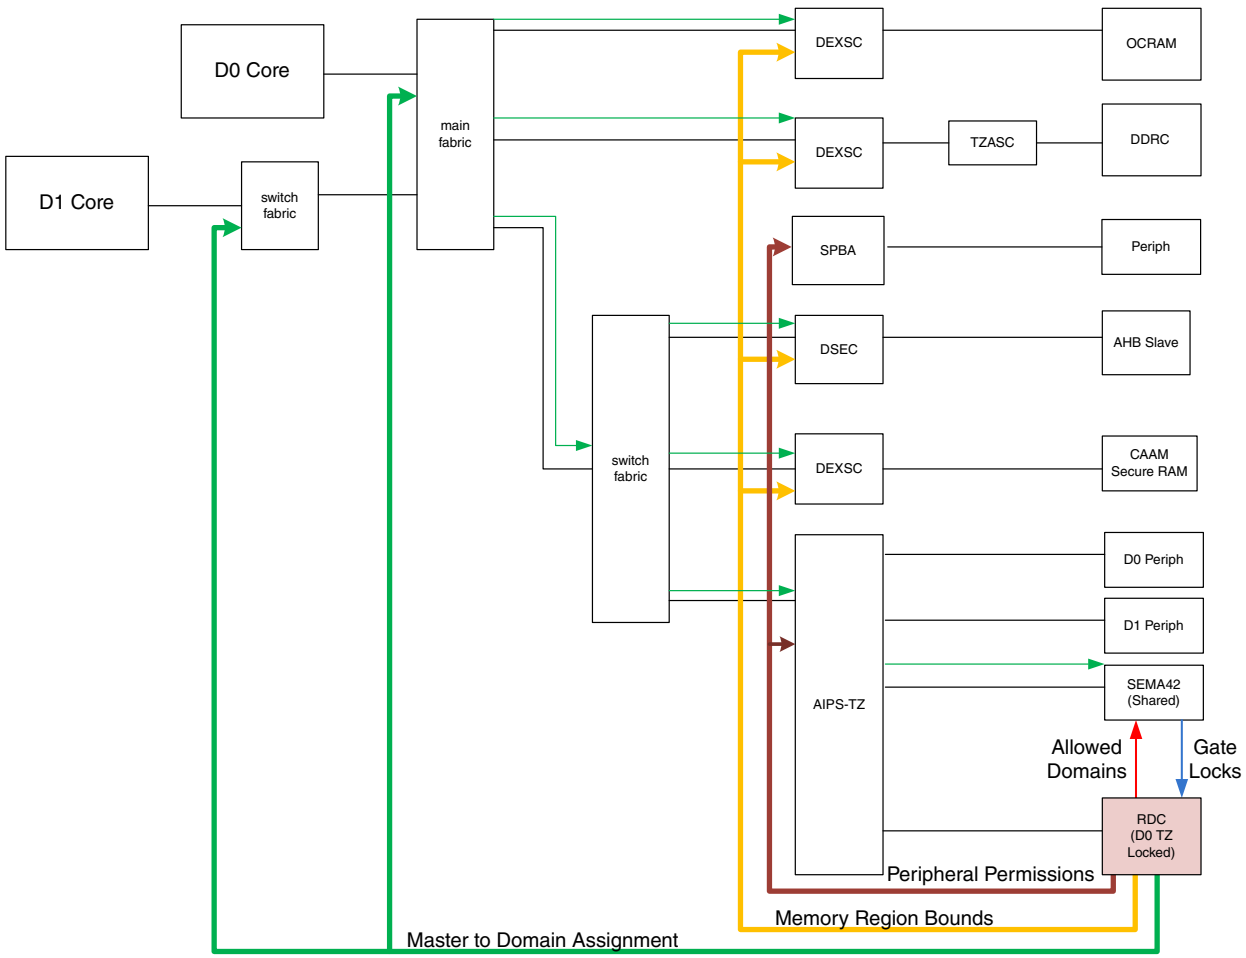

Figure 3-2. Example RDC Connections

For shared peripherals, RDC permits more than one domain access to a single peripheral. RDC also provides three ways to control synchronized use of shared peripherals. These methods include hardware-enforced synchronization, software-based semaphores, or no synchronization. The latter may be suitable for well-tuned multi-core operating systems that handle synchronization in the core platform, for instance.

For hardware-enforced synchronization, also known as "safe sharing", ownership of the peripheral must be claimed in the semaphore controller before access is allowed to the shared peripheral. The "semaphore required" bit (SREQ) is set in the PDAP register corresponding to the shared peripheral which causes the RDC to require that a semaphore is obtained by a domain before access by that domain to the shared peripheral is allowed. During the time that the domain has the semaphore in possession its bus masters have exclusive access to the peripheral.

When the semaphore is released then no domain masters have access until the semaphore is obtained again. When the SREQ is set, RDC does not allow masters to obtain semaphores of peripherals to which it is not allocated; the master must have designated access in the D-registers of the corresponding PDAP register (e.g. D3R bit set for Domain 3 access of the shared peripheral). There is a one-to-one mapping between the semaphore controller gate and the resource domain controller peripheral. The mapping of PDAP registers and peripherals can be found in the Peripheral Map section of the RDC chapter.

3.2.2.1 Domain ID

The RDC provides for an isolation of domain resources by use of a identifier called the Domain ID (DID). A core and its resources including memory, bus masters, and peripherals are all associated with a single DID. When software or a DMA attempts to access a peripheral or memory, the corresponding bus transaction includes the DID along with the other bus control information such as Read, Write, and privilege mode.

3.2.2.2 Resource Assignment

The RDC allows assignment of peripherals and memories to one or more domains while each bus master or core is placed in one of four domains. The masters are assigned a domain in the MDA register. A peripheral is given R/W access permissions to each domain in the PDAP register. Memory regions are bound by address space in start and end registers, the MRSA and MREA. Each memory region is assigned one or more allowed domains and R/W permissions in the MRC control register. Memory regions must be enabled before the permissions are active. Otherwise the permissions are not restricted.

The RDC itself should be isolated to ensure that only a trustworthy resource manager can configure the RDC registers. This process may either be present initially, during secure boot, or during the runtime in the secure world, for example. If the operating system does not support a runtime trusted execution then during the secure boot process the RDC configuration can be locked to prevent further modification after the operating systems are running.

NOTE

The CCM supports multicore awareness based on resource domain assignments programmed into the RDC. Refer to the CCM chapter regarding the relationship between core resource domains and their respective CCM resources. Failing to follow the proper sequence when updating the resource domain

assignments of the core can result in clocks being inadvertently gated.

3.2.2.3 Safe Sharing

For shared peripherals, the RDC can be configured to require a domain to obtain a semaphore lock before access to the peripheral is allowed. This feature helps prevent collisions from processes on separate cores that may want to use the same peripheral at the same time. The RDC sends a list of eligible domains to the semaphore module for each gate/peripheral. The eligible domains are those that are set in the peripheral domain access permissions (PDAP) registers. There is a one-to-one correspondence between semaphore gates and peripherals so each gate in the semaphore block represents a peripheral. The RDC receives semaphore locks from the hardware semaphore module (SEMA42). A semaphore lock is acquired when a core or bus master from a given domain requests a lock for a particular gate. The semaphore module compares the request's domain ID against the list of eligible domain IDs. If the domain ID is on the list and the lock is available then the lock is set and a signal is sent back to the RDC module indicating a lock has been acquired for a particular gate and to which domain ID the lock belongs. The RDC then restricts access to the corresponding peripheral to only transactions originating from the domain that has the lock. Another domain, though on the shared list to access the peripheral, must then wait until the lock is released before acquiring the lock and gaining access to the peripheral. To enable this feature of hardware enforcement for the semaphore locks, the SREQ bit is set in the RDC resource register.

If the SREQ is set, then when a process determines it needs a shared peripheral, it must first lock the resource in the semaphore module. Once the resource is locked, the semaphore module sends a signal to the RDC indicating the domain has access to the resource. The RDC will then set the access permissions to allow that domain access to the peripheral.

For a domain to acquire a lock on a peripheral, the domain must have been assigned to the peripheral in the RDC Peripheral Domain Access Permissions register (PDAP). The semaphore module only allows safe-sharing locks for those domains that are assigned to the peripheral. The semaphore module does not consider the access type (Read or Write) when allowing domains to acquire locks.

The SEMA42 module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Module definition supporting 64 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cp*X* is meant to represent core processor *X*
  - Gates appear as an *n*-entry byte-size array with read and write accesses (*n* = 16, 32, 64).
    - Processors lock gates by writing "Master_index" to the appropriate gate and must read back the gate value to verify the lock operation was successful. The Master_index value for the processors can be found in the Master Index Allocation table, which can be found in the AIPSTZ block.. Also note that after locking, the gate register contains the master_id value of the locking processor (in bits [3:0]), and also the value of the locking domain (in bits [5:4]).
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      if gate = 0x0, then state = unlocked
      if gate = 0x1, then state = locked by processor (master_index) 0
      if gate = 0x2, then state = locked by processor (master_index) 1
      …
      if gate = 0xF, then state = locked by processor (master_index) 14
    - Uses the logical bus master number (master_index) as a reference attribute plus the specified data patterns to validate all write operations.
    - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.
  - Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.
- Memory-mapped IPS slave peripheral platform module
  - Interface to the IPS bus for programming-model accesses

3.2.2.4 Resource Domain Control and Security Considerations

Conceptually, the RDC configuration is independent of the processor privilege mode and security domain. It is intended to allow for isolation between core processing environments to prevent collisions and increase reliability. Access between resource domains is mutually exclusive and each domain should be in control of its own privilege modes and access rights.

However, it is important to realize multi-core processors may have a multiple resource domains but only one overarching security domain. Chip security controls reside in one resource domain. In this configuration, a domain can affect at least one level of access privileges in the other domain. This may be acceptable but clarity and care is needed to ensure expected functionality.

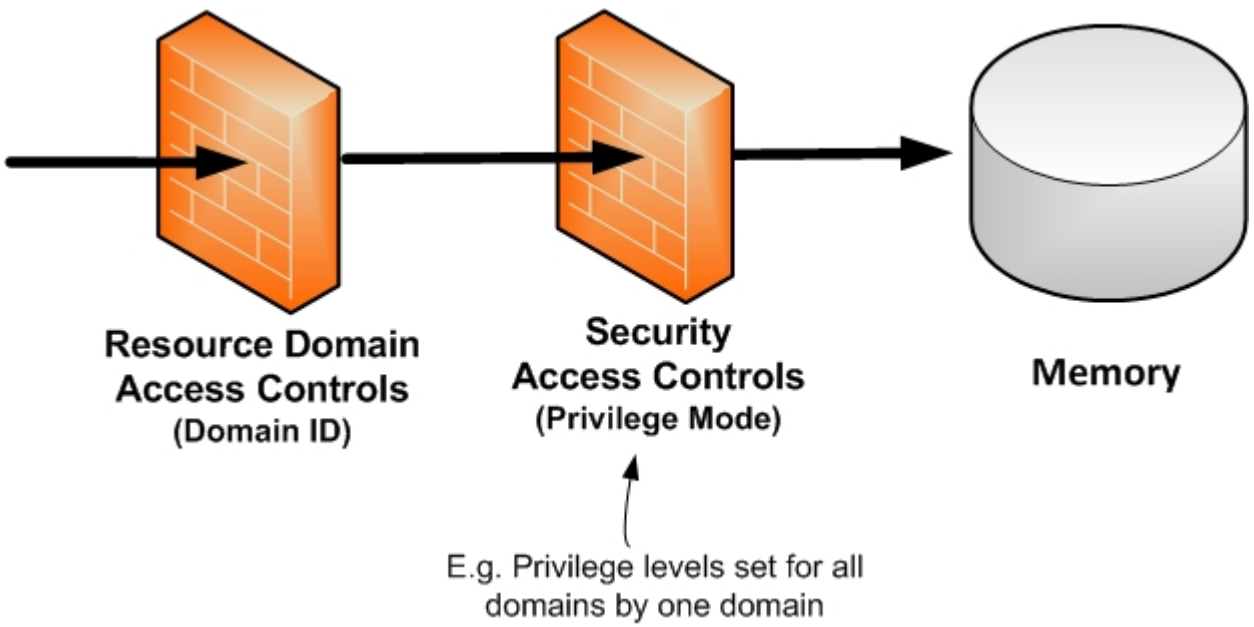

Figure 3-3. Access Control to Memory

Therefore, access to the security controls should be restricted to the most trustworthy operating mode of the core and privilege levels should be coordinated to ensure that shared peripherals and memory regions are accessible by both cores. For instance, if a memory region is designated for secure accesses then all domain masters that share that region must have secure privileges.

3.2.3 Modes of Operation

The RDC provides access controls to the resource domain subsystem. When the device is in a low power mode then some memory regions in the subsystem may be powered off. RDC responds to the impacted memory regions by automatically reconfiguring the memory regions once power returns and blocking access to those memory regions until the reconfiguration process is complete.

3.2.3.1 Low Power Modes

The RDC loads configuration information for memory regions (MRSA, MRSE, MRC) into access control mechanisms (gaskets) at the memory interface. The location of this configuration information may reside inside power domains that lose power during sleep modes for energy savings. To restore configuration information upon return from sleep mode, the RDC receives a global power control signal indicating power is restored. The RDC then automatically reconfigures the memory regions with the configuration information.

During reconfiguration, access is blocked to the previously powered down memories. When the RDC completes reconfiguration it issues an interrupt and allows access to the memory regions. Only the powered down regions are blocked during the reconfiguration. Memory regions in the "always-on" power domain (still powered during sleep mode) remain available according to the programmed access rights. If no memory regions were enabled then the powered down regions are available immediately when power is restored.

The figure below shows the Global Power Control signal which RDC uses to invalidate the configuration upon deassertion and to restore the configuration when re-asserted. The configuration is valid and bus transactions allowed once the memory regions have been restored.

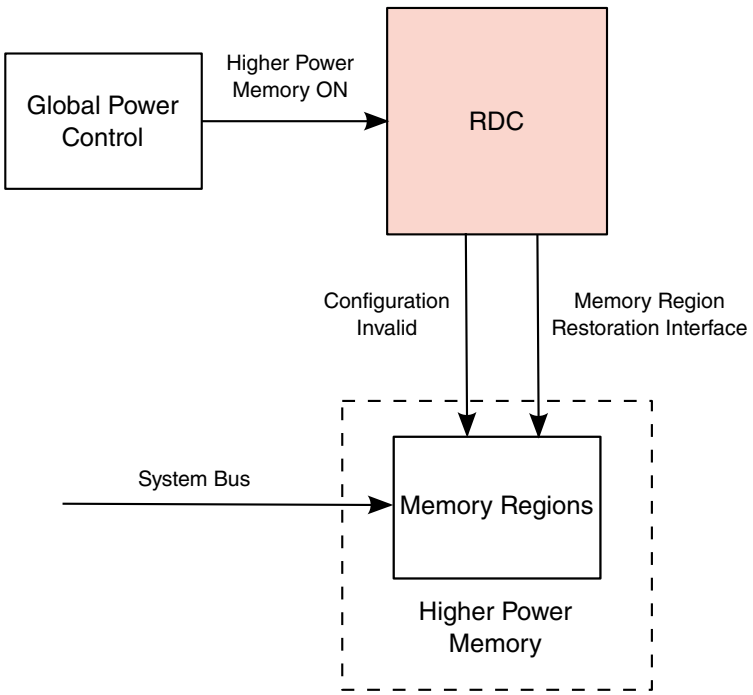

Figure 3-4. Memory Restoration Signaling

3.2.4 Programming Interface

This section provides product specific details describing the mapping of resources - peripherals, bus masters, and memory regions - to corresponding resource domain controls RDC registers.

The RDC and RDC_SEMA42 register maps are combined in this chapter. The base address for the one RDC map and two SEMA42 maps are each separated by 4KB. While there are two SEMA42 submodules and therefore two sets of SEMA42 registers, this chapter describes one. Please refer to the peripheral memory map for the base addresses of the RDC and SEMA42 modules.

3.2.4.1 Master Assignment Registers

3.2.4.2 Peripheral Mapping

Each peripheral has a corresponding resource domain assignment register in the RDC and semaphore lock register in the RDC_SEMA42 module. The following table shows allocation of the RDC PDAP and RDC_SEMA4 GATE registers for peripheral resource domain assignment.

NOTE

Access control of the RDC registers can be programmed using the respective PDAP register. The default setting of the PDAP register for the RDC allows access from all domains. Use caution when restricting access of the RDC registers to avoid conditions where access to the RDC registers is needed but no master is assigned to a domain with access rights to the RDC.

3.2.4.3 Memory Region Map

The number of memories with domain isolation support varies per device. The number of memory regions for a particular memory and the size of those regions varies per memory gasket. Each region of memory has a set of registers to define the boundaries of the region based on start and end addresses, a control register to set the domain access permissions and enable the region, and a status register to determin if access was denied to a region.

For this device, refer to the table below to determine the memories with domain support, the number of regions for each memory, the region resolution, the identifying numbers for the sets of memory region registers, and the addresses of the RDC registers to access the sets of Memory Region registers.

3.2.5 RDC Memory Map/Register Definition

RDC memory map

RDC_VIR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–20 NRGN	Number of Memory Regions Indicates the number of memory regions in this instance of the RDC.
19–12 NPER	Number of Peripherals Indicates the number of peripherals that can be isolated or safe-shared
11–4 NMSTR	Number of Masters Indicates the number of masters supported by this instance of RDC.
NDID	Number of Domains

Table continues on the next page...

RDC_VIR field descriptions (continued)

Field	Description
	Indicates the number of domain ids supported by this instance of the RDC. Add one to the register value to get the actual number of domains.

3.2.5.2 Status (RDC_STAT)

Address: 303D_0000h base + 24h offset = 303D_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

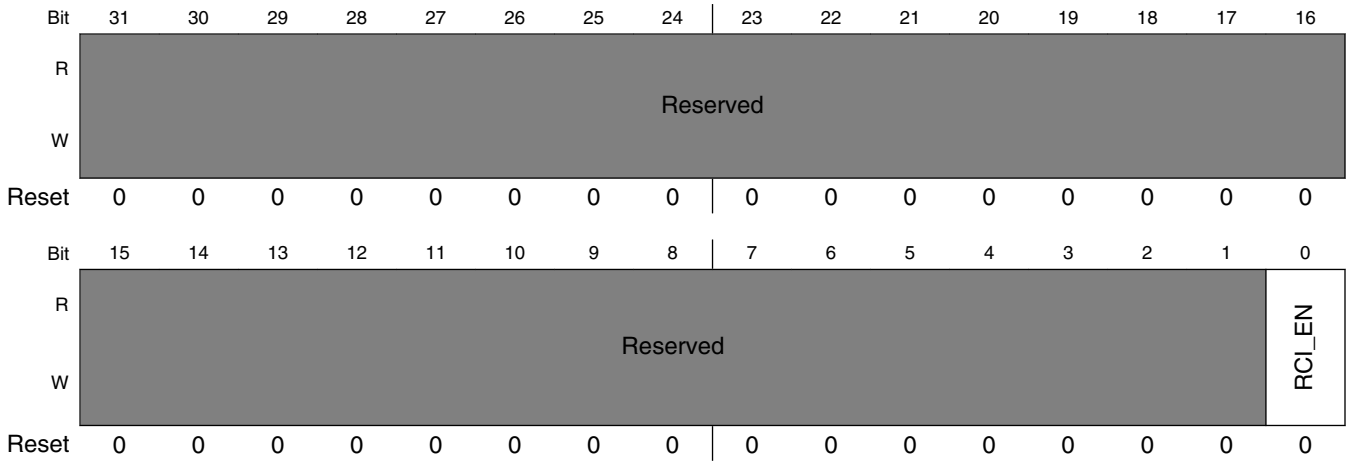
R W	Reserved							PDS	Reserved				DID			
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

RDC_STAT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 PDS	Power Domain Status Indicates if the "Power Down" memory regions are powered and available. Power Down memory regions are only those memory regions susceptible to power outage for power savings are unavailable if this is zero. "Always-On" memory regions remain available. Always On memory regions are those regions that are not powered down unless the entire SoC is powered down. This signal remains low until all access controls have been restored to the domain. 0 Power Down Domain is OFF 1 Power Down Domain is ON
7–4 Reserved	This field is reserved.
DID	Domain ID The Domain ID of the core or bus master that is reading this. The value is different for requests from different domains.

3.2.5.3 Interrupt and Control (RDC_INTCTRL)

Address: 303D_0000h base + 28h offset = 303D_0028h



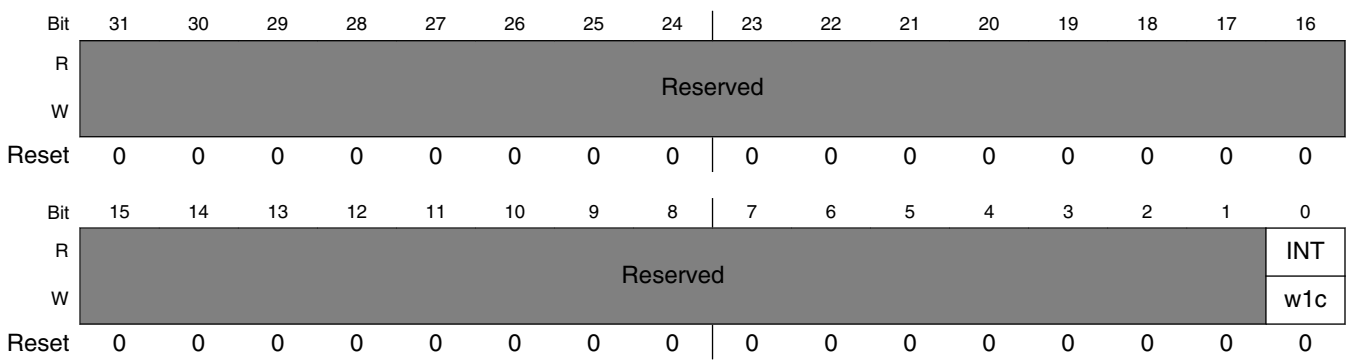
RDC_INTCTRL field descriptions

Field	Description
31–1 Reserved	This field is reserved.
0 RCI_EN	Restoration Complete Interrupt Interrupt generated when the RDC has completed restoring state to a recently re-powered memory regions. 0 Interrupt Disabled 1 Interrupt Enabled

3.2.5.4 Interrupt Status (RDC_INTSTAT)

Indication of Interrupt Pending for State Restoration

Address: 303D_0000h base + 2Ch offset = 303D_002Ch



RDC_INTSTAT field descriptions

Field	Description
31–1 Reserved	This field is reserved.
0 INT	Interrupt Status Indicates state of interrupt signal for state restoration. This is that status of the interrupt enabled in RDC_INTCTRL. Write one to interrupt status to clear it. 0 No Interrupt Pending 1 Interrupt Pending

3.2.5.5 Master Domain Assignment (RDC_MDA*n*)

Address: 303D_0000h base + 200h offset + (4d × i), where i=0d to 26d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
	0 No Read Access 1 Read Access Allowed
2 D1W	Domain 1 Write Access 0 No Write Access 1 Write Access Allowed
1 D0R	Domain 0 Read Access 0 No Read Access 1 Read Access Allowed
0 D0W	Domain 0 Write Access 0 No Write Access 1 Write Access Allowed

3.2.5.7 Memory Region Start Address (RDC_MRSA*n*)

NOTE

The DDR space is 33-bit width. The RDC memory region registers are 32-bit width. The RDC configuration is the most significant bits in the DDR address space (32:1). To set the start address for this configuration, the MRSA value should be shifted 1-bit and added to the DDR base address. The example below illustrates how to calculate the proper start and end address value. Please refer to the Memory Map for the actual DDR base address.

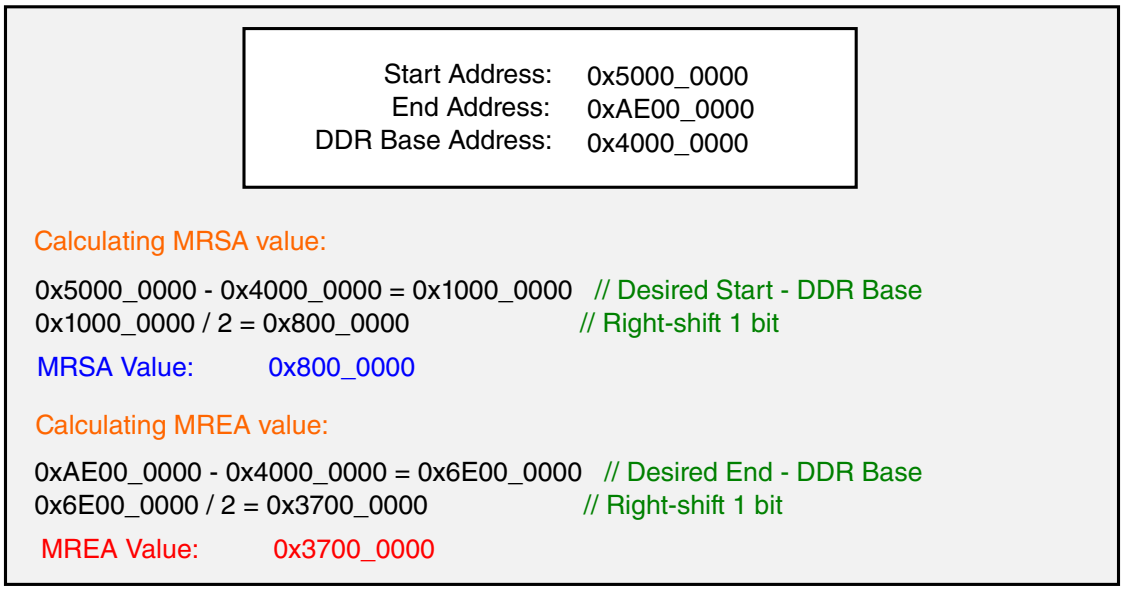

Figure 3-5. Calculating Address Value Examble

Address: 303D_0000h base + 800h offset + (16d × i), where i=0d to 51d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- x = Undefined at reset.

RDC_MRSA*n* field descriptions

Field	Description
31–7 SADR	Start address for memory region Lower bound (inclusive) modulo the defined granularity byte size of a region. The region size (granularity) is defined for each Memory/Port in the Memory Region Map section. Region boundaries are aligned to the minimum possible region size for the Memory/Port.
Reserved	This field is reserved.

3.2.5.8 Memory Region End Address (RDC_MREA*n*)

NOTE

The DDR space is 33-bit width. The RDC memory region registers are 32-bit width. The RDC configuration is the most significant bits in the DDR address space (32:1). To set the start address for this configuration, the MRSA value should be shifted 1-bit and added to the DDR base address. The example below illustrates how to calculate the proper start and end address value. Please refer to the Memory Map for the actual DDR base address.

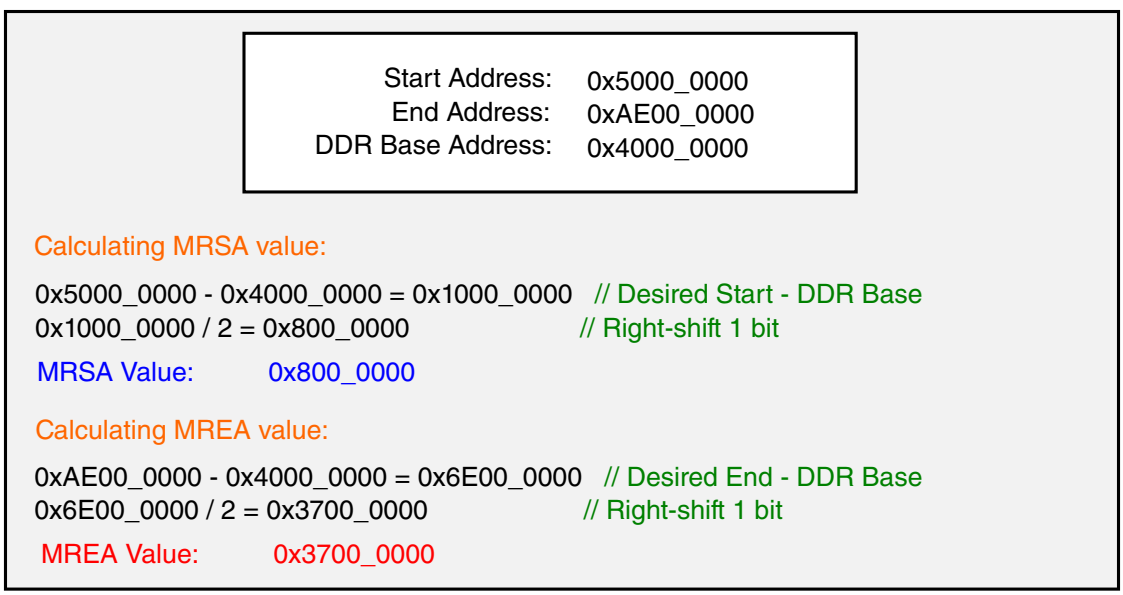

Figure 3-6. Calculating Address Value Examble

Address: 303D_0000h base + 804h offset + (16d × i), where i=0d to 51d

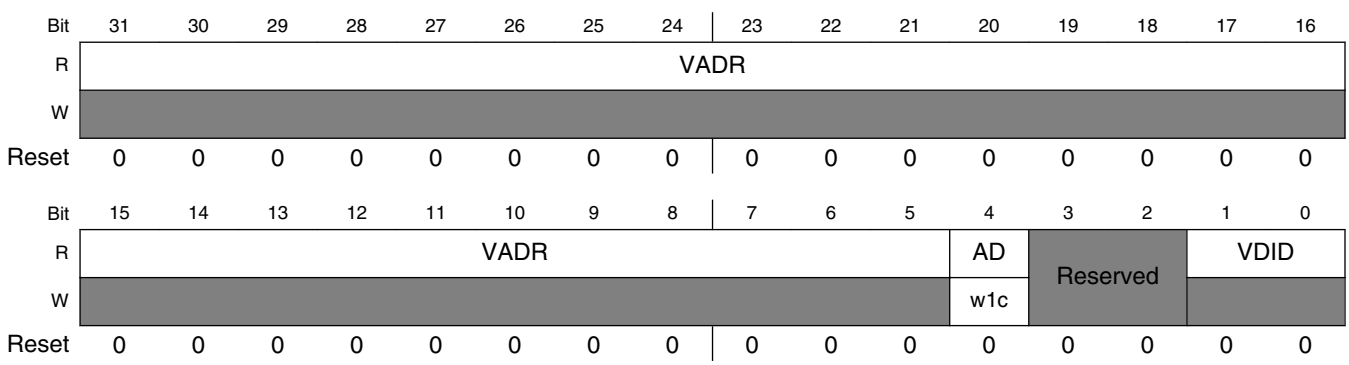
3.2.5.10 Memory Region Violation Status (RDC_MRVS*n*)

Address: 303D_0000h base + 80Ch offset + (16d × i), where i=0d to 51d



RDC_MRVS*n* field descriptions

Field	Description
31–5 VADR	Violating Address The address of the denied access. The first access violation is captured. Subsequent violations are ignored until the status register is cleared. Contents are cleared upon reading the register. Clearing of contents occurs only when the status is read by the memory region's associated domain ID (s).

Table continues on the next page...

RDC_MRVS*n* field descriptions (continued)

Field	Description
4 AD	Access Denied Access to a memory region denied. This bit is cleared when this bit is written by one of the allowed domains.
3–2 Reserved	This field is reserved.
VDID	Violating Domain ID The domain ID of the denied access. The first access violation is captured. Subsequent violations are ignored until the status register is cleared. Contents are cleared upon reading the register. 00 Processing Domain 0 01 Processing Domain 1 10 Processing Domain 2 11 Processing Domain 3

3.2.6 RDC SEMA42 Memory Map/Register Definition

Only Supervisor Mode accesses are allowed on these registers. User accesses generate an error termination.

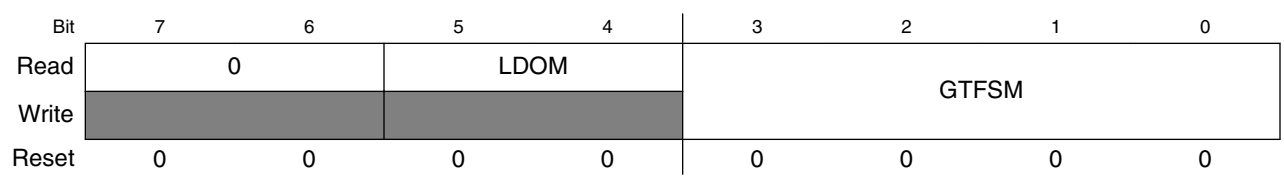
3.2.6.1 Gate Register (RDC_SEMAPHORE*x*_GATE*n*)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number (master_index) in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value nor the appropriate lock value (master_index + 1) are simply treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes. Processor dex values can be found in AIPSTZ Memory Map/Register Definition.

Address: Base address + 0h offset + (1d × i), where i=0d to 63d



RDC_SEMAPHORE*x*_GATE*n* field descriptions

Field	Description
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 LDOM	Read-only bits. They indicate which domain had currently locked the gate. 00 The gate is locked by domain 0. (True if bits [3:0] do not equal 0000.) 01 The gate has been locked by domain 1. 10 The gate has been locked by domain 2. 11 The gate has been locked by domain 3.
GTFSM	Gate Finite State Machine. The state of the gate reflects the last processor that locked it, which can be useful during system debug.

Table continues on the next page...

RDC_SEMAPHORE*x*_GATE*n* field descriptions (continued)

Field	Description
	The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor with master_index = 0. 0010 The gate has been locked by processor with master_index = 1. 0011 The gate has been locked by processor with master_index = 2. 0100 The gate has been locked by processor with master_index = 3. 0101 The gate has been locked by processor with master_index = 4. 0110 The gate has been locked by processor with master_index = 5. 0111 The gate has been locked by processor with master_index = 6. 1000 The gate has been locked by processor with master_index = 7. 1001 The gate has been locked by processor with master_index = 8. 1010 The gate has been locked by processor with master_index = 9. 1011 The gate has been locked by processor with master_index = 10. 1100 The gate has been locked by processor with master_index = 11. 1101 The gate has been locked by processor with master_index = 12. 1110 The gate has been locked by processor with master_index = 13. 1111 The gate has been locked by processor with master_index = 14.

3.2.6.2 Reset Gate Write (RDC_SEMAPHORE*x*_RSTGT_W)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the RDC Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the RDC_SEMA42RSTGT memory location. The least significant byte (RDC_SEMA42RSTGT[RSTGDP]) must be 0xE2; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the RDC_SEMA42RSTGT location. For this write, the lower byte (RDC_SEMA42RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the upper byte (RDC_SEMA42RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second

access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.

3. Reads of the RDC_SEMA42RSTGT location return information on the 2-bit state machine (RDC_SEMA42RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (RDC_SEMA42RSTGT[RSTGMS]), and the gate number(s) last cleared (RDC_SEMA42RSTGT[RSTGTN]). Reads of the RDC_SEMA42RSTGT register do not affect the secure reset finite state machine in any manner.

Address: Base address + 40h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	RSTGTN								0							
Write									RSTGDP							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDC_SEMAPHOREx_RSTGT_W field descriptions

Field	Description
15–8 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.
RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.

3.2.6.3 Reset Gate Read (RDC_SEMAPHOREx_RSTGT_R)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the RDC Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the RDC_SEMA42RSTGT memory location. The least significant byte (RDC_SEMA42RSTGT[RSTGDP]) must be 0xE2; the most significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the RDC_SEMA42RSTGT location. For this write, the lower byte

(RDC_SEMA42RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the upper byte (RDC_SEMA42RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.

3. Reads of the RDC_SEMA42RSTGT location return information on the 2-bit state machine (RDC_SEMA42RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (RDC_SEMA42RSTGT[RSTGMS]), and the gate number(s) last cleared (RDC_SEMA42RSTGT[RSTGTN]). Reads of the RDC_SEMA42RSTGT register do not affect the secure reset finite state machine in any manner.

Address: Base address + 40h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	RSTGTN								0		RSTGSM		RSTGMS			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDC_SEMAPHOREx_RSTGT_R field descriptions

Field	Description
15–8 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 RSTGSM	Reset Gate Finite State Machine. Reads of the RDC_SEMA42RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software will never be able to observe this state. 11 This state encoding is never used and therefore reserved.
RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.

Chapter 4
ARM Platform and Debug

4.1 ARM Cortex A53 Platform (A53)

4.1.1 Overview

The Cortex-A53 cluster is a mid-range, low-power processor that implements the ARMv8-A architecture. The Cortex-A53 cluster has four cores, each with an L1 memory system and a single shared L2 cache that has a set of additional functions, which are included in a single APR region.

The core supports debug through real-time trace via ETM, and static debug via JTAG. The core platform supports static debug through the debug logic to SoC. This includes the capability of real-time trace via ARM's CoreSight ETM modules. The CTI and CTM modules allow cross-triggering of internal and external trigger sources.

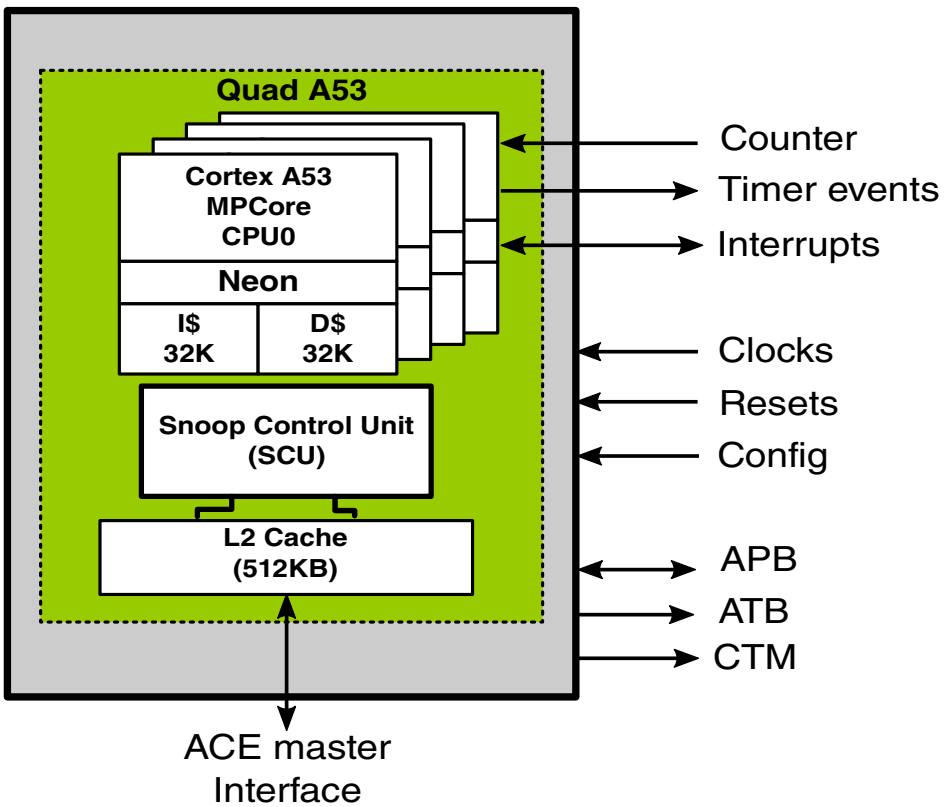


Figure 4-1. Cortex-A53 Block Diagram

4.1.1.1 Features

- 4x cores
- L1 instruction cache 32K with parity
- L1 data cache 32K with SECDED
- Advanced SIMD (NEON) per core
- Crypto extension per core
- CPU cache protection per core
- AMBA 4 ACE interface
- No ACP is included
- utilizes the ARMv8 debug map
- 512KB of L2 Cache
  - 1M with SECDED
  - Input latency 2 cycles
  - Output latency 2 cycles
  - SCU-L2 cache protection

4.1.2 Configuration

The configuration of the bus, cores and memory are detailed in the features and sections below. The core revision is r0p4-51rel0.

4.1.3 Performance

This section will discuss power and clocking performance of the Cortex-A53 Platform.

4.1.3.1 Power

There are several power states supported by the A53 Core Complex. Supported primary states are listed below:

- **Run** – At least one of 4 cores is running. The other cores may either be running, clock gated, or powered down.
- **L2 only coherent** – The L2 is powered up and servicing snoops. The cores are stopped (either powered down or clock gated). In this state the cache is retained coherent to the system.
- **L2 only non-coherent** – Both cores are stopped and powered down, the logic in the L2 controller are retaining the arrays only. In this state the L2 is not coherent, and as a result, the other AP cores must also be stopped.
- **Cluster Off** – The L2 has been flushed from the L2 only coherent state, using the HW flush mechanism (no core required). Then the cluster is fully powered off including the L2 arrays.

The power supply for the cluster is separated into two regions. The first is the control domain and second is for the remainder of the cluster (core and cluster domains). These regions are listed below:

- **Control domain** – The AON control domain contains the controls for powering up and down the rest of the core. The control domain is always powered on first and powered off last.
- **Core domains** – The core domains contains the whole core. The supply for the core domains is the same as the cluster domain, but require separate power down switches.
- **Cluster domain** – The cluster domain contains the rest of the cluster outside of the cores, which includes the shared logic of the L2 memory. The supply for the cluster power domain is the same as the core domains, but does not require power switches as it's shut down externally.

Isolation cells are required between each of these domains and is controlled by the signals on the control domain. These cells are necessary to force the output signal to be isolated to null values when the local power shuts down.

4.1.3.2 Clocking

The A53 platform is provided a main processor clock that supplies the component clocks to the cluster components, including CoreSight debug components. The maximum frequency targets are specified in the chip datasheet.

The cores are intended to support up to 1.5 GHz dependent on forward bias within the operating temperature range. Please see the datasheet for more information. The clocks are described in the table below:

Table 4-1. A53 Clocks

Clock Signal	Clock Name	Frequency	Description
Main Clock	CLKIN	Target	Main input clock.
APB Clock	PCLKENDBG	CLKIN/4	APB clock controls the timing on the debug port. Fixed frequency ratio to main frequency.
ACE Bus Clock	ACLKENM	CLKIN/2	ACE Interface bus clock. Controls the timing on the interface to CCI, but is not synchronous to CCI. Frequency is fixed ratio.
ATB Clock	ATCLKEN	CLKIN/4	ATB clock provides the clocks or outgoing trace. This clock needs to be reasonably high to enable sending samples out, but also needs to be the same as CNTCLKEN. Link to same signal as CNTCLKEN (1:4 core frequency fixed ratio).
Input Counter Clock	CNTCLKEN	CLKIN/4	Input counter clock. Timing is identical to debug port. The frequency is a fixed ratio (1:4) with the core clock. The same signal may be used for both inputs.

4.1.4 Platform sub-blocks

The sections below discuss the high-level overview of the ARM® Cortex®-A53 Platform components.

4.1.4.1 ARM Cortex-A53 MPCore Processor

The information presented in this section focuses on the design aspects of the ARM Cortex-A53 MPCore in the AP subsystem. The Cortex-A53 processor is a mid-range, low-power processor that implements the ARMv8-A architecture. The A53 complex has four cores, each with an L1 memory system and a single shared L2 cache.

The ARM Cortex-A53 MPCore processor consists of:

- Tightly-coupled L2 cache and an integrated Snoop Control Unit (SCU), connecting the four cores within the cluster providing cluster memory coherency, and a configurable coherent external interface supporting AMBA4 bus architecture.
- The Cortex-A53 implements the ARM Generic Interrupt Controller v3 (GICv3) architecture.

4.1.4.2 Advanced SIMD (Neon)

The Cortex-A53 processor supports the Advanced SIMD and Scalar Floating-point instructions in the A64 instruction set, and the Advanced SIMD and VFP instructions in the A32 and T32 instruction sets.

The ARMv8 architecture eliminates the concept of version numbers for Advanced SIMD and Floating-point in the AArch64 execution state.

4.1.4.3 Generic Interrupt Controller (GIC)

The Generic Interrupt Controller (GIC) supports and manages interrupts in the cluster. The GIC provides registers for managing:

- Interrupt sources
- Interrupt behavior
- Interrupt routing to one or more cores

The Cortex-A53 processor implements the GIC CPU interface as described in the Generic Interrupt Controller (GICv4) architecture. This interfaces with an external GICv3 or GICv4 interrupt distributor component within the system. The GICv4 architecture supports:

- Two security states
- Interrupt virtualization
- Software-generated Interrupts (SGIs)
- Message Based Interrupts
- System register access
- Memory-mapped register access
- Interrupt masking and prioritization

- Cluster environments
- Wake-up events in power management environments

The GIC includes interrupt grouping functionality that supports:

- Signaling interrupt groups to the target core using either the IRQ or the FIQ exception request, based on software configuration
- A unified scheme for handling the priority of Group 0 and Group 1 interrupts.

4.1.4.4 L1 Cache

The L1 instruction memory system has the following features:

- 32KB Instruction Cache
  - Instruction side cache line length of 64 bytes
  - 2-way set associative L1 Instruction cache
  - 128-bit read interface to the L2 memory system
- 32KB Data Cache
  - Data side cache line length of 64 bytes
  - 4-way set associative L1 Data cache
  - 256-bit write interface to the L2 memory system
  - 128-bit read interface to the L2 memory system
  - Read buffer that services the Data Cache Unit (DCU), the Instruction Fetch Unit (IFU) and the TLB
  - 64-bit read path from the data L1 memory system to the datapath
  - 128-bit write path from the datapath to the L1 memory system
  - Support for three outstanding data cache misses
  - Merging store buffer capability. This handles writes to:
    - Device memory
    - Normal Cacheable memory
    - Normal Non-cacheable memory
    - Data side prefetch engine

4.1.4.5 L2 Cache

The L2 cache consists of an integrated Snoop Control Unit (SCU), connecting four cores within the A53 cluster. The SCU also has duplicate copies of the L1 Data cache tags for coherency support. The L2 memory system interfaces to the external memory system through an AMBA 128-bit bus. The tightly-coupled L2 cache includes the following features:

- 1MB shared cache size
- AMBA 4 ACE Interface
- Fixed line length of 64 bytes

- Physically indexed and tagged cache
- 16-way set-associative cache structure
- No ACP support
- ECC/parity support

4.2 ARM Cortex M4 Platform (M4)

4.2.1 Overview

This block details the ARM Cortex-M4 core and platform. The Cortex-M4 implements the ARMv7- ME instruction set architecture (ISA) and adds significant capabilities with DSP and SIMD extensions. The ARM Cortex-M4 core provides additional general processing capability to the SoC with lower power and fast interrupt response time.

The Cortex-M4 also includes a single-precision floating-point unit (FPU) and two 32-bit system bus interfaces. The Cortex-M4 implementation includes two tightly coupled local memories, two cache memories connected to bus interfaces, 64-bit system bus interconnect, and supports a 32-byte cache line size.

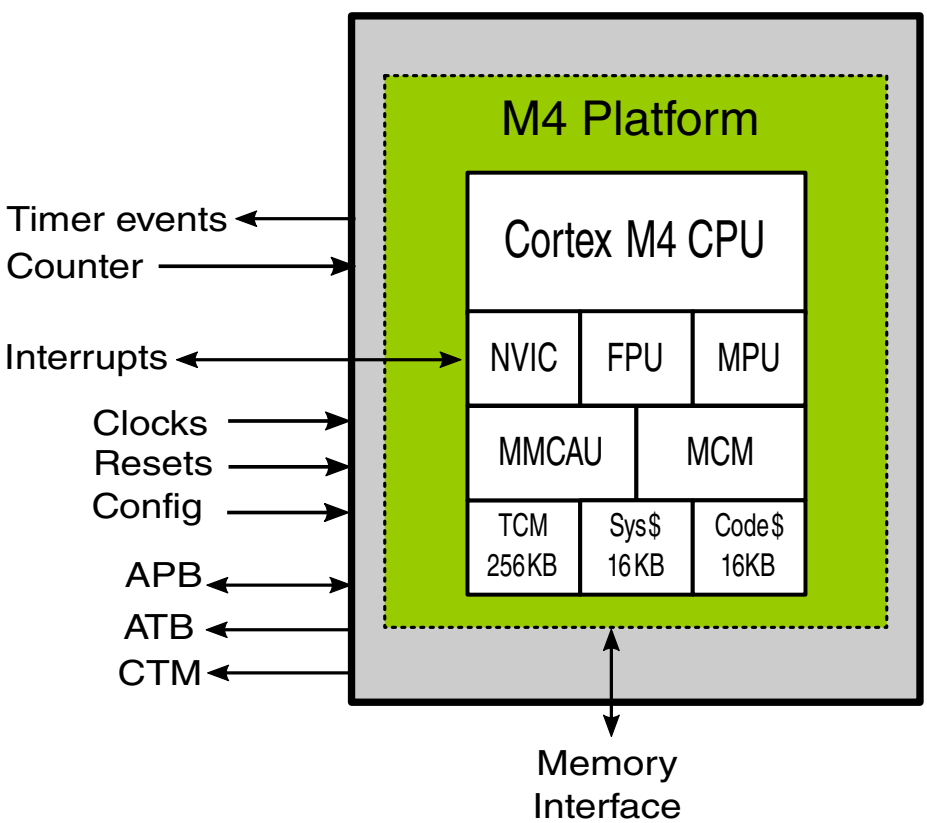

Figure 4-2. Cortex-M4 Block Diagram

4.2.1.1 Features

The features of the Cortex-M4 platform are detailed below:

- 1x Cortex-M4 processor
- AHB LMEM (Local Memory Controller) including controllers for TCM and cache memories
- 256 KB TCM (128 KB TCMU, 128 KB TCML)
- 16 KB Code Bus Cache
- 16 KB System Bus Cache
- ECC for TCM memories and parity for code and system caches
- Integrated Nested Vector Interrupt Controller (NVIC)
- Wakeup Interrupt Controller (WIC)
- FPU (Floating Point Unit)
- Core MPU (Memory Protection Unit)
- Support for exclusive access on the system bus
- MMCAU (Crypto Acceleration Unit)
- MCM (Miscellaneous Control Module)

4.2.2 Configuration

The configuration of the bus, core, and memory are detailed in the features and sections below.

Table 4-2. Cortex-M4 Configuration

Parameter	Description	Setting
NUM_IRQ	Number of Interrupts	128
LVL_WIDTH (translates to 2^n levels)	Number of interrupt priority bits	4
MPU_PRESENT	Exclude (0) or include (1) optional ARM MPU	1
DEBUG_LVL	Level of debug support	3
TRACE_LVL	Level of trace support 0 = No Trace 1 = ITM and DWT 2 = ITM, DWT, and ETM 3 = ITM, DWT, ETM, and HTM	2
RESET_ALL_REGS	Select whether all registers are reset (1)	1
JTAG_PRESENT	SWJ-DP (1) SW-DP (0)	1
CLKGATE_PRESENT	Disable (0) or enable (1) instantiation of architectural clock gates at all levels	1

Table continues on the next page...

Table 4-2. Cortex-M4 Configuration (continued)

WIC_PRESENT	Exclude (0) or include (1) optional ARM provided WIC	1
WIC_LINES	Select number of interrupts and/or events that WIC is sensitive to	NUM_IRQ+3
FPU_PRESENT	Exclude (0) or include (1) Floating Point Unit (FPU)	1
BB_PRESENT	Exclude (0) or include (1) Bit Banding logic	0
CONST_AHB_CTRL	Specifies whether the external AHB-Lite buses maintain control information during wait stated transfers	0

4.2.3 Performance

This section will discuss power and clocking performance of the Cortex-M4 Platform.

4.2.3.1 Power

There are several power states supported by the Cortex-M4. Supported primary core states are listed below:

- **Run** - Normal run state. CM4 Platform, TCM and cache memories on nominal voltage.
- **Sleep** – Wait power state. Depending on power state, CM4 Platform, TCM and cache memories can either be in nominal or low-voltage. State recovery through NVIC. NVIC clock is still running in this state.
- **Deep Sleep** – Stop power state. Depending on power state, CM4 Platform, TCM and cache memories can either be in nominal or low-voltage. State recovery through AWIC. Clocks can be completely stopped in this state.

4.2.3.2 Clocking

The M4 platform is provided a main processor clock that supplies the component clocks to the cluster components. The maximum frequency targets are specified in the chip datasheet. Please see the datasheet for more information. The clocks are described in the table below:

Table 4-3. CM4 Clocks

Clock Signal	Clock Name	Target Frequency	Description
Core gated clock	cpu_hclk	266 MHz	Cortex-M4 core clock.
Core Free-Running Clock	cpu_fclk	266 MHz	CM4 NVIC and timer clock

Table continues on the next page...

Table 4-3. CM4 Clocks (continued)

TCM Controller Clock	tcmc_hclk	266 MHz	CM4 platform TCM controller clock
Platform Clock	hclk	266 MHz	CM4 platform AXBS fabric and bus masters. Synchronous to the core clock.
Bus Clock	ipg_clk	133 MHz	Clock for bus slaves and peripherals. Synchronous to the system clock.

4.2.4 Platform sub-blocks

The sections below discuss the high-level overview of the ARM® Cortex®-M4 Platform components.

4.2.4.1 ARM Cortex-M4 Processor

The Cortex-M4 processor is a low-power processor that features low gate count, low interrupt latency, and low-cost debug. The Cortex-M4 includes floating point arithmetic functionality. The processor is intended for deeply embedded applications that require fast interrupt response features.

The ARM Cortex-M4 processor consists of:

- A processor core
- A Nested Vectored Interrupt Controller (NVIC) closely integrated with the processor core to achieve low-latency interrupt processing
- Multiple high-performance bus interfaces
- A low-cost debug solution with the optional ability to:
  - Implement breakpoints and code patches
  - Implement watchpoints, tracing, and system profiling
  - Support printf() style debugging
  - Bridge to a Trace Port Analyzer (TPA)
- Memory Protection Unit (MPU)
- Floating Point Unit (FPU)
- Miscellaneous Control Module (MCM)
- The Cortex-M4 implements the ARM the ARMv7-M architecture.

4.2.4.2 Nested Vectored Interrupt Controller (NVIC)

The M4 platform includes a Nested Vectored Interrupt Controller (NVIC) that is closely integrated with the processor core to achieve low-latency interrupt processing. The platform supports 16 priority levels for interrupts. The NVIC IPR registers will define 4 bits per IRQ.

NOTE

M4_NMI is Non-maskable Interrupt of M4 with fixed priority. It is available by selecting ALT1 mux_mode for pad GPIO1_IO05. Refer to ARM official document *Cortex™-M4 Devices Generic User Guide* for more details.

4.2.4.3 Floating Point Unit (FPU)

The Cortex-M4 platform supports Floating Point Unit (FPU). The FPU implements the single precision variant of the ARMv7-M Floating-Point Extension (FPv4-SP), which supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. FPU also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard. The FPU contains 32 single-precision extension registers, which you can also access as 16 doubleword registers for load, store, and move operations.

4.2.4.4 Memory Protection Unit (MPU)

The Cortex-M4 platform supports Memory Protection Unit (MPU). The MPU enforces privilege rules, separates processes, and enforces access rules to memory, and supports the standard ARMv7 Protected Memory System Architecture model. The MPU provides full support for:

- Protection regions
- Overlapping protection regions, with ascending region priority:
  - 7 = highest priority
  - 0 = lowest priority
- Access permissions
- Exporting memory attributes to the system

MPU mismatches and permission violations invoke the programmable-priority MemManage fault handler. You can use the MPU to:

- Enforce privilege rules
- Separate processes
- Enforce access rules

4.2.4.5 Tightly-Coupled Memory (TCM)

The Cortex-M4 uses Tightly-Coupled Memory (TCM) to perform low-latency memory operations including speculative read accesses. The TCM is split between upper and lower regions with each TCM interface operating independently of each other.

The Cortex-M4 supports 32-bit ECC error detection and correction for the TCM memories. TCM ECC can indicate to the processor that an access must be retried to return the corrected data.

Because AHB-Lite does not support write data strobes when accessing AHB-Lite slaves from an AXI master, care must be taken not to generate transactions that have partial strobes. Make sure to not have unaligned accessing to TCM from an AXI master. For example, when writing data to TCM from A53, ensure every write strobe address is 64bit aligned. When the MMU is enabled, the TCM memory range must have the MT_DEVICE_NGNRNE type attribute set. This will avoid A53 sparse writes to the TCM memory region.

4.2.5 Local Memory Controller (LMEM)

The Local Memory Controller provides the Arm®Cortex-M4™ processor with tightly-coupled processor-local memories and bus paths to all slave memory spaces.

4.2.5.1 LMEM Block Diagram

The Cortex-M4 processor has a modified 32-bit Harvard bus architecture. Using a 32-bit address space, low-order addresses (0x0000_0000 through 0x1FFF_FFFF) use the Processor Code (PC) bus, and high-order addresses (0x2000_0000 through 0xFFFF_FFFF) use the Processor System (PS) bus. As the bus names imply, normal operation has code accesses on the PC bus and data accesses on the PS bus.

This device has been augmented with tightly-coupled memories for the PC and PS buses. The memories include RAMs and caches. These local memories provide zero wait state access to RAM and cacheable address spaces.

The local memory controller includes four memory controllers and their attached memories:

- SRAM lower (SRAM_L) controller via the PC bus
- SRAM upper (SRAM_U) controller via the PS bus
- Cache memory controller via the PC bus
- Cache memory controller via the PS bus

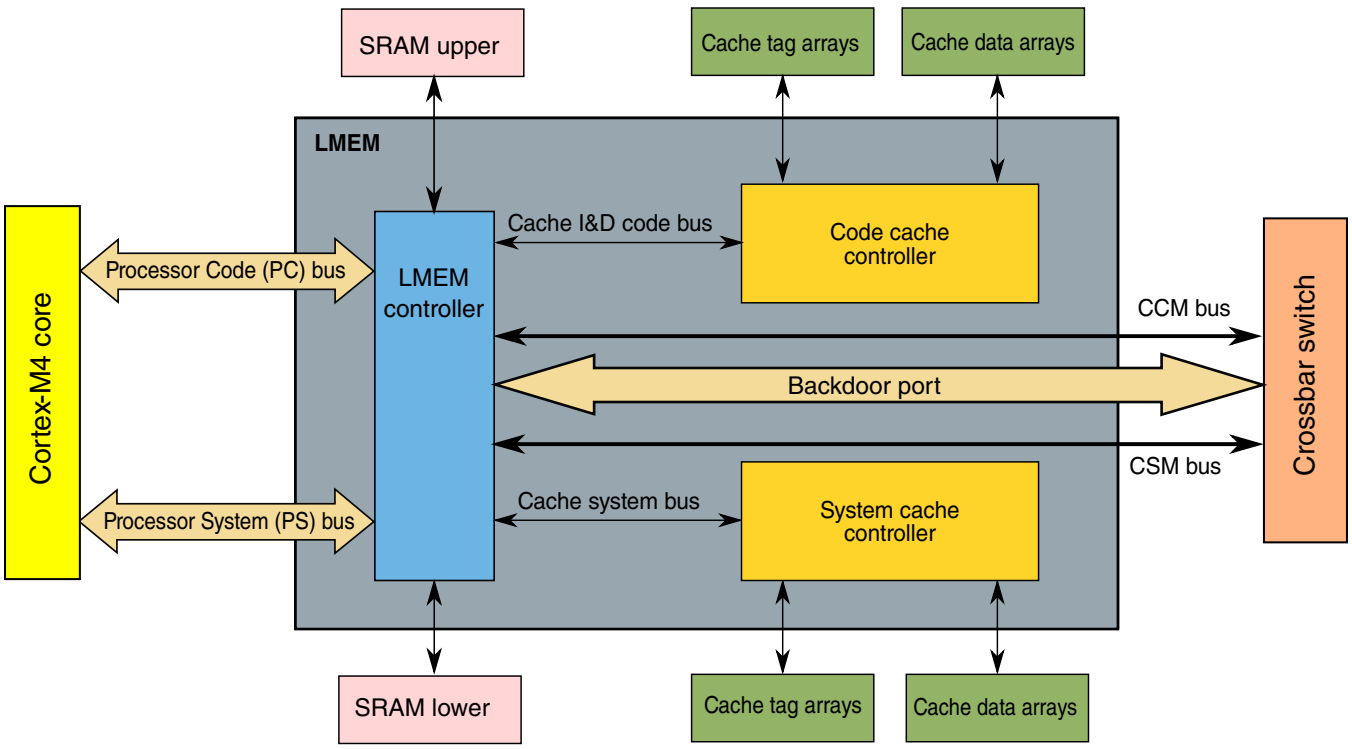

Figure 4-3. Local memory controller block diagram

NOTE

The SRAM and cache controllers reside within the LMEM, but the single-port synchronous RAM arrays used by these controllers are external.

The LMEM contains address decode logic for the PC and PS buses. This logic routes the core's accesses to the various system resources. The address spaces are device-specific and are specified in the device's Chip Configuration chapter.

4.2.5.2 Cache features

A cache is a block of high-speed memory locations containing address information (commonly known as a tag) and the associated data. The purpose is to decrease the average time of a memory access. Caches operate on two principles of locality:

- Spatial locality — An access to one location is likely to be followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — An access to an area of memory is likely to be repeated within a short time period (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property is used to group several locations together under the same tag. This logical block is commonly known as a cache line.

When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would normally expect them,
- the existence of multiple physical locations where a data item can be held.

The local memory controller supports three modes of operation:

1. Write-through — access to address spaces with this cache mode are cacheable.
    - A read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and is marked as valid and not modified.
    - A write-through read hit to a valid cache location returns data from the cache with no output bus access.
    - A write-through write miss bypasses the cache and writes to the output bus (no allocate on write miss policy for write-through mode spaces).
    - A write-through write hit updates the cache hit data and writes to the output bus.
2. Write-back — access to address spaces with this cache mode are cacheable.
    - A write-back read miss on the input bus will cause a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and marked as valid and not modified.

- A write-back read hit to a valid cache location will return data from the cache with no output bus access.
- A write-back write miss will do a "read-to-write" (allocate on write miss policy for write-back mode spaces). A line read on the output bus of a 16 byte aligned memory address containing the desired write address is performed. This miss data is loaded into the cache and marked as valid and modified; and the write data will then update the appropriate cache data locations.

3. Non-cacheable — access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

4.2.5.3 LMEM Function

The LMEM receives the following requests:

- Core master bus requests on the Processor Code (PC) bus,
- Core master bus requests on the Processor Space (PS) bus, and
- SRAM controller requests from all other bus masters on the backdoor port.

The LMEM address decode logic routes these accesses and also provides any crossbar switch slave target logic. Finally, the Local Memory controller provides the needed MPU connections for checking all SRAM controller and cacheable accesses.

The programming model for the Code and System Caches is accessed via the core's Private Peripheral Bus (PPB).

4.2.5.3.1 Processor Code accesses

Processor Code accesses are routed to the SRAM_L if they are mapped to that space. All other PC accesses are routed to the Code Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master0 port.

4.2.5.3.2 Processor Space accesses

Processor Space accesses are routed to the SRAM_U if they are mapped to that space. All other PS accesses are routed to the PS Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master1 port.

4.2.5.3.3 Backdoor port accesses

All LMEM backdoor port accesses are for the SRAM controller. These accesses go to the SRAM_L or the SRAM_U depending on their specific address.

4.2.5.3.4 SRAM Function

4.2.5.3.4.1 SRAM Configuration

The figure below shows how the SRAM controller is configured.

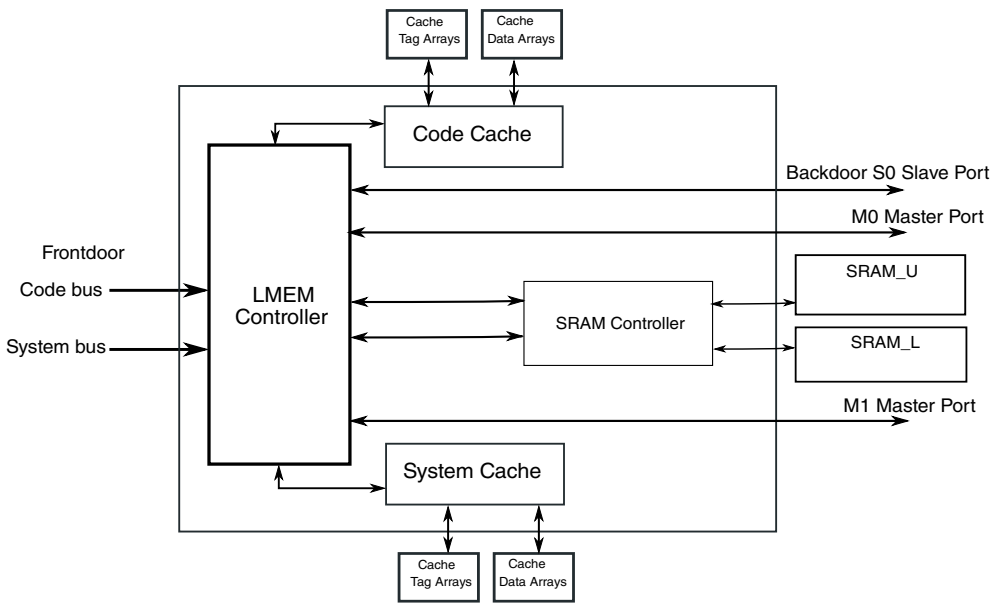

Figure 4-4. SRAM Configuration

4.2.5.3.4.2 SRAM Arrays

The on-chip SRAM is split into two logical arrays, SRAM_L and SRAM_U.

From equal-sized memories, valid address ranges for SRAM_L and SRAM_U are then defined as:

- SRAM_U = 0x2000_0000 - (0x2000_0000 + SRAM_size/2)

4.2.5.3.4.3 SRAM accesses

The SRAM is split into two logical arrays that are 64-bits wide:

- SRAM_L — Accessible by the code bus of the Cortex-M4 core and by the backdoor port.
- SRAM_U — Accessible by the system bus of the Cortex-M4 core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA).

The figure below illustrates the SRAM accesses within the device.

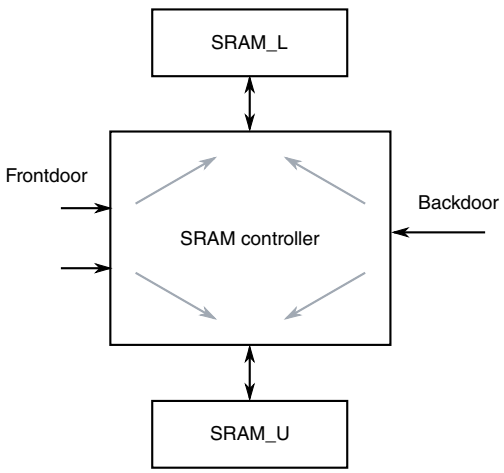

Figure 4-5. SRAM access diagram

The following simultaneous accesses can be made to different logical halves of the SRAM:

- Core code and core system
- Core code and non-core master
- Core system and non-core master

NOTE

Two non-core masters cannot access SRAM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The SRAM_{L,U} arbitration is controlled by the SRAM controller based on the configuration bits in the MCM module.

4.2.5.3.5 Cache Function

The caches on this device are structured as follows. Both caches have a 2-way set-associative cache structure with a total size of 32 KBytes. The caches have a 32-bit address, 64-bit data paths and a 32-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For these 16-KByte caches, each cache TAG function uses two 256 x 22-bit RAM arrays and the cache DATA function uses two 1024 x 32-bit RAM arrays. The cache TAG entries store 20 bits of upper address as well as a modified and valid bit per cache line. The cache DATA entries store eight byes of code or data.

All normal cache accesses use physical addresses. This leads to the following cache address use:

CACHE - 16 KByte size = (256 sets) x (32-byte lines) x (2-way set associative)

TAG:

DATA

- address[31:13] not used
- address[12:5] used to select one of 256 sets
- address[4:2] used to select one of eight 32-bit words within a set
- address[1:0] used to select the byte within the 32-bit word

4.2.5.3.6 Cache Control

The Code and System Caches are disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable the caches, cache commands must be done to clear and initialize the required tag array bits and to configure and enable the caches.

4.2.5.3.6.1 Cache set commands

The cache set commands may operate on:

- all of way 0,
- all of way 1, or
- all of both ways (complete cache).

Cache set commands are initiated using the upper bits in the CCR register. Cache set commands perform their operation on the cache independent of the cache enable bit, CCR[ENCACHE].

A cache set command is initiated by setting the CCR[GO] bit. This bit also acts as a busy bit for set commands. It stays set while the command is active and is cleared by the hardware when the set command completes.

Supported cache set commands are given in the table below. Set commands work as follows:

- Invalidate – Unconditionally clear valid and modify bits of a cache entry.

- Push – Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is.
- Clear – Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

Table 4-4. Cache Set Commands

CCR[27:24]				Command
PUSH W1	INVW1	PUSH W0	INVW0	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1; clear all way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, setting CCR to 0x8500_0003 will invalidate the cache and enable the cache and write buffer.

4.2.5.3.6.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. Cache line commands can be performed using a physical or cache address.

- A cache address consists of a set address and a way select. The line command acts on the specified cache line.
- Cache line commands with physical addresses first search both ways of the cache set specified by bits [11:4] of the physical address. If they hit, the commands perform their action on the hit way.

Cache line commands are specified using the upper bits in the CLCR register. Cache line commands perform their operation on the cache independent of the cache enable bit (CCR[ENCACHE]). Using a cache address, the command can be completely specified using the CLCR register. Using a physical address, the command must also use the CSAR register to specify the physical address.

A line cache command is initiated by setting the line command go bit (CLCR[LGO] or CSAR[LGO]). This bit also acts a a busy bit for line commands. It stays set while the command is active and is cleared by the hardware when the command completes.

The CLCR[27:24] bits select the line command as follows:

Table 4-5. Cache Line Commands

CLCR[27:24]			Command
LACC	LADSEL	LCMD	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	*xx*	Reserved, NOP

4.2.5.3.6.2.1 Executing a series of line commands using cache addresses

A series of line commands with incremental cache addresses can be performed by just writing to the CLCR.

- Place the command in CLCR[27:24],
- Set the way (CLCR[WSEL]) and tag/data (CLCR[TDSEL]) controls as needed,
- Place the cache address in CLCR[CACHEADDR], and
- Set the line command go bit (CLCR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the cache address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CLCR[LGO]).

4.2.5.3.6.2.2 Executing a series of line commands using physical addresses

Perform a series of line commands with incremental physical addresses using the following steps:

- Write to the CLCR.
  - Place the command in CLCR[27:24]
  - Set the tag/data (CLCR[TDSEL]) control
- Place the physical address in CSAR[PHYADDR] and set the line command go bit (CSAR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the physical address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CSAR[LGO]).

The line command go bit is shared between the CLCR and CSAR registers, so that the above steps can be completed in a single write to the CSAR register.

4.2.5.3.6.2.3 Line command results

At completion of a line command, the CLCR register contains information on the initial state of the line targeted by the command. For line commands with cache addresses, this information is read before the line command action is performed from the targeted cache line. For line commands with physical addresses, this information is read on a hit before the line command action is performed from the hit cache line or has initial valid bit cleared if the command misses. In general, if the valid indicator (CLCR[LCIVB] is cleared, the targeted line was invalid at the start of the line command and no line operation was performed.

Table 4-6. Line command results

CLCR[22:20]			For cache address commands	For physical address commands
LCWAY	LCIMB	LCIVB		
0	0	0	Way 0 line was invalid	No hit
0	0	1	Way 0 valid, not modified	Way 0 valid, not modified
0	1	0	Way 0 line was invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified

Table continues on the next page...

Table 4-6. Line command results (continued)

CLCR[22:20]			For cache address commands	For physical address commands
LCWAY	LCIMB	LCIVB		
1	0	0	Way 1 line was invalid	No hit
1	0	1	Way 1 valid, not modified	Way 1 valid, not modified
1	1	0	Way 1 line was invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

At completion of a line command other than a write, the CCVR (Cache R/W Value Register) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, the CCVR holds the write data.

4.2.6 Miscellaneous Control Module (MCM)

The Miscellaneous Control Module (MCM) provides a myriad of miscellaneous control functions.

4.2.6.1 MCM features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision

4.2.6.2 MCM Interrupts

The MCM generates the following interrupt requests:

- Normal interrupt

4.2.6.2.1 Normal interrupt

The MCM's normal interrupt is generated if any of the following is true:

- ISCR[ETBI] is set, when
  - The ETB counter is enabled, ETBCC[CNTEN] = 1
  - The ETB count expires
  - The response to counter expiration is a normal interrupt, ETBCC[RSPT] = 01

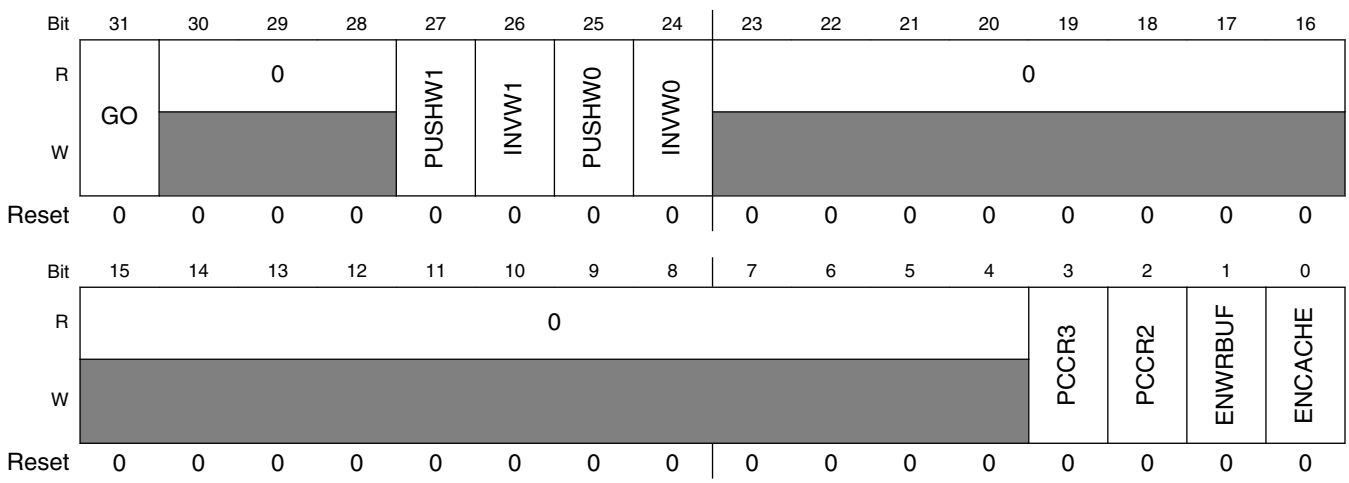
4.2.7 LMEM Memory Map/Register Definition

LMEM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E008_2000	Cache control register (LMEM_PCCCR)	32	R/W	0000_0000h	4.2.7.1/99
E008_2004	Cache line control register (LMEM_PCCLCR)	32	R/W	0000_0000h	4.2.7.2/100
E008_2008	Cache search address register (LMEM_PCCSAR)	32	R/W	0000_0000h	4.2.7.3/103
E008_200C	Cache read/write value register (LMEM_PCCCVR)	32	R/W	0000_0000h	4.2.7.4/104
E008_2800	Cache control register (LMEM_PSCCR)	32	R/W	0000_0000h	4.2.7.5/104
E008_2804	Cache line control register (LMEM_PSCLCR)	32	R/W	0000_0000h	4.2.7.6/106
E008_2808	Cache search address register (LMEM_PSCSAR)	32	R/W	0000_0000h	4.2.7.7/108
E008_280C	Cache read/write value register (LMEM_PSCCVR)	32	R/W	0000_0000h	4.2.7.8/109

4.2.7.1 Cache control register (LMEM_PCCCR)

Address: E008_2000h base + 0h offset = E008_2000h



LMEM_PCCCR field descriptions

Field	Description
31 GO	Initiate Cache Command Setting this bit initiates the cache command indicated by bits 27-24. Reading this bit indicates if a command is active **NOTE:** This bit stays set until the command completes. Writing zero has no effect. 0 Write: no effect. Read: no cache command active. 1 Write: initiate command indicated by bits 27-24. Read: cache command active.

Table continues on the next page...

LMEM_PCCCR field descriptions (continued)

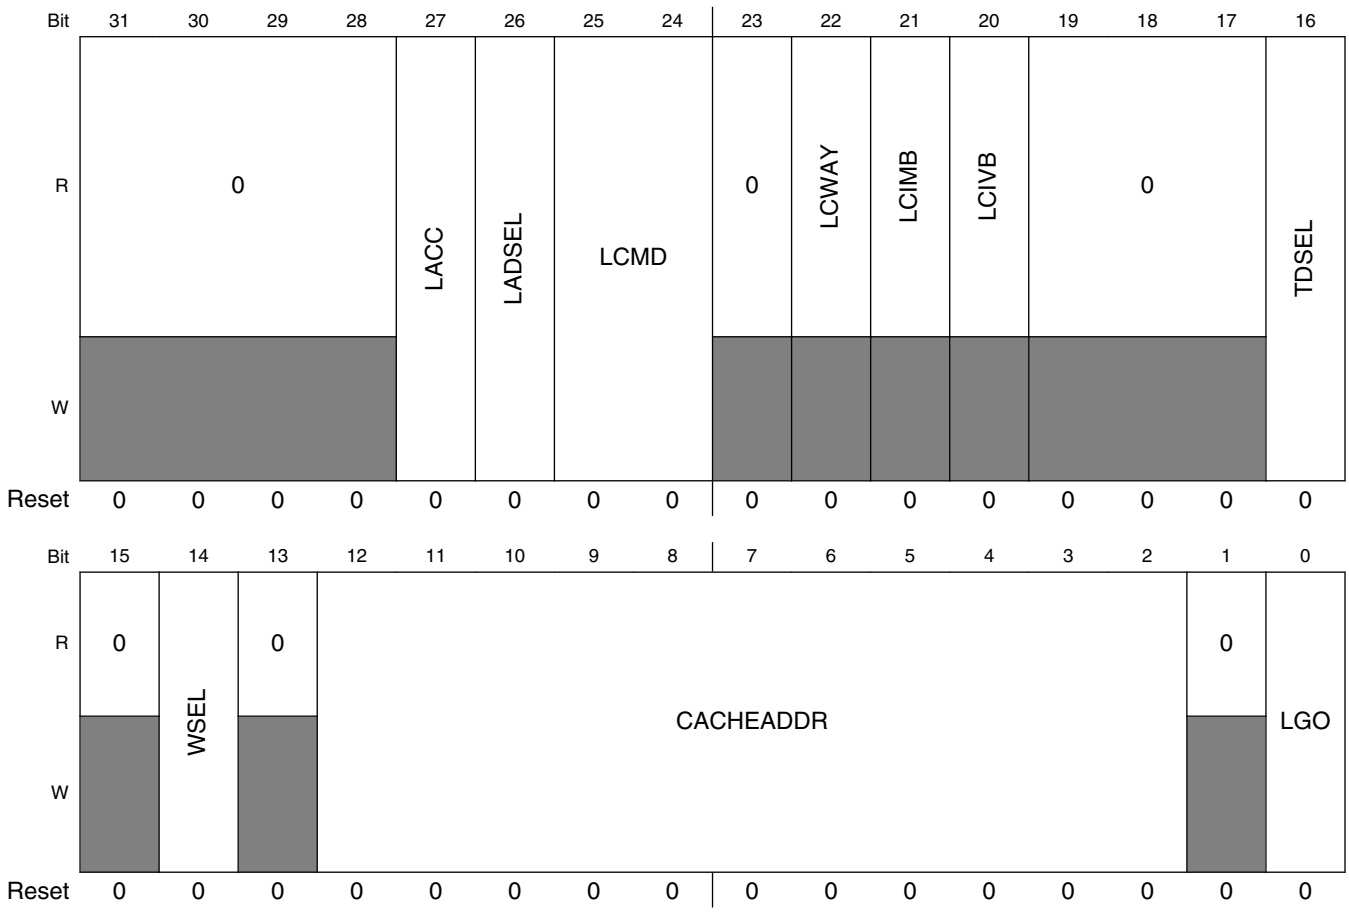
Field	Description
30–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PUSHW1	Push Way 1 0 No operation 1 When setting the GO bit, push all modified lines in way 1
26 INVW1	Invalidate Way 1 **NOTE:** If the PUSHW1 and INVW1 bits are set, then after setting the GO bit, push all modified lines in way 1 and invalidate all lines in way 1 (clear way 1). 0 No operation 1 When setting the GO bit, invalidate all lines in way 1
25 PUSHW0	Push Way 0 0 No operation 1 When setting the GO bit, push all modified lines in way 0
24 INVW0	Invalidate Way 0 **NOTE:** If the PUSHW0 and INVW0 bits are set, then after setting the GO bit, push all modified lines in way 0 and invalidate all lines in way 0 (clear way 0). 0 No operation 1 When setting the GO bit, invalidate all lines in way 0.
23–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 PCCR3	Forces no allocation on cache misses (must also have ACCR2 asserted)
2 PCCR2	Forces all cacheable spaces to write through
1 ENWRBUF	Enable Write Buffer 0 Write buffer disabled 1 Write buffer enabled
0 ENCACHE	Cache enable 0 Cache disabled 1 Cache enabled

4.2.7.2 Cache line control register (LMEM_PCCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008_2000h base + 4h offset = E008_2004h



LMEM_PCCLCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LACC	Line access type 0 Read 1 Write
26 LADSEL	Line Address Select When using the cache address, the way must also be specified in CLCR[WSEL]. When using the physical address, both ways are searched and the command is performed only if a hit. 0 Cache address 1 Physical address
25–24 LCMD	Line Command 00 Search and read or write 01 Invalidate 10 Push 11 Clear

Table continues on the next page...

LMEM_PCCLCR field descriptions (continued)

Field	Description
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LCWAY	Line Command Way Indicates the way used by the line command.
21 LCIMB	Line Command Initial Modified Bit If command used cache address and way, then this bit shows the initial state of the modified bit If command used physical address and a hit, then this bit shows the initial state of the modified bit. If a miss, this bit reads zero.
20 LCIVB	Line Command Initial Valid Bit If command used cache address and way, then this bit shows the initial state of the valid bit If command used physical address and a hit, then this bit shows the initial state of the valid bit. If a miss, this bit reads zero.
19–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TDSEL	Tag/Data Select Selects tag or data for search and read or write commands. 0 Data 1 Tag
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WSEL	Way select Selects the way for line commands. 0 Way 0 1 Way 1
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–2 CACHEADDR	Cache address CLCR[11:4] bits are used to access the tag arrays CLCR[11:2] bits are used to access the data arrays
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active **NOTE:** This bit stays set until the command completes. Writing zero has no effect. **NOTE:** This bit is shared with CSAR[LGO] 0 Write: no effect. Read: no line command active. 1 Write: initiate line command indicated by bits 27-24. Read: line command active.

4.2.7.3 Cache search address register (LMEM_PCCSAR)

The CSAR register is used to define the explicit cache address or the physical address for line-sized commands specified in the CLCR[LADSEL] bit.

Address: E008_2000h base + 8h offset = E008_2008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PHYADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PHYADDR														0	LGO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

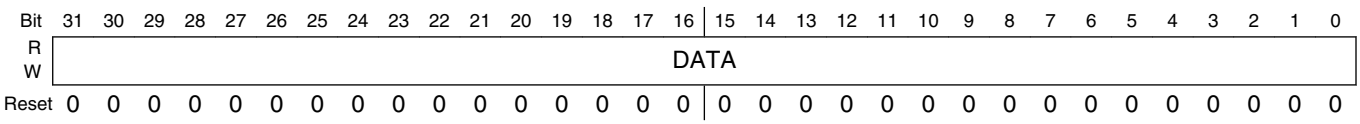
LMEM_PCCSAR field descriptions

Field	Description
31–2 PHYADDR	Physical Address PHYADDR represents bits [31:2] of the system address. CSAR[31:12] bits are used for tag compare CSAR[11:4] bits are used to access the tag arrays CSAR[11:2] bits are used to access the data arrays
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active **NOTE:** This bit stays set until the command completes. Writing zero has no effect. **NOTE:** This bit is shared with CLCR[LGO] 0 Write: no effect. Read: no line command active. 1 Write: initiate line command indicated by bits CLCR[27:24]. Read: line command active.

4.2.7.4 Cache read/write value register (LMEM_PCCCVR)

The CCVR register is used to source write data or return read data for the commands specified in the CLCR register.

Address: E008_2000h base + Ch offset = E008_200Ch

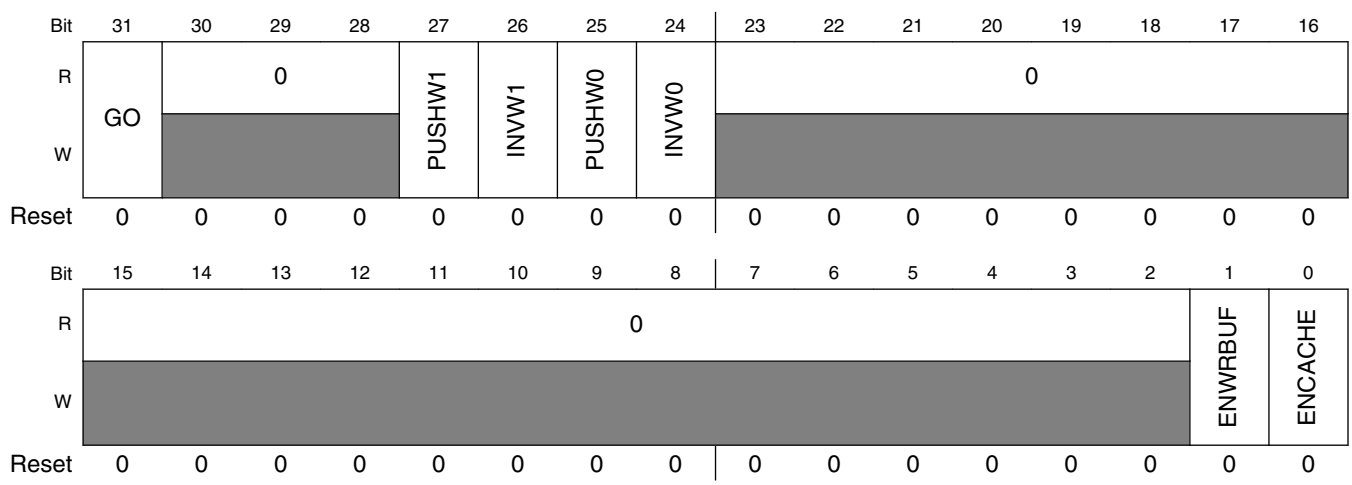


LMEM_PCCCVR field descriptions

Field	Description
DATA	Cache read/write Data For tag search, read or write: • CCVR[31:12] bits are used for tag array R/W value • CCVR[11:4] bits are used for tag set address on reads; unused on writes • CCVR[3:2] bits are reserved For data search, read or write: • CCVR[31:0] bits are used for data array R/W value

4.2.7.5 Cache control register (LMEM_PSCCR)

Address: E008_2000h base + 800h offset = E008_2800h



LMEM_PSCCR field descriptions

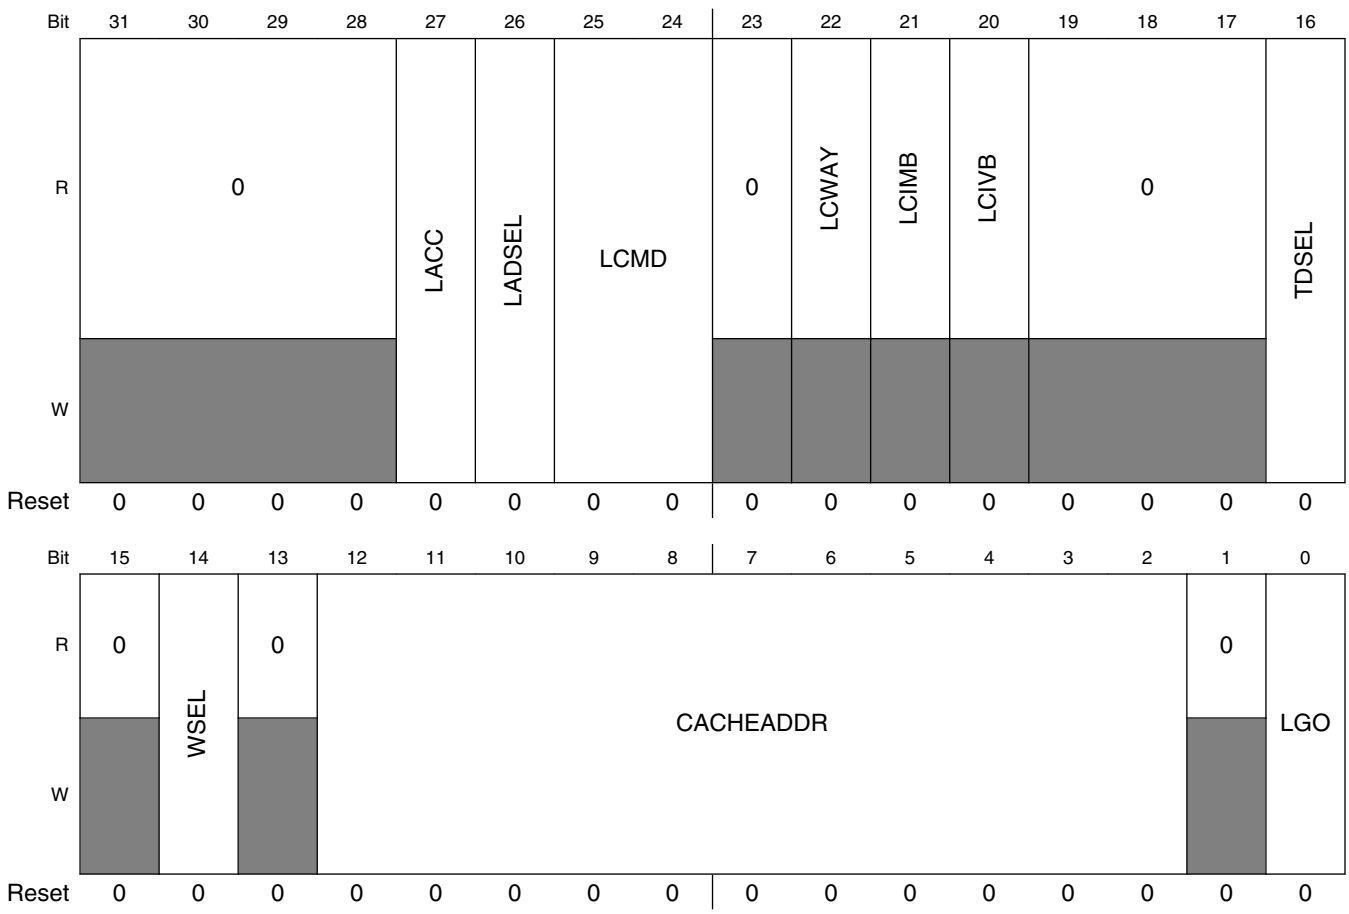
Field	Description
31 GO	Initiate Cache Command Setting this bit initiates the cache command indicated by bits 27-24. Reading this bit indicates if a command is active **NOTE:** This bit stays set until the command completes. Writing zero has no effect. 0 Write: no effect. Read: no cache command active. 1 Write: initiate command indicated by bits 27-24. Read: cache command active.
30–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PUSHW1	Push Way 1 0 No operation 1 When setting the GO bit, push all modified lines in way 1
26 INVW1	Invalidate Way 1 **NOTE:** If the PUSHW1 and INVW1 bits are set, then after setting the GO bit, push all modified lines in way 1 and invalidate all lines in way 1 (clear way 1). 0 No operation 1 When setting the GO bit, invalidate all lines in way 1
25 PUSHW0	Push Way 0 0 No operation 1 When setting the GO bit, push all modified lines in way 0
24 INVW0	Invalidate Way 0 **NOTE:** If the PUSHW0 and INVW0 bits are set, then after setting the GO bit, push all modified lines in way 0 and invalidate all lines in way 0 (clear way 0). 0 No operation 1 When setting the GO bit, invalidate all lines in way 0.
23–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 ENWRBUF	Enable Write Buffer 0 Write buffer disabled 1 Write buffer enabled
0 ENCACHE	Cache enable 0 Cache disabled 1 Cache enabled

4.2.7.6 Cache line control register (LMEM_PSCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008_2000h base + 804h offset = E008_2804h



LMEM_PSCLCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LACC	Line access type 0 Read 1 Write
26 LADSEL	Line Address Select When using the cache address, the way must also be specified in CLCR[WSEL].

Table continues on the next page...

4.2.8 MCM Memory Map/Register Definition

MCM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E008_0008	Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)	16	R	0002h	4.2.8.1/110
E008_000A	Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)	16	R	0003h	4.2.8.2/110
E008_000C	Crossbar Switch (AXBS) Control Register (MCM_PLACR)	32	R/W	0000_0000h	4.2.8.3/111
E008_0020	Fault address register (MCM_FADR)	32	R	Undefined	4.2.8.4/111
E008_0024	Fault attributes register (MCM_FATR)	32	R	Undefined	4.2.8.5/112
E008_0028	Fault data register (MCM_FDR)	32	R	Undefined	4.2.8.6/114

4.2.8.1 Crossbar Switch (AXBS) Slave Configuration (MCM_PLASC)

PLASC is a 16-bit read-only register identifying the presence/absence of bus slave connections to the device's crossbar switch.

Address: E008_0000h base + 8h offset = E008_0008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ASC							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

MCM_PLASC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
ASC	Each bit in the ASC field indicates whether there is a corresponding connection to the crossbar switch's slave input port. 0 A bus slave connection to AXBS input port *n* is absent 1 A bus slave connection to AXBS input port *n* is present

4.2.8.2 Crossbar Switch (AXBS) Master Configuration (MCM_PLAMC)

PLAMC is a 16-bit read-only register identifying the presence/absence of bus master connections to the device's crossbar switch.

Address: E008_0000h base + Ah offset = E008_000Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								AMC							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

MCM_PLAMC field descriptions

Field	Description
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
AMC	Each bit in the AMC field indicates whether there is a corresponding connection to the AXBS master input port.

Table continues on the next page...

MCM_PLAMC field descriptions (continued)

Field	Description
	0 A bus master connection to AXBS input port *n* is absent 1 A bus master connection to AXBS input port *n* is present

4.2.8.3 Crossbar Switch (AXBS) Control Register (MCM_PLACR)

The PLACR register selects the arbitration policy for the crossbar masters.

Address: E008_0000h base + Ch offset = E008_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MCM_PLACR field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Reserved	This field is reserved.

4.2.8.4 Fault address register (MCM_FADR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting address is captured in the MCM_FADR register. The MCM logic supports capturing a single cache write buffer bus error event; if a subsequent error is detected before the captured error information has been read from the corresponding registers and the MCM_ISCR[CWBER] indicator cleared, the MCM_FATR[BEOVR] flag is set. However, no additional information is captured.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 20h offset = E008_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- x = Undefined at reset.

MCM_FADR field descriptions

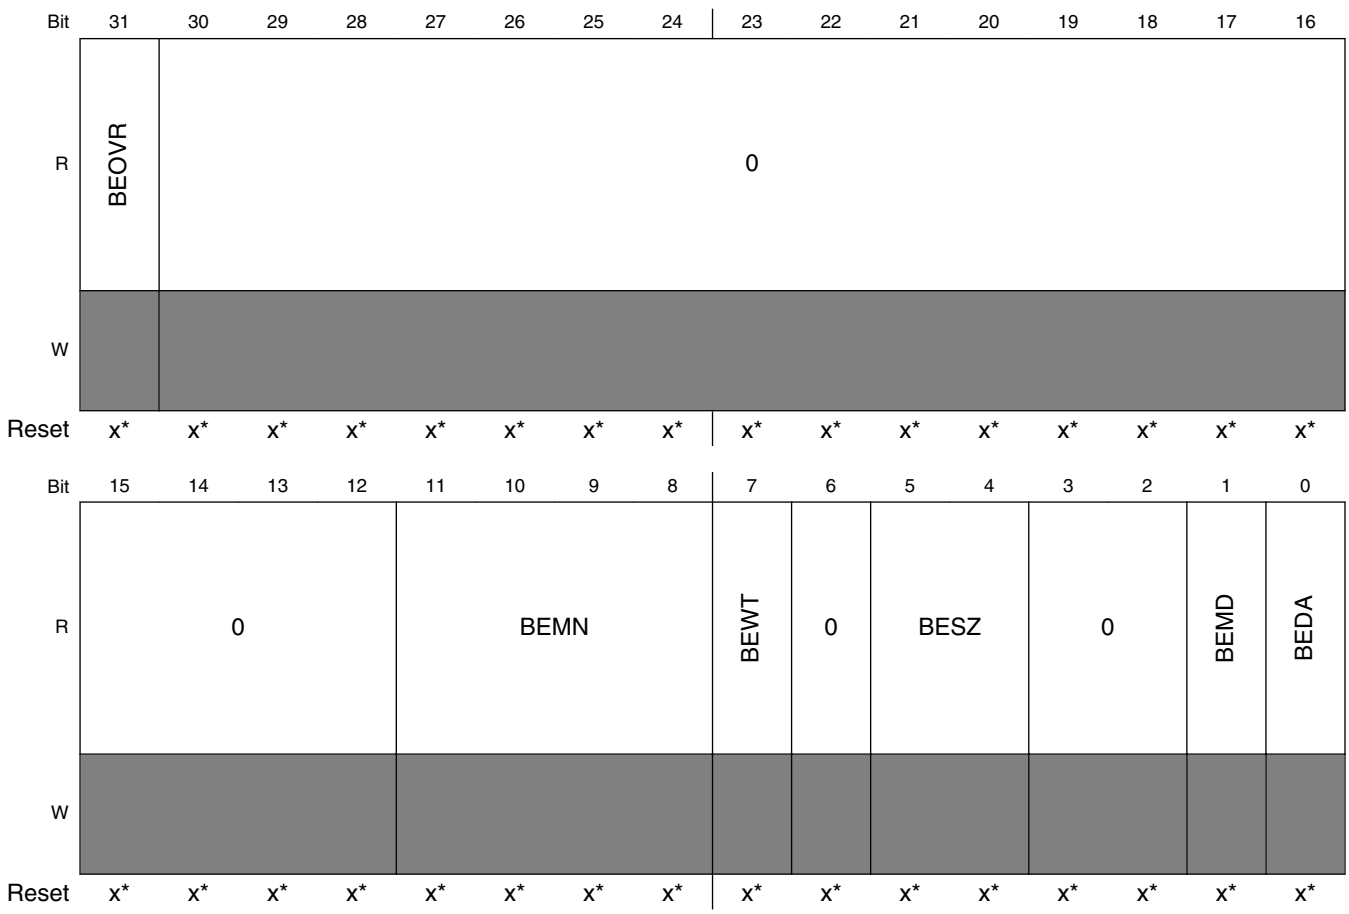
Field	Description
ADDRESS	Fault address

4.2.8.5 Fault attributes register (MCM_FATR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting attributes are captured in the MCM_FATR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 24h offset = E008_0024h



* Notes:
- x = Undefined at reset.

MCM_FATR field descriptions

Field	Description
31 BEOVR	Bus error overrun Indicates if anothercache write buffer bus error is detected before system software has retrieved all the error information from the original event, this overrun flag is set. The window of time is defined from the detection of the original cache write buffer error termination until the MCM_ISCR[CWBER] is written with a 1 to clear it and rearm the capture logic. This bit is set by the hardware and cleared whenever software writes a 1 to the CWBER bit. 0 No bus error overrun 1 Bus error overrun occurred. The FADR and FDR registers and the other FATR bits are not updated to reflect this new bus error.
30–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 BEMN	Bus error master number Crossbar switch bus master number of the captured cache write buffer bus error. For this device, this value is always 0x1.
7 BEWT	Bus error write Indicates the type of system bus access when the error was detected. Since this logic is monitoring data transfers from the cache write buffer, this bit is always a logical one, signaling a write operation. 0 Read access 1 Write access
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 BESZ	Bus error size Indicates the size of the cache write buffer access when the error was detected. 00 8-bit access 01 16-bit access 10 32-bit access 11 Reserved
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BEMD	Bus error privilege level Indicates the privilege level of the cache write buffer access when the error was detected. 0 User mode 1 Supervisor/privileged mode
0 BEDA	Bus error access type Indicates the type of cache write buffer access when the error was detected. This attribute is always a logical one signaling a data reference. 0 Instruction 1 Data

4.2.8.6 Fault data register (MCM_FDR)

When a properly-enabled cache write buffer error interrupt event is detected, the faulting data is captured in the MCM_FDR register.

The bits in this register are set by hardware and signaled by the assertion of MCM_ISCR[CWBER]. For byte and halfword writes, only the accessed byte lanes contain valid data; the contents of the other bytes are undefined. Attempted writes to this location are terminated with an error.

Address: E008_0000h base + 28h offset = E008_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
DATA	Fault data

4.3 Messaging Unit (MU)

4.3.1 Overview

The Messaging Unit module enables two processors within the SoC to communicate and coordinate by passing messages (e.g. data, status and control) through the MU interface. The MU also provides the ability for one processor to signal the other processor using interrupts.

Because the MU manages the messaging between processors, the MU uses different clocks (from each side of the different peripheral buses). Therefore, the MU must synchronize the accesses from one side to the other. The MU accomplishes synchronization using two sets of matching registers (Processor A-facing, Processor B-facing).

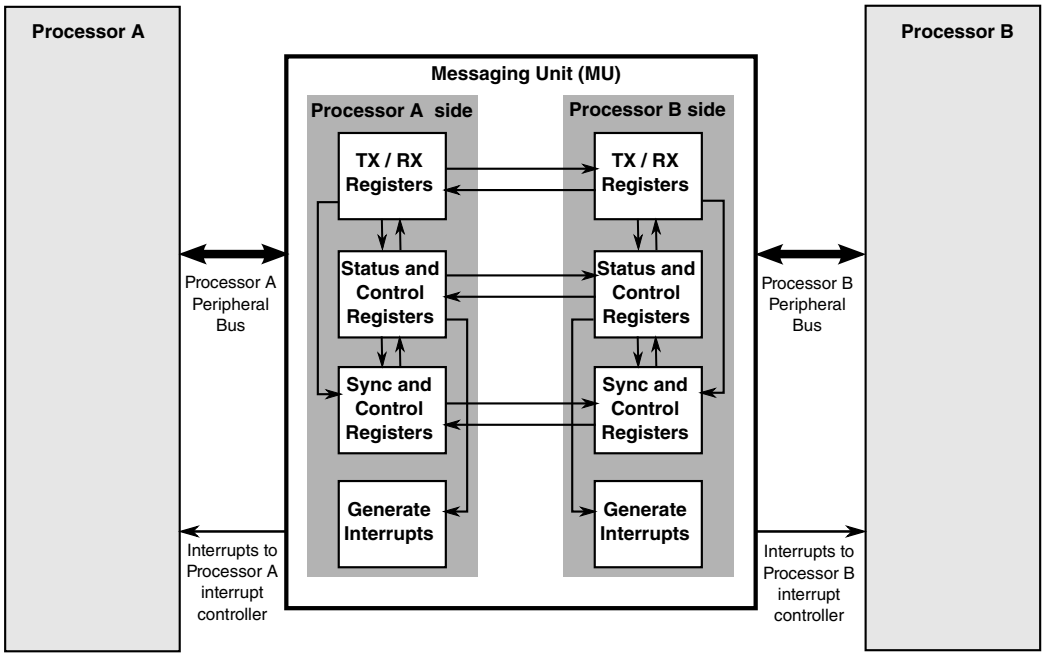

Figure 4-6. MU Block Diagram

4.3.1.1 Features

The MU includes the following features:

- Messaging control by interrupts or by polling
- The Processor B can take the Processor A out of low-power modes by asserting one of the above twelve interrupts to the Processor A and vice versa
- Symmetrical processor interfaces with each side supporting the following:
  - Four general-purpose interrupt requests reflected to the other side
  - Three general-purpose flags reflected to the other side
  - Four receive registers with maskable interrupt
  - Four transmit registers with maskable interrupt

4.3.1.2 Modes of Operation

The MU supports the modes described in the indicated sections:

- Operating Modes
- Low Power Modes

4.3.2 Functional Description

Table 4-7. Major Features of the MU

Major Feature	Description
Interprocessor Interrupts	• The MU has 12 interrupt sources on each side (Processor A-side, Processor B-side) that are used for signaling the other processor. The interrupts can be used for notification of RX/TX events and general-purpose signaling between the processors.
MU Reset	• The Processor A can issue a reset to the entire MU, using a control bit (MUR) in the Processor A Control Register (ACR). • The MUR bit is a self-clearing bit.

Processor B Boot Configuration	• The Boot Source for Processor B can be configured with the BBOOT bits in the ACR register.
	• Boot Source Options are:
	  • DMEM Base Address
	  • IMEM Base Address
	  • Address 0x00
	• The value at reset is loaded from Flash IFR

Processor B Reset Hold	• Processor B can be held in reset following any reset event. This is done by setting the BRSTH bit in the ACR register. • Processor B will be released from reset when this bit is cleared. • The value at reset is loaded from Flash IFR.
Processor A/B Clock Enable	• The Processor A/B platform clock can be enabled to continue running when Processor A/B enters Stop Mode, until Processor B/A also enters Stop Mode. This allows Processor B/A to continue accessing peripherals on Processor A/B's AIPS bus even when it has entered a Stop Mode.
Status and Control Communications between Cores	• The MU provides a way for the two cores to communicate using the status and control registers present on both the Processor B and Processor A sides of the MU. • The status register of one MU side reflects the status of the other MU side. • The control register is used for control operations, such as enabling an interrupt and sending an interrupt to the other processor.
Synchronized Message Transfers between Cores	• The transfer of data messages between cores uses transmit empty and receive full flags provided on both sides of the MU. • The update of these transmit and receive flags is accomplished using a synchronization mechanism. There is inherent latency between updating the flag on one side and reflecting its status on other side. For more about latency, see Event Update Timing
Accessing Shared Memory Directly and Avoiding Collisions	• For sending data or messages from one MU-side to the other MU-side, the MU provides 4 transmit registers and 4 receive registers on each side of the MU. • The Processor A or Processor B can access shared memory resources of the SoC directly. However, to avoid simultaneous access to shared memory by both cores, the MU provides a method (to prevent simultaneous access) using interrupts and transmit-receive registers for both processors.
Support for Different Clocks in the Two Cores	• The heart of the MU module is the event control mechanism, which synchronizes the access of one MU-side to the other MU-side, because these two MU-sides can operate using different clocks. • Formulated event update latency.
Memory-Mapped Registers	• The MU is connected as a peripheral under the Peripheral bus on both sides—on the Processor A-side, the Processor A Peripheral Bus, and on the Processor B-side, the Processor B Peripheral Bus.

4.3.2.1 Processor A Side Memory-Mapping

The messaging, control, and status registers of the Processor A-side for the MU are mapped to the Processor A memory as a regular peripheral. The Peripheral bus data bus is 32 bits wide inside the MU module.

4.3.2.2 Processor B Side Memory-Mapping

The messaging, control, and status registers of the Processor B-side for the MU are mapped to the Processor B memory as a regular peripheral. The Peripheral bus data bus is 32 bits wide inside the MU module.

4.3.2.3 MU Messaging

The MU provides 32-bit status and control registers to the Processor B and Processor A sides for control operations (such as interrupts and reset), and for status checking of the other MU-side.

For messaging, the MU has four, 32-bit write-only transmit registers and four, 32-bit read-only receive registers on the Processor B and Processor A-sides. These registers are used for sending messages to each other. These messages can be also be controlled using the 3 general purpose flags provided in the control and status registers of either MU-side.

4.3.2.3.1 Programmer Model

The messaging logic is used in conjunction with external memory. You have various messaging methods, which you can use to implement a messaging protocol. Some of these messages could mean “I have just written a message of N words, starting at offset X in the memory,” or “I have just finished reading the previous data block that was sent.” Having the messaging logic independent from the memory array does not restrict you to a predefined hardware protocol. On the other hand, the software needed to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric; they are duplicated and are available on both the Processor B-side and the Processor A-side. The messaging mechanisms are:

- Four, 32-bit write-only transmit registers, which are each reflected in four, read-only receive registers in the other processor’s side. You can use these registers to transfer 32-bit word messages or frame information of messages written to the shared memory (number of words, initial address, and message type code).

- A write to a transmit register on the transmitter side clears a “transmitter empty” bit in the Status Register on the transmitter side, and sets a “receiver full” bit in the Status Register on the receiver side. The setting of the bit at the receiver side can optionally trigger an interrupt at the receiver side (maskable receive interrupt).
- A read of one of the receive registers at the receiver side clears the “receiver full” bit in the Status Register at the receiver side, and sets the “transmitter empty” bit in the Status Register on the transmitter side. The setting of the “transmitter empty” bit can optionally trigger an interrupt at the transmitter side (maskable transmit interrupt).
- Four general purpose flags are reflected in the Status Register on the receiver side
- A read/write access to any reserved location and a write to a read-only register on the Processor A-side of the MU will generate a module transfer error acknowledge to the Processor A.
- A read/write access to any reserved location and write to a read-only register on the Processor B-side of the MU will generate a module transfer error acknowledge to the Processor B.

4.3.2.3.2 Messaging Examples

The following are messaging examples:

- **Passing short messages:** Transmit register(s) can be used to pass short messages from one to four words in length. For example, when a four-word message is desired, only one of the registers needs to have its corresponding interrupt enable bit set at the receiver side; the message’s first three words are written to the registers whose interrupt is masked, and the fourth word is written to the other register (which triggers an interrupt at the receiver side).
- **Passing frame information:** Transmit registers can be used to pass frame information for long messages written to the shared system (SDRAM and SyncFLASH). Such frame information normally includes a start address, number of words, and perhaps a message type code.
- **Passing event notices and requests:** Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the general interrupts, such as acknowledging that a long message was read from the shared system memory.
- **Passing fixed length data:** Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general interrupt (Processor A or Processor B) to signal the other processor that the data is ready.
- **Passing announcements:** The three flags can be used by a processor to announce its current program state or other billboard messages to the other processor.

Figure 4-7 shows the MU registers schematic.

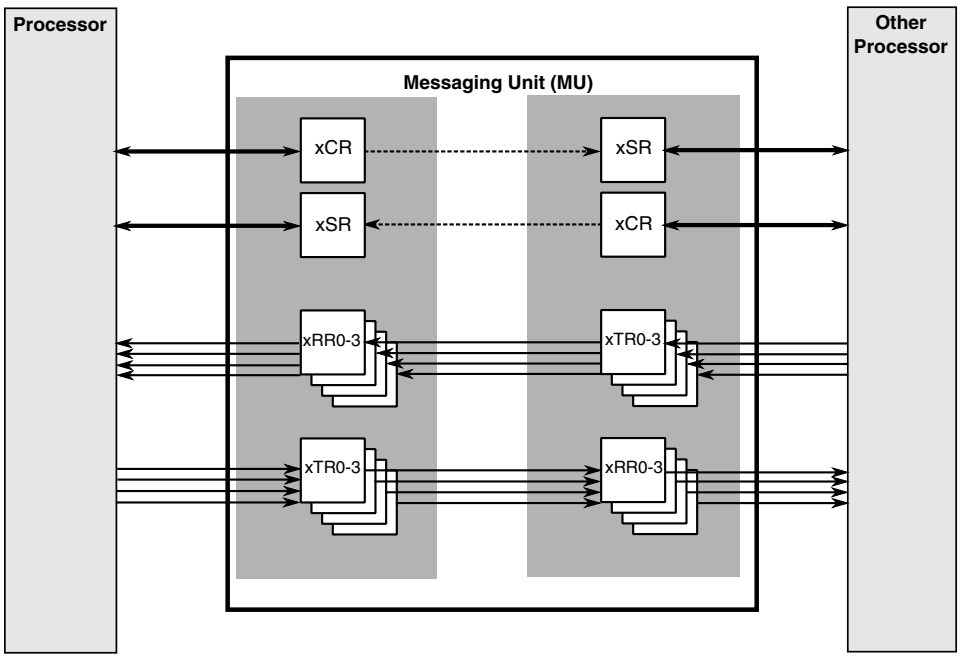

Figure 4-7. MU Registers

4.3.2.4 Operating Modes

This section describes all functional operation modes of the module.

4.3.2.5 Low Power Modes

This section describes the low power operating modes of the MU module.

4.3.2.5.1 Low Power Clocks and Synchronization

The Processor B and the Processor A clocks operate at different frequencies and from different sources. The MU design does not assume any frequency relationship between the Processor A and the Processor B clocks. Be aware, however, that the frequency relationship affects the MU's throughput performance.

- The data buffers and control logic of each MU-side operate with its corresponding clock.

4.3.2.5.2 Processor Low Power Modes

The Processors have four power modes:

- Run
- WAIT

- STOP
- DSM

The Processor can be awakened from a low-power mode by any enabled Processor side MU interrupt, as reflected in the xSR “status” register (RF0–3, TE0–3, GIP0–3 bits are set) and enabled in the xCR control register. Using these bits, the Processor can actively control when to wake the other Processor.

While the Processor is in STOP mode (such that the xSR register bits cannot be updated with events), special logic drives the enabled Processor interrupts directly from the other Processor-side (instead of from the xSR register).

While the Processor is in STOP mode, the asynchronous Processor interrupt will be asserted to wake the Processor:

- If any transmit data register of the other Processor-side is full, because of a write to it (transmit data register); that is, its “empty” bit in the xSR register is cleared while its corresponding receive interrupt is enabled on the Processor-side.
- If any receive data register of the other Processor-side is empty, because of a read on the other Processor -side; that is, its “full” bit in the xSR register is cleared while its corresponding transmit interrupt is enabled on the Processor-side.
- If any general purpose interrupt is set in the xCR register while the corresponding interrupt is enabled on the Processor-side.
- If the other Processor issues a non-maskable interrupt to the Processor.

The logic enables the other Processor to operate independently while the Processor is in any power mode (including STOP). However, the Processor power mode change protocol should be handled with care regarding:

- The interrupts that are enabled on the Processor-side
- The events that could be triggered by the other Processor-side
- The compatibility with the other Processor protocol of entering STOP mode

If the Processor is in STOP mode and an event on the other Processor is triggered, the EP bit (in the xSR register) will remain high until the Processor wakes up.

Before entering STOP mode, the Processor programmer should verify that the EP bit (in the xSR register) is cleared. This check is needed to ensure that all pending updates from the Processor, including the power mode change when STOP or WAIT is executed, will be updated in the xSR register.

- If the other Processor is in STOP mode or DSM mode, the EP bit (in the xSR register) may be stuck high; in this case, the Processor need not check the EP bit before entering STOP mode.

4.3.2.6 Event Update Timing

Each processor's MU messaging side (Processor B or Processor A) has a hardware mechanism to send "event update requests" to the other processor's side. An "event" is considered when any information change should be reflected at the Status Register of the receiving processor. The event update latency is the delay between the event being ready at one processor and the resulting update at the Status Register of the other processor.

- The minimum event latency is "1 clock of the sending side" + "2 1/2 clocks of the receiving side". The minimum case is if there is no event pending when the new event occurs.
- The maximum event latency is "6 clocks of the sending side" + "6 1/2 clocks of the receiving side." The maximum case is if the event occurred just after a previous event was sent to the other side. The event update latency will vary between the above-mentioned minimum and maximum latencies, depending on the time at which the subsequent event is triggered.

4.3.2.7 Interrupts

The MU controls the Processor B interrupt requests to the Processor A, and the Processor A interrupt requests to the Processor B. This section describes all the interrupts that the module generates.

4.3.2.7.1 Interrupts to the Processors

There are 12 interrupt sources from the MU to the Processors:

- Four receive interrupts (asserted when the Processors receive full bits are set and enabled in the xCR register) for each of the receive registers
- Four transmit interrupts (asserted when the Processor transmit empty bits are set and enabled in the xCR register) for each of the transmit registers
- Four general purpose interrupts (asserted when the GIP bits are set and enabled in the xCR register)

All the interrupts are maskable in the Processor Control Register (xCR). The MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, Receive 0 and Receive 1 interrupts or any of the transmit and general purpose interrupts) can be asserted at one time. The priority of these interrupts should be resolved by the interrupt controller at the chip level.

The General Purpose Interrupt Pending bits (GIP0, GIP1, GIP2, and GIP3) should be cleared by the software (as part of the interrupt service routine) to de-assert the request to the interrupt controller.

4.3.2.7.2 General Purpose Interrupt Clearing Sequence

When a Processor writes to the general interrupt bit (GIR), the write event is synchronized to the other Processor clock to set the general interrupt request pending bit (GIP). When the GIP bit is set, and if the general purpose interrupt is enabled on the transmitting Processor side (GIE bit is set), then the receiving Processor general purpose interrupt is issued to the transmitting Processor. The transmitting Processor clears this interrupt by writing a “1” on the GIP bit. The interrupt is de-asserted as soon as the GIP bit is written. The write event of the GIP bit is synchronized to the other Processor clock. The synchronized signal clears the GIR bit. The software should not write the GIR bit again until the GIR bit is cleared.

4.3.2.8 Interrupt Messaging Protocols

4.3.2.8.1 Messaging Protocols using Interrupts

The example below describes a four-word messaging sequence sent by the Processor to the other Processor.

In this example, the first, second, and third receive interrupts are disabled, and the fourth receive interrupt is enabled. We write registers sequentially for n = 0, 1, 2, 3. For n = 0, 1, 2, the interrupts are disabled, therefore no interrupt will go to the other core (although interrupt conditions occur). For n = 3, the interrupt is enabled, and the last Receive Interrupt request is generated.

1. Write Sequence
   - The Processor writes the message information sequentially to its Transmit Registers 0, 1, 2.
   - When the write to the Transmit Register 3 occurs, the RF3 bit of the xSR is set after synchronization, and it immediately trigger the Receive 3 interrupt to the other Processor.
2. Read Sequence
   - The other Processor receives the Receive 3 interrupt and starts reading the message transferred from the receive registers.
   - After Receive Register 3 is read, the interrupt bit is cleared.

Figure 4-8 shows the programmer’s model of a messaging protocol using transmit and receive registers. Use Table 4-8 and Figure 4-8 to understand the generalized protocol sequence.

Table 4-8. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A Data write	A data write to the ATRn register by Processor A is immediately reflected in the Processor B BRRn register.
2	Clear Tx Empty bit and Set Rx Full bit	The data write to the ATRn register • Clears the transmitter empty bit (TEn) in the Processor A Transmit Status Register • Sets the receiver full bit (RFn) in the Processor B Receive Status Register
3	Generate Receive Interrupt request	The setting of the receiver full bit (RFn) in the Receive Status Register generates a Receive Interrupt request to Processor B.
4	Processor B Data read	After receiving the Receive Interrupt request, Processor B performs a data read of the BRRn register.
5	Clear Rx Full bit and Set Tx Empty bit	Reading the data out of the BRRn register • Clears the receiver full bit (RFn) in the Processor B Receive Status Register • Sets the transmitter empty bit (TEn) in the Processor A Transmit Status Register
6	Generate Transmit Interrupt request	The setting of the transmitter empty bit (TEn) in the Transmit Status Register generates a Transmit Interrupt request to Processor A.

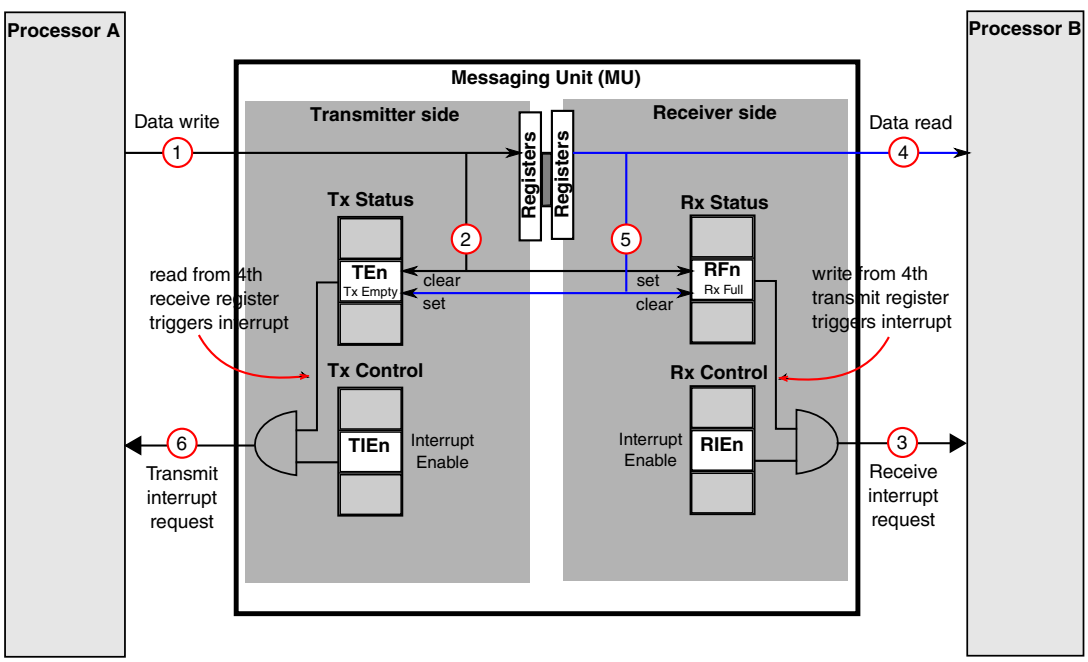

Figure 4-8. Messaging Model Using Transmit and Receive Registers

NOTE

The Transmit registers can be used to pass frame information on long messages written to the shared memory. Such frame

information would typically include an initial address, number of words, and perhaps a message type code.

The messaging hardware can be used by software to implement messaging protocols for a wide array of message types. Full support is given for both interrupt and polling management schemes.

4.3.2.8.2 Messaging Protocols using Event Interrupts

Events and requests that do not include data words can be signaled from the Processor B to the Processor A using the two general interrupts.

Formatted data with a fixed length can be written in predetermined locations in the shared memory. A processor can use a general purpose interrupt to signal the other processor that the data is ready.

The three flags can be used by a processor to announce to the other processor the program state it is currently in, or to announce similar messages.

Table 4-9 and Figure 4-9 describe the event sequence when the Processor triggers an interrupt.

Table 4-9. Interrupt Messaging Protocol (Generalized)

Sequence	Action	Description
1	Processor A sets General Interrupt request bit	Processor A sets its associated General Interrupt request bit (GIRn = 1) in the control register (ACR).
2	General Interrupt Request Pending status bit is set	The General Interrupt Request Pending status bit (GIPn) in the status register (BSR) is set to "1"
3	General Interrupt request to Processor B is generated	Setting the GIPn bit generates the General Interrupt request to Processor B (Interrupt Request Enable bit, GIEn, must be set for Processor B)
4	Processor B reads status register	The Processor B reads the GIPn bit in the BSR register.
5	Processor B services the interrupt	-
6	Processor B sets GIPn bit to clear interrupt	The Processor B writes "1" to the corresponding GIPn bit to clear the interrupt
7	GIRn bit is cleared	Setting the GIPn bit to "1" clears the General Interrupt request bit (GIRn) in the Processor A control register (ACR).

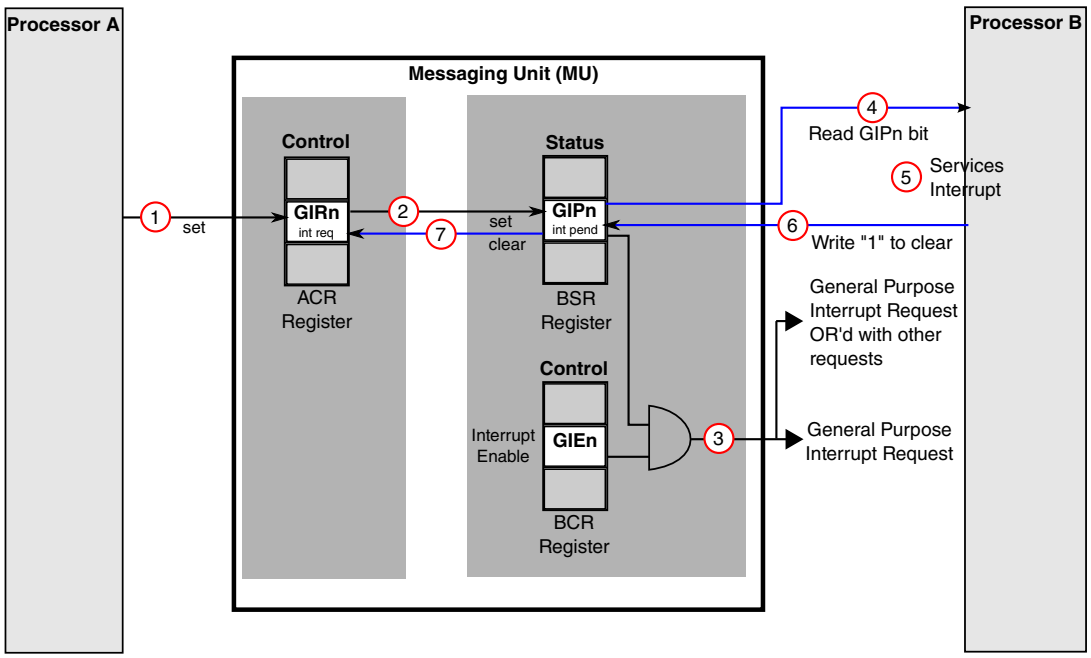

Figure 4-9. Messaging Model Using a General Purpose Interrupt

4.3.2.9 Exclusive Access to Shared Memory

You can use the MU to signal one processor about its current access to the shared memory, so that the data is not overwritten by the other processor during the exclusive memory access period.

The following tables describe the signaling protocol that the Processor A uses to inform the Processor B about its current access (write) to the shared memory, assuming that the set of bits and registers (GIR0 bit, BRR0 register, BTR0 register, GIR0 bit, ARR0 register, ATR0 register) are reserved to support exclusive access to the shared memory protocol.

Table 4-10. How the Processor A Performs an Exclusive Access to Shared Memory

Sequence	Action	Description
1	Processor A sends GIRn request to Processor B using Processor A control register	When the Processor A wants to perform an exclusive access to the shared memory, the Processor A sends an GIR0 request to the Processor B.
2	Processor A sends an exclusive-access request using a transmit data register (ATRn)	The Processor A will send an exclusive-access request (command, location, and length of target access) to Processor B using a selected transmit data register (ATR0).
3	Processor A waits for a dedicated interrupt from Processor B	The Processor A waits for a dedicated interrupt (as an acknowledgement) triggered by the Processor B before proceeding.

Table continues on the next page...

Table 4-10. How the Processor A Performs an Exclusive Access to Shared Memory (continued)

Sequence	Action	Description
4	Processor A accesses shared memory	After receiving a dedicated interrupt from the Processor B, Processor A proceeds.

Table 4-11. How the Processor B Scans for Transaction Information

Sequence	Action	Description
1	Processor B receives an interrupt from a receive data register (BRRn)	-
2	Processor B reads the receive data register (BRRn)	-
3	Processor B scans the receive data register contents	For transaction information (whether Processor A has requested an exclusive-access)

Table 4-12. How the Processor B Accepts Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B triggers a dedicated interrupt	Processor B acknowledges the Processor A request by triggering a dedicated interrupt (ack) to the Processor A.
2	Processor B sends a code message to Processor A	Along with the acknowledge interrupt, the Processor B sends a code message to the Processor A through the selected transmit register (BTRn). The message informs the Processor A that it can exclusively access the shared memory.

Table 4-13. How the Processor B Rejects Exclusive Access by Processor A

Sequence	Action	Description
1	Processor B ignores Processor A request for exclusive access	If the Processor B does not want to give go-ahead permission to the Processor A, Processor B ignores the exclusive access request.

4.3.2.10 Packet Data Transfers

The following example describes the packet transfer sequence between the Processor B and Processor A subsystems:

Table 4-14. Packet Data Transfer Sequence

Action	Sequence	Description
Processor B requests DMA	1	The Processor B sends a DMA request to initiate the packet data transfer

Table continues on the next page...

Table 4-14. Packet Data Transfer Sequence (continued)

Action	Sequence	Description
DMA data transfer	2	DMA acknowledges.
	3	DMA starts transferring data from the specified Processor B location to the specified shared memory
	4	DMA interrupts the Processor B to signal that the packet transfer has finished.
Processor B informs Processor A that data is in shared memory	5	Using an MU Processor B-side transmit register, the Processor B sends a packet information message to the Processor A to inform the Processor A of the arrival of new packet data that is stored in shared memory . The message contains the command, location, and length of packet data information.
Processor A receives interrupt	6	The Processor A receives an interrupt (assuming its corresponding Processor A MU-side receive interrupt is enabled), and the pending processing task becomes active and processes packet data from memory.
Processor A reads data, writes data	7	The Processor A reads or processes packet data from shared memory.
	8	The Processor A writes the result from packet processing to a separate buffer.
Processor A informs Processor B that transfer is finished	9	After the processing of the packet data finishes, the Processor A informs the Processor B (using the MU Processor A-side transmit register, ATRn).
Processor A sends interrupt to Processor B (request for more data)	10	The Processor B receives the next interrupt from the Processor A, in which the Processor A requests more packet data.

4.3.2.11 MU Resets

The MU has two sources of reset, and each reset has a different function from the MU or system perspective.

- One asynchronous system that is connected to both sides of the MU interface.
- One programmable hardware reset (MUR bit) in the ACR register (on the Processor A-side).

Table 4-15. MU programmable resets

Reset	Description
Processor A MU reset	• Processor A MU Reset bit (MUR) of the ACR register • The MUR reset affects the messaging section on both the Processor A and the Processor B sides. The MUR reset causes all control and status registers to return to their default values and all internal states to be cleared. • It is up to the Processor A software to decide whether to use the MUR reset or not. • The instruction immediately following assertion of the MUR bit should not write to MU registers. Such a write may be overwritten by the reset sequence and the register will remain with the reset value. You should wait at least one instruction (after assertion of the MUR bit) before attempting a write to MU registers.

After issuing MUR bit reset events, the Processor A programmer can verify that the reset sequence on the Processor B-side has ended, by checking the RS bit in the ASR register.

NOTE

MUR bit assertion is a delicate operation because it affects the other side's registers asynchronously. MUR bit assertion may cause unpredictable behavior if, for example, the Processor B is concurrently testing an MU register bit (TE bit in Processor B SR register). Before asserting the MUR bit, you should verify that the Processor B is not presently engaged in an MU signalling activity.

4.3.3 Software Restrictions

This section describes certain software restrictions when accessing the MU.

4.3.3.1 General Restrictions

This section lists the restrictions that apply to both the sides (Processor A, Processor B) of the MU.

4.3.3.1.1 Write-After-Write to a Transmit Register

A write to a transmit register signals the receiver side that data is ready for retrieval.

- Writing to the transmit register again without verifying that the data was retrieved is prohibited, because the transmitter side has no way of knowing the exact time that the receiver will attempt to retrieve the data.
- Before attempting to write the transmit register again, the transmitter side should wait for a "Transmitter Empty" interrupt, or should poll the "Transmitter Empty" bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being read on the receiver side of the MU.

4.3.3.1.2 Read-After-Read from a Receive Register

A read of a receive register signals the transmitter side that data can be written to that register. In the same way, the receiver processor should not read a receive register before receiving a "Receiver Full" interrupt or polling the "Receiver Full" bit in the Status Register.

- Reading the receive register again without verifying that the data was written is prohibited, because the receiver side has no way of knowing the exact time that the transmitter will attempt to write the data.
- Before attempting to read the receive register again, the receiver side should wait for a “Receiver Full” interrupt, or should poll the “Receiver Full” bit in the Status Register.
- Failure to follow this restriction may result in the wrong data being written on the transmitter side of the MU.

4.3.3.2 Processor Restrictions

This section lists the restrictions that apply each side of the processor in the MU.

4.3.3.2.1 Before Entering Low Power Mode

Before entering Low Power mode, the Processor should verify that the Processor Event Pending (EP) bit in the Status Register is cleared.

- If the Event Pending bit (EP) is still set to “1”, then the Processor should wait and poll the EP bit until it is cleared, before executing the LPM instruction.
- Note that if the other Processor is in Low Power mode (programmed for clock gating in CCM), the EP bit may be stuck high. In this case, the other Processor clock must be turned ON to get the EP bit cleared before the Processor can enter Low Power mode.
- To discover which power mode the other Processor is in, the Processor can check the PM bits in the xSR register.

4.3.3.2.2 Before Setting a General Interrupt Request Bit (GIR0–3)

Before setting a General Interrupt Request bit (GIR0–3), you must verify that the GIRn bit is cleared, which means that a general interrupt is not pending. Generally, setting the GIRn bit while the bit is set to “1” will be ignored, but in some cases it may issue a second interrupt. This restriction is meant to prevent this indeterministic behavior.

4.3.3.2.3 Reset Bit Restrictions

The reset bit (MUR, HR) restrictions are:

- Before asserting the MUR bit in the ACR register, verify that the Processor B-side is not engaged in some MU activity.
- Do not write to an MU register in the instruction immediately after the assertion of the MUR bit in the ACR register, because the written data can be overridden by the reset value.

4.3.4 MU Processor A-side Memory Map/Register Definition

This section contains the detailed register descriptions for the Processor A-side MU registers.

MUA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
30AA_0000	Processor A Transmit Register 0 (MUA_ATR0)	32	R/W	0000_0000h	4.3.4.1/130
30AA_0004	Processor A Transmit Register 1 (MUA_ATR1)	32	R/W	0000_0000h	4.3.4.2/131
30AA_0008	Processor A Transmit Register 2 (MUA_ATR2)	32	R/W	0000_0000h	4.3.4.3/132
30AA_000C	Processor A Transmit Register 3 (MUA_ATR3)	32	R/W	0000_0000h	4.3.4.4/132
30AA_0010	Processor A Receive Register 0 (MUA_ARR0)	32	R	0000_0000h	4.3.4.5/133
30AA_0014	Processor A Receive Register 1 (MUA_ARR1)	32	R	0000_0000h	4.3.4.6/134
30AA_0018	Processor A Receive Register 2 (MUA_ARR2)	32	R	0000_0000h	4.3.4.7/134
30AA_001C	Processor A Receive Register 3 (MUA_ARR3)	32	R	0000_0000h	4.3.4.8/135
30AA_0020	Processor A Status Register (MUA_ASR)	32	R/W	00F0_0080h	4.3.4.9/136
30AA_0024	Processor A Control Register (MUA_ACR)	32	R/W	0000_0000h	4.3.4.10/ 139

4.3.4.1 Processor A Transmit Register 0 (MUA_ ATR0)

Use Processor A Transmit Register 0 (ATR0, 32-bit, write-only) to transmit a message or data to the Processor B.

- You can only write to the ATR0 register when the TE0 bit in ASR register is set to “1”.
- Reading the ATR0 register returns all zeros.

Address: 30AA_0000h base + 0h offset = 30AA_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ATR0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MUA_ATR0 field descriptions

Field	Description
ATR0	Processor A Transmit Register 0. (Write-only)

MUA_ATR0 field descriptions (continued)

Field	Description
	• Data written to the ATR0 register is reflected on the Processor B-side in the Processor B Receive Register 0 (BRR0). The ATR0 and BRR0 registers are not double-buffered—a write to the ATR0 register overrides the data readable at the BRR0 register. • A write to the transmit register clears a “transmitter empty” bit (TE0) in the Processor A Status Register (ASR) on the transmitter side, and sets a “receiver full” bit (RF0) in the Processor B Status Register (BSR) on the receiver side (optionally triggering an interrupt 0 on the Processor B-side). • Any write to the ATR0 register will update all status information.

4.3.4.2 Processor A Transmit Register 1 (MUA_ATR1)

Use Processor A Transmit Register 1 (ATR1, 32-bit, write-only) to transmit a message or data to the Processor B.

- You can only write to the ATR1 register when the TE1 bit in ASR register is set to “1”.
- Reading the ATR1 register returns all zeros.

Address: 30AA_0000h base + 4h offset = 30AA_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MUA_ATR1 field descriptions

Field	Description
ATR1	Processor A Transmit Register 1. (Write-only) • Data written to the ATR1 register is reflected on the Processor B-side in the Processor B Receive Register 1 (BRR1). The ATR1 and BRR1 registers are not double-buffered—a write to the ATR1 register overrides the data readable at the BRR1 register. • A write to the transmit register clears a “transmitter empty” bit (TE1) in the Processor A Status Register (ASR) on the transmitter side, and sets a “receiver full” bit (RF1) in the Processor B Status Register (BSR) on the receiver side (optionally triggering an interrupt 1 on the Processor B-side). • Any write to the ATR1 register will update all status information.

4.3.4.3 Processor A Transmit Register 2 (MUA_ATR2)

Use Processor A Transmit Register 2 (ATR2, 32-bit, write-only) to transmit a message or data to the Processor B.

- You can only write to the ATR2 register when the TE2 bit in ASR register is set to "1".
- Reading the ATR2 register returns all zeros.

Address: 30AA_0000h base + 8h offset = 30AA_0008h

MUA_ATR2 field descriptions

Field	Description
ATR2	Processor A Transmit Register 2. (Write-only) • Data written to the ATR2 register is reflected on the Processor B-side in the Processor B Receive Register 2 (BRR2). The ATR2 and BRR2 registers are not double-buffered—a write to the ATR2 register overrides the data readable at the BRR2 register. • A write to the transmit register clears a "transmitter empty" bit (TE2) in the Processor A Status Register (ASR) on the transmitter side, and sets a "receiver full" bit (RF2) in the Processor B Status Register (BSR) on the receiver side (optionally triggering an interrupt 2 on the Processor B-side). • Any write to the ATR2 register will update all status information.

4.3.4.4 Processor A Transmit Register 3 (MUA_ATR3)

Use Processor A Transmit Register 3 (ATR3, 32-bit, write-only) to transmit a message or data to the Processor B.

- You can only write to the ATR3 register when the TE3 bit in ASR register is set to "1".
- Reading the ATR3 register returns all zeros.

Address: 30AA_0000h base + Ch offset = 30AA_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MUA_ATR3 field descriptions

Field	Description
ATR3	Processor A Transmit Register 3. (Write-only) • Data written to the ATR3 register is reflected on the Processor B-side in the Processor B Receive Register 3 (BRR3). The ATR3 and BRR3 registers are not double-buffered—a write to the ATR3 register overrides the data readable at the BRR3 register. • A write to the transmit register clears a “transmitter empty” bit (TE3) in the Processor A Status Register (ASR) on the transmitter side, and sets a “receiver full” bit (RF3) in the Processor B Status Register (BSR) on the receiver side (optionally triggering an interrupt 3 on the Processor B-side). • Any write to the ATR3 register will update all status information.

4.3.4.5 Processor A Receive Register 0 (MUA_ARR0)

Use Processor A Receive Register 0 (ARR0, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR0 register is immediately reflected in the ARR0 register.
- You can only read the ARR0 register when the RF0 bit in the ASR register is set to “1”.
- Writing to the ARR0 register generates an error response to the Processor A.

Address: 30AA_0000h base + 10h offset = 30AA_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MUA_ARR0 field descriptions

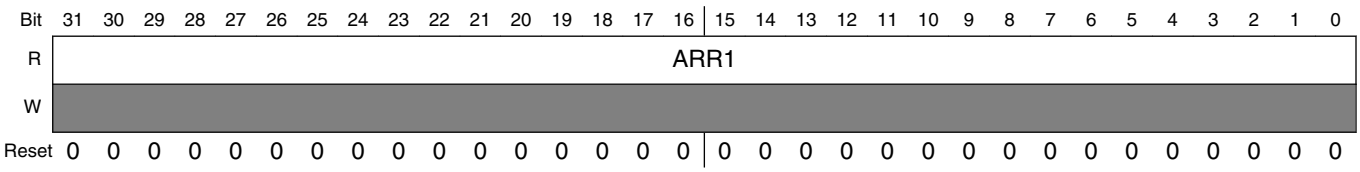
Field	Description
ARR0	Processor A Receive Register 0. (Read-only) • Reflects the data written to Processor B Transmit Register 0 (BTR0). • Reading the ARR0 register clears the “receiver full” bit (RF0) in the Processor A Status Register (ASR) on the receiver side, and sets the “transmitter empty” bit (TE0) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the Processor B-side). • Any read of the ARR0 register will update all status information.

4.3.4.6 Processor A Receive Register 1 (MUA_ARR1)

Use Processor A Receive Register 1 (ARR1, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR1 register is immediately reflected in the ARR1 register.
- You can only read the ARR1 register when the RF1 bit in the ASR register is set to "1".
- Writing to the ARR1 register generates an error response to the Processor A.

Address: 30AA_0000h base + 14h offset = 30AA_0014h



MUA_ARR1 field descriptions

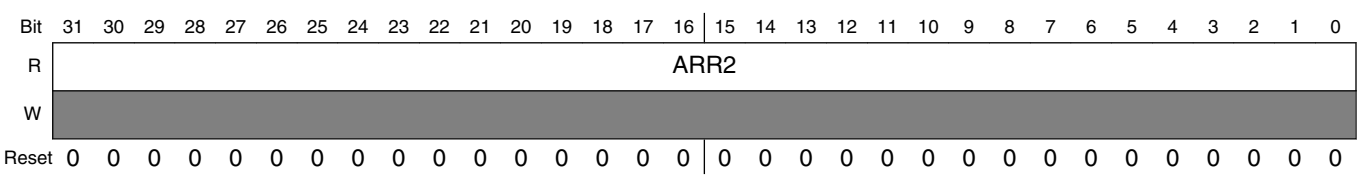
Field	Description
ARR1	Processor A Receive Register 1. (Read-only) • Reflects the data written to Processor B Transmit Register 1 (BTR1). • Reading the ARR1 register clears the "receiver full" bit (RF1) in the Processor A Status Register (ASR) on the receiver side, and sets the "transmitter empty" bit (TE1) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 1 on the Processor B-side). • Any read of the ARR1 register will update all status information.

4.3.4.7 Processor A Receive Register 2 (MUA_ARR2)

Use Processor A Receive Register 2 (ARR2, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR2 register is immediately reflected in the ARR2 register.
- You can only read the ARR2 register when the RF2 bit in the ASR register is set to "1".
- Writing to the ARR2 register generates an error response to the Processor A.

Address: 30AA_0000h base + 18h offset = 30AA_0018h



MUA_ARR2 field descriptions

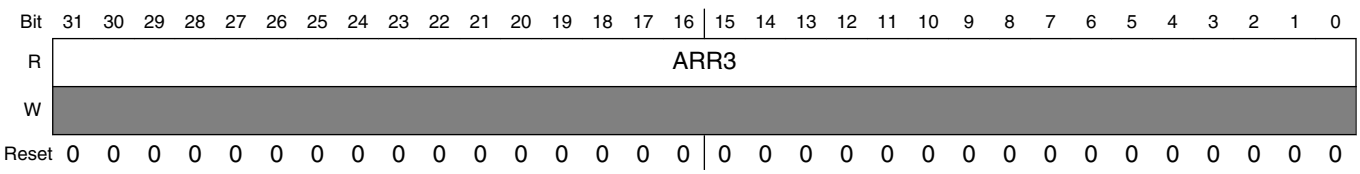
Field	Description
ARR2	Processor A Receive Register 2. (Read-only) • Reflects the data written to Processor B Transmit Register 1 (BTR2). • Reading the ARR2 register clears the “receiver full” bit (RF2) in the Processor A Status Register (ASR) on the receiver side, and sets the “transmitter empty” bit (TE2) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 2 on the Processor B-side). • Any read of the ARR2 register will update all status information.

4.3.4.8 Processor A Receive Register 3 (MUA_ARR3)

Use Processor A Receive Register 3 (ARR3, 32-bit, read-only) to receive a message or data from the Processor B.

- Data written to the BTR3 register is immediately reflected in the ARR3 register.
- You can only read the ARR3 register when the RF3 bit in the ASR register is set to “1”.
- Writing to the ARR3 register generates an error response to the Processor A.

Address: 30AA_0000h base + 1Ch offset = 30AA_001Ch



MUA_ARR3 field descriptions

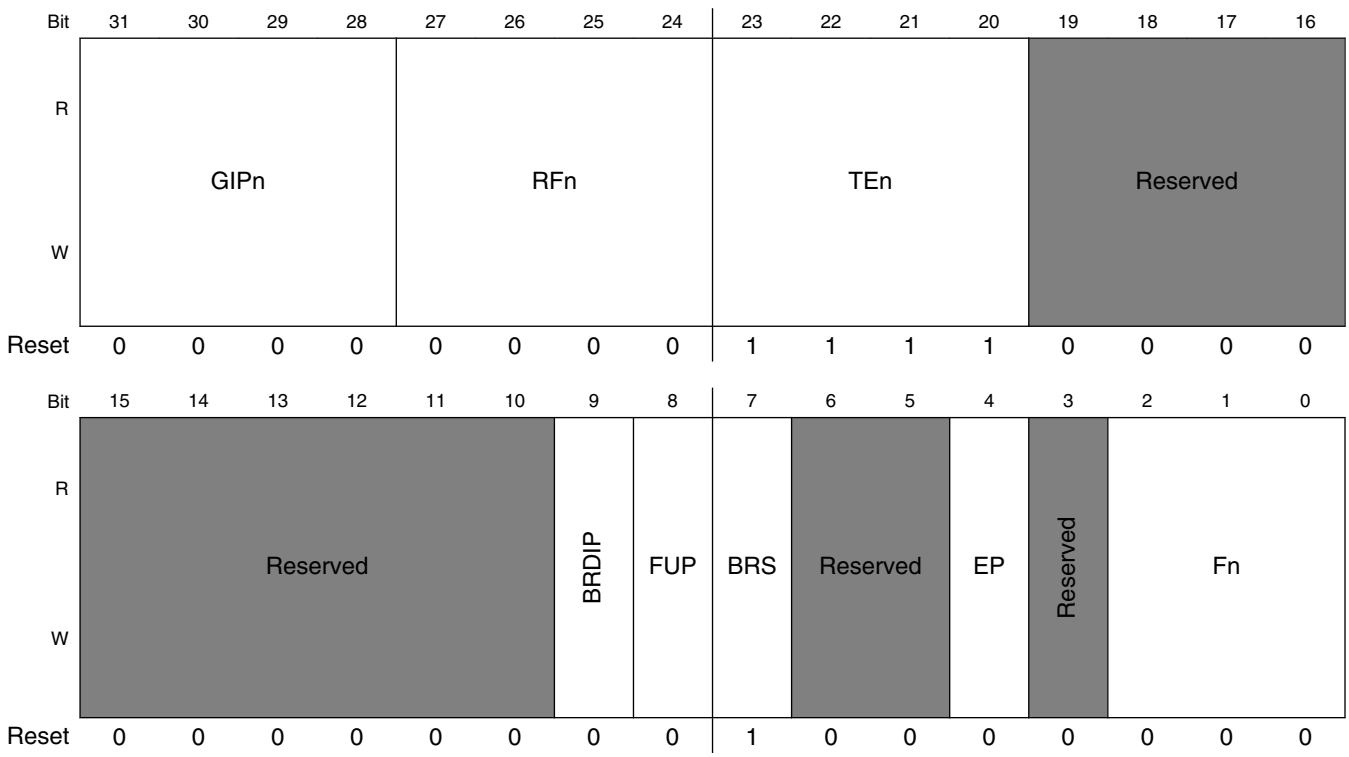
Field	Description
ARR3	Processor A Receive Register 3. (Read-only) • Reflects the data written to Processor B Transmit Register 3 (BTR3). • Reading the ARR3 register clears the “receiver full” bit (RF3) in the Processor A Status Register (ASR) on the receiver side, and sets the “transmitter empty” bit (TE3) in the Processor B Status Register on the transmitter side (optionally triggering a transmit interrupt 3 on the Processor B-side). • Any read of the ARR3 register will update all status information.

4.3.4.9 Processor A Status Register (MUA_ASR)

Use the Processor A Status Register (ASR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, and to set dual function control-status bits.

- Some dual-purpose bits are set by the MU logic, and cleared by the Processor A-side programmer
- Other dual-purpose bits are set by the Processor A-side programmer, and cleared by the MU logic.

Address: 30AA_0000h base + 20h offset = 30AA_0020h



MUA_ASR field descriptions

Field	Description
31–28 GIPn	For n = {0, 1, 2, 3} Processor A General Interrupt Request n Pending. (Read-Write) • GIPn bit signals the Processor A that the GIRn bit in the BCR register on the Processor B-side was set from “0” to “1”. If the GIEn bit in the ACR register is set to “1”, a General Interrupt n request is issued. • The GIPn bit is cleared by writing it back as “1”. Writing “0”, or writing “1” when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. The proper bit clearing sequence is: clear an Processor A register, set the desired bit in it (Processor A register), and write it to the ASR register, thus clearing the GIPn bit. • GIPn bit is cleared when the MU is reset.

Table continues on the next page...

MUA_ASR field descriptions (continued)

Field	Description
	0 Processor A general purpose interrupt n is not pending. (default) 1 Processor A general purpose interrupt n is pending.
27–24 RFn	For n = {0, 1, 2, 3} Processor A Receive Register n Full. (Read-only) • The RFn bit is set to “1” when the BTRn register is written on the Processor B-side. • After the RFn bit is set to “1”, the RFn bit signals the Processor A-side that new data is ready to be read by the Processor A in the ARRn register, and a Receive n interrupt is issued on the Processor A-side (if the RIEn bit in the ACR register has been set to “1”). • RFn bit is cleared when the ARRn register is read, and when the MU is reset. 0 ARRn register is not full (default). 1 ARRn register has received data from BTRn register and is ready to be read by the Processor A.
23–20 TEn	For n = {0, 1, 2, 3} Processor A Transmit Register n Empty. (Read-only) • The TEn bit is set to “1” after the BRRn register is read on the Processor B-side. • After the TEn bit is set to “1”, the TEn bit signals the Processor A-side that the ATRn register is ready to be written on the Processor A-side, and a Transmit n interrupt is issued on the Processor A-side (if the TEn bit in the ACR register is set to “1”). • TEn bit is cleared after the ATRn register is written on the Processor A-side. • TEn bit is set to “1” when the MU is reset. 0 ATRn register is not empty. 1 ATRn register is empty (default).
19–10 -	This field is reserved. Reserved.
9 BRDIP	Processor B Reset De-asserted Interrupt Pending. (Read-Write) • BRDIP bit signals the Processor A-side that the Processor B-side has come out of reset. • BRDIP bit is set to “1” after the MU Processor B-side comes out of reset, after synchronization. The interrupt generated by a Processor B-side reset de-assertion is ORed with the Processor A general purpose interrupt 3. The Processor A general purpose interrupt 3 is issued when the Processor B-side comes out of reset (if the interrupt is enabled). • To clear the BRDIP bit, write “1”, which also clears general purpose interrupt 3. • When Processor A-side of MU comes out of reset BRDIP bit has value “0”(default).Then Processor A sees the status of Processor B-side and if Processor B-side has come out of reset then BRDIP bit goes high.This takes 5-6 clock cycles.And if you read BRDIP bit now you will see it as high although its reset value was "0". 0 The Processor A general purpose interrupt 3, because of a Processor B-side reset de-assertion, is cleared (default). 1 The Processor B-side is out of reset.
8 FUP	Processor A Flags Update Pending. (Read-only) • FUP bit is set to “1” when the Processor A-side sends a Flags Update request to the Processor B-side. • A Flags Update request is generated when the ABF[2:0] bits of the ACR register change. No flag update changes are allowed while the FUP bit is set to “1”. Any write to the ABF[2:0] bits, while the FUP bit is set to “1”, will not generate a Flags Update event, and the ABF[2:0] bits will stay unchanged. • FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU Processor B-side, and during MU reset.

Table continues on the next page...

MUA_ASR field descriptions (continued)

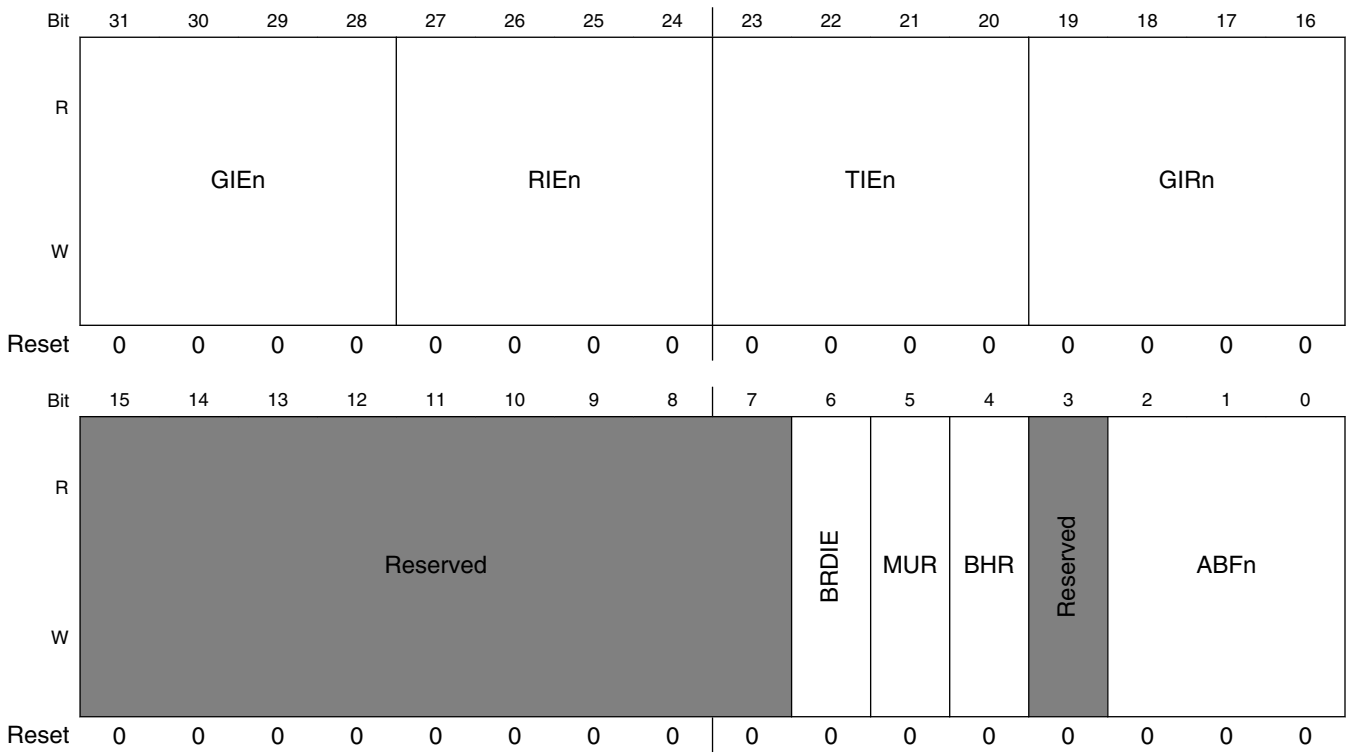
Field	Description
	0 No flags updated, initiated by the Processor A, in progress (default) 1 Processor A initiated flags update, processing
7 BRS	Processor B-side Reset State. (Read-only) • BRS bit indicates if the Processor B-side of the MU is in a reset state or not. • If the BRS bit is set to “1”, then the Processor B-side of the MU is still in the reset state. • If the BRS bit is cleared, then the Processor B-side of the MU are out of reset. • The BRS bit is set to “1” during: a Processor B system reset, or an MU reset (caused by setting the MUR bit at the ACR register). • The BRS bit is cleared when the reset sequence on the Processor B-side of the MU ends. After issuing any of the reset events mentioned previously, you should verify that the BRS bit is cleared before starting any accesses. • When Processor A side of MU comes out of reset BRS bit has value “1”(default).Then Processor A sees the status of Processor B-side and if Processor B-side has come out of reset then BRS bit goes low.This takes 5-6 clock cycles.And if you read BRS bit now you will see it as low although its reset value was "1" . 0 The Processor B-side of the MU is not in reset. 1 The Processor B-side of the MU is in reset.
6–5 -	This field is reserved. Reserved
4 EP	Processor A-Side Event Pending. (Read-only) • EP bit is set to “1” when the Processor A-side mechanism sends an event update request to the Processor B-side. • EP bit is cleared when the event update acknowledge is received. An “event” is any hardware message that is reflected in the BSR register on the Processor B-side (for example, “transmit register 0 written”). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically. • To ensure events have been posted to Processor B before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to “1”, you should wait and continue to poll it (EP bit) before entering STOP mode. • Reading the ASR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOPor WAIT modes; otherwise, the EP bit may be set by subsequent additional actions. • The EP bit is cleared when the MU resets. 0 The Processor A-side event is not pending (default). 1 The Processor A-side event is pending.
3 -	This field is reserved. Reserved.
Fn	For n = {0, 1, 2} Processor A-Side Flag n. (Read-only) • Fn bit is the Processor A-side flag that reflects the values written to the BAFn bit in the Processor B control register. • Every time that the BAFn bit is written, the BAFn bit write event updates the Fn bit after the event update latency, which is measured in terms of the number of clocks of the Processor B and the Processor A. 0 BAFn bit in BCR register is written 0 (default). 1 BAFn bit in BCR register is written 1.

4.3.4.10 Processor A Control Register (MUA_ACR)

Use the Processor A Control Register (ACR, 32-bit, read-write) to enable the MU interrupts on the Processor A-side, and trigger events and interrupts on the Processor B-side (general purpose interrupt, flag update).

For the fields GIEn, RIEn, TIEn and GIRn, n=0 corresponds to the high order bit and n=3 corresponds to the low order bit.

Address: 30AA_0000h base + 24h offset = 30AA_0024h



MUA_ACR field descriptions

Field	Description
31–28 GIEn	For n = {0, 1, 2, 3} Processor A General Purpose Interrupt Enable n. (Read-Write) When GIEn=0 corresponds to the high order bit and GIE3 corresponds to the low order bit. • GIEn bit enables Processor A General Interrupt n. • If GIEn bit is set to “1” (enabled), then a General Interrupt n request is issued when the GIPn bit in the ASR register is set to “1”. • If GIEn is cleared (disabled), then the value of the GIPn bit is ignored and no General Interrupt n request will be issued. • GIEn bit is cleared when the MU resets. 0 Disables Processor A General Interrupt n. (default) 1 Enables Processor A General Interrupt n.

Table continues on the next page...

MUA_ACR field descriptions (continued)

Field	Description
27–24 RIEn	For n = {0, 1, 2, 3} Processor A Receive Interrupt Enable n. (Read-Write) • RIEn bit enables Processor A Receive Interrupt n. • If RIEn bit is set to “1” (enabled), then an Processor A Receive Interrupt n request is issued when the RFn bit in the ASR register is set to “1”. • If RIEn bit is cleared (disabled), then the value of the RFn bit is ignored and no Processor A Receive Interrupt n request will be issued. • RIEn bit is cleared when the MU resets. 0 Disables Processor A Receive Interrupt n. (default) 1 Enables Processor A Receive Interrupt n.
23–20 TIEn	For n = {0, 1, 2, 3} Processor A Transmit Interrupt Enable n. (Read-Write) • TIEn bit enables Processor A Transmit Interrupt n. • If TIEn bit is set to “1” (enabled), then an Processor A Transmit Interrupt n request is issued when the TEn bit in the ASR register is set to “1”. • If TIEn bit is cleared (disabled), then the value of the TEn bit is ignored and no Processor A Transmit Interrupt n request will be issued. • TIEn bit is cleared when the MU resets. 0 Disables Processor A Transmit Interrupt n. (default) 1 Enables Processor A Transmit Interrupt n.
19–16 GIRn	For n = {0, 1, 2, 3} Processor A General Purpose Interrupt Request n. (Read-Write) • Writing “1” to the GIRn bit sets the GIPn bit in the BSR register on the Processor B-side. If the GIEn bit in the BCR register is set to “1” on the Processor B-side, a General Purpose Interrupt n request is triggered. • The GIRn bit is cleared if the GIPn bit (in the BSR register on the Processor B-side) is cleared by writing it (GIPn bit) as “1”, thereby signalling the Processor A that the interrupt was accepted (cleared by the software). The GIPn bit cannot be written as “0” on the Processor A-side. • To ensure proper operations, you must verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit). • GIRn bit is cleared when the MU resets. 0 Processor A General Interrupt n is not requested to the Processor B (default). 1 Processor A General Interrupt n is requested to the Processor B.
15–7 -	This field is reserved. Reserved.
6 BRDIE	Processor B Reset De-assertion Interrupt Enable. (Read-Write) • BRDIE bit enables Processor A General Interrupt 3. • If BRDIE bit is set to “1”, then General Interrupt 3 request is issued to the Processor A when the BRDIP bit in the ASR register is set to “1”. • If BRDIE is cleared, then the value of the BRDIP bit is ignored and no General Interrupt 3 request will be issued. • The BRDIE bit is cleared when the MU resets. 0 Disables the Processor A General Purpose Interrupt 3 request due to the Processor B reset de-assertion to the Processor A. Processor B reset deassertion causes Processor B and MU-Processor B side to come out of reset thus setting BRDIP bit to “1”. 1 Enables Processor A General Purpose Interrupt 3 request due to the Processor B reset de-assertion to the Processor A.

Table continues on the next page...

MUA_ACR field descriptions (continued)

Field	Description
5 MUR	Processor A MU Reset. • Setting MUR bit to “1” resets both the Processor B and the Processor A sides of the MU module, forcing all control and status registers to return to their default values (except the BHR bit in the ACR register and BHRM bit in BCR register), and all internal states to be cleared. • Before setting the MUR bit to “1”, it is advisable to interrupt the Processor B, because setting the MUR bit may affect the ongoing Processor B program. • After setting the MUR bit, you should monitor the value of the BRS bit in the ASR register to know when the reset sequence on the Processor B-side has ended. • MUR bit can only be written as “1”. • MUR bit is always read as “0”. • MUR bit is cleared during the MU reset sequence. 0 N/A. Self clearing bit (default). 1 Asserts the Processor A MU reset.
4 BHR	Processor B Hardware Reset. (Read-Write) • BHR bit asserts and de-asserts the hardware reset of the Processor B. • Set BHR bit to “1” to start a hardware reset of the Processor B. • Clear the BHR bit to de-assert the Processor B hardware reset input. • Assert the BHR bit for a minimum of 3 clock cycles of network clock (sampling clock in SRC) clock. The BRS bit in MU_ASR register (b[7]) indicates the state of the Processor B. As soon as the Processor B goes into Reset (BRS bit is set to “1”), the BHR bit can be de-asserted. • Strobe-setting the BHR bit will not cause an internal MU reset but will be routed outside MU to Processor B domain reset logic • After clearing the BHR bit, monitor the value of the BRS bit at the ASR to know when the Processor B reset sequence has ended. • The BHR reset issued by the Processor A to the Processor B is maskable by the Processor B (according to the settings of the BHRM bit in the BCR register). If the BHRM bit (in the BCR register) is set to “1”, then the BHR reset is masked; if the BHRM bit (in the BCR register) is cleared (default), then the BHR reset is enabled. • The BHR bit does not return to the reset value during the software (MUR) reset. 0 De-assert Hardware reset to the Processor B. (default) 1 Assert Hardware reset to the Processor B.
3 -	This field is reserved. Reserved
ABFn	For n = {0, 1, 2} Processor A to Processor B Flag n. (Read-Write) • ABFn bit is a read-write flag that is reflected in Fn bit in the BSR register on the Processor B-side. • ABFn bit is cleared when the MU resets. 0 N/A. Self clearing bit (default). 1 Asserts the Processor A MU reset.

4.3.5 MU Processor B-side Memory Map/Register Definition

This section contains the detailed register descriptions for the Processor B-side MU registers.

MUB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
30AB_0000	Processor B Transmit Register 0 (MUB_BTR0)	32	R/W	0000_0000h	4.3.5.1/142
30AB_0004	Processor B Transmit Register 1 (MUB_BTR1)	32	R/W	0000_0000h	4.3.5.2/143

30AB_0020	Processor B Status Register (MUB_BSR)	32	R/W	00F0_0080h	4.3.5.9/148
30AB_0024	Processor B Control Register (MUB_BCR)	32	R/W	0000_0000h	4.3.5.10/ 151

4.3.5.1 Processor B Transmit Register 0 (MUB_BTR0)

Use Processor B Transmit Register 0 (BTR0, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR0 register when the TE0 bit in BSR register is set to “1”.
- Reading the BTR0 register returns all zeros.

Address: 30AB_0000h base + 0h offset = 30AB_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MUB_BTR0 field descriptions

Field	Description
BTR0	Processor B Transmit Register 0. (Write-only)

MUB_BTR0 field descriptions (continued)

Field	Description
	• Data written to the BTR0 register is reflected on the Processor A-side in the Processor A Receive Register 0 (ARR0). The BTR0 and ARR0 registers are not double-buffered—a write to the BTR0 register overrides the data readable at the ARR0 register. • A write to the transmit register clears a “transmitter empty” bit (TE0) in the Processor B Status Register (BSR) on the transmitter side, and sets a “receiver full” bit (RF0) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 0 on the Processor A-side). • Any write to the BTR0 register will update all status information.

4.3.5.2 Processor B Transmit Register 1 (MUB_BTR1)

Use Processor B Transmit Register 1 (BTR1, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR1 register when the TE1 bit in BSR register is set to “1”.
- Reading the BTR1 register returns all zeros.

Address: 30AB_0000h base + 4h offset = 30AB_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MUB_BTR1 field descriptions

Field	Description
BTR1	Processor B Transmit Register 1. (Write-only) • Data written to the BTR1 register is reflected on the Processor A-side in the Processor A Receive Register 1 (ARR1). The BTR1 and ARR1 registers are not double-buffered—a write to the BTR1 register overrides the data readable at the ARR1 register. • A write to the transmit register clears a “transmitter empty” bit (TE1) in the Processor B Status Register (BSR) on the transmitter side, and sets a “receiver full” bit (RF1) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 1 on the Processor A-side). • Any write to the BTR1 register will update all status information.

4.3.5.3 Processor B Transmit Register 2 (MUB_BTR2)

Use Processor B Transmit Register 2 (BTR2, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR2 register when the TE2 bit in BSR register is set to "1".
- Reading the BTR2 register returns all zeros.

Address: 30AB_0000h base + 8h offset = 30AB_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MUB_BTR2 field descriptions

Field	Description
BTR2	Processor B Transmit Register 2. (Write-only) • Data written to the BTR2 register is reflected on the Processor A-side in the Processor A Receive Register 2 (ARR2). The BTR2 and ARR2 registers are not double-buffered—a write to the BTR2 register overrides the data readable at the ARR2 register. • A write to the transmit register clears a "transmitter empty" bit (TE2) in the Processor B Status Register (BSR) on the transmitter side, and sets a "receiver full" bit (RF2) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 2 on the Processor A-side). • Any write to the BTR2 register will update all status information.

4.3.5.4 Processor B Transmit Register 3 (MUB_BTR3)

Use Processor B Transmit Register 3 (BTR3, 32-bit, write-only) to transmit a message or data to the Processor A.

- You can only write to the BTR3 register when the TE3 bit in BSR register is set to "1".
- Reading the BTR3 register returns all zeros.

Address: 30AB_0000h base + Ch offset = 30AB_000Ch

MUB_BTR3 field descriptions

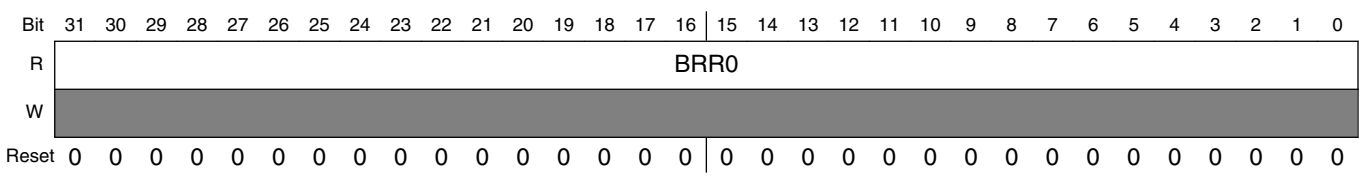
Field	Description
BTR3	Processor B Transmit Register 3. (Write-only) • Data written to the BTR3 register is reflected on the Processor A-side in the Processor A Receive Register 3 (ARR3). The BTR3 and ARR3 registers are not double-buffered—a write to the BTR3 register overrides the data readable at the ARR3 register. • A write to the transmit register clears a “transmitter empty” bit (TE3) in the Processor B Status Register (BSR) on the transmitter side, and sets a “receiver full” bit (RF3) in the Processor A Status Register (ASR) on the receiver side (optionally triggering an interrupt 3 on the Processor A-side). • Any write to the BTR3 register will update all status information.

4.3.5.5 Processor B Receive Register 0 (MUB_BRR0)

Use Processor B Receive Register 0 (BRR0, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR0 register is immediately reflected in the BRR0 register.
- You can only read the BRR0 register when the RF0 bit in the BSR register is set to “1”.
- Writing to the BRR0 register generates an error response to the Processor B.

Address: 30AB_0000h base + 10h offset = 30AB_0010h



MUB_BRR0 field descriptions

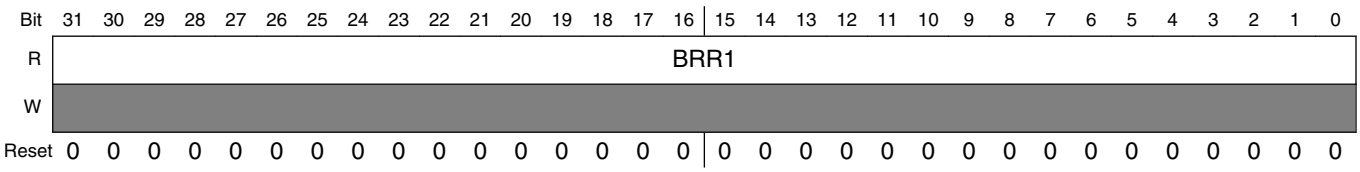
Field	Description
BRR0	Processor B Receive Register 0. (Read-only) • Reflects the data written to Processor A Transmit Register 0 (ATR0). • Reading the BRR0 register clears the “receiver full” bit (RF0) in the Processor B Status Register (BSR) on the receiver side, and sets the “transmitter empty” bit (TE0) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 0 on the Processor A-side). • Any read of the BRR0 register will update all status information.

4.3.5.6 Processor B Receive Register 1 (MUB_BRR1)

Use Processor B Receive Register 1 (BRR1, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR1 register is immediately reflected in the BRR1 register.
- You can only read the BRR1 register when the RF1 bit in the BSR register is set to "1".
- Writing to the BRR1 register generates an error response to the Processor B.

Address: 30AB_0000h base + 14h offset = 30AB_0014h



MUB_BRR1 field descriptions

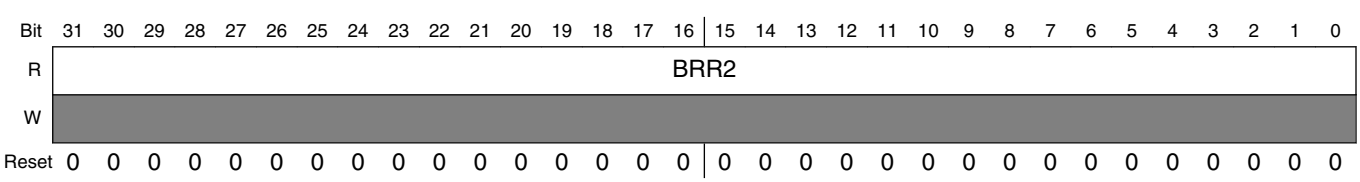
Field	Description
BRR1	Processor B Receive Register 1. (Read-only) • Reflects the data written to Processor A Transmit Register 1 (ATR1). • Reading the BRR1 register clears the "receiver full" bit (RF1) in the Processor B Status Register (BSR) on the receiver side, and sets the "transmitter empty" bit (TE1) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 1 on the Processor A-side). • Any read of the BRR1 register will update all status information.

4.3.5.7 Processor B Receive Register 2 (MUB_BRR2)

Use Processor B Receive Register 2 (BRR2, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR2 register is immediately reflected in the BRR2 register.
- You can only read the BRR2 register when the RF2 bit in the BSR register is set to "1".
- Writing to the BRR2 register generates an error response to the Processor B.

Address: 30AB_0000h base + 18h offset = 30AB_0018h



MUB_BRR2 field descriptions

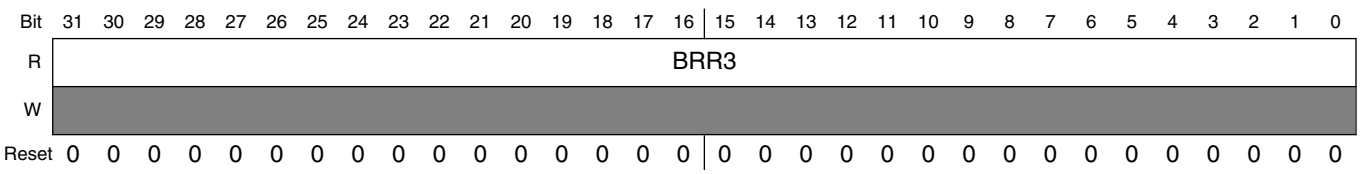
Field	Description
BRR2	Processor B Receive Register 2. (Read-only) • Reflects the data written to Processor A Transmit Register 1 (ATR2). • Reading the BRR2 register clears the “receiver full” bit (RF2) in the Processor B Status Register (BSR) on the receiver side, and sets the “transmitter empty” bit (TE2) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 2 on the Processor A-side). • Any read of the BRR2 register will update all status information.

4.3.5.8 Processor B Receive Register 3 (MUB_BRR3)

Use Processor B Receive Register 3 (BRR3, 32-bit, read-only) to receive a message or data from the Processor A.

- Data written to the ATR3 register is immediately reflected in the BRR3 register.
- You can only read the BRR3 register when the RF3 bit in the BSR register is set to “1”.
- Writing to the BRR3 register generates an error response to the Processor B.

Address: 30AB_0000h base + 1Ch offset = 30AB_001Ch



MUB_BRR3 field descriptions

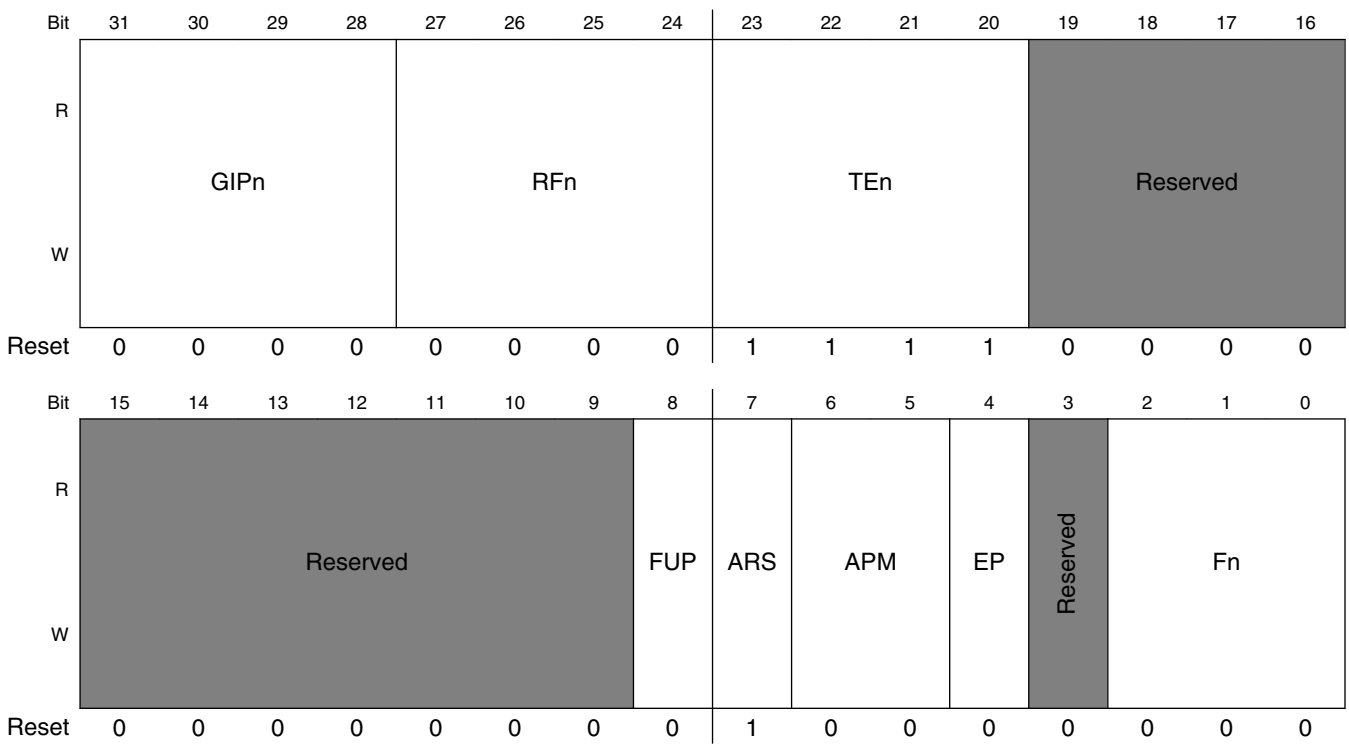
Field	Description
BRR3	Processor B Receive Register 3. (Read-only) • Reflects the data written to Processor A Transmit Register 3 (ATR3). • Reading the BRR3 register clears the “receiver full” bit (RF3) in the Processor B Status Register (BSR) on the receiver side, and sets the “transmitter empty” bit (TE3) in the Processor A Status Register on the transmitter side (optionally triggering a transmit interrupt 3 on the Processor A-side). • Any read of the BRR3 register will update all status information.

4.3.5.9 Processor B Status Register (MUB_BSR)

Use the Processor B Status Register (BSR, 32-bit, read-write) to show interrupt status from the Processor B, general purpose flags, the Processor A power mode, and to set dual function control-status bits.

- Dual-purpose bits are set by the Processor B-side programmer, and cleared by the MU logic.

Address: 30AB_0000h base + 20h offset = 30AB_0020h



MUB_BSR field descriptions

Field	Description
31–28 GIPn	For n = {0, 1, 2, 3} Processor B General Interrupt Request n Pending. (Read-Write) • GIPn bit signals the Processor B that the GIRn bit in the ACR register on the Processor A-side was set from “0” to “1”. If the GIEn bit in the BCR register is set to “1”, a General Interrupt n request is issued. • The GIPn bit is cleared by writing it back as “1”. Writing “0”, or writing “1” when the GIPn bit is cleared is ignored. Use this feature in the interrupt routine, where the GIPn bit is cleared in order to de-assert the interrupt request source at the interrupt controller. • GIPn bit is cleared when the MU is reset. 0 Processor B general purpose interrupt n is not pending. (default) 1 Processor B general purpose interrupt n is pending.

Table continues on the next page...

MUB_BSR field descriptions (continued)

Field	Description
27–24 RFn	For n = {0, 1, 2, 3} Processor B Receive Register n Full. (Read-only) • RFn bit signals to the Processor B-side that new data was written by the Processor A to the ATRn register, and is ready to be read by the Processor B in the BRRn register. • The RFn bit is set to “1” when the ATRn register is written on the Processor A-side. • After the RFn bit is set to “1”, the RFn bit signals the Processor B-side that new data is ready to be read by the Processor B in the BRRn register, and a Receive n interrupt is issued on the Processor A-side (if the RIEn bit in the BCR register has been set to “1”). • RFn bit is cleared when the BRRn register is read, and when the MU is reset. 0 BRRn register is not full (default). 1 BRRn register has received data from ATRn register and is ready to be read by the Processor B.
23–20 TEn	For n = {0, 1, 2, 3} Processor B Transmit Register n Empty. (Read-only) • When TEn = “1”, it signals to the Processor B-side that the BTRn register is ready to be written on the Processor B-side. • The TEn bit is set to “1” after the ARRn register is read on the Processor A-side. • Setting TEn bit will issue a transmit n interrupt on the Processor B-side (if the TIEn bit in the BCR register is set to “1”. • TEn bit is cleared after the BTRn register is written on the Processor B-side. • TEn bit is set to “1” when the MU is reset. 0 BTRn register is not empty. 1 BTRn register is empty (default).
19–9 Reserved	This field is reserved.
8 FUP	Processor B Flags Update Pending. (Read-only) • FUP bit is set to “1” when the Processor B-side sends a Flags Update request to the Processor A-side. • A Flags Update request is generated when the BAF[2:0] bits of the BCR register change. No flag update changes are allowed while the FUP bit is set to “1”. Any write to the BAF[2:0] bits, while the FUP bit is set to “1”, will not generate a Flags Update event, and the BAF[2:0] bits will stay unchanged. • FUP bit is cleared when this Flags Update request is internally acknowledged (that the flag is updated) from the MU Processor A-side, and during MU reset. 0 No flags updated, initiated by the Processor B, in progress (default) 1 Processor B initiated flags update, processing
7 ARS	Processor A Reset State. (Read-only) • ARS bit indicates if the Processor A-side of the MU is in a reset state or not. • If the ARS bit is set to “1”, then the Processor A-side of the MU is still in the reset state. • If the ARS bit is cleared, then both the Processor A and the Processor A-side of the MU are out of reset. • The ARS bit is set to “1” during: a Processor A system reset, or an MU reset (caused by setting the MUR bit at the BCR register).

Table continues on the next page...

MUB_BSR field descriptions (continued)

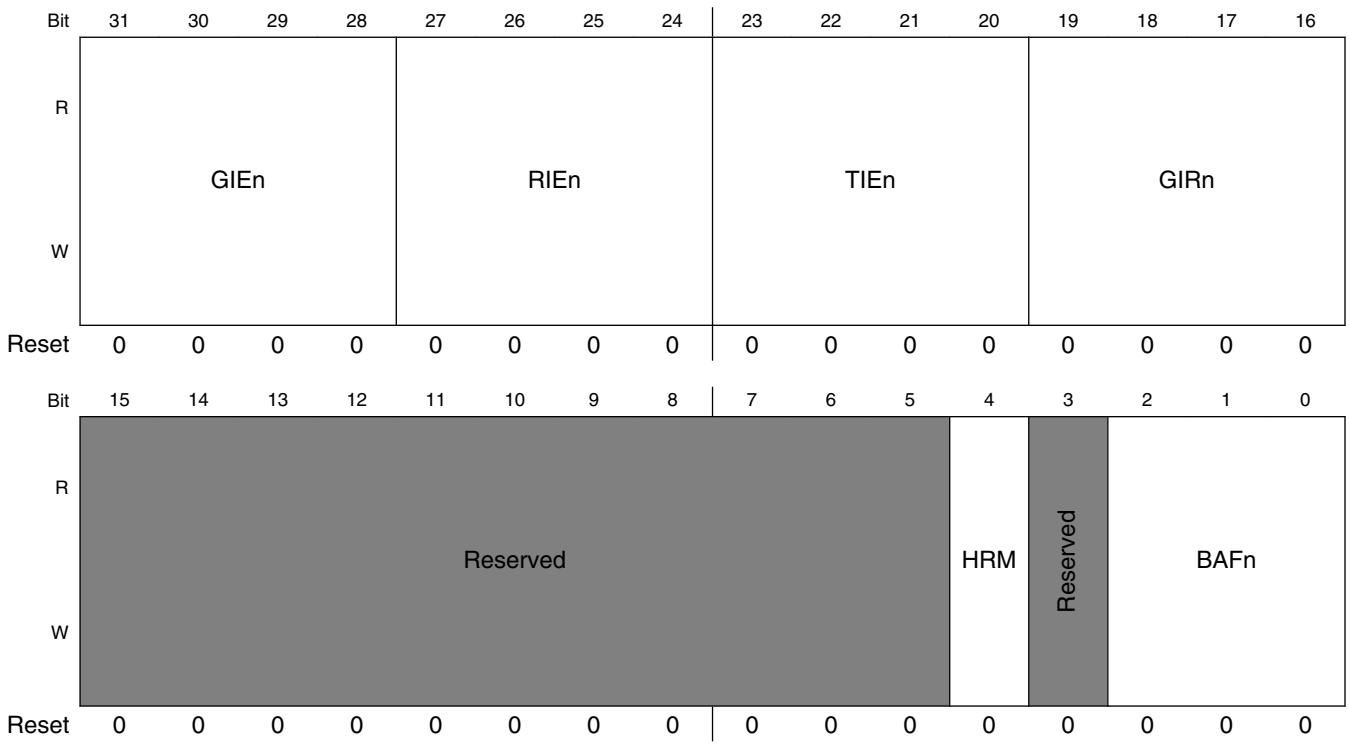
Field	Description
	• The ARS bit is cleared when the reset sequence on the Processor A-side of the MU ends. After issuing any of the three reset events mentioned previously, you should verify that the ARS bit is cleared before starting any accesses. • When Processor B side of MU comes out of reset ARS bit has value “1”(default).Then Processor B sees the status of Processor A side and if Processor A has come out of reset then ARS bit goes low.This takes 5-6 clock cycles.And if you read ARS bit now you will see it as low although its reset value was "1" . 0 The Processor A or the Processor A-side of the MU is not in reset. 1 The Processor A or the Processor A-side of the MU is in reset.
6–5 APM	Processor A Power Mode. (Read-only) • APM[1:0] bits indicate the Processor A power mode. 00 The System is in Run Mode. 01 The System is in WAIT Mode. 10 Reserved. 11 The System is in STOP Mode.
4 EP	Processor B-Side Event Pending. (Read-only) • EP bit is set to “1” when the Processor B-side mechanism sends an event update request to the Processor A-side. • EP bit is cleared when the event update acknowledge is received. An “event” is any hardware message that is reflected in the ASR register on the Processor A-side (for example, “transmit register 0 written”). During normal operations, you do not have to deal with the state of the EP bit because the event update mechanism works automatically. • To ensure events have been posted to Processor A before entering STOP mode, you should verify that the EP bit is cleared. If EP bit is set to “1”, you should wait and continue to poll it (EP bit) before entering STOP mode. • Reading the BSR register (to check the EP bit) should be the last access to the MU that should be performed before entering STOP mode; otherwise, the EP bit may be set by subsequent additional actions. • Due to Processor B pipeline effects, three NOP operations (or their timing equivalent) should be given after an instruction that sets an event before the EP bit can reflect this event. • The EP bit is cleared when the MU resets. 0 The Processor B-side event is not pending (default). 1 The Processor B-side event is pending.
3 Reserved	This field is reserved.
Fn	For n = {0, 1, 2} Processor B-Side Flag n. (Read-only) • Fn bit is the Processor B-side flag that reflects the values written to the ABFn bit in the Processor A control register. • Every time that the ABFn bit is written, the ABFn bit write event updates the Fn bit after the event update latency, which is measured in terms of the number of clocks of the Processor A and the Processor B. 0 ABFn bit in ACR register is written 0 (default). 1 ABFn bit in ACR register is written 1.

4.3.5.10 Processor B Control Register (MUB_BCR)

Use the Processor B Control Register (BCR, 32-bit, read-write) to enable the MU interrupts on the Processor B-side, and trigger events and interrupts on the Processor A-side (wake from STOP, hardware reset, flag update).

For the fields GIEn, RIEn, TIEn and GIRn, n=0 corresponds to the high order bit and n=3 corresponds to the low order bit.

Address: 30AB_0000h base + 24h offset = 30AB_0024h



MUB_BCR field descriptions

Field	Description
31–28 GIEn	For n = {0, 1, 2, 3} Processor B General Purpose Interrupt Enable n. (Read-Write) • GIEn bit enables Processor B General Interrupt n. • If GIEn bit is set to “1” (enabled), then a General Interrupt n request is issued when the GIPn bit in the BSR register is set to “1”. • If GIEn is cleared (disabled), then the value of the GIPn bit is ignored and no General Interrupt n request will be issued. • GIEn bit is cleared when the MU resets. 0 Disables Processor B General Interrupt n. (default) 1 Enables Processor B General Interrupt n.
27–24 RIEn	For n = {0, 1, 2, 3} Processor B Receive Interrupt Enable n. (Read-Write)

Table continues on the next page...

MUB_BCR field descriptions (continued)

Field	Description
	• RIEn bit enables Processor B Receive Interrupt n. • If RIEn bit is set to “1” (enabled), then an Processor B Receive Interrupt n request is issued when the RFn bit in the BSR register is set to “1”. • If RIEn bit is cleared (disabled), then the value of the RFn bit is ignored and no Processor B Receive Interrupt n request will be issued. • RIEn bit is cleared when the MU resets. 0 Disables Processor B Receive Interrupt n. (default) 1 Enables Processor B Receive Interrupt n.
23–20 TIEn	For n = {0, 1, 2, 3} Processor B Transmit Interrupt Enable n. (Read-Write) • TIEn bit enables Processor B Transmit Interrupt n. • If TIEn bit is set to “1” (enabled), then an Processor B Transmit Interrupt n request is issued when the TEn bit in the BSR register is set to “1”. • If TIEn bit is cleared (disabled), then the value of the TEn bit is ignored and no Processor B Transmit Interrupt n request will be issued. • TIEn bit is cleared when the MU resets. 0 Disables Processor B Transmit Interrupt n. (default) 1 Enables Processor B Transmit Interrupt n.
19–16 GIRn	For n = {0, 1, 2, 3} Processor B General Purpose Interrupt Request n. (Read-Write) • Writing “1” to the GIRn bit sets the GIPn bit in the ASR register on the Processor A-side. If the GIEn bit in the ACR register is set to “1” on the Processor A-side, a General Purpose Interrupt n request is triggered. • The GIRn bit is cleared if the GIPn bit (in the ASR register on the Processor A-side) is cleared by writing it (GIPn bit) as “1”, thereby signalling the Processor B that the interrupt was accepted (cleared by the software). The GIPn bit cannot be written as “0” on the Processor B-side. • To ensure proper operations, you must verify that the GIRn bit is cleared (meaning that there is no pending interrupt) before setting it (GIRn bit). • GIRn bit is cleared when the MU resets. 0 Processor B General Interrupt n is not requested to the Processor A (default). 1 Processor B General Interrupt n is requested to the Processor A.
15–5 Reserved	This field is reserved.
4 HRM	Processor B Hardware Reset Mask. (Read-Write) • The Processor A can give a hardware reset to the Processor B by setting the BHR bit in the ACR Register to “1”. • When the HRM bit is set to “1” by the Processor B, the BHR reset issued by the Processor A is masked (disabled by the Processor B). • When the HRM bit is cleared, the BHR reset issued by the Processor A to the Processor B is not masked (enabled by the Processor B). 0 BHR bit in ACR is not masked, enables the hardware reset to the Processor B (default after hardware reset). 1 BHR bit in ACR is masked, disables the hardware reset request to the Processor B.
3 Reserved	This field is reserved.
BAFn	For n = {0, 1, 2} Processor B to Processor A Flag n. (Read-Write)

Table continues on the next page...

MUB_BCR field descriptions (continued)

Field	Description
	• BAFn bit is a read-write flag that is reflected in Fn bit in the ASR register on the Processor A-side. • BAFn bit is cleared when the MU resets. 0 Clears the Fn bit in the ASR register. 1 Sets the Fn bit in the ASR register.

4.4 Semaphore (SEMA4)

4.4.1 Overview

The IPS_Semaphores module provides a platform IPS slave device which implements 16 hardware-enforced gates with the following features:

- Module definition supports 16 hardware-enforced gates in a dual-processor configuration, where cp0 is core processor 0 and cp1 is core processor 1
  - Hardware gates appear as a 16-entry byte-size array with read and write accesses
    - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor
  - Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
  - Secure reset mechanisms are supported to clear the contents of individual semaphore gates or notification logic, as well as a clear_all capability
  - Programming model allocates memory space to support up to 8 processors and up to 64 gates

A simplified block diagram of the Semaphores module is shown in Figure 4-10. In the diagram, the register blocks named gate0, gate1,…, gate 15 include the finite state machines implementing the semaphore gates plus the interrupt notification logic.

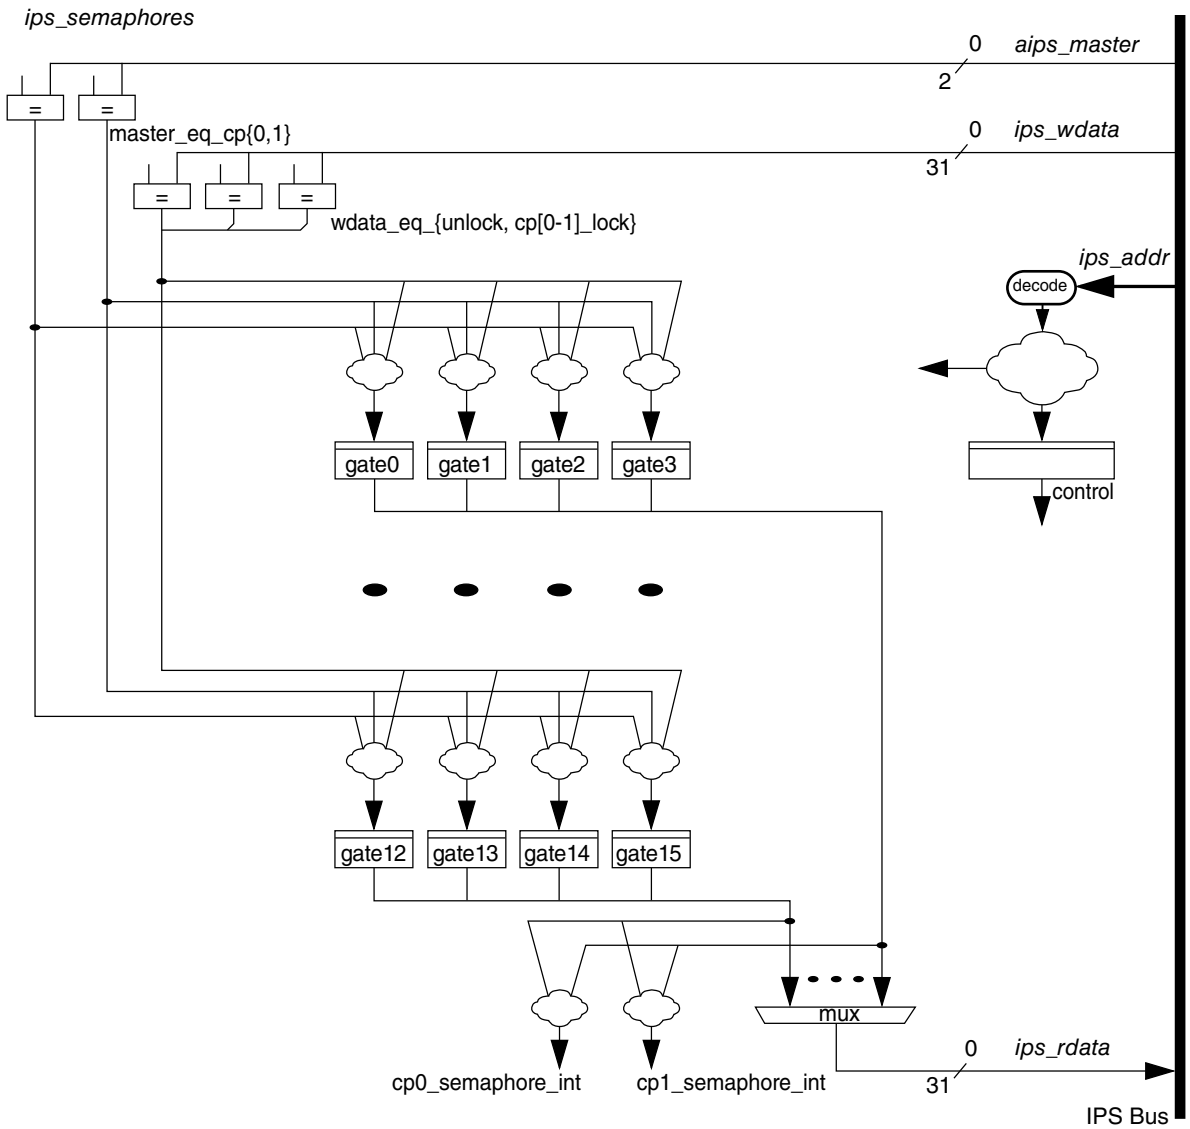


Figure 4-10. IPS_Semaphores Block Diagram

4.4.1.1 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a dual-processor configuration
  - Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array
    - 3-state implementation

      if gate = 0b00, then state = unlocked
      if gate = 0b01, then state = locked by processor 0

if gate = 0b10, then state = locked by processor 1

- Uses the bus master number as a reference attribute plus the specified data patterns to validate all write operations
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor

- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
- Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear_all capability

- Memory-mapped IPS slave peripheral platform module
  - Interface to the IPS bus for programming-model accesses
  - Two outputs (one per processor) for interrupt notification of failed lock writes

4.4.1.2 Modes of Operation

The Semaphores module does not support any special modes of operation. As a slave peripheral memory-mapped device located on the platform's IPS slave bus, it responds based strictly on the memory addresses of the connected bus. The IPS bus is used to access the Semaphores ' programming model.

4.4.2 External Signal Description

The Semaphores module does not include any external interfaces.

4.4.3 Functional Description

In this section, the functional operation of the Semaphores module, specifically the state machines of the SEMA4_GATEn and SEMA4_CPnNTF registers are detailed.

4.4.3.1 SEMA4_GATEn Operation

Recall each of the SEMA4_GATEn registers implements a 2-bit, 3-state machine. The state transitions for each gate are shown in the following figure.

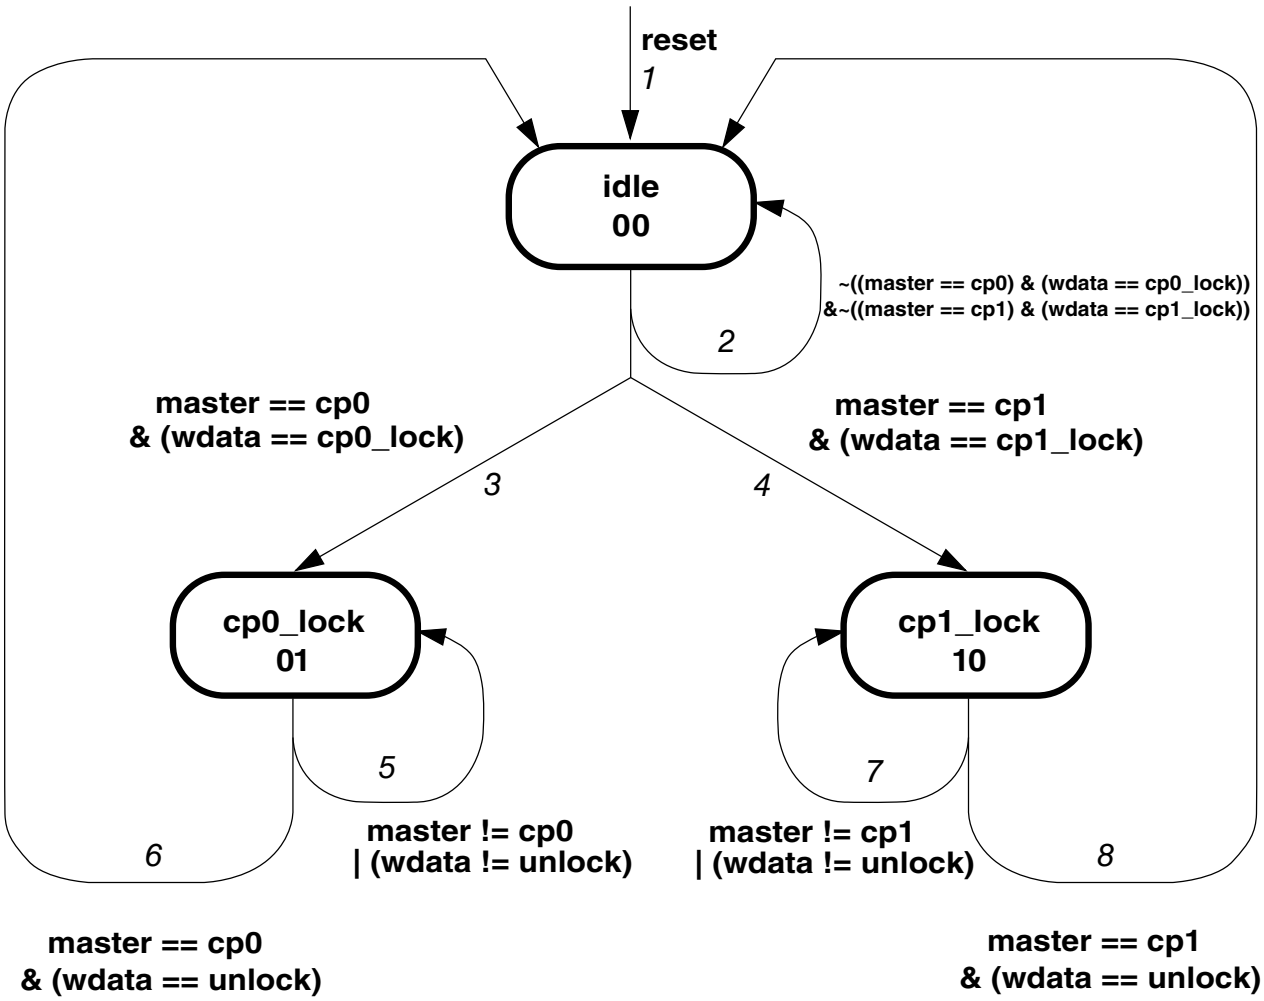

Figure 4-11. SEMA4_GATEn State Machine

The bus master number is used to identify core processor 0 (cp0) or core processor 1 (cp1). The Standard (or Reduced) Product Platform passes the AHB bus master number (`hmaster[2:0]`) through the AIPS (or AIPS-Lite) controller and drives an `aips_master[2:0]` output to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4_GATEn are defined in the following table.

Table 4-16. SEMA4_GATEn State Transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, whether a system reset or an individual gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.

Table continues on the next page...

Table 4-16. SEMA4_GATEn State Transitions (continued)

Current State	Next State	Transition	Description
idle	cp1_lock	4	When a write of the "cp1_lock" value is initiated by processor 1, the gate transitions into the cp1_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cp1_lock	cp1_lock	7	Once in this state, the gate remains here if any attempted write is not from cp1 with the unlock data value.
cp1_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cp1 with the unlock data value occurs.

4.4.3.2 SEMA4_CPnNTF Operation

The failed lock write notification interrupt request is implemented in a 3-bit, 5-state machine which records failed lock attempts and transitions based on gate locking and unlocking. Two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn]. See the following figure.

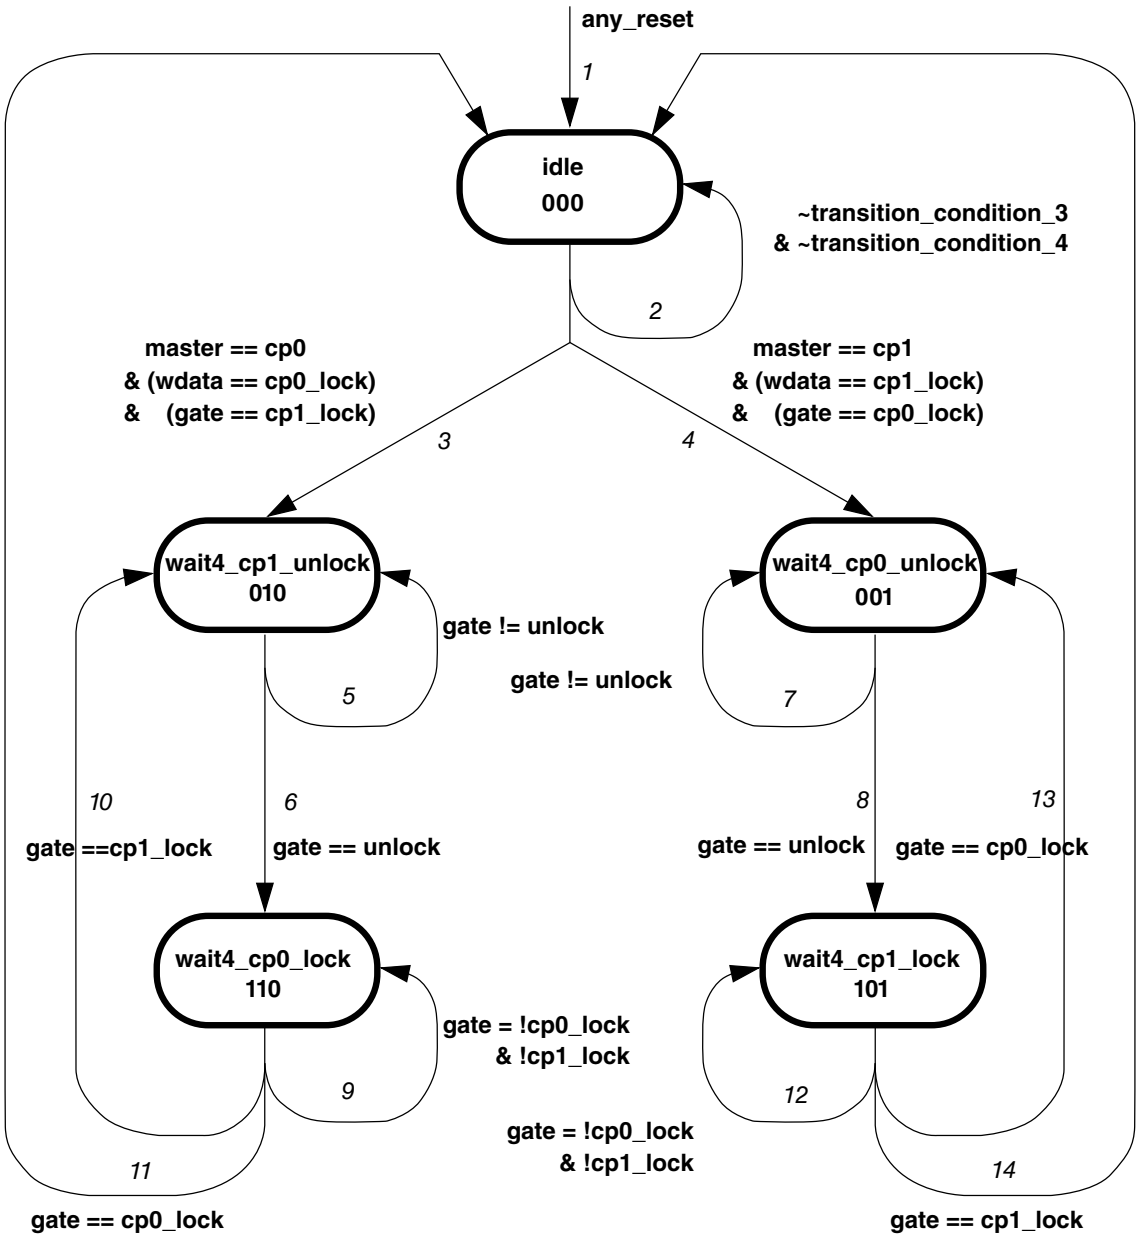

Figure 4-12. IRQ Notification State Machine

The state transitions of the IRQ notification function are defined in the following. Specific states of this machine are program-visible as the SEMA4_CPnNTF registers. In particular, two states are program-visible:

```
if state = wait4_cp0_lock (0b110) // generate cp0_semaphore_int if properly enabled
               then SEMA4_CP0NTF[GNn] = 1; else SEMA4_CP0NTF[GNn] = 0
if state = wait4_cp1_lock (0b101) // generate cp1_semaphore_int if properly enabled
               then SEMA4_CP1NTF[GNn] = 1; else SEMA4_CP1NTF[GNn] = 0
```

Table 4-17. IRQ Notification State Transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, including a system reset or an individual notification or secure gate reset, unconditionally forces the machine into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor to an already-locked gate occurs, the machine remains in the idle state.
idle	wait4_cp1_unlock	3	When a write of the "cp0_lock" data value is initiated by processor 0 but the gate is already locked by cp1, the machine transitions into this state, where it waits for cp1 to unlock the gate.
idle	wait4_cp0_unlock	4	When a write of the "cp1_lock" data value is initiated by processor 1but the gate is already locked by cp0, the machine transitions into this state, where it waits for cp0 to unlock the gate
wait4_cp1_unlock	wait4_cp1_unlock	5	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp1_unlock	wait4_cp0_lock	6	From this state, the machine transitions into the next state, waiting for cp0 to lock the gate, once it has been unlocked.
wait4_cp0_unlock	wait4_cp0_unlock	7	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp0_unlock	wait4_cp1_lock	8	From this state, the machine transitions into the next state, waiting for cp1 to lock the gate, once it has been unlocked.
wait4_cp0_lock	wait4_cp0_lock	9	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 0 or the gate is again locked by processor 1.
wait4_cp0_lock	wait4_cp1_unlock	10	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 1. With this transition, the notification interrupt request is negated.
wait4_cp0_lock	idle	11	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	wait4_cp1_lock	12	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 1or the gate is again locked by processor 0.
wait4_cp1_lock	wait4_cp0_unlock	13	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	idle	14	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 1. With this transition, the notification interrupt request is negated.

The Semaphores module generates two interrupt request output signals, one per processor, combining the SEMA4_CPnINE and SEMA4_CPnNTF registers, where the boolean equations are:

```
cp0_semaphore_int
    =    sema4_cp0ine[ine0]    &    sema4_cp0ntf[gn0]
    |    sema4_cp0ine[ine1]    &    sema4_cp0ntf[gn1]
    |    sema4_cp0ine[ine2]    &    sema4_cp0ntf[gn2]
    ...
    |    sema4_cp0ine[ine15]    &    sema4_cp0ntf[gn15]
cp1_semaphore_int
    =    sema4_cp1ine[ine0]    &    sema4_cp1ntf[gn0]
    |    sema4_cp1ine[ine1]    &    sema4_cp1ntf[gn1]
    |    sema4_cp1ine[ine2]    &    sema4_cp1ntf[gn2]
    ...
    |    sema4_cp1ine[ine15]    &    sema4_cp1ntf[gn15]
```

4.4.4 Initialization Information

The reset state of the IPS_Semaphores module allows it to begin operation without the need for any further initialization. All the internal state machines are cleared by any reset event, allowing the module to immediately begin operation.

4.4.5 Application Information

In an operational multi-core system, most interactions involving the Semaphores module involves reads and writes to the SEMA4_GATEn registers for implementation of the hardware-enforced software gate functions. Typical code segments for gate functions perform the following operations:

- To lock (close) a gate
    - The processor performs a byte write of "logical_processor_number + 1" to gate[i]
    - The processor reads back gate[i] and checks for a value of "logical_processor_number + 1"

If the compare indicates the expected value, then the gate is locked; proceed with the protected code segment. If the compare does not indicate the expected value, the lock operation failed; repeat the process beginning with byte write to gate[i] in spin-wait loop, or proceed with another execution path and wait for failed lock interrupt notification.

A simple C-language example of a `gateLock` function is shown in the following figure. This function follows the Hennessy/Patterson example described in Multi-Core Programming 101: Software Gates.

```
#define UNLOCK      0
#define CP0_LOCK    1
#define CP1_LOCK    2

void gateLock (n)
int   n;                                        /* gate number to lock */
{
   int i;
   int current_value;
   int locked_value;

   i = processor_number();  /* obtain logical CPU number */

   if (i == 0)
      locked_value = CP0_LOCK;
   else
      locked_value = CP1_LOCK;

   /* read the current value of the gate and wait until the state == UNLOCK */
   do {
        current_value = gate[n];
   } while (current_value != UNLOCK);

   /* the current value of the gate == UNLOCK. attempt to lock the gate for this
        processor. spin-wait in this loop until gate ownership is obtained */
   do {
      gate[n] = locked_value;  /* write gate with processor_number + 1 */
      current_value = gate[n]; /* read gate to verify ownership was obtained */
   } while (current_value != locked_value);
```

Figure 4-13. Sample gateLock Function

- To unlock (open) a gate
    - After completing the protected code segment, the locking processor performs a byte write of zeroes to gate[i], opening (unlocking) the gate

A few comments on the logical CPU number are appropriate. In this example, a reference to `processor_number()` is used to retrieve this hardware configuration value. Typically, the logical processor numbers are defined by a hardwired input vector to the individual cores. The exact method for accessing the logical processor number varies by architecture. For PowerPC cores, there is a processor ID register (PIR) which is SPR 286 and contains this value. A single instruction can be used to move the contents of the PIR into a general-purpose register: mfspr rx,286 where rx is the destination GPRn. Other architectures may support a specific instruction to move the contents of the logical processor number into a general-purpose register, e.g., rdcpn rx for a "read CPU number" instruction.

If the optional failed lock IRQ notification mechanisms are used, then accesses to the related registers (SEMA4_CPnINE, SEMA4_ CPnNTF) are required. Note that there is no required negation of the failed lock write notification interrupt as the request is automatically negated by the Semaphores module once the gate has been successfully locked by the "failing" processor.

Finally, in the event a system state requires a software-controlled reset of a gate or IRQ notification register(s), accesses to the secure reset control registers (SEMA4_RSTGT, SEMA4_RSTNTF) are required. For these situations, it is recommended that the appropriate IRQ notification enable(s) (SEMA4_CPnINE) bits be disabled *before* initiating the secure reset 2-write sequence to avoid any race conditions involving spurious notification interrupt requests.

4.4.6 Memory map and register definition

The Semaphores module provides an IPS programming model mapped to an SPP-standard on-platform 16 KB space. The description here specifies a dual-core configuration with 16 semaphore gates. All the register names are prefixed with "Sema4" as an abbreviation for the full module name.

The programming model is referenced using 8-, 16- and 32-bit accesses. Reads can use any reference size, while writes are generally restricted to the size of the register. Exceptions to the write size restrictions are detailed in the individual register descriptions. Attempted references using inappropriate access sizes, to undefined (reserved) addresses, or with a non-supported access type (for example, a write to a read-only register) generate an IPS error termination.

Finally, the programming model allocates space for a definition with up to 64 gates and up to 8 processor cores, even though this definition is considerably larger than any currently-planned module implementations. The number of gates and supported processor cores are independent; there is no relationship between these two system variables.

The 16 KB Semaphores programming model map is shown in the following table.

SEMA4 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
30AC_0000	Semaphores Gate 0 Register (SEMA4_Gate00)	8	R/W	00h	4.4.6.1/163

4.4.6.1 Semaphores Gate 0 Register (SEMA4_Gate00)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate

register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

Address: 30AC_0000h base + 0h offset = 30AC_0000h

For more details, see SEMA4_GATEn Operation . **NOTE:** The state of the gate reflects the last processor that locked it, which can be useful during system debug. 00 The gate is unlocked (free). 01 The gate has been locked by processor 0. 10 The gate has been locked by processor 1. 11 This state encoding is never used and therefore reserved. Attempted writes of 0x03 are treated as "no operation" and do not affect the gate state machine.

4.4.6.13 Semaphores Gate 12 Register (SEMA4_Gate12)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

4.4.6.17 Semaphores Processor n IRQ Notification Enable (SEMA4_CP*n*INE)

The application of a hardware semaphore module provides an opportunity for implementation of helpful system-level features. An example is an optional mechanism to generate a processor interrupt after a failed lock attempt. Recall traditional software gate functions execute a spin-wait loop in an effort to obtain and lock the referenced gate. With this module, the processor that fails in the lock attempt could continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function.

The optional notification interrupt function consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnINE registers, unimplemented bits read as zeroes, and writes are ignored.

4.4.6.18 Semaphores Processor n IRQ Notification (SEMA4_CP*n*NTF)

The Semaphores module optionally allows the processor that fails in the lock attempt to continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function rather than simply execute in a spin-wait loop.

The optional notification interrupt mechanism consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the read-only notification interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnNTF registers, unimplemented bits read as zeroes.

The notification interrupt is generated via a unique finite state machine, one per hardware gate. This machine operates in the following manner:

1. When an attempted lock fails, the FSM enters a first state where it waits until the gate is unlocked.
2. Once unlocked, the FSM enters a second state where it generates an interrupt request to the “failed lock” processor.
3. When the “failed lock” processor succeeds in locking the gate, the IRQ is automatically negated and the FSM returns to the idle state. However, if the other processor again locks the gate, the FSM returns to the first state, negates the interrupt request, and then waits for the gate to be unlocked (again).

The notification interrupt request is implemented in a 3-bit, 5-state machine, where tw specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn].

4.4.6.19 Semaphores (Secure) Reset Gate n (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism which allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The most significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xe2; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the upper byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1d) and the lower byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are cleared.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) which implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]) and the gate number(s) last cleared (SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

</table>

4.4.6.20 Semaphores (Secure) Reset IRQ Notification (SEMA4_RSTNTF)

As with the case of the secure reset function and the hardware gates, it is recognized that system operation may require a reset function to re-initialize the state of the IRQ notification logic without requiring a system-level reset.

To support this special notification reset requirement, the Semaphores module implements a "secure" reset mechanism which allows an IRQ notification (or all the notifications) to be initialized by following a specific dual-write access pattern. When successful, the specified IRQ notification state machine(s) are reset. Using a technique

similar to that required for the servicing of a software watchdog timer, the secure reset mechanism requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the IRQ notification(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTNTF memory location. The most significant byte (SEMA4_RSTNTF[RSTNDP]) must be 0x47; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTNTF location. For this write, the upper byte (SEMA4_RSTNTF[RSTNDP]) is the logical complement of the first data pattern (0xb8) and the lower byte (SEMA4_RSTNTF[RSTNTN]) specifies the notification(s) to be reset. This field can specify a single notification be cleared, or that all notifications are cleared.
3. Reads of the SEMA4_RSTNTF location return information on the 2-bit state machine (SEMA4_RSTNTF[RSTNSM]) which implements this function, the bus master performing the reset (SEMA4_RSTNTF[RSTNMS]) and the notification number(s) last cleared (SEMA4_RSTNTF[RSTNTN]). Reads of the SEMA4_RSTNTF register do not affect the secure reset finite state machine in any manner.

	Write-Only	7-0 RSTNDP	Reset Notification Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the notification reset mechanism. For the first write, RSTNDP = 0x47 while the second write requires RSTNDP = 0xb8.

4.5 On-Chip RAM Memory Controller (OCRAM)

4.5.1 Overview

Various options are provided for adding a pipeline or wait-states in a read/write access, in order to ensure flexible timing control at both high and low frequencies.

The internal block diagram is shown in the figure below.

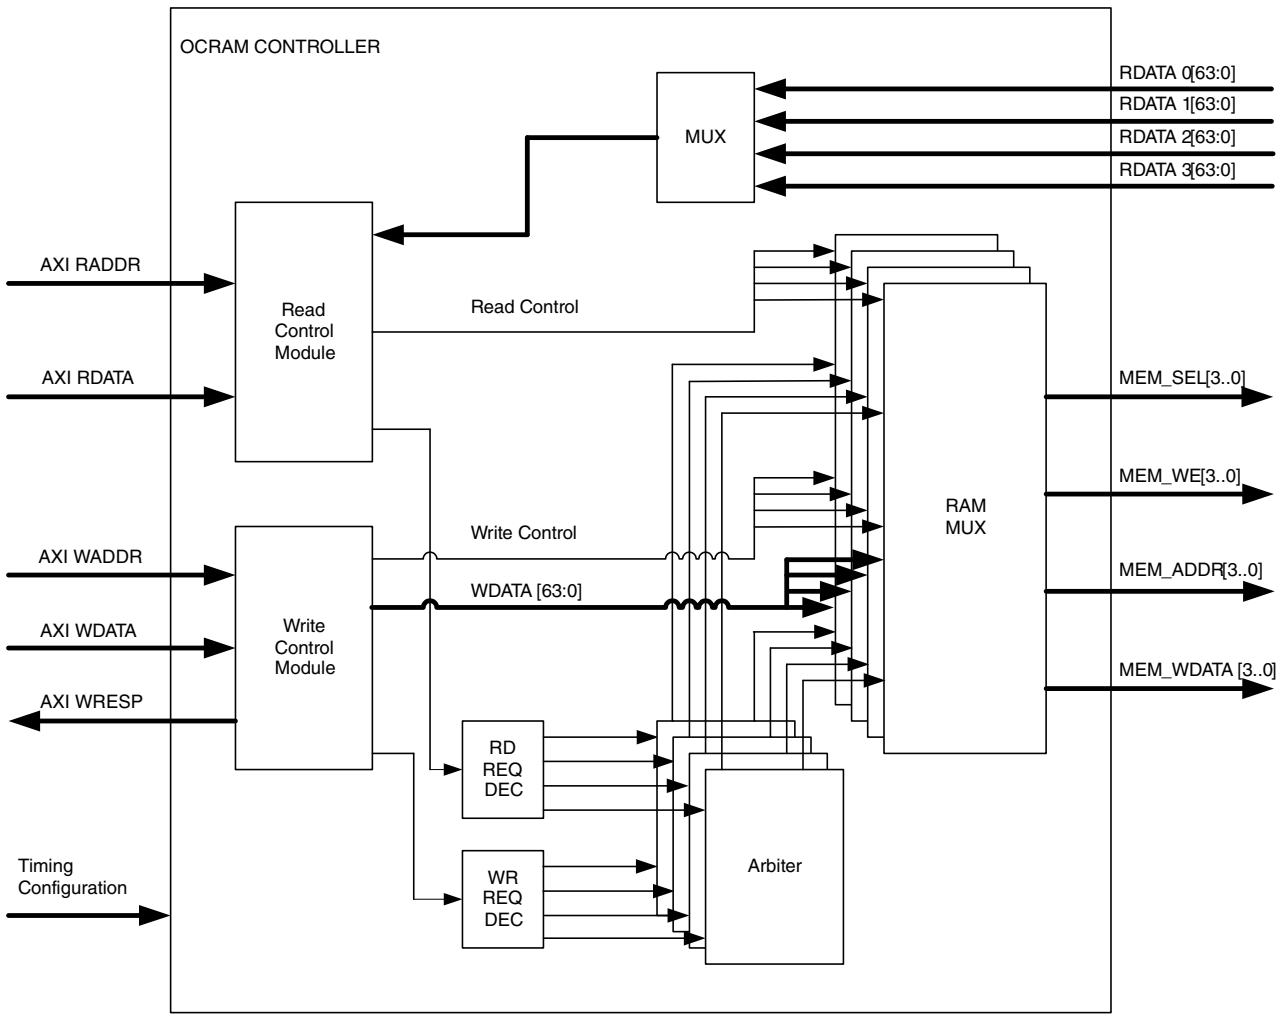

Figure 4-14. On-chip RAM Block Diagram

4.5.2 Basic Functions

4.5.2.1 Read/Write Arbitration

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.

- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

4.5.3 Advanced Features

This section describes some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

4.5.3.1 Read Data Wait State

When the wait state is enabled, it will take 2 cycles for each read access (each beat of a read burst).

This can avoid the potential timing problem caused by the longer memory access time at higher frequency.

When this feature is disabled, it only takes 1 clock cycle to finish a read transaction. That is, read data is available in the next cycle of read request becomes valid on the bus.

4.5.3.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

4.5.3.3 Write Data Pipeline

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

4.5.3.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would take at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

4.5.4 Programmable Registers

There are no programmable registers in this block;

4.6 Network Interconnect Bus System (NIC)

4.6.1 Overview

This section provides an overview of the NIC-301 (Network Inter-Connect) AXI arbiter IP.

The NIC-301 (by Arm Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

NOTE

The NIC-301 default settings are configured by NXP's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

4.6.2 External Signals

There are no external I/O interfaces for NIC-301.

4.7 AHB to IP Bridge (AIPSTZ)

4.7.1 Overview

This section provides an overview of the AHB to IP Bridge (AIPSTZ). This particular peripheral is designed as the bridge between AHB bus and peripherals with the lower bandwidth IP Slave (IPS) buses.

4.7.1.1 Features

The following list summarizes the key features of the bridge:

- The bridge supports the IPS slave bus signals.
- The bridge supports 8-, 16-, and 32-bit IPS peripherals. (Accesses larger than the size of a peripheral are not supported, except to 32-bit memory.)
- The bridge supports a pair of IPS accesses for 64-bit and certain misaligned AHB transfers to 32-bit memory in 64-bit platforms.
- The bridge directly supports up to 32 64-Kbyte external IPS peripherals, and 2 global external IPS peripheral spaces. The bridge occupies 1 MBytes of total address space.
- The bridge provides configurable per-block and per-master access protections. Access permissions are based on bus master (e.g. DMA or core) privilege levels and resource domain. More details on the protection features and configuration can be found in the Security Reference Manual

- Peripheral read transactions require a minimum of 2 hclk clocks, and unbuffered write transactions require a minimum of 3 hclk clocks.
- The bridge uses one single asynchronous reset and one global clock.

4.7.2 Clocks

The following table describes the clock sources for AIPSTZ. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 4-18. AIPSTZ Clocks

Clock name	Clock Root	Description
hclk	ahb_clk_root	Module clock

4.7.3 Functional Description

The AIPS bridge serves as a protocol translator between the AHB system bus and the IP bus.

Support is provided for generating a pair of 32-bit IP bus accesses when targeted by a 64-bit system bus access, or a misaligned access which crosses a 32-bit boundary. No other bus-sizing access support is provided.

The AHB to IP bridge is the interface between the AHB and on-chip IPS peripherals, which are sub-blocks containing readable/writable control and status registers.

The AHB master reads and writes these registers through the AIPSTZ. The bridge generates block enables, the block address, transfer attributes, byte enables and write data as inputs to the IPS peripherals. The bridge captures read data from the IPS interface and drives it on the AHB.

Each bridge that connects to the IPS (or peripherals) are referred as AIPS. The chip has three separate AIPS modules, and peripherals are grouped and assigned under each AIPS block. The list of peripherals are indicated as n-1, n-2, and n-3 for AIPS-1, AIPS-2, and AIPS-3 respectively.

AIPS occupies a 1-Mbyte portion of the address space. The register maps of the IPS peripherals are located on 64-Kbyte boundaries. Each IPS peripheral is allocated one 64-Kbyte block of the memory map, and is activated by one of the block enables from the bridge. Up to thirty-two 64-Kbyte external IPS peripherals may be implemented, occupying contiguous blocks of 64-Kbytes. Two global external IPS block enables are

available for the remaining address space to allow for customization and expansion of addressed peripheral devices. In addition, a single "non-global" block enable is also asserted whenever any of the thirty-two non-global block enables is asserted.

The bridge is responsible for indicating to IPS peripherals if an access is in supervisor or user mode. It may block user mode accesses to certain IPS peripherals or it may allow the individual IPS peripherals to determine if user mode accesses are allowed. In addition, peripherals may be designated as write-protected.

The bridge supports the notion of "trusted" masters for security purposes. Masters may be individually designated as trusted for reads, trusted for writes, or trusted for both reads and writes, as well as being forced to look as though all accesses from a master are in user-mode privilege level. Refer to AIPSTZ Memory Map/Register Definition for more information.

The AIPSTZ prevents access to a peripheral if the transaction originated from a source from a resource domain that has been explicitly omitted. Resource domains are assigned in the RDC submodule. Please refer to the RDC chapter for programming details.

All peripheral devices are expected to only require aligned accesses equal to or smaller in size than the peripheral size. An exception to this rule is supported for 32-bit peripherals to allow memory to be placed on the IPS.

4.7.4 Access Protections

The AIPSTZ bridge provides programmable access protections for both masters and peripherals. It allows the privilege level of a master to be overridden, forcing it to user-mode privilege, and allows masters to be designated as trusted or untrusted.

Peripherals may require supervisor privilege level for access, may restrict access to a trusted master only, and may be write-protected. IP bus peripherals are subject to access control policies set in both CSU registers and AIPSTZ registers. An access is blocked if it is denied by either policy.

Masters and peripherals are assigned to one or more resource domains in the RDC submodule (see the RDC chapter for details). Depending on RDC programming, masters transactions through the AIPSTZ may or may not be allowed access to peripherals in different resource domains.

4.7.5 Access Support

Aligned 64-bit accesses, aligned and misaligned word and half word accesses, as well as byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the IPS.

Peripheral registers must not be misaligned, although no explicit checking is performed by the AIPS bridge. The bridge will perform two IPS transfers for 64-bit accesses, word accesses with byte offsets of 1, 2, or 3, and for half word accesses with a byte offset of 3. All other accesses will be performed with a single IPS transfer.

Only aligned half word and byte accesses are supported for 16-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

Only byte accesses are supported for 8-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

4.7.6 Initialization Information

The AIPS bridge should be programmed before use.

The following registers should be initialized: The Master Privilege Registers (AIPSTZ_MPRs), the Peripheral Access Control registers (AIPSTZ_PACRs), and the Off-platform Peripheral Access Control registers (AIPSTZ_OPACRs) described in AIPSTZ Memory Map/Register Definition.

4.7.6.1 Security Block

The AIPSTZ contains a security block that is connected to each off-platform peripheral. This block filters accesses based on write/read, non-secure, and supervisor signals.

Each peripheral can be individually configured to allow or deny each of the following transactions as described in the table below:

Table 4-19. Peripheral Access Configuration options

Config Bit	Write	Non-Secure	Supervisor	Meaning
0	0	0	0	Secure User Read
1	0	0	1	Secure Supervisor Read

Table continues on the next page...

Table 4-19. Peripheral Access Configuration options (continued)

Config Bit	Write	Non-Secure	Supervisor	Meaning
2	0	1	0	Non-Secure User Read
3	0	1	1	Non-Secure Supervisor Read
4	1	0	0	Secure User Write
5	1	0	1	Secure Supervisor Write
6	1	1	0	Non-Secure User Write
7	1	1	1	Non-Secure Supervisor Write

Each peripheral has a security configuration (sec_config_X) input for determining whether to allow or deny a given access type. These are 8-bit vectors, with each bit corresponding to one of the transactions above as listed in the Config Bit column of Table 4-19. If the bit is asserted (1'b1), the transaction is allowed. If the bit is negated (1'b0), the transaction is not allowed.

For example, if peripheral 0 is configured as follows:

sec_config_0 [7:0] = 8'b0011_0011

This peripheral can only be accessed by secure transactions. Bits 0, 1, 4, and 5 are asserted and these bits refer to the four types of secure transactions. If an insecure transaction is attempted to this peripheral, it will result in an error.

Eight bits per peripheral across an entire system can result in a large number of configuration bits that must be assigned and controlled, most likely in a series of registers in another block. To reduce the number of register bits required predefined sets of security profiles can be defined and encapsulated in an external security translation block. The table below describes one set of security profiles that has been proposed for use with the AIPSTZ.

Table 4-20. Security Levels

CSU_SEC_LEVEL	Non-Secure User	Non-Secure Supervisor	Secure User	Secure Supervisor
0	RD+WR	RD+WR	RD+WR	RD+WR
1	NOT ALLOWED	RD+WR	RD+WR	RD+WR
2	Read Only	Read Only	RD+WR	RD+WR
3	NOT ALLOWED	Read Only	RD+WR	RD+WR
4	NOT ALLOWED	NOT ALLOWED	RD+WR	RD+WR
5	NOT ALLOWED	NOT ALLOWED	NOT ALLOWED	RD+WR
6	NOT ALLOWED	NOT ALLOWED	Read Only	Read Only
7	NOT ALLOWED	NOT ALLOWED	NOT ALLOWED	NOT ALLOWED

Information regarding CSU is provided in the Security Reference Manual. Contact your NXP representative for information about obtaining this document.

A 3-bit input, 8-bit output translation block can be used such that only three register bits are required to set the security profile and the translation block will drive the correct 8-bit configuration vector. Each peripheral connected to the AIPSTZ would require this translation block. The top level AIPSTZ has this three bit input line `csu_sec_level[2:0]' corresponding to each peripheral X.

4.7.7 AIPSTZ Memory Map/Register Definition

The memory map for the AIPS SW-visible registers is shown in the table below.

The MPROT and OPACR fields are 4 bits in width. Some bits may be reserved depending on device.

AIPSTZ memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3000_0000	Master Priviledge Registers (AIPSTZ_MPR)	32	R/W	7700_0000h	4.7.7.1/195
3000_0040	Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR)	32	R/W	4444_4444h	4.7.7.2/198
3000_0044	Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR1)	32	R/W	4444_4444h	4.7.7.3/201
3000_0048	Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR2)	32	R/W	4444_4444h	4.7.7.4/204
3000_004C	Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR3)	32	R/W	4444_4444h	4.7.7.5/207
3000_0050	Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR4)	32	R/W	4444_4444h	4.7.7.6/210

4.7.7.1 Master Priviledge Registers (AIPSTZ_MPR)

Each AIPSTZ_MPR specifies 16 4-bit fields defining the access privilege level associated with a bus master in the platform, as well as specifying whether write accesses from this master are bufferable shown in Table 4-21

The registers provide one field per bus master, where field 15 corresponds to master 15, field 14 to master 14,... field 0 to master 0 (typically the processor core). The master index allocation is shown in the table below.

Table 4-21. MPROT Field

Bit	Field	Description
3	MBW	**Master Buffer Writes** - This bit determines whether the AIPSTZ is enabled to buffer writes from this master.
2	MTR	**Master Trusted for Reads** - This bit determines whether the master is trusted for read accesses.
1	MTW	**Master Trusted for Writes** - This bit determines whether the master is trusted for write accesses.
0	MPL	**Master Privilege Level** - This bit determines how the privilege level of the master is determined.

NOTE

The reset value is set to 0000_0000_7700_0000, which makes master 0 and master 1 (Arm CORE) the trusted masters. Trusted software can change the settings after reset.

Table 4-22. Master Index Allocation

Master Index	Master Name	Comments
Master 0	All masters excluding Arm core	Share the same number allocation.
Master 1	Arm A53	
Master 4	SDMA	
Master 6	M4

4.7.7.2 Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ_OPACR has the following format shown in Table 4-23

Table 4-23. OPAC Field

Bit	Field	Description
3	BW	**Buffer Writes** - This bit determines whether write accesses to this peripheral are allowed to be buffered.[1]
2	SP	**Supervisor Protect** - This bit determines whether the peripheral requires supervisor privilege level for access.
1	WP	**Write Protect** - This bit determines whether the peripheral allows write accesses.
0	TP	**Trusted Protect** - This bit determines whether the peripheral allows accesses from an untrusted master.

1. Buffered writes are not available for AIPSTZ. This bit should be set to '0'.

4.7.7.3 Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR1)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ_OPACR has the following format shown in Table 4-23

Address: 3000_0000h base + 44h offset = 3000_0044h

4.7.7.6 Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACR4)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ_OPACR has the following format shown in Table 4-23

Address: 3000_0000h base + 50h offset = 3000_0050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OPAC32				OPAC33				Reserved																							
Reset	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0

AIPSTZ_OPACR4 field descriptions

Field	Description
31–28 OPAC32	Off-platform Peripheral Access Control 32 xxx0 **TP0** — Accesses from an untrusted master are allowed.

Table continues on the next page...

AIPSTZ_OPACR4 field descriptions (continued)

Field	Description
	xxx1 **TP1** — Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. xx0x **WP0** — This peripheral allows write accesses. xx1x **WP1** — This peripheral is write protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. x0xx **SP0** — This peripheral does not require supervisor privilege level for accesses. x1xx **SP1** — This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor via the hprot[1] access attribute, and the MPROTx[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. 0xxx **BW0** — Write accesses to this peripheral are not bufferable by the AIPSTZ. 1xxx **BW1** — Write accesses to this peripheral are allowed to be buffered by the AIPSTZ.
27–24 OPAC33	Off-platform Peripheral Access Control 33 xxx0 **TP0** — Accesses from an untrusted master are allowed. xxx1 **TP1** — Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. xx0x **WP0** — This peripheral allows write accesses. xx1x **WP1** — This peripheral is write protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. x0xx **SP0** — This peripheral does not require supervisor privilege level for accesses. x1xx **SP1** — This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor via the hprot[1] access attribute, and the MPROTx[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the IPS bus. 0xxx **BW0** — Write accesses to this peripheral are not bufferable by the AIPSTZ. 1xxx **BW1** — Write accesses to this peripheral are allowed to be buffered by the AIPSTZ.

4.8 Shared Peripheral Bus Arbiter (SPBA)

4.8.1 Overview

The Shared Peripheral Bus Arbiter (SPBA) is a three-to-one IP Bus interface arbiter. Three masters arbitrate for shared peripheral access through the SPBA.

The SPBA has three primary functions:

- The IP Bus Line switches a master to one peripheral

- The Masters arbiter arbitrates between the three masters to solve concurrent access or restricted access to peripherals
- The Control Registers and Ownership Control includes a set of registers which are reachable through software and permit the access scheme to be defined for each peripheral (Resource Ownership and Access Control). It generates signals for the external steering logic of interrupts and DMA signals.

The figure below shows the SPBA block diagram

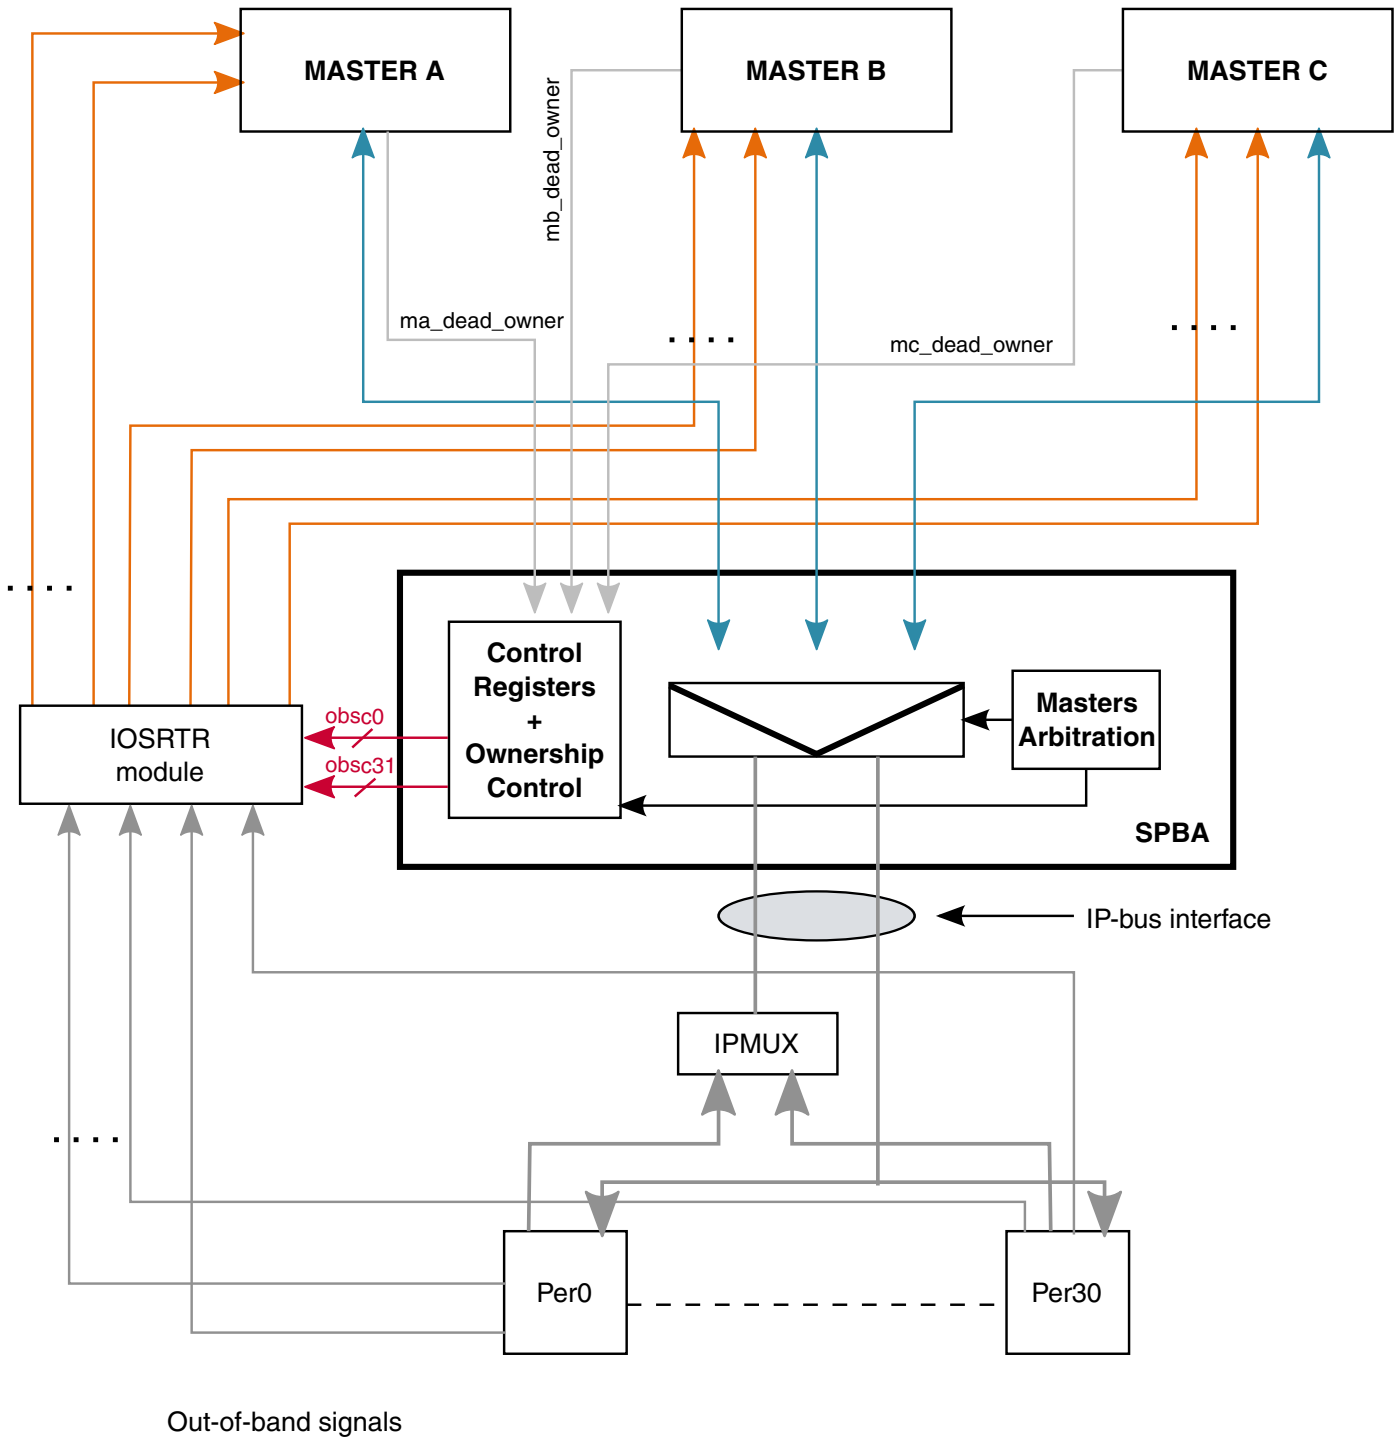

Figure 4-15. SPBA Block Diagram

4.8.1.1 Features

The SPBA includes the following features:

- Three IP Bus masters arbitration: Master A, B and C
- Support for DMA masters
- 32-bit data
- Supports up to 31 shared peripherals, each consuming 64 kilobytes of address space
- SPBA can be considered the 32nd peripheral, used for resource ownership and access control of the 31 peripherals
- Provides 31 sets of out of band steering control (OBSC) signals to the off-block steering logic
- Operating frequency up to 67 MHz
- Clocks: ipg_clk, ipg_clk_s

4.8.1.2 Modes of operation

SPBA behavior is transparent when accessing a peripheral, though it has these distinct modes of operation.

Reset/Abort

The SPBA has a hardware reset which initializes all registers, arbitration and peripherals rights registers (PRRs).

An abort signal input is provided allowing each master to abort its current access and release ownership (in case of master reset sequence).

Functional

Once a master request is granted, its IP Bus signals are steered to the requested peripheral.

Standby

No clock needed. The SPBA needs clocks only during access to the PRRs, arbitration, and abort phases. It generates two clock enable signals indicating when the clocks must be provided.

Configuration

During this phase, a master accesses the SPBA PRRs. The SPBA memory-mapped registers are seen as a shared peripheral.

4.8.2 Clocks

The table found here describes the clock sources for SPBA.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 4-24. SPBA Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

4.8.3 Functional description

4.8.3.1 Masters arbitration

The arbitration mechanism determines which port will control the master port, based on a simple round-robin arbitration scheme.

There are several use cases to consider.

- Only one master request per access. The master is switched to the shared peripheral bus, without arbitration. Figure 4-16 shows the MB request on the global module enable signal, served without wait state.
- If two masters simultaneously access SPBA, the last granted master is held off using the <master>_ips_xfr_wait output signal (default value is high). When the master is granted sips_xfr_wait, shared IP Bus peripheral is connected to <master>_ips_xfr_wait outputs.
- If three masters simultaneously access SPBA, then the last two granted masters are held off using <master>_ips_xfr_wait. Figure 4-17 shows a case in which the last two accesses granted are MA and MB. The requests are used even if they are in the same cycle.
- If after reset, at the first multiple access, no master has been granted, the priority is static: Master A (MA), Master B (MB) and last Master C (MC) port.
- No master request. No master switch to shared peripherals.

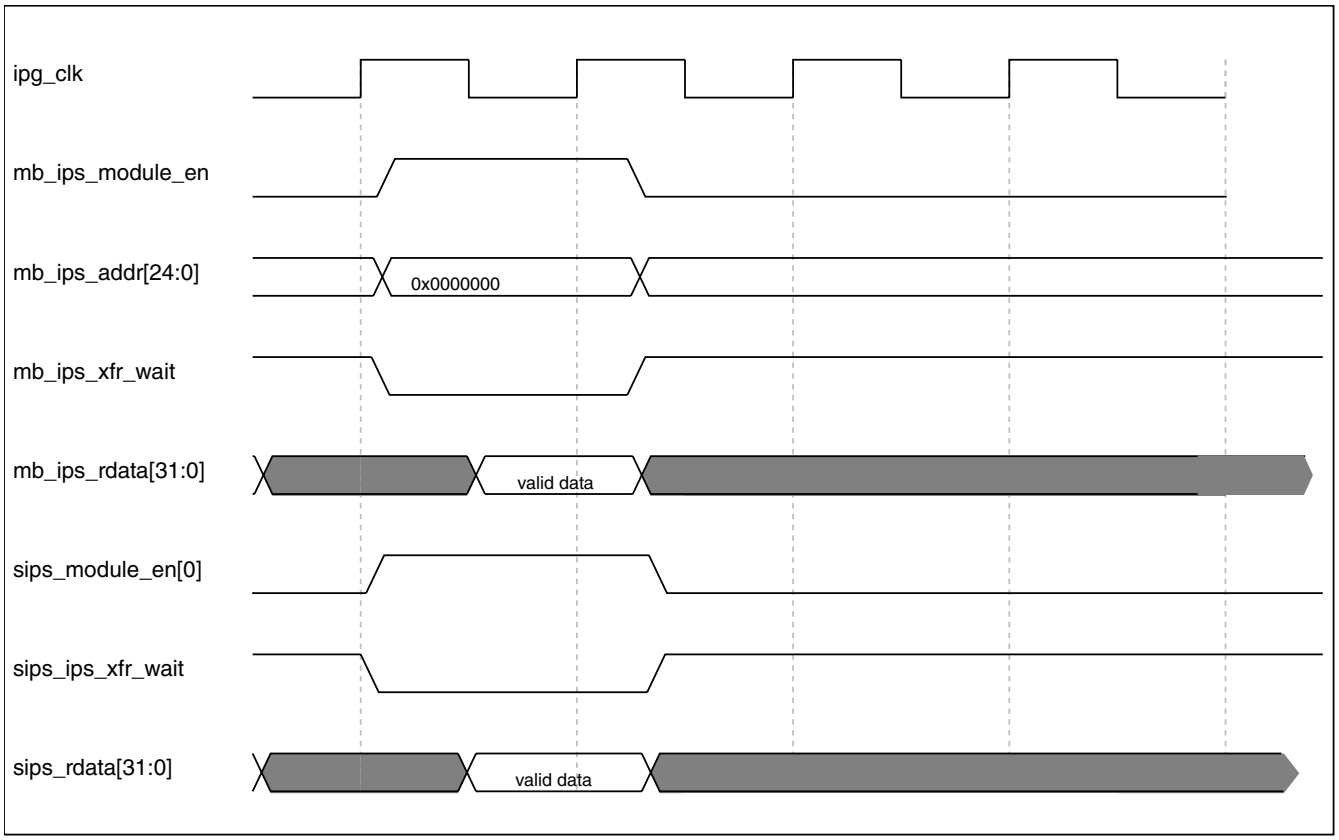

Figure 4-16. Example of one master request, no SPBA arbitration

The following figure assumes MA and MB have been the last two masters granted in the previous transfers (MA then MB).

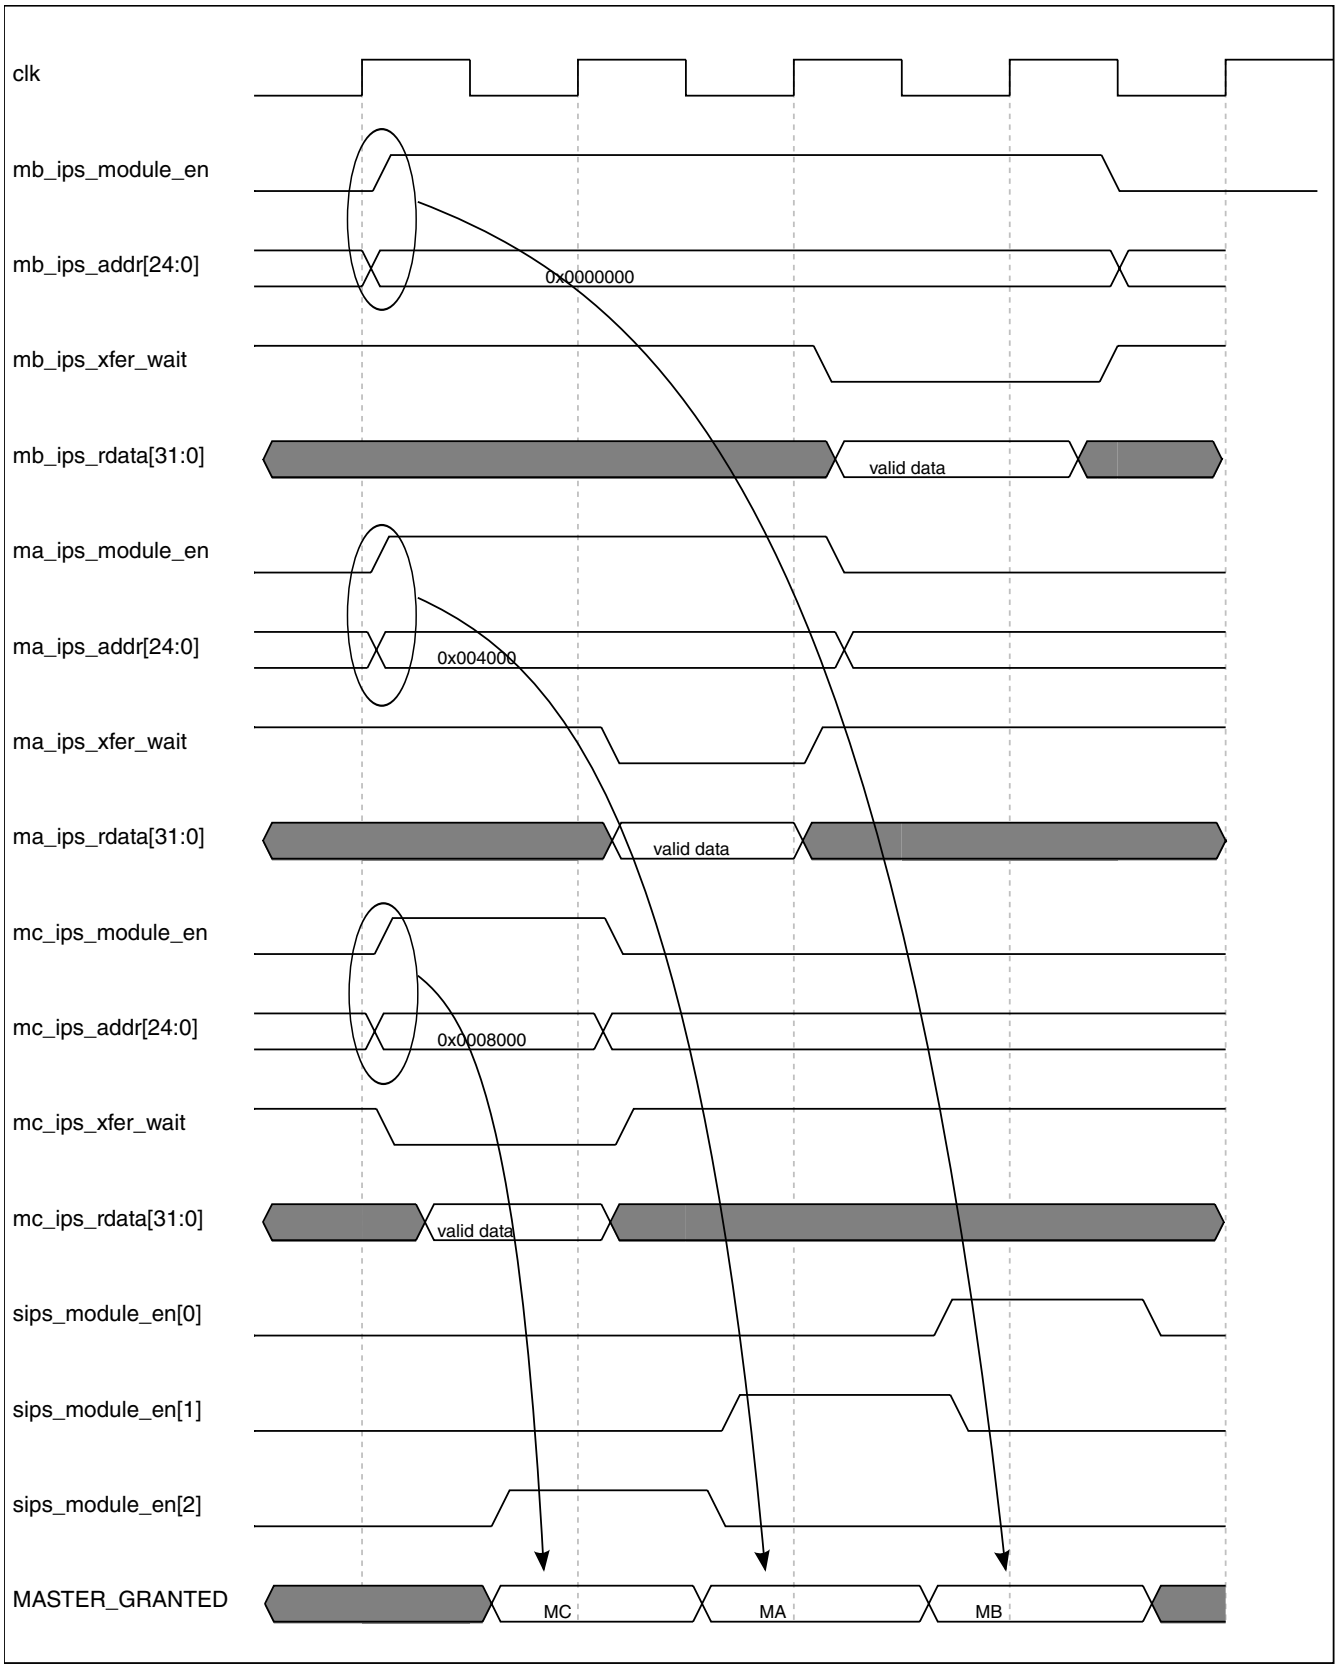

Figure 4-17. Example of three master requests: Masters already granted are "waited";

4.8.4 Resource ownership control

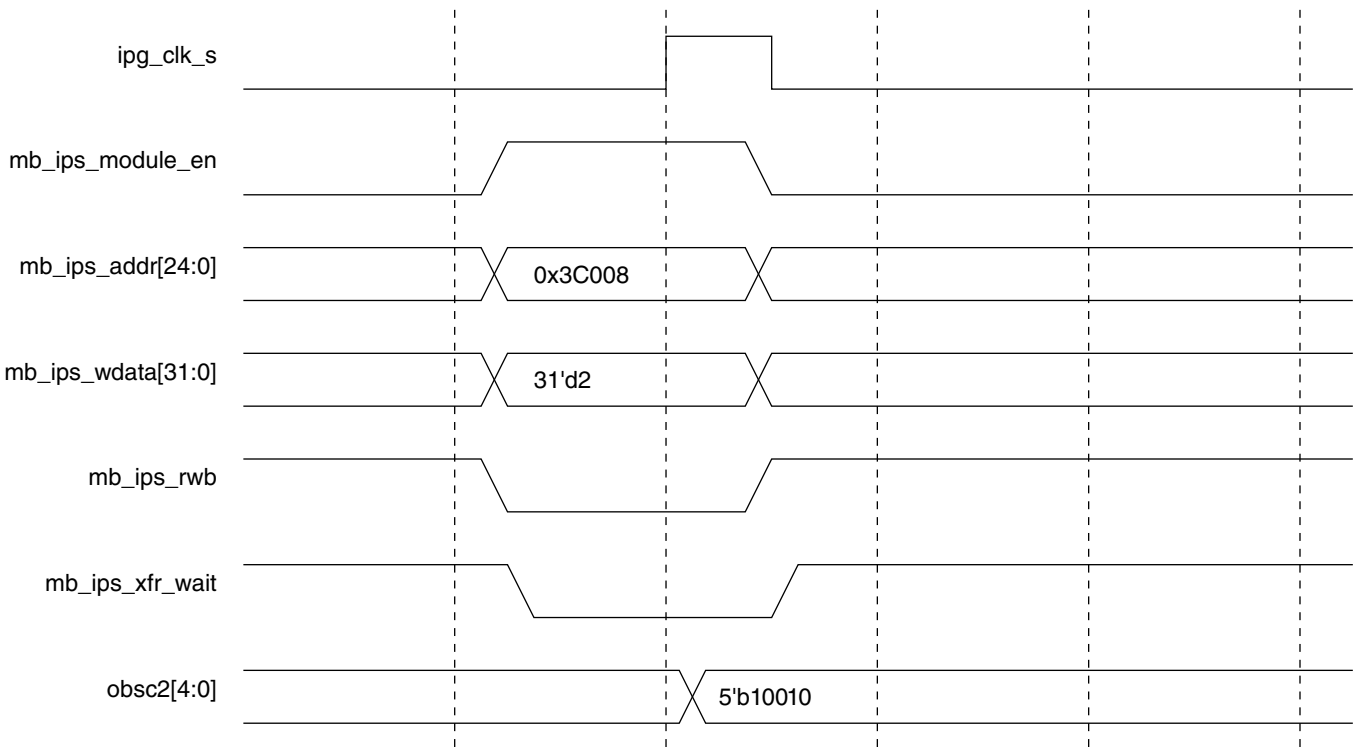
The resource ownership control regulates access to the shared peripherals and determines the steering of out-of-band signals.

4.8.4.1 Access control

4.8.4.1.1 Peripheral access

The peripheral access (resource access) of the requesting master is given by the corresponding RAR bit of the Peripheral Right Register. It determines if the master has access privilege to the resource.

Any attempt at access made by a requesting master whose access privilege bit is not set (in the PRR) is terminated with a bus error (**<master>_ips_xfr_err** is asserted by SPBA logic). The master that owns the resource can lock the peripheral for itself and/or grant other masters access to the peripheral by setting the appropriate bit(s) in the RAR field.



Master B is taking ownership of peripheral 2 by writing 3'b010 in the SPBA peripheral 2 right register (rarfield)
This ownership can be checked on obsc2 output as roi2[1:0] = 2'b10 and rar2[2:0] = 3'b010
(obsc[4:0] = {roi2[1], roi2[0], rar2[2], rar2[1], rar2[0]})

Figure 4-18. Example of one master B gaining ownership of peripheral 2

4.8.4.1.2 Peripheral Right Register access

The ROI bits of the Peripheral Right Register (PRR) determine which master is allowed to make write access to PRR. The identification of the requesting master is compared to the ROI bits of the PRR to determine if the master has ownership of the corresponding register.

Any attempted write access to a PRR already owned by another master will be ignored.

4.8.4.2 Owner election

When the peripheral is not owned by any master (ROI="00", after coming out of reset for instance), the first master to perform successfully a write to the RAR bits of the PRR is granted ownership of the peripheral and its associated PRR.

After writing to the PRR (RAR bit(s)), the master must read it back to make sure that it was granted ownership. If the RMO field is 2'b11, then the ownership claim is successful. If RMO is 2'b10, another master claimed ownership before this master was able to complete its write. This resolves the case in which two or more masters attempt to write the PRR at the same time; only the first master will be granted ownership. However all masters must read the PRR to determine if this case occurred, and if so, whether they were the first master which was granted ownership.

NOTE

A master that has been granted ownership of the PRR does not automatically have the right access to the peripheral; it must still set its own RAR bits in the PRR to access the peripheral.

4.8.4.3 Ending ownership

Ownership may be voluntarily ended by the owning master, or automatically upon assertion of a master-specific dead_owner signal.

The former is appropriate for software-controlled yielding of ownership. The latter is appropriate for automatic yielding of ownership when the owner has gone into reset.

When a master is reset, it clears the ROI bits of the PRRs owned by the corresponding master. When the owner is dead (in reset), all peripherals previously owned by that master must be changed to the un-owned state.

NOTE

It is the programmer's responsibility to make sure the peripherals are placed in an appropriate state before ending ownership.

4.8.4.3.1 Software Controlled Ownership Ending

The ROI bits will be automatically cleared when the master that owns the PRR access right clears (write) the RAR bits (Table 2).

It will then end the ownership of the PRR.

4.8.4.4 The Un-owned State

During the time when the peripheral is un-owned (i.e the ROI field contains all 0's), all masters have full access to it (RAR bits can then be modified by a master if ROI[1:0] = 2'b0).

In such cases it is necessary for software to ensure any necessary coherency in the resource, there is no hardware protection.

4.8.5 SPBA Memory Map/Register Definition

The SPBA control registers (Peripheral Right Registers) are mapped as a virtual shared peripheral.

SPBA can support up to 31 shared peripherals. Each of them has its own Peripheral Right Register (PRR) accessible within the SPBA memory-mapped registers, and consists of the Requesting Master Owner, the Resource Owner ID and the Resource Access Right fields.

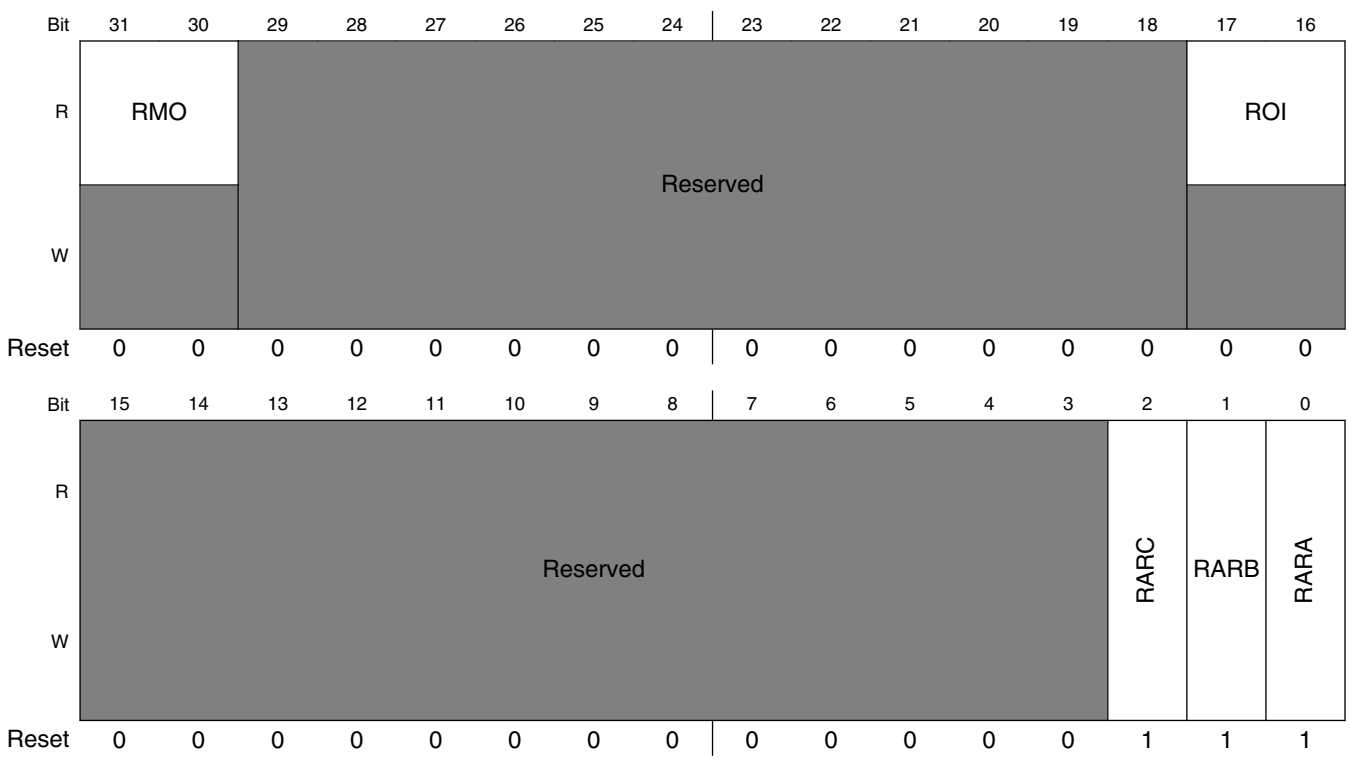
4.8.5.1 Peripheral Rights Register (SPBAx_PRR*n*)

This register controls master ownership and access for a peripheral.

Address: Base address + 0h offset + (4d × i), where i=0d to 31d



SPBAx_PRR*n* field descriptions

Field	Description
31–30 RMO	Requesting Master Owner. This 2-bit register field indicates if the corresponding resource is owned by the requesting master or not. This register is reset to 2'b0 if ROI = 2'b0. 00 **UNOWNED** — The resource is unowned. 01 Reserved. 10 **ANOTHER_MASTER** — The resource is owned by another master. 11 **REQUESTING_MASTER** — The resource is owned by the requesting master.
29–18 -	This field is reserved. Reserved
17–16 ROI	Resource Owner ID. This field indicates which master (one at a time) can access to the PRR for rights modification. This is a read-only register. After reset, ROI bits are cleared ("00" -> un-owned resource). A master performing a write access to the an un-owned PRR will get its ID automatically written into ROI, while modifying RARx bits. It can then read back the RMO, RAR, ROI bits to make sure RMO returns the right value, ROI bits contain its ID and RARx bits are correctly asserted. Then no other master (whom ID is different from the one stored in ROI) will be able to modify RAR fields. Owner master of a peripheral can assert its dead_owner signal, or write 1'b0 in the RARx to release the ownership (ROI[1:0] reset to 2'b0). 00 **UNOWNED** — Unowned resource. 01 **MASTER_A** — The resource is owned by master A port. 10 **MASTER_B** — The resource is owned by master B port. 11 **MASTER_C** — The resource is owned by master C port.
15–3 -	This field is reserved. Reserved
2 RARC	Resource Access Right. Control and Status bit for master C. This field indicates whether master C can access the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA). 0 **PROHIBITED** — Access to peripheral is not allowed. 1 **ALLOWED** — Access to peripheral is granted.
1 RARB	Resource Access Right. Control and Status bit for master B. This field indicates whether master B can access the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA). 0 **PROHIBITED** — Access to peripheral is not allowed. 1 **ALLOWED** — Access to peripheral is granted.
0 RARA	Resource Access Right. Control and Status bit for master A. This field indicates whether master A can access the peripheral. From 0 up to 3 masters can have permission to access a resource (all the master can be granted on a peripheral, but only one access at a time will be granted by SPBA). 0 **PROHIBITED** — Access to peripheral is not allowed. 1 **ALLOWED** — Access to peripheral is granted.

4.9 TrustZone Address Space Controller (TZASC)

4.9.1 Overview

The TrustZone Address Space Controller (TZASC) protects security-sensitive SW and data in a trusted execution environment against potentially compromised SW running on the platform.

The TZASC block diagram is shown in figure below.

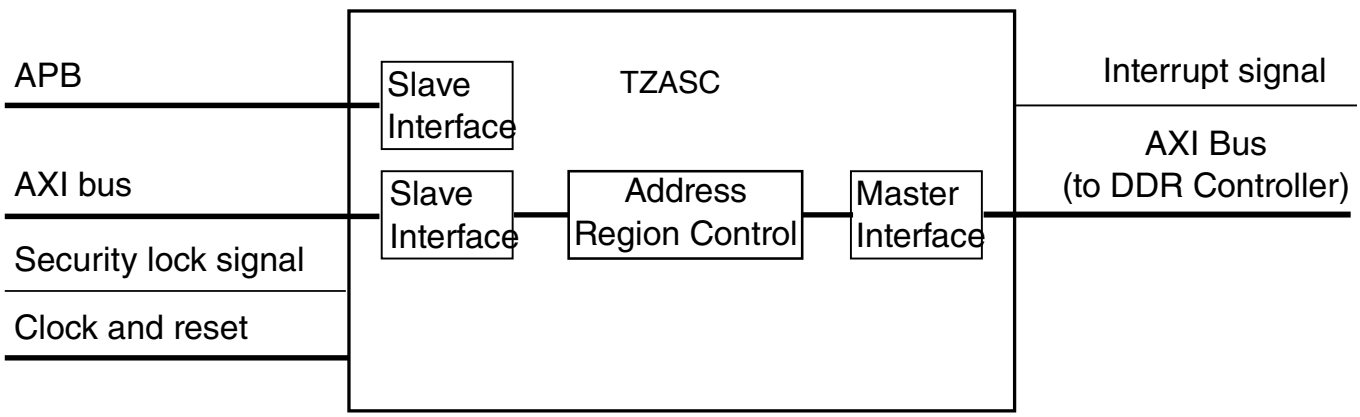


Figure 4-19. TZASC Block Diagram

The TZASC is an IP by Arm ("CoreLink™ TrustZone Address Space Controller TZC-380"), designed to provide configurable protection over program (SW) memory space.

The main features of TZASC are:

- Supports 16 independent address regions
- Access controls are independently programmable for each address region
- Sensitive registers may be locked
- Host interrupt may be programmed to signal attempted access control violations
- AXI master/slave interfaces for transactions
- APB slave interface for configuration and status reporting

NOTE

In this device it is necessary to set TZASC_ID_SWAP_BYPASS in IOMUXC_GPR10[1] to avoid an AXI bus error when using GPU.

4.9.2 Clocks

The table found here describes the clock sources for TZASC.

Table 4-25. TZASC Clocks

Clock name	Clock Root	Description
aclk	ccm_clk_root	Module clock

4.9.3 Address Mapping in various memory mapping modes

The TZASC region base address starts at the beginning of DDR memory space (0x40000000) instead of the beginning of memory map (0x00000000). In this case the addresses configured in TZASC controller will be 1GB (0x40000000) offset and does not match the local addresses.

For example, setting region_setup_low_x=0xBE000000 maps DDR_ADDR=0xFE000000, the same behavior is observed with fail_address_x registers.

Memory "aliasing" implications on TZASC settings - in systems which does not utilize the maximal supported DDR space the controller is designed for, the whole DDR memory map becomes "aliased" (replicated) by the size of the physical memory used. In such cases, the TZASC must be configured to protect all aliased regions as well (i.e. effectively reducing the number of available TZASC regions, since all aliased regions must be handled, for each "real" space needing protection).

For complete details on TZASC functionality and the programming model, see the Arm document, “CoreLink™ TrustZone Address Space Controller TZC-380 Technical Reference Manual, (Rev r0p1 or newer)”, available at **http://infocenter.arm.com**.

4.10 System Debug

4.10.1 Debug

4.10.1.1 Debug Architecture

The chapter describes the debug architecture of the chip.

4.10.1.2 Debug System Features

The chip debug is based on Arm's CoreSight platform, with support for Quad-core A53 platform and Cortex-M4 core. The key features of the debug system include:

- Support 5-pins(JTAG) interface.
- Support both non-intrusive and halt-mode trace/debug options.
- MDM-AP registers for debugger to control mutli-core halt/resume cores.
- Trace Memory Controller (TMC) is used to enable capturing trace.
- 4KB in SOC trace block.
- ETR is used to allow routing trace data to system memory.
- Support ARM real time trace interface (TPIU) 16-bit @133MHz.
- Support cross trigger between Quad Cortex-A53 and Cortex M4.
- 4 JTAG security levels, via SJC security functions together with e-Fuse (challenge response, field return, intrusive detection)

4.10.1.3 System level debug architecture

The debug architecture is shown in the following figure:

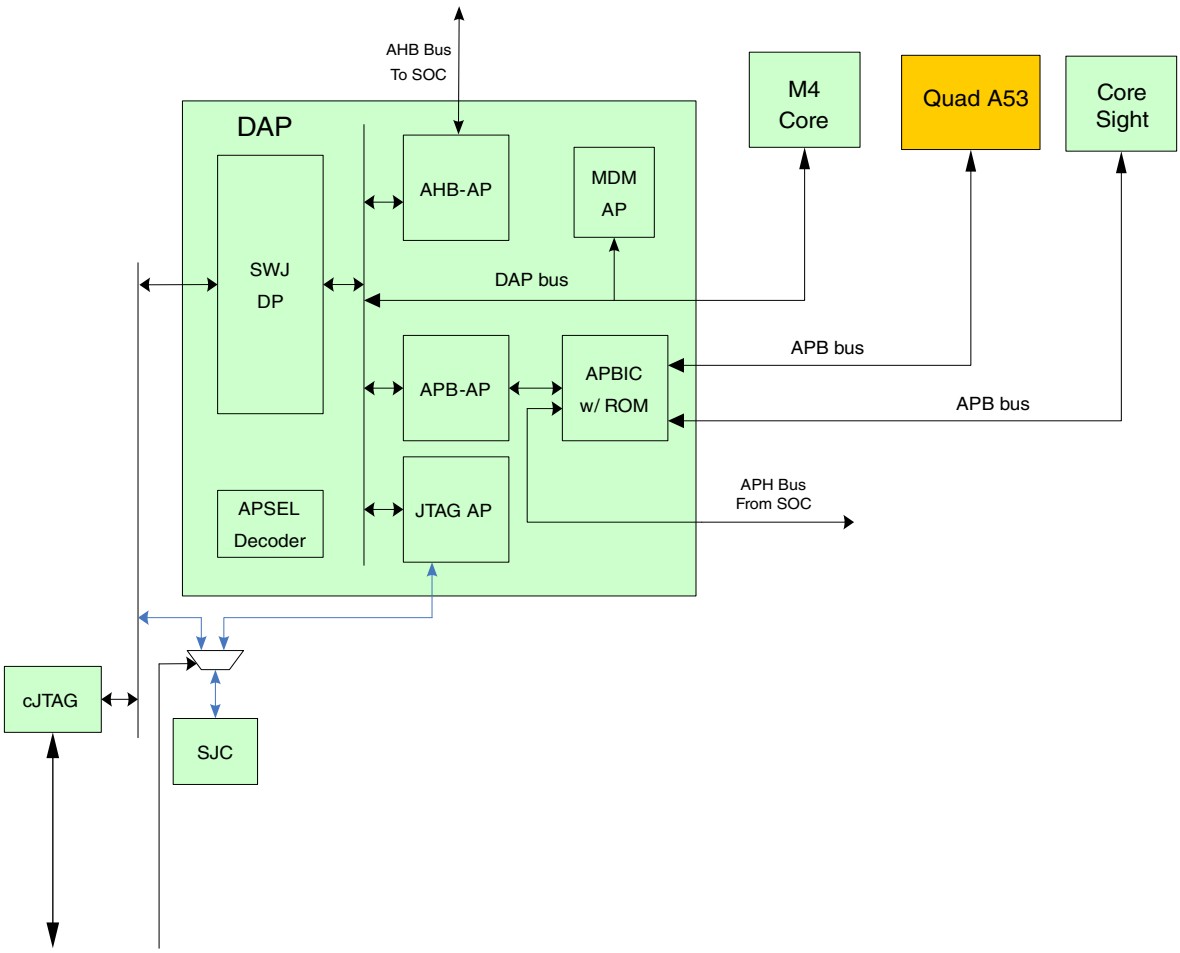

Figure 4-20. Debug Architecture Diagram

4.10.1.4 Functional description

This section gives a brief overview of the modules that are implemented within the Cortex-M/Cortex-A Core Platform. The debug blocks are part of the overall CoreSight platform debug system, which include the ETR, CTM, CTI, ATB replicator, APB address decode, TPIU and DAP. The CoreSight™ compatible Embedded Trace Macrocell (ETM) enables traces of program flow to be collected, compressed, and fed into the trace infrastructure. The Cross Trigger Interface (CTI) is included to provide a common programming model for use by the debug tools, control the trigger sources, and interface to the Cross Trigger Matrix (CTM). The debug is controlled via an ARM Debug Access Port (DAP).

4.10.1.4.1 Embedded Trace Router (ETR)

The Embedded Trace Router (ETR) is a CoreSight trace component which buffers trace data before dumping that data into DRAM through the AXI bus (via AXI master port). The output of the funnel is the ETR, and has the ability to buffer a certain amount before writing the data to DRAM.

4.10.1.4.2 Embedded Trace Macrocell (ETM)

The Embedded Trace Macrocell (ETM) is a CoreSight component. The ETM trace unit is a module that performs real-time instruction flow tracing based on the Embedded Trace Macrocell (ETM) architecture ETMv4.

4.10.1.4.3 Cross Trigger Matrix (CTM)

The CoreSight CTI channel signals from all the cores are combined using a Cross Trigger Matrix (CTM) block so that a single cross trigger channel interface is presented in the Cortex processor. This module can combine four internal channel interfaces corresponding to each core along with one external channel interface.

In the Cortex processor CTM, the external channel output is driven by the OR output of all internal channel outputs. Each internal channel input is driven by the OR output of internal channel outputs of all other CTIs in addition to the external channel input.

4.10.1.4.4 Cross Trigger Interface (CTI)

The Cortex processor has a single external cross trigger channel interface. This external interface is connected to the CoreSight Cross Trigger Interface (CTI) interface corresponding to each core through a Cross Trigger Matrix (CTM). A number of Embedded Cross Trigger (ECT) trigger inputs and trigger outputs are connected between debug components in the Cortex-A processor and CoreSight CTI blocks.

The CTI enables the debug logic, ETM trace unit, and performance monitoring, to interact with each other and with other CoreSight components. This is called cross triggering. For example, you configure the CTI to generate an interrupt when the ETM trace unit trigger event occurs.

4.10.1.4.5 AMBA Trace Bus Interface (ATB)

The AMBA Trace Bus (ATB) CoreSight debug components are part of the Trace stream block. The ATB components consist of the ATB Funnel and ATB Replicator. The ATB Funnel is used to merge several streams together to produce a single output to the ATB Replicator. The ATB Replicator enables two trace sinks to be wired together and receive ATB trace data from the same trace source.

4.10.1.4.6 Advanced Peripheral Bus Interface (APB)

The APB asynchronous interface / bridge connects several debug components. Each component has a single separate APB interface from the APB-IC (w/ ROM), which hooks up to a separate APB asynchronous component. The APB interface connects the core debug functions to the DAP.

4.10.1.4.7 Instrumentation Trace Macrocell (ITM)

The Instrumentation Trace Macrocell (ITM) is a application-driven trace source that supports printf style debugging to trace operating system and application events. The ITM generates diagnostic system information as packets. Multiple sources can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. These sources in decreasing order of priority are:

- **Software trace.** Software can write directly to ITM stimulus registers to generate packets.
- **Hardware trace.** The DWT generates these packets, and the ITM outputs them.
- **Time stamping.** Timestamps are generated relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M4 clock or the bitclock rate of the Serial Wire Viewer (SWV) output clocks the counter.

4.10.1.4.8 Data Watchpoint and Trace (DWT)

The Data Watchpoint and Trace (DWT) debug unit provides watchpoints, data tracing, and system profiling for the processor.

4.10.1.4.9 Debug Access Port (DAP)

The Debug Access Port (DAP) is a physical port that connects to external debug tools. The DAP is part of the standardized ARM Debug Interface, and provides a bridge between a JTAG pin interface and on-chip memory mapped peripherals via the DAP bus. Transactions generated by the DAP are referred to as External Debugger Accesses.

4.10.1.5 JTAG topology

There is only one JTAG on the chip, and two JTAG modes are supported. Select via the JTAG_MOD pin.

- Debug mode: JTAG_MOD == 0, DAP is the only TAP controller in the daisy chain. SJC will be attached to JTAG-AP of DAP.
- Test mode: JTAG_MOD == 1, SJC is the only TAP controller in the daisy chain. 1149.1-compliant, and support 1149.6 AC coupled test.

When the JTAG interface is in Debug Mode, it can be operating in standard 5-pin JTAG interface. cJTAG/SWD interface can be supported by the IP, but since they are not needed by the targeted application, they will not be supported by this chip.

4.11 System JTAG Controller (SJC)

4.11.1 Overview

The System JTAG Controller (SJC) provides debug and test control with the maximum security.

The test access port (TAP) is designed to support features compatible with the IEEE Standard 1149.1 v2001 (JTAG).

The figure below shows an overview of the JTAG architecture.

Figure 4-21. System JTAG Controller (SJC) Block Diagram

4.11.1.1 Features

The System JTAG Controller (SJC) provides the following capabilities:

- JTAG IEEE1149.1 mandatory instructions, see EXTEST Instruction, SAMPLE/ PRELOAD Instruction , and BYPASS Instruction .
- JTAG IEEE1149.1 optional instructions, see ID_CODE Instruction (IDCODE) , and HIGHZ Instruction.
- JTAG IEEE P1149.1 (standard JTAG) interface to off-chip test and development equipment including an SJC-only mode for true IEEE 1149.1 compliance, used primarily for board-level implementation of boundary scan.

- IEEE P1149.6 (JTAG) mandatory instructions, see EXTEST_PULSE instruction and EXTEST_TRAIN instruction. These two instructions enable edge-detecting behavior on the signal path containing AC pins.
- Debug-related control and status, such as putting selected cores into reset and/or debug mode and the ability to monitor individual core status signals via JTAG.
- Provides means for accessing each OnCE/ICE TAP controller independently to control a target system (see Modes of Operation).
- ExtraDebug logic (see ENABLE_ExtraDebug Instruction).
- The maximum clock speed of the SJC is one-eight of the lowest frequency of the accessed OnCE/ICE. For example in normal operation (no core in low-power mode), this frequency is one-eight of the SDMA frequency if this core is present in the TDI-TDO chain (serially connected with other cores or standalone). The user must also consider the 25 MHz frequency limitation on the CE bus.
- Core compliant modes to support standalone core debuggers (see Modes of Operation).
- Multi-cores daisy chained mode (default one) to support multi-core debuggers (see Modes of Operation).

Detailed information about the SJC is provided in the Security Reference Manual. Contact your NXP representative for information about obtaining this document.

4.11.1.2 Modes of Operation

The SJC modes are controlled through both the TAP select register (SJC_TSR) and the MOD input port.

The MOD port (typically connected to pad of the same name) selects between two possible topologies of TAP connections, as seen at SoC level:

- Negating it (this should be the default state) selects all the TAPs (SJC, SDMA, DAP and Arm/ETM) to be connected in the TDI-TDO chain, which is referred to as "daisy chain" mode, throughout this chapter.
- Asserting it only selects the SJC TAP to be connected in the TDI-TDO chain.

IEEE1149.1 standard features are enabled by configuring the SJC input pin: MOD. Refer to the following table for MOD settings details:

Table 4-26. SJC Modes

MOD	Name	Description
0	Daisy chain ALL	For common SW debug (High speed and production)
1	SJC only	IEEE 1149.1 JTAG compliant mode

The following figure shows the SJC mode selection flow. The numbers shown in parenthesis below each block name indicates the TAP's IR length.

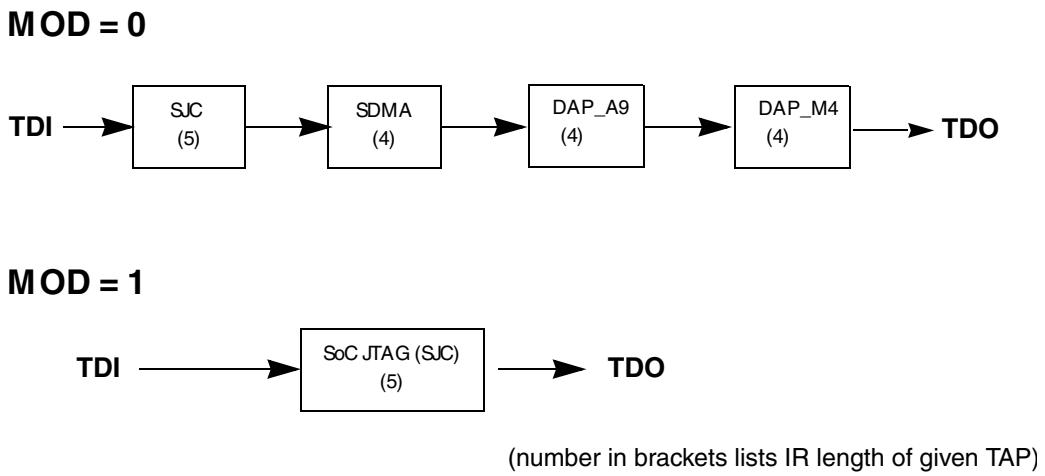

Figure 4-22. SJC Mode Selection Using MOD Pin Sampling

The Connect SDMA bit inside TAP select register controls the SDMA TAP bypass.

- When negated (should be the default state), the SDMA TAP is bypassed with a single D-FF (Flip-flop) during Shift-Dr path
- When asserted SDMA TAP is connected inside the chain
- When taking the SDMA into bypass or out of bypass (by writing to tapsel reg), additional cycle with TMS '0' should be given

The TAP selection block (TSB) provides a simple method of integrating various pieces of IP that have embedded TAPs.

- Provides a way to connect up multiple TAPs within a single SoC
- Identify the SJC TAP as the master TAP which controls the boundary chain (for IEEE 1149.1 standard compliance)
- Follow the state of SJC TAP, and when the Test-Logic-Reset (TLR) state is reached, reset all TAPs

The figure below shows the TAP Selection Block and SOC TAP Chain Scheme.

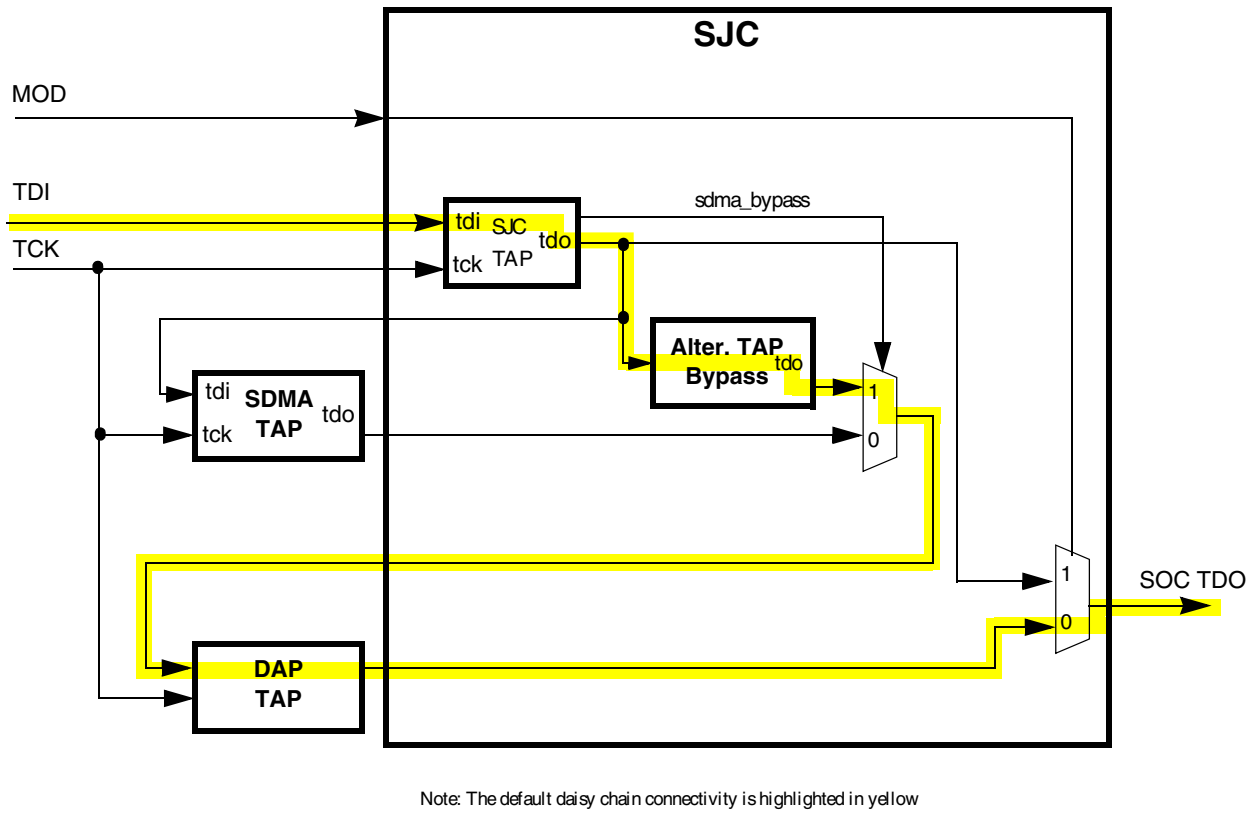

Figure 4-23. TAP Selection Block and SoC TAP Chain Scheme

NOTE

It is the responsibility of the user to ensure that in any configuration of the TAP controllers chosen, all of the TAPs in the chain comply with the demands of TCK clock frequency as well as the required ratio between TCK clock frequency and that of the core's to which the TAP refers.

4.11.2 TAP Selection Block (TSB)

As described in Modes of Operation, the SJC can access cores in different modes selected through a TSB.

4.11.2.1 Select Mode Using Software

Conceptually, the SJC_TSR is a data register which is accessed through Access TSR IR instruction of SJC TAP.

The following figure shows the process of using reserved IR to access the SJC_TSR.

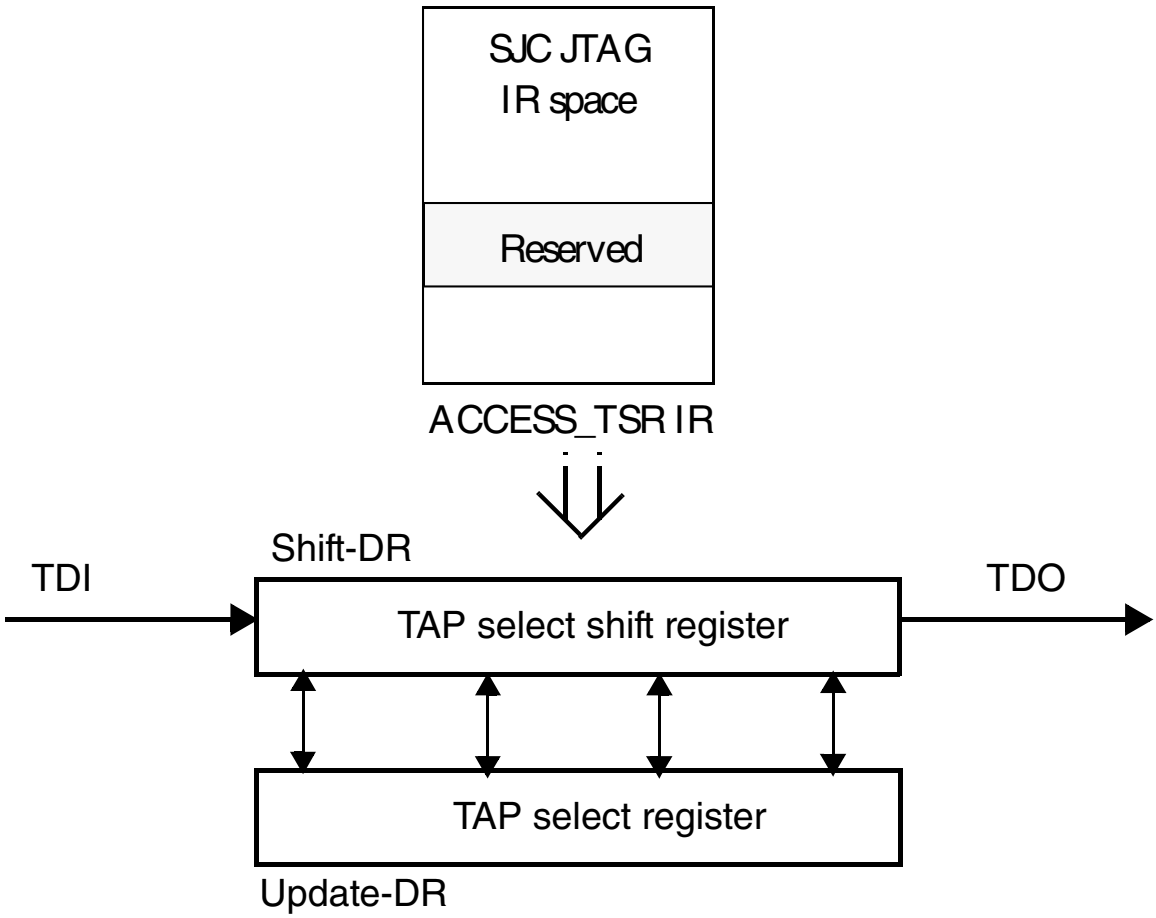

Figure 4-24. Using Reserved IR to Access the TAP Select Register (SJC_TSR)

The SJC_TSR can only be changed during the update-DR state of the TSB JTAG state machine. This is necessary to prevent a TAP that is being selected from losing synchronization with the TSB state machine when the TSB state machine returns to run-test-idle. Therefore, an associated shift register for the SJC_TSR is loaded into the SJC_TSR during the update-DR state (see the figure above). The shift register must also capture the state of the SJC_TSR when in the Capture-DR state for visibility of the contents of the SJC_TSR. See TAP Select Instruction , for more information.

4.11.3 Boundary Scan Register (BSR)

The Boundary Scan Register (BSR) in the JTAG implementation contains bits for all device signal and clock pins and associated control signals.

All SoC bidirectional pins have a single register bit in the boundary scan register for pin data, and are controlled by an associated control bit in the boundary scan register.

4.11.4 SoC JTAG Instruction Register (SJIR)

The SoC JTAG Instruction register is provided in the following table. The SoC JTAG Instruction register is 5 bits wide.

Table 4-27. SoC JTAG Instruction Register (SJIR)

Code					SJC IR
B4	B3	B2	B1	B0	
0	0	0	0	0	IDCODE
0	0	0	0	1	SAMPLE/PRELOAD
0	0	0	1	0	EXTEST
0	0	0	1	1	HI-Z
0	0	1	0	0	ENABLE_ExtraDebug
0	0	1	0	1	ENTER_DEBUG (secured)
0	0	1	1	0	Reserved
0	0	1	1	1	TAP select
0	1	0	0	0	EXTEST_PULSE
0	1	0	0	1	EXTEST_TRAIN
0	1	0	1	0	Reserved
0	1	0	1	1	Reserved
0	1	1	0	0	Security Output challenge
0	1	1	0	1	Security Enter response
-					Reserved
1	1	1	1	1	BYPASS

The instruction register is reset to 0b00000 in the test-logic-reset controller state which is equivalent to the IDCODE instruction.

During the capture-IR controller state, the parallel inputs to the instruction register are loaded with the code 01 in the least significant bits as required by the standard; the most significant bits are loaded with the values 00, leading to a capture value of 0b00001.

4.11.4.1 ID_CODE Instruction (IDCODE)

Selects the ID register, and the system logic controls the I/O pins. This instruction is provided as a public instruction to allow the manufacturer, part number and version of a component to be determined through the TAP.

The table below shows the ID register configuration.

Table 4-28. ID Configuration Register Description (IDCODE)

Field	Description
31-28 Version Information	IC/SoC Version information number. Initial value: '0000' This number is subject to changes, for new IC/SoC (System On A Chip) revision releases.
27-12 Part Number	Customer Part Number The 16-bit Part Number value is unique for every NXP SoC / IC. See System Debug chapter for exact register value for a specific SoC.
11-1 Manufacturer Identity	Manufacturer Identity NXP Manufacturer Identity code. Bits [11:1] - 00000001110
0	Tied to logic 1.

One application of the ID register is to distinguish the manufacturer(s) of components on a board when multiple sourcing is used. As more components emerge which conform to the IEEE 1149.1 standard, it is desirable to allow for a system diagnostic controller unit to blindly interrogate a board design to determine the type of each component in each location. This information is also available for factory process monitoring and for failure mode analysis of assembled boards.

Once the IDCODE instruction is decoded, it selects the ID register which is a 32 Bit data register. Because the bypass register loads a logic 0 at the start of a scan cycle, whereas the ID register loads a logic 1 into its least significant bit, examination of the first bit of data shifted out of a component during a test data scan sequence immediate following exit from Test-Logic-Reset controller state shows whether such a register is included in the design. When the IDCODE instruction is selected, the operation of the test logic has no effect on the operation of the on-chip system logic as required by the IEEE 1149.1 standard.

4.11.4.2 SAMPLE/PRELOAD Instruction

Selects the boundary scan register and the system logic controls the I/O pins.

The SAMPLE/PRELOAD instruction provides two separate functions:

- First, it provides a means to obtain a snapshot of system data and control signals. The snapshot occurs on the rising edge of TCK in the capture-DR controller state. The data can be observed by shifting it transparently through the boundary scan register.
- The second function of SAMPLE/PRELOAD is to initialize the boundary scan register output cells prior to selection of EXTEST. This initialization ensures that known data appears on the outputs when entering the EXTEST instruction.

NOTE

Because there is no internal synchronization between the JTAG clock (TCK) and the system clock (CLK), the user must provide some form of external synchronization to achieve meaningful results.

For more details on the function and use of SAMPLE/PRELOAD, refer to the appropriate IEEE 1149.1 document.

4.11.4.3 EXTEST Instruction

Selects the boundary scan register, and the 1149.1 test logic has control of the I/O pins.

By using the TAP controller, the register is capable of:

- Scanning user-defined values into the output buffers,
- Capturing values presented to input pins
- Controlling the direction of bidirectional pins,
- Controlling the output drive of tri-statable output pins.

For more details on the function and use of EXTEST, refer to the appropriate IEEE 1149.1 document.

The EXTEST instruction also asserts internal reset for the cores (through CCM, refer to Figure 4-27) to force a predictable internal state while performing external boundary scan operations.

4.11.4.4 HIGHZ Instruction

All output drivers, including the two-state drivers, are turned off (that is, high impedance). The instruction selects the bypass register.

In this mode, all internal pullup resistors on all the pins (except for the TMS, TDI, TCK, TRSTB pins) are disabled. This disabling functionality is not built into SJC, but should be implemented by some logic in the SOC/IO Pads.

For more details on the function and use of HIGHZ, refer to the IEEE 1149.1 document.

The HIGHZ instruction also asserts internal reset for the cores (through CCM, refer to Figure 4-27) to force a predictable internal state while performing external boundary scan operations.

4.11.4.5 BYPASS Instruction

Selects the single Bit bypass register and the system logic controls the I/O pins.

This creates a shift-register path from TDI to the bypass register and, finally, to TDO, circumventing the boundary scan register. This instruction is used to enhance test efficiency when a component other than the SoC Core based device becomes the device under test.

When the bypass register is selected by the current instruction, the shift-register stage is set to a logic zero on the rising edge of TCK in the capture-DR controller state. Therefore, the first bit to be shifted out after selecting the bypass register is always a logic zero.

For more details on the function and use of BYPASS, refer to the appropriate IEEE 1149.1 document.

4.11.4.6 ENABLE_ExtraDebug Instruction

The TDI and TDO pins are connected directly to the ExtraDebug registers, the SJC TAP controller remaining connected to TDI and TMS.

The ExtraDebug shift register consists of 38 bits (maximum) comprising a 32-bits data field (maximum length, see Accessing ExtraDebug Registers,), a 5 bits address field and read/$\overline{\text{write}}$ bit. On a register read, the data field does not need to be filled in. The particular ExtraDebug register connected between TDI and TDO at a given time is selected by the ExtraDebug controller depending on the ExtraDebug Address being currently decoded. All communication with the ExtraDebug controller is done through the Select-DR-Scan path of the JTAG TAP Controller.

4.11.4.7 ENTER_DEBUG instruction

The ENTER_DEBUG instruction is used to generate a debug request event to SDMA and the Arm Core Platform simultaneously (practically, inherited minimal skew is expected, due to difference in event signal propagation in the different modules).

The TDI and TDO are connected to the Instruction Register (IR). After the acknowledgment of the Debug Mode is received (can be checked by reading the Core Status Register part of the ExtraDebug logic), the user can perform system debug functions on the cores.

NOTE

The ENTER_DEBUG event issue to the cores, can be masked, by bits in DCR register.

NOTE

It is user's responsibility to shift-in another IR value (like IDCODE) before trying to bring the cores out of debug mode, as the debug request signals to the cores remains asserted as long as ENTER_DEBUG IR is in place.

NOTE

The user need to check that cores are in debug mode (watching debug acknowledge signal) before leaving ENTER_DEBUG instruction, otherwise debug request might not take affect.

4.11.4.8 TAP Select Instruction

By means of TAP select instruction a user can access TAP select register and by controlling its only bit SDMA Bypass, control whether SDMA TAP is bypassed or not.

Table 4-29. TAP Select Register (TSR)

	TAP Select Register
	BIT 0
	Connect SDMA
TYPE	rw
RESET	0
Note:	

Table 4-30. TAP Select Register Description

Field	Description
0 SDMA Bypass	Connect SDMA Control whether SDMA TAP is bypassed or not: • 0 - SDMA TAP is bypassed by the alternate TAP inside SJC (emulating 4-bit IR and 1-bit bypass path). • 1 - SDMA TAP is connected to the TDI-TDO chain. **NOTE:** Additional cycle with TMS '0' should be inserted, after writing to this register, to allow the SDMA tap be sync before SDMA get into / out of bypass.

4.11.4.9 EXTEST_PULSE instruction

The EXTEST_PULSE instruction implements test behaviors for AC pins and simultaneously behaves identically to IEEE Std 1149.1 EXTEST for DC pins.

4.11.4.10 EXTEST_TRAIN instruction

The EXTEST_TRAIN instruction implements test behaviors for AC pins and simultaneously behaves identically to IEEE Std 1149.1 EXTEST for DC pins.

4.11.5 Security

JTAG manipulation is one of the known hackers' ways of executing unauthorized program code, getting control over the OS and run code in privileged modes.

The SJC provides a debug access to several H/W blocks including the Arm processor and the system bus. This allows for program control and manipulation as well as visibility into system peripherals and memory. The ETM and NEXUS interfaces allow bus transactions to be traced. Together these tools provide the hacker all the access needed to completely comprise the system. Means must be provided to block any malicious JTAG access.

The SJC provides a way of regulating the JTAG access.

The following are the different JTAG security modes:

- **Mode #1: No Debug**-Maximum Security. All security sensitive JTAG features are permanently blocked.
- **Mode #2: Secure JTAG**-High security. JTAG use is regulated by secret key based authentication mechanism.
- **Mode #3: JTAG Enabled**-Low security. JTAG always enabled.

The JTAG security modes are configured using eFUSEs which can burned after packaging by applying electrical signals. The fuse burning is irreversible process, once a fuse is burned (e-fuse or laser fuse) it is impossible to change the fuse back to the un-burned state.

4.11.5.1 JTAG Security Modes

JTAG can be in one of JTAG security modes which is selected by setting the SJC eFUSE configuration. The physical location of the fuses is not in the SJC.

4.11.5.1.1 Mode 1: No Debug - Maximum Security

No Debug JTAG security mode provides the highest security level.

In this mode, all JTAG features are disabled except for:

- ScanBoundary Scan
- PLL bypass- Bypass Arm or/and USB PLL.
- Visibility of the following status bits: power mode - normal, standby, stop, shutdown, and so on

These features do not reduce the security level of the product, and they allows to perform important tests and board connectivity checks.

4.11.5.1.2 Mode 2: Secure JTAG - High Security

The Secure JTAG mode limits the JTAG access by using challenge/response based authentication mechanism. Any access to JTAG port is being checked. Only authorized debug devices (that is, devices having the right response) can access the JTAG, unauthorized JTAG access attempts are denied.

The intent of this mode is to allow return field testing. When a secured JTAG device is being returned for debugging, this mode allows authorized re-activation of the JTAG.

4.11.5.1.2.1 Challenge/Response Mechanism in System JTAG Mode

When SJC is in Sysytem JTAG mode the authentication process is as follows:

1. Shift Output Challenge instruction to IR.
2. Passing through Capture-DR state of the SJC and by performing Shift-DR operations Challenge code can be accessed from TDO.
3. Shift Enter Response instruction to IR. By performing Shift-DR, operations enter Response code value through TDI. As Update-DR state is entered, Response code is compared with the correct one.

In Fixed challenge-response pair mode, each part has its individual challenge - response pair which is determined at manufacturing time, and does not change later on. The SJC compares the user's response to the expected response.

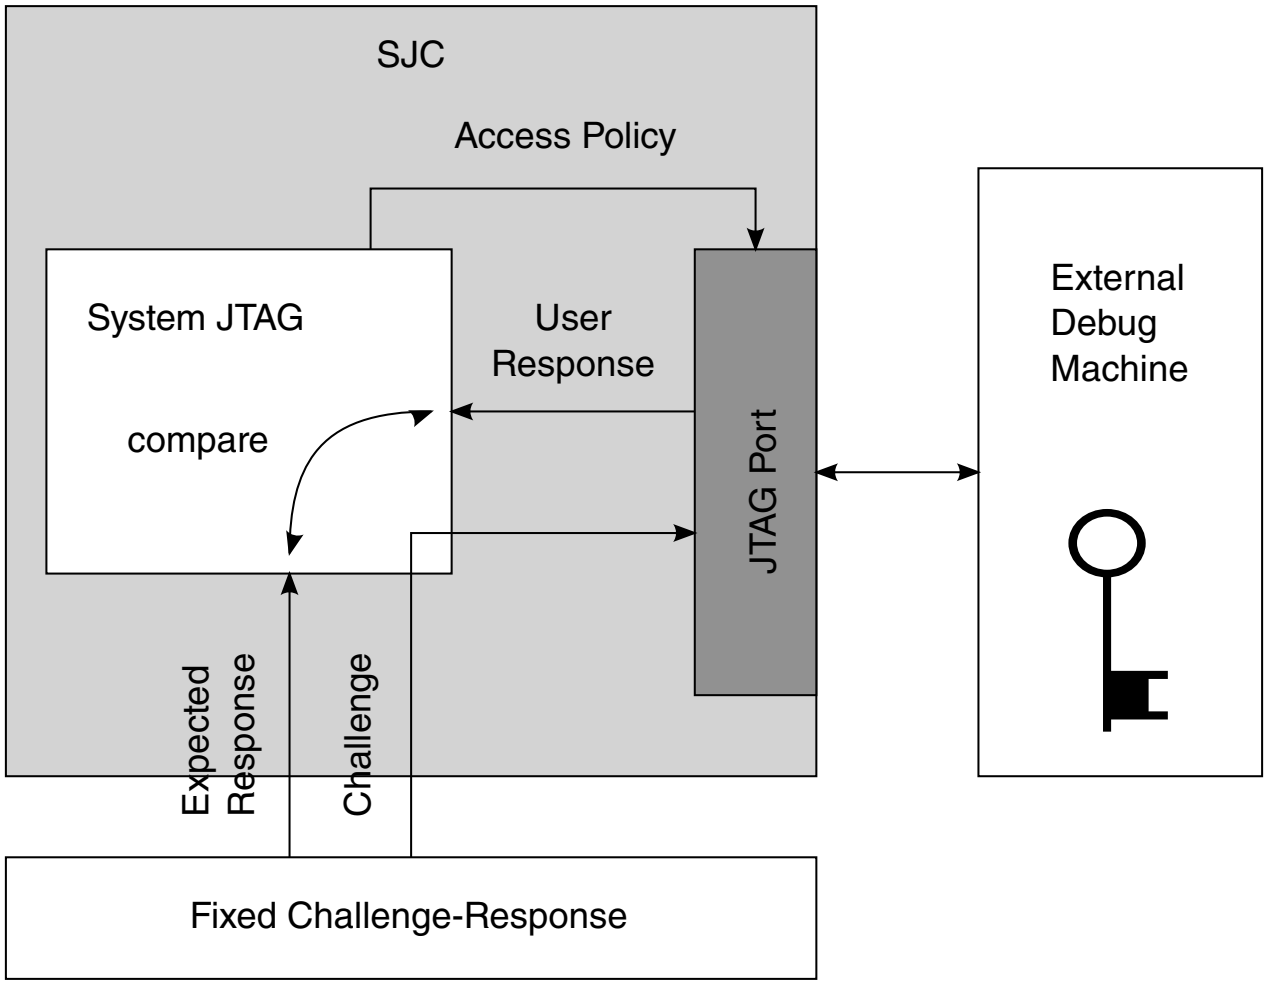

Figure 4-25. Mode #2 - Secure JTAG with Fixed Challenge-response Pair

4.11.5.1.3 Mode 3: JTAG Enabled - Low Security

In the JTAG Enabled JTAG security mode, all JTAG features are enabled.

4.11.5.2 Software Enabled JTAG

To increase the flexibility of the SJC, an option to enable the JTAG via software is added and is available only in Secure JTAG mode. By writing '1' to HAB_JDE (HAB JTAG DEBUG ENABLE) bit in the e-fuse controller module, the JTAG is opened, regardless of its security mode. It is the responsibility of software to assert or negate this bit.

Additionally, a corresponding lock bit is available (in the e-fuse control module) to ensure that only trusted software is able to set the JDE bit. When the LOCK bit is set, no future change of JDE is possible, until the next POR (power-on-reset) cycle.

The platform initialization software should set the LOCK bit for JDE bit before transferring control to the application code.

The S/W JTAG enable allows JTAG enabling without activating the challenge-Response mechanism (which requires JTAG access tool enhancement or special H/W). The JTAG S/W enable does not allow debug in case of boot or memory fault as it requires reset before entering debug.

This feature can be permanently blocked by burning the dedicated e-fuse.

NOTE

The S/W enabled JTAG feature reduces the overall security level of the system as it relies on S/W protections. If this feature is not required, it is strongly recommended to burn the JTAG_HEO e-fuse which disables this feature.

4.11.5.3 Kill Trace

The kill trace signal disables any output of the ETM block. The ETM can be accessed either via JTAG port and/or by direct software code. Blocking the JTAG port also yields assertion of the kill trace signal. This resulted in blocking of trace port. The intention of this action is to block any attempt to break into the system via software manipulation of the debug modules. The kill trace, when active, prevents trace output even in case where it can be activated via chip pin.

The kill trace feature needs to be activated by burning a dedicated e-fuse. If the fuse is left intact, kill trace is never activated as seen in Figure 4-26.

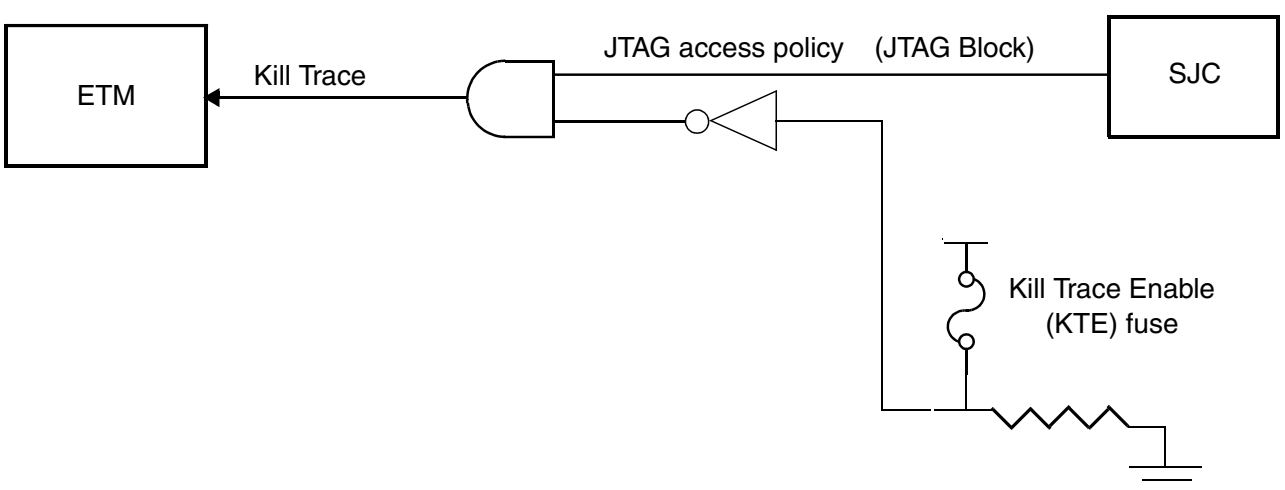

Figure 4-26. Kill Trace eFUSE

The kill trace is asserted when "kill trace enable" fuse is burned and "ipt_secur_block" signal in SJC is asserted, which happens when at least one of the following is true:

- Mode #2 (Secure JTAG) and no code has been entered
- Mode #2 (Secure JTAG) with burned Bypass and Re-enable fuses
- Mode #2 (Secure JTAG) with incorrect response entered
- Mode #1 (No debug)
- TRST_B signal is active
- POR has not ever been asserted

4.11.5.4 SJC Disable Fuse

In addition to the different JTAG security modes that are implemented internally in the System JTAG Controller (SJC), there is an option to disable the SJC functionality by eFUSE configuration. This creates additional JTAG mode that is, JTAG Disabled with highest level of JTAG protection. In this mode all JTAG features are disabled.

Specifically, the following debug features are disabled in addition to the features that were already disabled in No Debug JTAG mode:

- Boundary scan register (SJC_BSR)
- Non-Secure JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secure JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

4.11.6 Functional Description

This section provides a complete functional description of the block.

4.11.6.1 Static Core Debug

The SJC JTAG TAP controller is fully compatible with the IEEE 1149.1a-2001 Standard Test Access Port and Boundary Scan Architecture specifications.

The Arm platform has an integrated JTAG interface and a TAP controller to manage its own ICE. Also it can access an embedded trace ETM interface, see Arm core and ETM Technical reference guide for more information.

The SDMA has a TAP controller to manage its own OnCE, see SDMA OnCE specifications for more details.

The OnCE and ICE provide a mean of interacting with the cores and their peripherals non-intrusively so that a user may examine registers, memories to facilitate hardware and software development. Refer to TAP Selection Block (TSB), for more information.

4.11.6.2 Reset Mechanism

The following figure shows the SJC reset logic

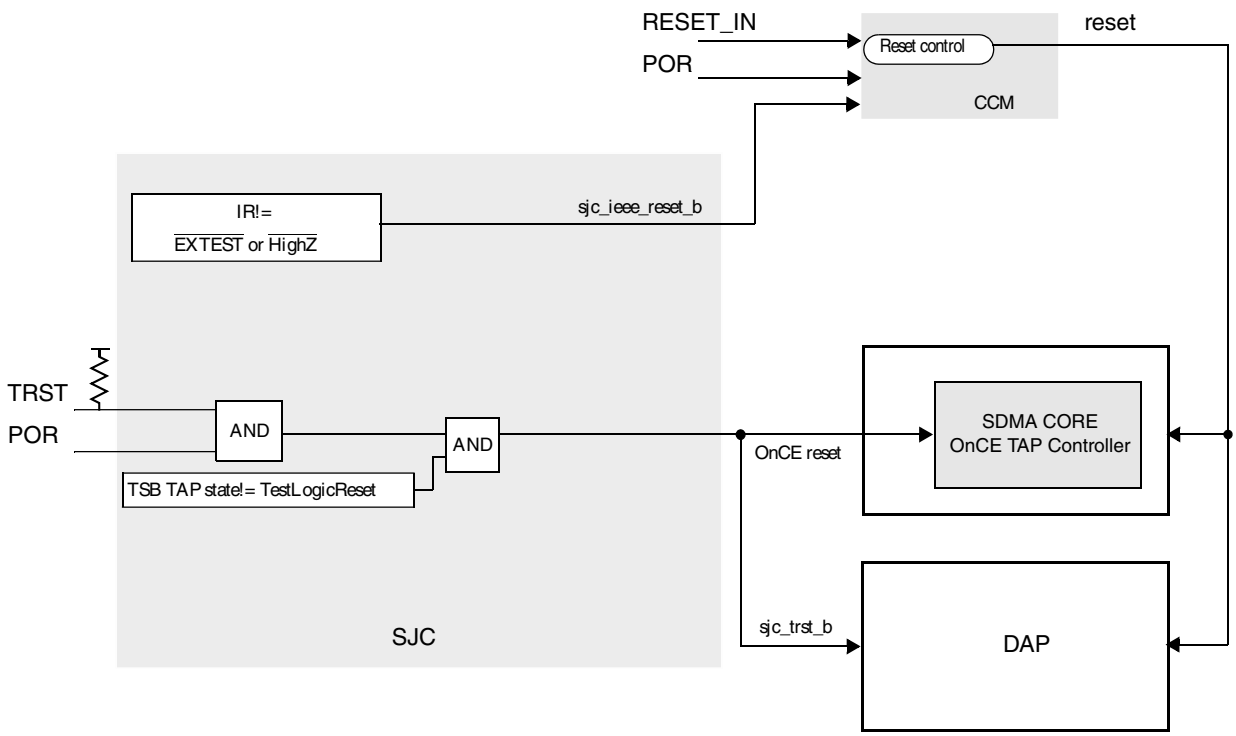

Figure 4-27. SJC Reset Logic

NOTE

- Asserting TRSTB in any scan mode resets the TCR loosing the testmode configuration and selects default TAP.
- SJC generates an IEEE reset signal to the CCM when in one of the IEEE modes HIGHZ or EXTEST. This signal generates a system reset to the cores until exit from one of these modes.
- The TSB generates Once/ICE reset (either TRSTB if implemented or other) when its TAP state reaches Test-Logic-Reset (meaning that TAP accessed is also reaching Test-Logic-Reset).

4.11.7 Initialization/Application Information

The control afforded by the output enable signals using the boundary scan register and the EXTEST instruction requires a compatible circuit-board test environment to avoid device-destructive configurations. The user must avoid situations in which the SJC output drivers are enabled into actively driven networks.

There are two constraints related to the JTAG interface:

- Ensure that the JTAG test logic is kept transparent to the system logic by forcing TAP into the Test-Logic-Reset controller state. During power-up, SJC's internal TRSTB is asserted as IC's POR_B is asserted which forces the TAP controller into this state. After that, if TMS either remains unconnected or is connected to VCC, then the TAP controller cannot leave the Test-Logic-Reset state, regardless of the state of TCK.
- DE_B is an IO pin with pullup and care must be taken of the direction when driving this signal.

4.11.8 SJC Memory Map/Register Definition

In addition to the standard accessible JTAG registers (per IEEE1149.1 standard) listed in SoC JTAG Instruction Register (SJIR) , the chip contains the following registers accessed using the ExtraDebug mechanism, controlled via "ENABLE_ExtraDebug" IR instruction.

NOTE

SJC registers are only accessible by JTAG interface. They are not memory mapped to processor address space, so the absolute addresses provided by default in the SJC memory map are not valid.

This section assumes the JTAG controller is accessed in standalone mode or daisy chained (defined by TAP Selection Block) using the appropriate TSB configuration.

See "System Debug" chapter for more details about the general purpose register descriptions that are unique to this chip.

SJC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	General Purpose Unsecured Status Register 1 (SJC_GPUSR1)	32	R	0000_0000h	4.11.8.1/ 249

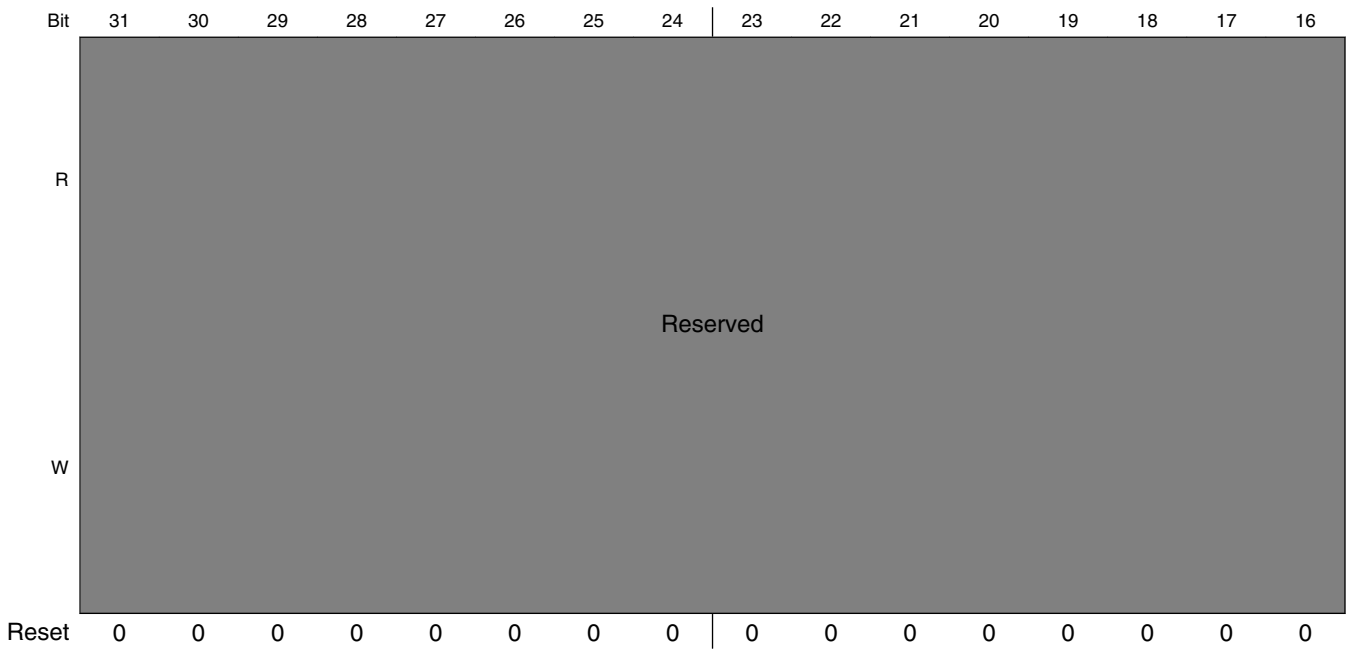
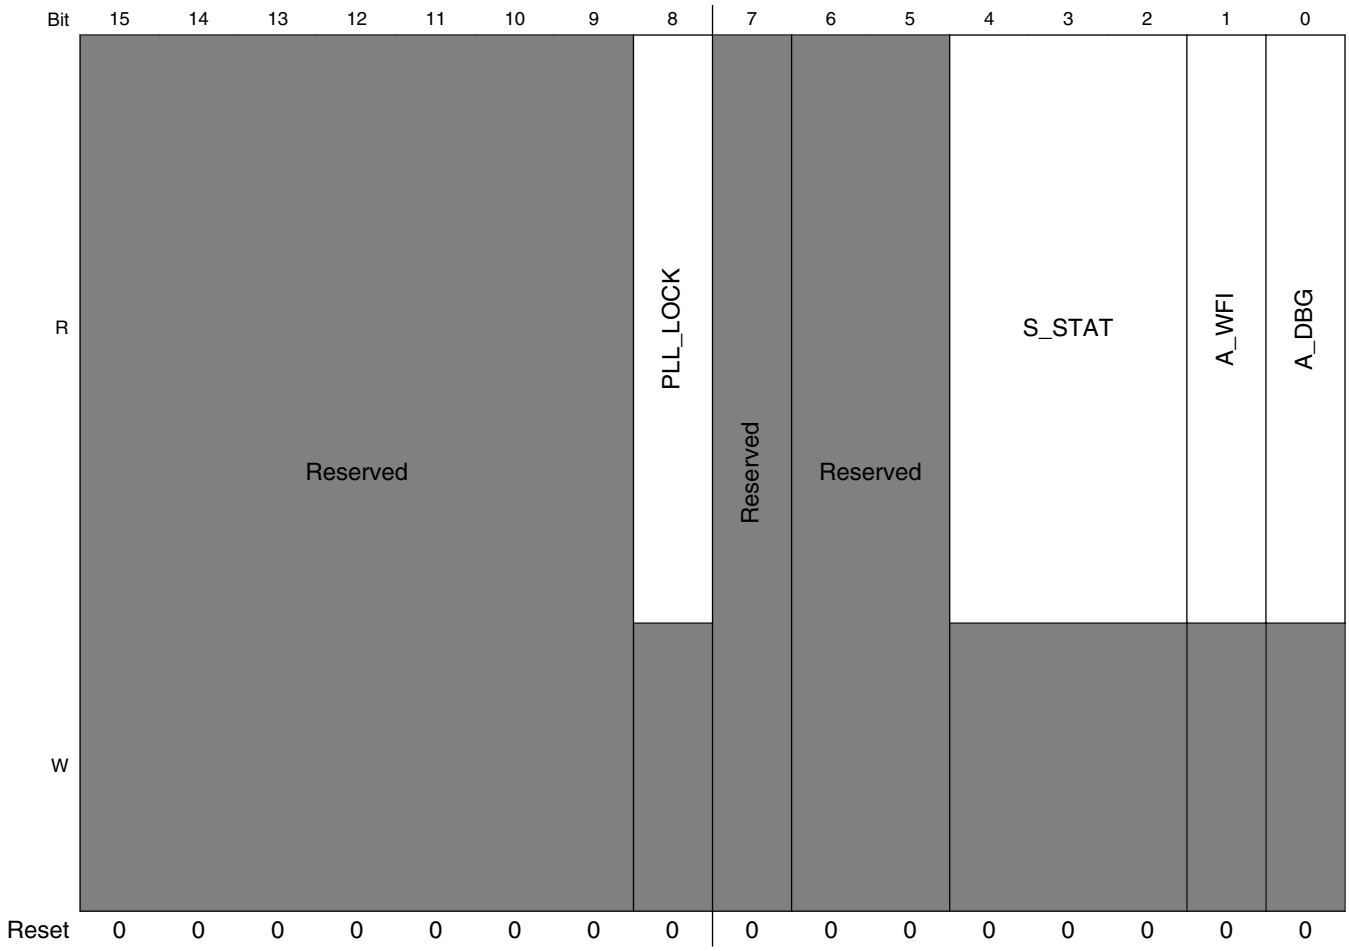
7	General Purpose Clocks Control Register (SJC_GPCCR)	32	R/W	0000_0000h	4.11.8.7/ 258

4.11.8.1 General Purpose Unsecured Status Register 1 (SJC_GPUSR1)

The General Purpose Unsecured Status Register 1 is a read only register used to check the status of the different Cores and of the PLL. The rest of its bits are for general purpose use.

Address: 0h base + 0h offset = 0h



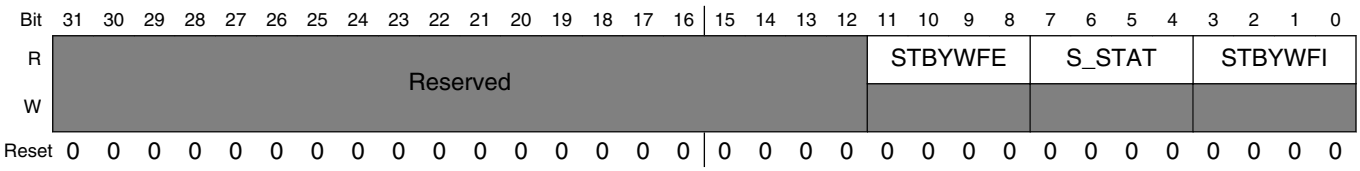


SJC_GPUSR1 field descriptions

Field	Description
31–9 -	This field is reserved. Reserved.
8 PLL_LOCK	PLL_LOCK A Combined PLL-Lock flag indicator, for all the PLL's.
7 -	This field is reserved. Reserved
6–5 -	This field is reserved. Reserved.
4–2 S_STAT	3 LSBits of SDMA core statusH.
1 A_WFI	Arm core wait-for interrupt bit Bit 1 is the Arm core standbywfi (stand by wait-for interrupt). When this bit is HIGH, Arm core is in wait for interrupt mode.
0 A_DBG	Arm core debug status bit Bit 0 is the Arm core DBGACK (debug acknowledge) DBGACK can be overwritten in the Arm core DCR to force a particular DBGACK value. Consequently interpretation of the DBGACK value is highly dependent on the debug sequence. When this bit is HIGH, Arm core is in debug.

4.11.8.2 General Purpose Unsecured Status Register 2 (SJC_GPUSR2)

Address: 0h base + 1h offset = 1h

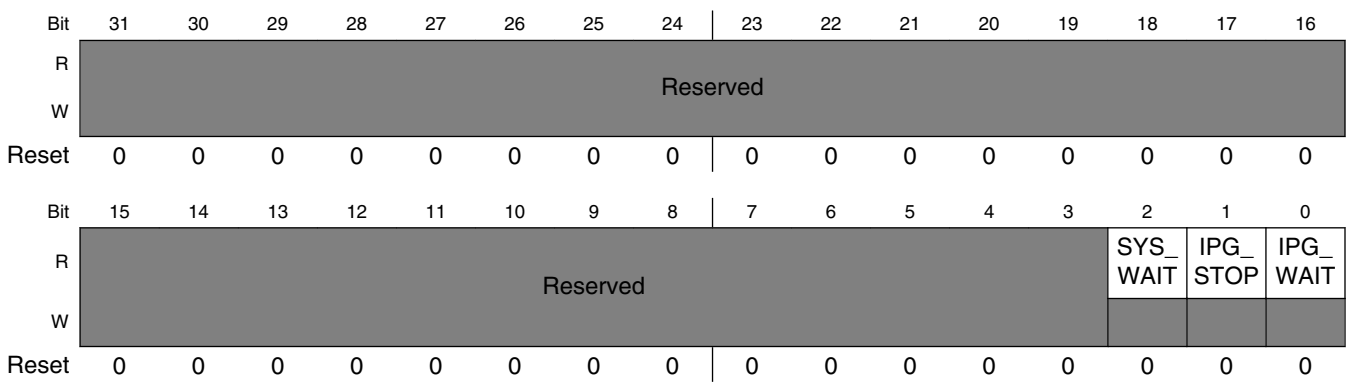


SJC_GPUSR2 field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11–8 STBYWFE	STBYWFE[3:0] Reflecting the "Standby Wait For Event" signals of all cores.
7–4 S_STAT	S_STAT[3:0] SDMA debug status bits: debug_core_state[3:0]
STBYWFI	STBYWFI[3:0] These bits provide status of "Standby Wait-For-Interrupt" state of all Arm cores.

4.11.8.3 General Purpose Unsecured Status Register 3 (SJC_GPUSR3)

Address: 0h base + 2h offset = 2h



SJC_GPUSR3 field descriptions

Field	Description
31–3 -	This field is reserved. Reserved

Table continues on the next page...

SJC_GPUSR3 field descriptions (continued)

Field	Description
2 SYS_WAIT	System In wait Indication on System in wait mode (from CCM).
1 IPG_STOP	IPG_STOP CCM's "ipg_stop" signal indication
0 IPG_WAIT	IPG_WAIT CCM's "ipg_wait" signal indication

4.11.8.4 General Purpose Secured Status Register (SJC_GPSSR)

The General Purpose Secured Status Register is a read-only register used to check the status of the different critical information in the SoC. This register cannot be accessed in secure modes.

Address: 0h base + 3h offset = 3h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GPSSR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

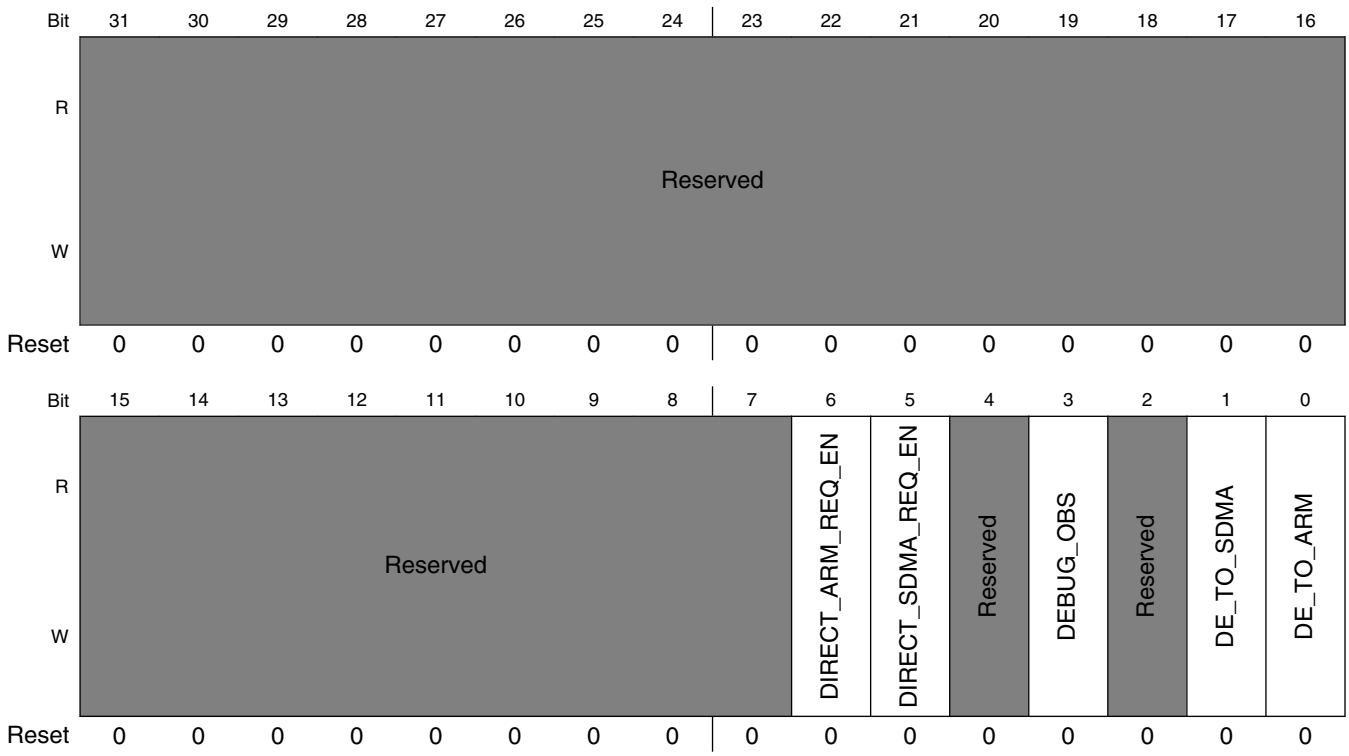
SJC_GPSSR field descriptions

Field	Description
GPSSR	General Purpose Secured Status Register Register is used for testing and debug.

4.11.8.5 Debug Control Register (SJC_DCR)

This register is used to control propagation of debug request from DE_B pad to the cores and debug signals from internal logic to the DE_B pad.

Address: 0h base + 4h offset = 4h



SJC_DCR field descriptions

Field	Description
31–7 -	This field is reserved. Reserved
6 DIRECT_ARM_REQ_EN	Pass Debug Enable event from DE_B pin to Arm platform debug request signal(s). This bit controls the propagation of debug request DE_B to the Arm platform. 0 Disable propagation of system debug to (DE_B pin) to Arm platform. 1 Enable propagation of system debug to (DE_B pin) to Arm platform.
5 DIRECT_SDMA_REQ_EN	Debug enable of the sdma debug request This bit controls the propagation of debug request DE_B to the sdma. 0 Disable propagation of system debug to (DE_B pin) to sdma. 1 Enable propagation of system debug to (DE_B pin) to sdma.
4 -	This field is reserved. Reserved

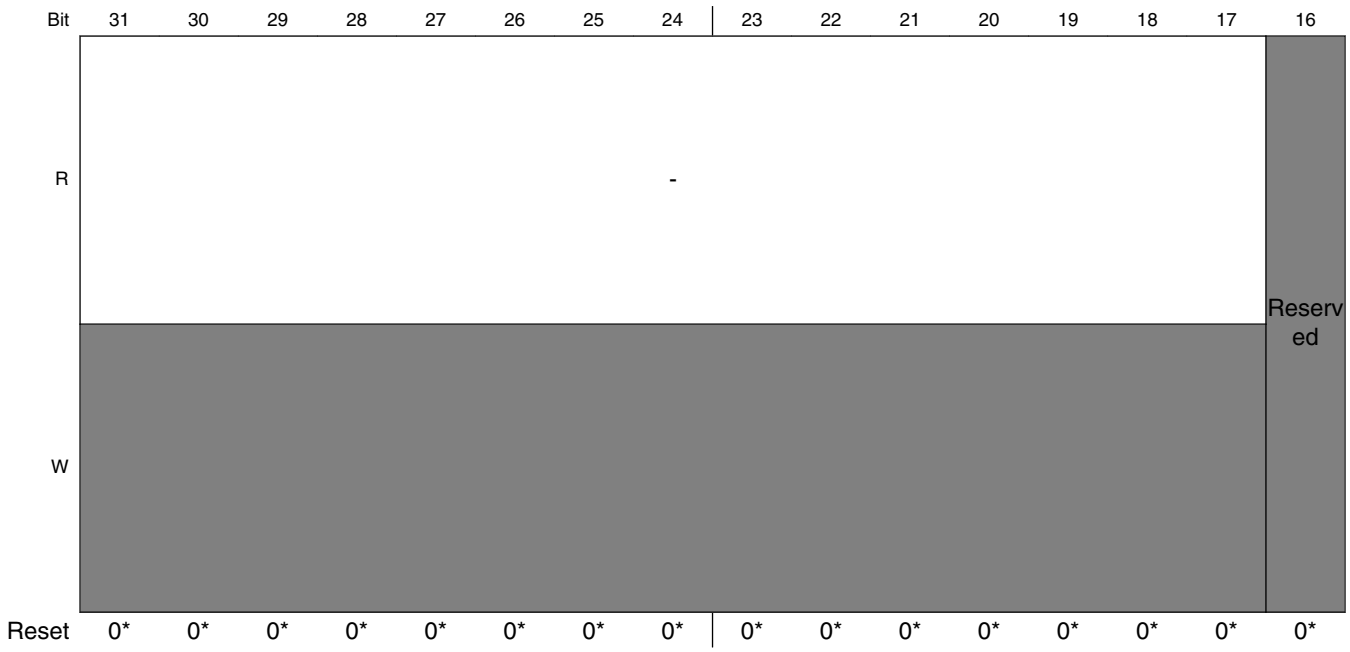
Table continues on the next page...

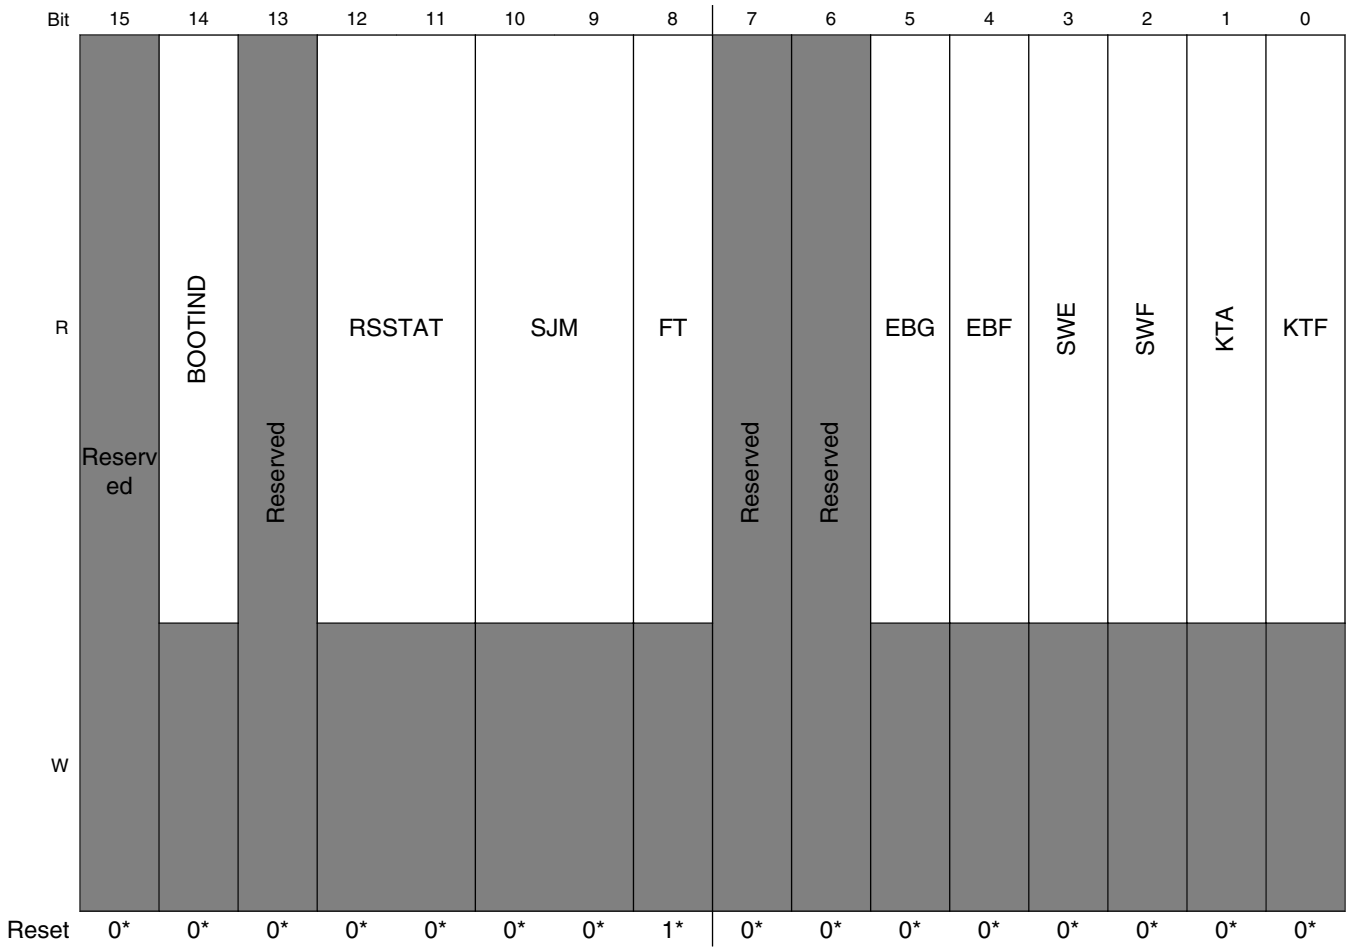
SJC_DCR field descriptions (continued)

Field	Description
3 DEBUG_OBS	Debug observability This bit controls the propagation of the "system debug" input to SJC (driven by the ECT logic), to the DE_B pad. (This logic can be used to pass debug acknowledge event from ECT out to the PAD, for example). The SJC's "system_debug" input is tied to logic HIGH value, therefore, set of "debug_obs" bit, will result in unconditional assertion of DE_B pad. 0 Disable propagation of system debug to DE_B pin 1 Unconditional assertion of pad DE_B
2 -	This field is reserved. Reserved
1 DE_TO_SDMA	SDMA debug request input propagation This bit controls the propagation of debug request to SDMA, when the JTAG state machine is put in "ENTER_DEBUG" IR instruction.. 0 Disable propagation of debug request to SDMA 1 Enable propagation of debug request to SDMA
0 DE_TO_ARM	Arm platform debug request input propagation This bit controls the propagation of debug request to Arm platform ("dbgreq"), when the JTAG state machine is put in "ENTER_DEBUG" IR instruction. 0 Disable propagation of debug request to Arm platform 1 Enable propagation of debug request to Arm platform

4.11.8.6 Security Status Register (SJC_SSR)

Address: 0h base + 5h offset = 5h





* Notes:
- The SJM reset value, reflects the JTAG security state, as defined by status of JTAG_SMODE[1:0] fuses. See the SJM bitfield description for details on valid values.

SJC_SSR field descriptions

Field	Description
31–17 -	Reserved.
16–15 -	This field is reserved. Reserved
14 BOOTIND	Boot Indication Inverted Internal Boot indication, i.e inverse of SRC: "src_int_boot" signal
13 -	This field is reserved. Reserved
12–11 RSSTAT	Response status Response status bits 00 Response wasn't entered 01 Response was entered but not verified

Table continues on the next page...

SJC_SSR field descriptions (continued)

Field	Description
	10 Response was entered and is incorrect 11 Response is correct
10–9 SJM	SJC Secure mode Secure JTAG mode, as set by external fuses. 00 No debug (#1) 01 Secure JTAG (#2) 10 Reserved 11 JTAG enabled (#3)
8 FT	Fuse type Fuse type bit - e-fuse or laser fuse 0 E-fuse technology 1 Laser fuse technology
7 -	This field is reserved. Reserved
6 -	This field is reserved. Reserved
5 EBG	External boot granted External boot enabled, requested and granted 1 granted 0 not granted
4 EBF	External Boot fuse Status of the external boot disable fuse 0 (intact) - external boot is allowed 1 (burned) - external boot is disabled
3 SWE	SW enable SW JTAG enable status 1 enabled 0 disabled
2 SWF	Software JTAG enable fuse Status of the no SW disable JTAG fuse 0 (intact) - SW enable possible 1 (intact) - no SW enable possible
1 KTA	Kill Trace is active 1 active 0 not active
0 KTF	Kill Trace Enable fuse value 0 (intact) - kill trace is never active 1 (burned) - kill trace functionality enabled

4.11.8.7 General Purpose Clocks Control Register (SJC_GPCCR)

This register is used to configure clock related modes in SOC, see System Configuration chapter for more information. Those bits are directly connected to JTAG outputs. Bit 0 of GPCCR controls SDMA clocks invocation. When out of reset, the SDMA is in sleep mode with no SDMA clock running. Unlike events, debug requests does not wake SDMA if it is in sleep mode. The debug request is recognized by the SDMA only when it exits sleep mode upon reception of an event. To be able to enter debug mode even if no event is triggered, the SDMA clock on bit needs to be set prior to sending the debug request (clear at reset).

Address: 0h base + 7h offset = 7h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	-														ACLKOFFDIS	SCLKR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SJC_GPCCR field descriptions

Field	Description
31–2 -	Reserved
1 ACLKOFFDIS	Disable/prevent Arm platform clock/power shutdown
0 SCLKR	SDMA Clock ON Register - This bit forces the clock on of the SDMA

Chapter 5
Clocks and Power Management

5.1 Clock Control Module (CCM)

5.1.1 Overview

Clock Control Module (CCM) manages the on-chip module clocks. CCM receives clocks from PLLs and oscillators and creates clocks for on-chip peripherals through a set of multiplexers, dividers and gates. When entering or exiting a low power mode, CCM automatically turns on and off PLLs and peripheral clocks.

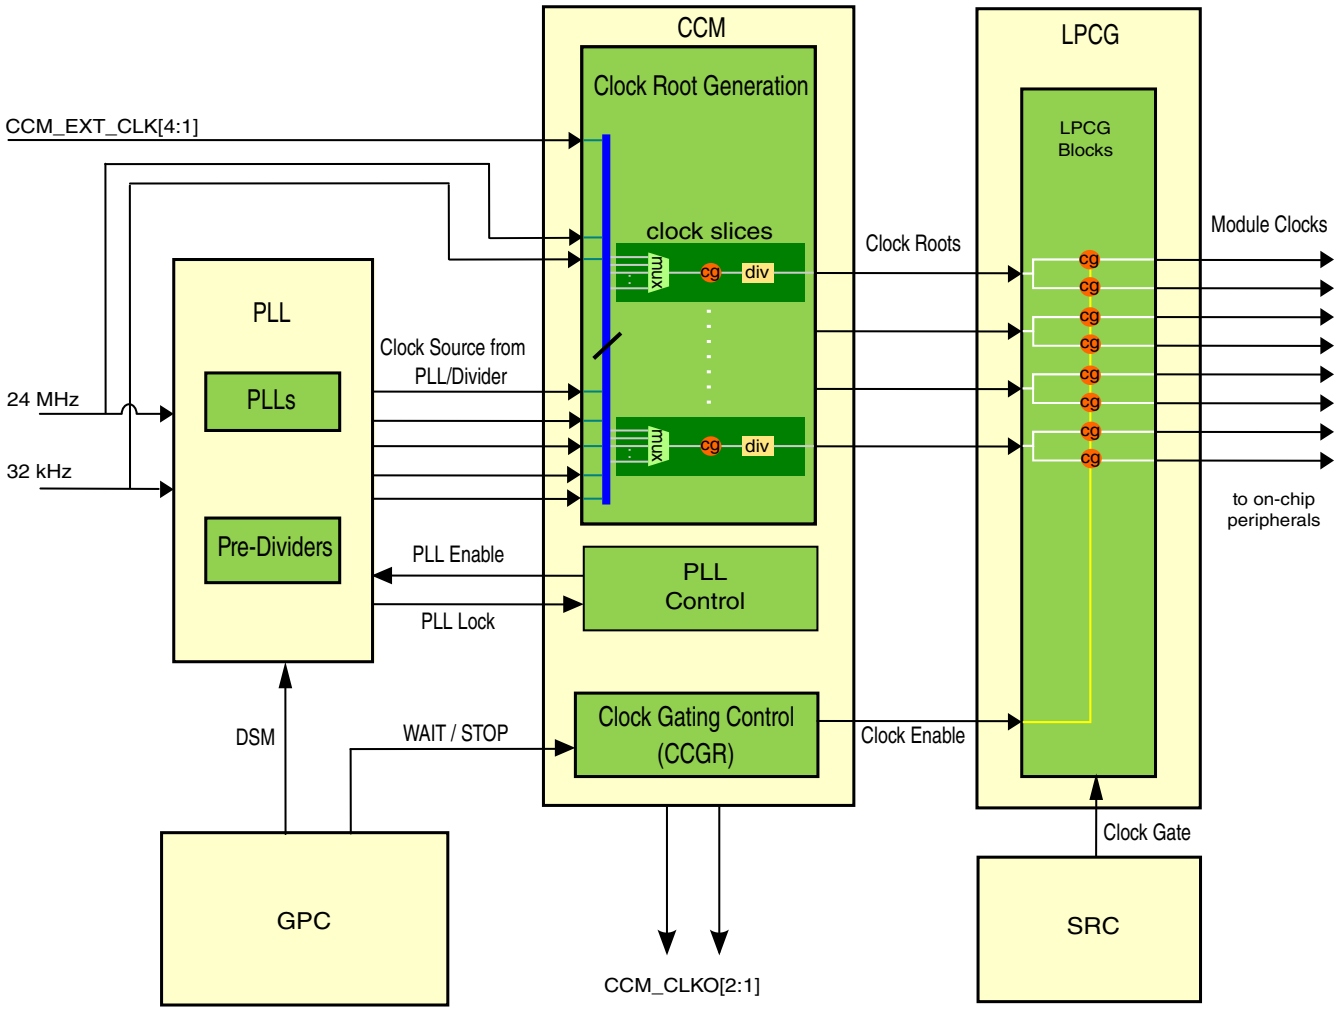

Figure 5-1. CCM Block Diagram

5.1.2 Clock Root Selects

The table below details the clock root slices and clock source inputs.

NOTE

The value of all clock root slice registers are zero after POR with the exception of DRAM clock. Please see System Boot for ROM reset values and default frequency settings for the clock root slices.

Table 5-1. Clock Root Table

Slice	Clock Root	Offset	Max Freq (MHz)	Source Select (CCM_TARGET_ROOT[MUX])

5.1.5 Functional Description

The following sections describe the functional details of CCM.

5.1.5.1 Input Clocks

The table below describes the input clock sources that supply the muxes to the clock slices in the clock root generator. Please see PLL Interface for PLL programming information.

Control Register (CCM_PLL_CTRLn)	Input Clock	Frequency (MHz)	Description
12	ARM_PLL_CLK	1600	Arm PLL
13	GPU_PLL_CLK	1600	GPU PLL clock output
14	VPU_PLL_CLK	800	VPU PLL clock output
15	DRAM_PLL1_CLK	800	DDR PLL
16	SYSTEM_PLL1_CLK	800	System PLL1 output clock

Table continues on the next page...

Control Register (CCM_PLL_CTRLn)	Input Clock	Frequency (MHz)	Description
17	SYSTEM_PLL1_DIV2	400	System PLL1 divided 2 clock output
18	SYSTEM_PLL1_DIV3	266	System PLL1 divided 3 clock output
19	SYSTEM_PLL1_DIV4	200	System PLL1 divided 4 clock output
20	SYSTEM_PLL1_DIV5	160	System PLL1 divided 5 clock output
21	SYSTEM_PLL1_DIV6	133	System PLL1 divided 6 clock output
22	SYSTEM_PLL1_DIV8	100	System PLL1 divided 8 clock output
23	SYSTEM_PLL1_DIV10	80	System PLL1 divided 10 clock output
24	SYSTEM_PLL1_DIV20	40	System PLL divided 20 clock output
25	SYSTEM_PLL2_CLK	1000	System PLL2 output clock
26	SYSTEM_PLL2_DIV2	500	System PLL2 divided 2 clock output
27	SYSTEM_PLL2_DIV3	333	System PLL2 divided 3 clock output
28	SYSTEM_PLL2_DIV4	250	System PLL2 divided 4 clock output
29	SYSTEM_PLL2_DIV5	200	System PLL2 divided 5 clock output
30	SYSTEM_PLL2_DIV6	166	System PLL2 divided 6 clock output
31	SYSTEM_PLL2_DIV8	125	System PLL2 divided 8 clock output
32	SYSTEM_PLL2_DIV10	100	System PLL2 divided 10 clock output
33	SYSTEM_PLL2_DIV20	50	System PLL2 divided 20 clock output
34	SYSTEM_PLL3_CLK	1000	System PLL3 output clock
35	AUDIO_PLL1_CLK	650	Audio PLL1 clock output
36	AUDIO_PLL2_CLK	650	Audio PLL2 clock output
37	VIDEO_PLL1_CLK	650	Video PLL1 clock output
external source	32K_REF_CLK	0.032	32K oscillator clock output
external source	24M_REF_CLK	24	24M oscillator clock output
external source	EXT_CLK_1	133	Clock input from external IO
external source	EXT_CLK_2	133	Clock input from external IO
external source	EXT_CLK_3	133	Clock input from external IO
external source	EXT_CLK_4	133	Clock input from external IO

NOTE

CKIL_SYNC needs to be configured the same as the PLL for ipg_clk

5.1.5.2 CKIL Synchronizer

CCM provides a synchronized version of the 32K clock called CKIL Synchronizer (CKIL_SYNC). The CKIL_SYNC clock is generated and synchronized by the IPG_CLK_ROOT when IPG_CLK_ROOT is active.

When the system enters low-power mode that requires the shutdown of IPG_CLK_ROOT, the CKIL Synchonrizer needs to be bypassed and fed directly from the XTALOSC 32K source.

The control for the CKIL_SYNC bypass comes from source control. The control for CKIL_SYNC bypass needs to be configured exactly the same as the contols for the PLL output that is used to generate IPG_CLK_ROOT.

In cases where a module ipg_clk is not tied to IPG_CLK_ROOT, the bypass signal to the ipg_clk is controlled by LPCG. To avoid issues on their 32K input, the LPCG must also be shutdown at the same time as the PLL clock output for that particular ipg_clk generation.

5.1.5.3 Clock Components

The details of the CCM clock components are detailed below.

5.1.5.3.1 Clock Divider

Synchronized clock dividers can be used to perform integer division on the source clock frequency. The divider guarantees a clean clock signal on its output during the change of the divide factor. Dividers perform a 1/(N+1) divide. A glitch can cause a sync-divider to go into an unrecoverable state, therefore a clean clock signal must be provided to a sync-divider.

When updating the divider value, a read enable signal (read_en) deasserts to stop the related control registers from fetching the divider value. To change a divider factor value, the bus enters a transition state and the divide logic latches the divider factor value. After this value is latched, the read_en is reasserted. The divider will begin to update its internal divide logic. After it finishes updating, the divider sends an acknowledge signal (sw_ack) to indicate a new value is in effect.

5.1.5.3.2 Clock Switching Multiplexer

Clock switching multiplexers can guarantee a clean clock signal when switching between 2 clock sources. Both clock inputs must be active when switching. Glitches in the selected source may be transferred to the output clock while the de-selected source is blocked. Glitches that occur during switching may cause an unpredictable state, and will recover in 2~3 cycles.

Clock switching multiplexers first shutdown the current active clock, then switch. After receiving an acknowledge that the current clock stopped. The multiplexer turns on the new selected clock source. As the acknowledge of turning on the new clock source is received, the source switch finishes.

5.1.5.3.3 Clock Gate

A clock gate cell is used to gate clocks. When gated, the clock will stop at 0. A clock gate cell can accept glitches on its clock inputs. If the gate cell is off, it will block or absorb glitches. If the gate cell is on, it may pass glitches to its output. A gate cell needs 2~3 clock cycles to change states. The state during this period is either on or off and will recover in 2~3 cycles, but cannot be predicted which state it is in during this period.

5.1.5.3.4 8 to 1 Multiplexer

The 8-to-1 multiplexer is a combinational multiplexer that can switch anytime. The multiplexer output does not guarantee a clean clock signal. During switching, the output must be gated or all 8 inputs will require the same value.

5.1.5.4 Clock Slices

There are several types of clock generation slices in CCM. The slices are categorized as Core, Bus, Peripheral (IP), and DRAM.

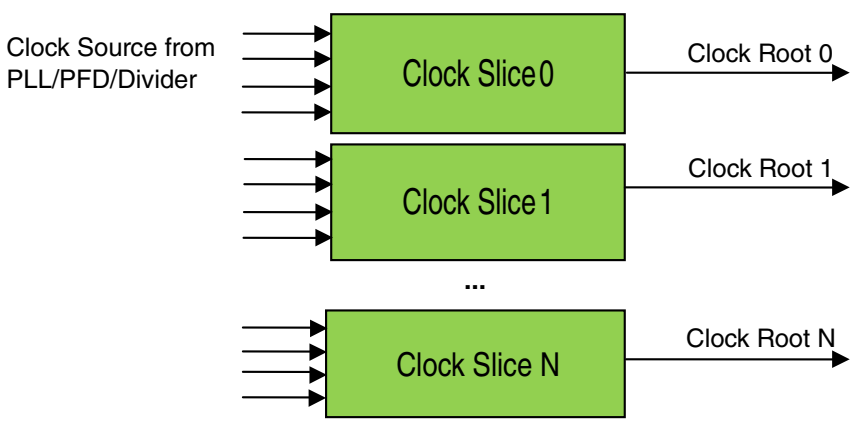

Figure 5-4. Clock Slices

5.1.5.4.1 Core clock slice

Core clock slices are designed for high speed, non-stop clock generation, typically for an Arm core. A core clock slice is comprised of a post divider and clock switching multiplexer. Each has a clock gate and a clock multiplexer inside. To run at high frequency, post divider is 3 bits, which is half the bit width of other slices. The two 8-to-1 multiplexers are not glitch-less, so switching them should only be done when their output is not routed to a clock output.

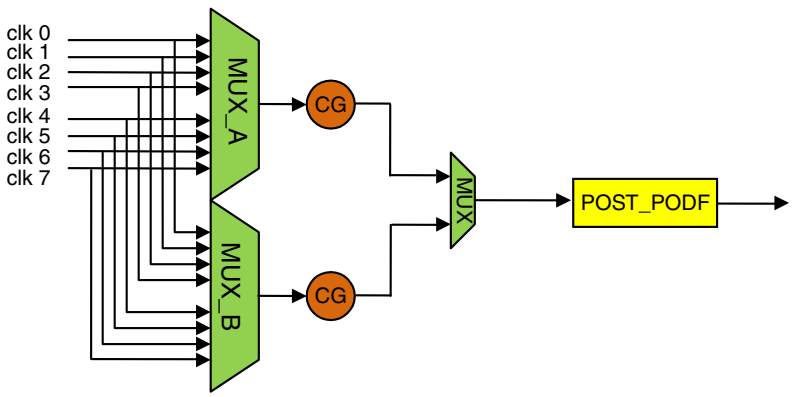

Figure 5-5. Core clock slice

5.1.5.4.2 Bus clock slice

Bus clock slices are comprised of a post divider and a clock switching multiplexer. Each has a pre-divider, clock gate and a clock multiplexer inside. The pre-divider is three bits and provides a maximum division factor of 8. The post-divider is six bits and can divide down the clock input to 1MHz on clock output. The two 8-to-1 multiplexers are not glitch-less, so switching should only be done when their output is not routed to clock output.

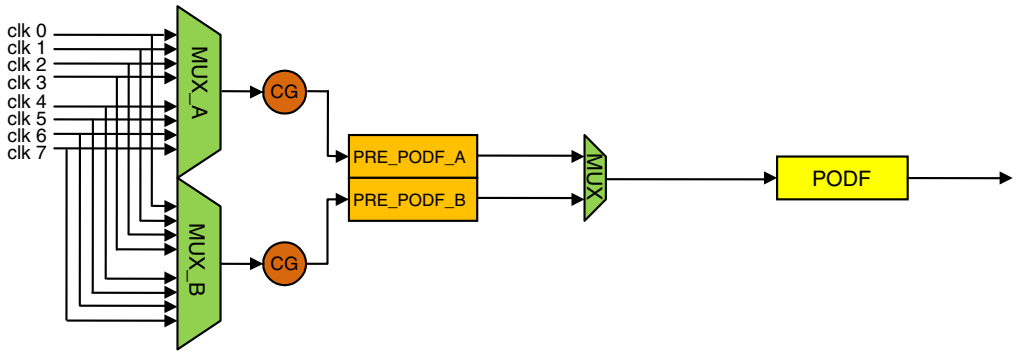

Figure 5-6. Bus clock slice

5.1.5.4.3 Peripheral clock slice

IP peripheral clock slices are comprised of a post-divider, pre-divider, clock gate and a clock multiplexer. The pre-divider is three bit and can divide down by a factor of 8. The post-divider is six bit and can divide down the input clock to 1MHz on clock output. The 8-to-1 multiplexer is not glitch-less, so switching should only be done when their output is not routed to clock output.

IP clock slices must be stopped to change the clock source.

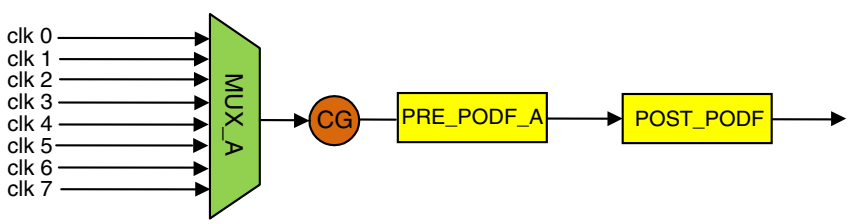

Figure 5-7. Peripheral clock slice

5.1.5.4.4 SSCG and Fractional PLLs

The SSCG and Fractional-N PLLs are detailed below. The SSCG block diagram is shown below. Please see CCM ANALOG for more information.

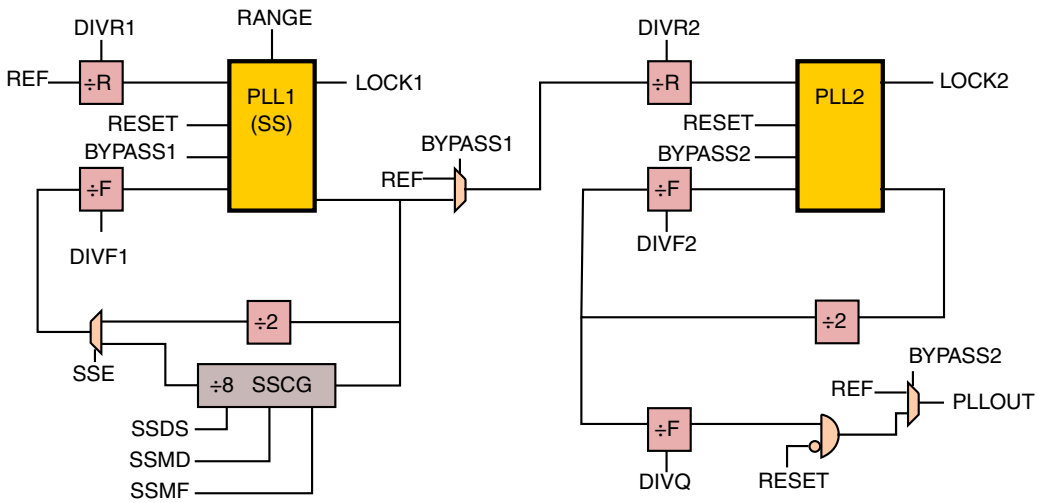

Figure 5-8. SSCG PLL Block Diagram

Formula for SSCG PLLOUT:

- SSE=0: PLLOUT = REF/DIVR1 * 2 * DIVF1/DIVR2 * DIVF2/DIVQ
- SSE=1: PLLOUT = REF/DIVR1 * 8 * DIVF1/DIVR2 * DIVF2/DIVQ

The ARM PLL, GPU PLL, VPU PLL, Audio PLL1/2, and Video PLL1 are fractional PLLs. The frequency on these can be tuned to be very accurate to meet audio and video interface requirements. The figure below shows the Fractional PLL block diagram.

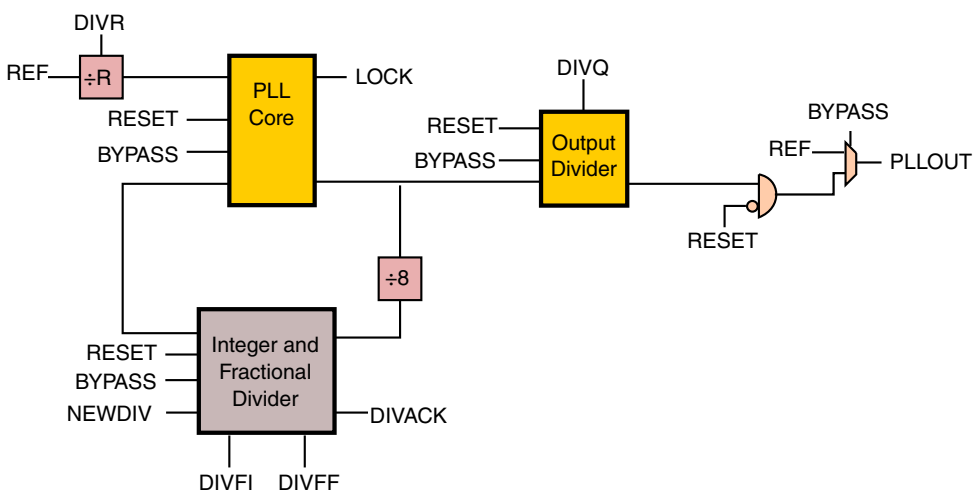

Figure 5-9. Fractional PLL Block Diagram

Formula for Fraction PLLOUT:

- PLLOUT = REF/DIVR_VAL * 8 * DIVF_VAL/DIVQ_VAL
- Where, DIVF_VAL = 1 + DIVFI + (DIVFF/2^24)

5.1.5.5 Clock gate control

CCM can perform automatic clock shutdown of on-chip peripherals according to system low power mode. Each logic domain can respectively declare its dependency level on each clock. If a clock is detected that is not dependant on any domain, it will be shutdown to save power.

Clock generation inside the CCM creates a clock root for on-chip peripherals. Before the clock root goes into peripherals via low power clock gating cells. By controlling these LPCGs, CCM can manage on-chip peripheral clocks.

Clock gate controls use active clock gating, which means the low power clock gating (LPCG) requires an active clock root. The clock generation module only performs multiplexing, gating and dividing on clock sources. Therefore, the clock root from the generation module will stop when the corresponding clock source stops.

The ENABLE bit must be set for the clock root that LPCG is actively gating.

5.1.5.6 Clock source control

CCM can perform automatic PLL shutdown of CCM_ANALOG according to system low power mode. Each logic domain can respectively declare its dependency level on each clock. If a PLL is detected not depended by any domain, it will be shutdown to save power.

PLL in ANATOP can be set be controlled by CCM via setting some CCM override bits. Also there is control on 32K IPG_CLK_ROOT synchronized version inside clock source control module.

For PLLs, we have channel on every PLL, every PFD and every divider. PLL is the source of PFDs and dividers. For any clock, its source must be left on when it is kept on. Behavior is undefined if this rule is violated.

For a shutdown clock source, if it is declared depended by writing clock source control registers, the controlling logic will turn on the source immediately, while the setting goes into a shadow register. After clock source get ready, the setting will be accepted by source control logic, and copied from shadow register to setting register.

5.1.5.7 Access control

CCM can implement its own access control based on domain to provide more precise control on shared resources. Access controls are implemented on clock root generation, clock gate control, and clock source control. Access control logic does not impact read access, but blocks unauthentic write access.

Access controls on clock root generation are independent between every clock root. A sticky authentic fail flag is set when a domain writes to a register and authentication fails. The access control logic contains a whitelist and a semaphore. By default, each clock root's access control logic is disabled after power-on reset. Software can enable access control anytime after reset.

NOTE

Once access logic is enabled, it cannot be disabled until the next power-on reset.

Table 5-3. Whitelist

Enabled	Write access will be authenticated before being performed.
Disabled	every access on protected item will be performed.

NOTE

Only domains that are on the whitelist can perform write access to this clock root when access control is enabled.

Table 5-4. Semaphore

Enabled	A domain must obtain the semaphore’s ownership before its write access can be authenticated. Only a domain on the whitelist can obtain the ownership and the ownership will last until the domain explicitly releases the ownership. Semaphore obtain will fail if it is already fetched by some other domain.
Disabled	Authentic check will check only on whitelist.

NOTE

Semaphore is intended to help software keep the clock root from unexpectedly changing.

Access control of clock gate and clock source control is performed in a simple operation. Every domain can only write on the bits for it's own setting. Any write to irrespective domain will be ignored.

5.1.5.8 System level considerations

Clock shutdown strategy

Any clock shutdown should first shutdown the LPCG, then the PLL. If the LPCG is configured not to shutdown, the clock root for the LPCG should not stop either. Violating this rule leads the system into an unpredictable state.

Core clock root frequency

If the core clock is set lower that one third of the IPG clock, SRC needs to generate a longer reset signal to match the requirement from the Arm core. This typically happens when the Arm core runs at some divided value of the XTAL 24M while IPG clock is supplied by the PLL.

DRAM clock

The DRAM PHYM clock needs a clock frequency faster that 400MHz.

USB OTG CLOCK

The USB clock may not be a reliable clock source in some applications. This clock may stop when USB cable is disconnected.

5.1.6 Programming Guide

5.1.6.1 Set, Clear, and Toggle register features

Every register of the CCM has set, clear, and toggle features.

The set feature for a given register is located at:
Base Address of the register + 0x04

The clear feature for a given register is located at:
Base Address of the regsister + 0x08

The toggle feature is located at:
Base Address of the register + 0x0c

Read from all 4 locations to get the current register value. Writing to the base register bits sets the register to the write value. Writing 1 to the set register bits sets them to 1, while writing 0 has no effect. Writing 1 to the clear register bits clears them to 0, while writing 0 has no effect. Writing 1 to the toggle register bits sets them to invert the value, while writing 0 has no effect.

5.1.6.2 PLL Interface

CCM can control PLLs inside CCM_ANALOG when entering or leaving low-power mode. Software must set the PLL override inside CCM_ANALOG before entering low-power mode after power-on reset (POR).

There are four levels of low-power modes in a logic domain:

- Not needed
- Needed in RUN
- Needed in RUN and WAIT
- Needed in RUN, WAIT, and STOP

CCM only takes action while domain status are switching between STOP (DEEP SLEEP mode is considered the same as STOP). There are 4 domains that can be assigned. Any CPU platform can be assigned to any domain by RDC. If a domain is empty, the domain is considered as STOP.

Each domain can declare its dependency to CCM. The use of any clock, without declaring it in its own domain, is not permitted. A domain declares its dependency on a clock by writing the dependency level. Settings against behavior in low-power mode are as follows:

Table 5-5. Domain Dependency

Domain Level	Run	Wait	Stop / Deep sleep
0			
1	Required		
2	Required	Required	
3	Required	Required	Required

Table 5-6. CCGR Program Interface

CCGR		Domain3				Domain2				Domain1				Domain0			
	31-16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
				Level1	Level0			Level1	Level0			Level1	Level0			Level1	Level0

Each domain can change only bits assigned to control access. Any irrelevant write to it will be ignored. For example, Domain 0 can only write to bits [1:0]. Any bits written to, other than bits [1:0], will be ignored. Other domains can read all of the other domain settings. The default value for domain 0 is 2, and will enter STOP mode after shutting down. When the default value of the other domain setting is 0, it will not be required.

When setting clock source, the settings will not take effect immediately. The setting will enter the shadow register first. If a PLL shutdown or new setting enters the shadow register to declare dependency on the PLL, the PLL will turn on immediately. When the PLL is ready, the setting in shadow register will be updated to the new setting. During this period, the pending bit will be set and cleared. Then CCM will send the PLL control signal as a shadow register and inform GPC the PLL status according to the setting register. In other cases, the setting will be updated from the shadow register immediately. Clock sources have dependency on each other.

NOTE

Do not shutdown the parent clock when the required child clock is active. Attempting to do so will lead to unpredicable and unrecoverable behavior. It is recommended to shutdown the parent clock and child clock together.

5.1.6.3 CCGR Interface

Before a clock root goes to on–chip peripherals, the clock root is distributed through low power clock gates (LPCG). These LPCG are implemented to automatically perform clock shutdown when a domain enters and leaves a low-power state.

There are four levels of low-power modes in a logic domain:

- Not needed
- Needed in RUN
- Needed in RUN and WAIT
- Needed in RUN, WAIT, and STOP

CCM only takes action while domain status are switching between STOP (DEEP SLEEP mode is considered the same as STOP). There are 4 domains that can be assigned. Any CPU platform can be assigned to any domain by RDC. If a domain is empty, the domain is considered as STOP.

Each domain can declare its dependency to CCM. The use of any clock, without declaring it in its own domain, is not permitted. A domain declares its dependency on a clock by writing the dependency level. Settings against behavior in low-power mode are as follows:

Table 5-7. Domain Dependency

Domain Level	RUN	WAIT	STOP/ DEEP SLEEP
0			
1	Required		
2	Required	Required	

Table continues on the next page...

Table 5-7. Domain Dependency (continued)

3	Required	Required	Required

Table 5-8. CCGR Program Interface

CCGR		Domain3				Domain2				Domain1				Domain0			
	31-16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
				Level1	Level0			Level1	Level0			Level1	Level0			Level1	Level0

Each domain can change only bits assigned to control access. Any irrelevant write to it will be ignored. For example, Domain 0 can only write to bits [1:0]. Any bits written to, other than bits [1:0], will be ignored. Other domains can read all of the other domain settings. The default value for domain 0 is 2, and will enter STOP mode after shutting down. When the default value of the other domain setting is 0, it will not be required.

The table below lists the CCM Clock Gating Register (CCGR) and associated offset for each LPCG enable.

NOTE

Not all CCGRs are mapped.

NOTE

Sec_debug clock gating (CCGR60) must be active in low power mode. DO NOT gate this clock in low power mode to guarantee the low power mode functions such as stop WDOG counting.

5.1.6.4 Target Interface

The Target Interface is optimized to simplify software operation. Using this interface, all clock roots are in the same program model with the same register bit field mapping. The software does not handle the details of the clock slice and clock slice types. Software writes the desired settings to the register, and the internal hardware logic generates a required sequence to achieve the desired settings.

The Target Interface requires the software to provide whether a clock is active, the clock source number to be selected, pre-divide value, and post-divide value. If a clock slice does not support a setting, that setting is simply ignored, and will not effect the supported fields.

Freq = (clock source freq)/(pre_div+1)/(post_div+1)

The internal logic sequence of the Target Interface guarantees a clean clock on output without frequency overshoot. A requirement of the Target Interface's software is that the target clock source is active.

The Target Interface sequence begins by opening all clocks, applying highest divider value, switching to the new clock source, then decreasing divider value to the target frequency. If Shutdown is requested, it will be performed last.

The clock output is always active when using the Target Interface. For intermediate frequency requests, the Target Interface choses the lowest frequency source to avoid frequency overshoot on the Peripheral clock slices. For Core and Bus clock slices, the clock switching multiplexer is used to guarantee smooth clock switching.

A write operation on a target interface completes once the output clock is running at the desired setting. Software polling is not necessary to determine clock stability.

STEP	STATE	OPERATION
0	SMART_IDLE	Idle state, no write operation is pending
1	SMART_WAIT_READY	State occurs when a write access is received, wait for every field to be ready
2	SMART_APPLY_GATE1	Open all branches, all gates inside clock slices
3	SMART_WAIT_GATE1	Wait for gate applied
4	SMART_APPLY_PODF1	apply post divider and post divider for if new value generate slower clock
5	SMART_WAIT_PODF1	Wait for divider accept new value
6	SMART_APPLY_GATE2	shutdown spare branch if exist, else shutdown working branch
7	SMART_WAIT_GATE2	Wait for shutdown operation complete
8	SMART_APPLY_MUX	Change multiplexer to new source on spare branch if exist, else switch working one
9	SMART_APPLY_GATE3	open gates on all branches
10	SMART_WAIT_GATE3	Wait for gates opened
11	SMART_APPLY_SWITCH	Switch clock switching multiplexer if there is one
12	SMART_WAIT_SWITCH	Wait for clock switching multiplexer switch
13	SMART_APPLY_PODF2	apply post divider and post divider for if new value generate faster clock
14	SMART_WAIT_PODF2	Wait for divider accept new value
15	SMART_APPLY_GATE4	apply clock gate setting, shutdown spare one if there is
16	SMART_WAIT_GATE4	Wait for gate applied
17	SMART_APPLY_AUTO	apply auto and auto divider
18	SMART_DONE	Finish, wait for bus operation complete

5.1.6.5 Normal Interface

Normal interface provide more controllable thing that target interface. And also provide protections against dangerous operation.

Normal interface provides safe sequences to handle each clock component, divider, gate, multiplexer. But it is software that needs to care the order and relationship between updating components.

Writing to this interface will complete immediately, and internal logic will continue try to apply written values to clock components. A busy flag will be assert during applying.

Field access rule:

1. Only one field can be modified a time
2. No field can be modified when any field pending
3. Not violate change condition in following table

FIELD	CHANGE CONDITION	FINISH CONDITION
Auto		immediate
Auto-divider		immediate
Bypass	Gatea active and gateb active	Bypass switch complete
Post-divider		New divider value applied
Gate B	Bypass disable	New gate value active
Pre-divider B	Bypass disable and gateb not gated	New divider value applied
MUX B	Bypass disable and gateb gating	immediate
Gate A	Bypass	New gate value active
Pre-divider A	Bypass and gatea not gated	New divider value applied
MUX A	Bypass and gatea gating	immediate

- Error will be reported if access rules violated.
- Unsafe or ambiguous access will be ignored.

If a write access as blocked by normal interface, the write operation will be ignored. And a sticky bit “violate” will be set. The bit will last until software clears it explicitly. The violate bit is 4 bits inside CCM, each for a logic domain. Each domain can read and clear the bit for itself, the bits for other domain is neither visible nor clearable.

5.1.7 CCM Memory Map/Register Definition

The Memory Map below represents the full array for CCM.

NOTE

Not all mapped Clock Slices and CCGRs are tied to functional components.

Please see the following for the functional mapping tables and information:

- CCM_PLL_CTRL - Input Clocks
- CCM_TARGET_ROOT - Clock Root Selects
- CCM_CCGR - CCGR Interface

5.2 General Power Controller (GPC)

5.2.1 Overview

The General Power Controller (GPC) module controls the following functions:

- Provide low power mode control for A53 and M4 platform
- Provide Power domain management all Arm and SOC power domain
- Provide domain control mechanism based on A53 and M4 CPU domain
- Provide handshake with CCM for clock management in low power mode
- Provide handshake with SRC for power down and power up sequence
- Provide handshake with Analog for Deep Sleep Mode control

5.2.2 Features

The General Power Controller (GPC) module controls the following functions:

- Support programmable feature for WAIT/STOP/DSM low power mode
- Support time slot based power domain control
- Support flexible sleep and wakeup condition
- Support domain control for multi CPU platforms system
- All register accessed by IP bus
- Interface for the following IPs:
    - CCM – clock controller module
    - SRC – system reset controller
    - ANALOG – miscellaneous analog control

5.2.3 Block Diagram

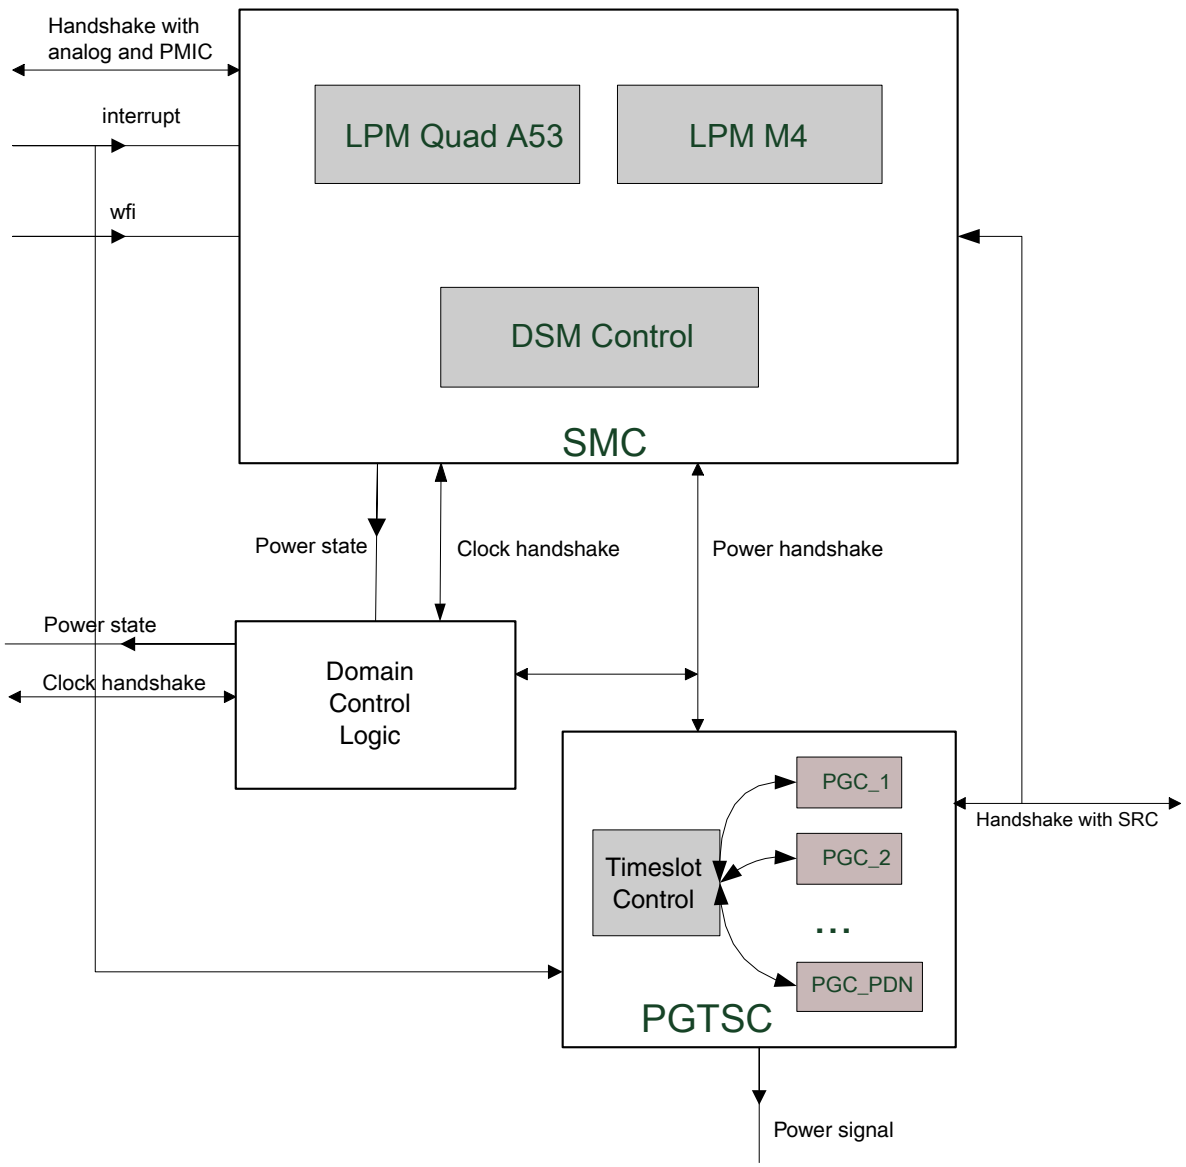

Figure 5-10. GPC Block Diagram

The GPC module contains two sub-modules: System Mode Controller (SMC) and Power Gating Time Slot Control (PGTSC):

- GPC Top: the top level GPC. It also includes the top memory map and registers, domain control information, and memory low power control.
- System Mode Controller (SMC):
  - The SMC supports two low power modes (LPM), WAIT and STOP. Each LPM corresponds to one mode for A53 platform and one mode for M4 platform.

- SMC controls the power sequence in Deep Sleep Mode (DSM)
- SMC support the power up and power down of A53 core0/core1/core2/core3 by IRQ/WFI signals without LPM triggered
- SMC can translate the LPM request for A53 and M4 platform to power up and power down request to PGTSC.
- Power Gating Time Slot Control (PGTSC):
  - The Power Gating Controller (PGC) is a power management component that controls the power-down and power-up sequencing of individual subsystems. For subsystems to be completely powered down in low power modes, a specific sequence of power control signals must be followed. The sequence timing is programmable using the PGC control registers.
  - There are 20 PGCs in the chip, all of them can be power down/up with a software trigger and all of them can be mapped to 20 timing slots and power-up and power down by request from SMC.

5.2.4 Functional Description

5.2.4.1 RUN mode

This is the normal/functional operating mode. In this mode, the CPU runs in its normal operational mode.

5.2.4.2 Low power mode

There are two CPU platforms (each of them represents a CPU domain): Quad core Cortex A53 platform and Cortex M4 platform. Each platform supports two low power modes: WAIT mode and STOP mode.

5.2.4.2.1 WAIT mode

In this low power mode:

- LPCG can be defined to be shut off or not in wait mode for each CPU domain
- PLL can be defined to be shut off or not in wait mode for each CPU domain

NOTE

The PLLs will only been closed in non-fast wake-up mode, relevant bit are

GPC_SLPCR[EN_A53_FASTWUP_WAIT_MODE] and
GPC_SLPCR[EN_M4_FASTWUP_WAIT_MODE]

- CPU clock can be defined been shut off or not in wait for each CPU platform. (GPC_LPCR_A53_BSC[CPU_CLK_ON_LPM] and GPC_LPCR_M4[CPU_CLK_ON_LPM])
- Power of different power domain can be defined be shut off or not in wait mode for each platform domain
- Some peripherals may go to wait mode along with A53 or M4 platform.

5.2.4.2.2 STOP mode

In this low power mode:

- LPCG can be defined been shut off or not in stop mode for each CPU domain
- PLL can be defined been shut off or not in stop mode for each CPU domain

NOTE

The PLLs will only been closed in non-fast wake-up mode, relevant bit are
GPC_SLPCR[EN_A53_FASTWUP_STOP_MODE] and
GPC_SLPCR[EN_M4_FASTWUP_STOP_MODE]

- CPU clock can be defined been shut off or not in stop for each CPU (GPC_LPCR_A53_BSC[CPU_CLK_ON_LPM] and GPC_LPCR_M4[CPU_CLK_ON_LPM])
- Power of different power domain can be defined be shut off or not in stop mode for each platform domain
- Some peripherals may go to stop mode along with A53 or M4 platform.

5.2.4.3 Deep Sleep Mode

The Deep Sleep Mode (DSM) is a system low power mode.

In this mode:

- On-chip OSC can be defined to be shut off or not in DSM (GPC_SLPCR[SBYOS])
- PMIC can be defined to be stand-by mode or not in DSM (GPC_SLPCR[VSTBY])
- Regulator can be defined to be BYPASS mode or not in DSM (GPC_SLPCR[RBC_EN])
- Memory can be defined to go to retention mode or not in DSM(GPC_MLPCR[MEMLP_CTL_DIS])
- A53 platform power (VDD_ARM) can be defined to be shut off or not in DSM.

NOTE

CCM configuration must make sure close all PLLs before system goes to DSM

NOTE

For the SoC to correctly power up after entering DSM, CCM_PLL_CTRLx must not be set to 0x0 or 0x3 for any domain in use.

5.2.4.4 LPM Sleep Process

CPU platform will go to WAIT/STOP under the following conditions:

- LPM registers (GPC_LPCR_A53_BSC[LPM0], GPC_LPCR_A53_BSC[LPM1], GPC_LPCR_A53_BSC2[LPM2], GPC_LPCR_A53_BSC2[LPM3], GPC_LPCR_M4[LPM]) are set to WAIT or STOP.

  NOTE

  Since A53 platform has four cores, the so each core has its own LPM register: GPC_LPCR_A53_BSC[LPM0] and GPC_LPCR_A53_BSC[LPM1], GPC_LPCR_A53_BSC2[LPM2] and GPC_LPCR_A53_BSC2[LPM3]. The unified LPM of A53 will be generated with the lower LPM of the cores.

- Asserting the WFI signal will trigger CPU sleep process. There are five WFIs that come from A53 platform: WFI_core0, WFI_core1, WFI_core2, WFI_core3, and WFI_scu. The A53 platform will go to LPM when all WFIs are asserted. If the GPC_LPCR_A53_AD[EN_C0_WFI_PDN] or GPC_LPCR_A53_AD[EN_C1_WFI_PDN] or GPC_LPCR_A53_AD[EN_C2_WFI_PDN] or GPC_LPCR_A53_AD[EN_C3_WFI_PDN] bit is set, the LPM trigger condition will be a little different. See Power control for A53 Platform for more information. Only one WFI comes from M4 platform. The M4 platform will go to LPM when WFI_m4 asserted.

  NOTE

  WFI condition can be masked by register bits GPC_LPCR_A53_BSC[MASK_n_WFI] and GPC_LPCR_M4[MASK_M4_WFI]

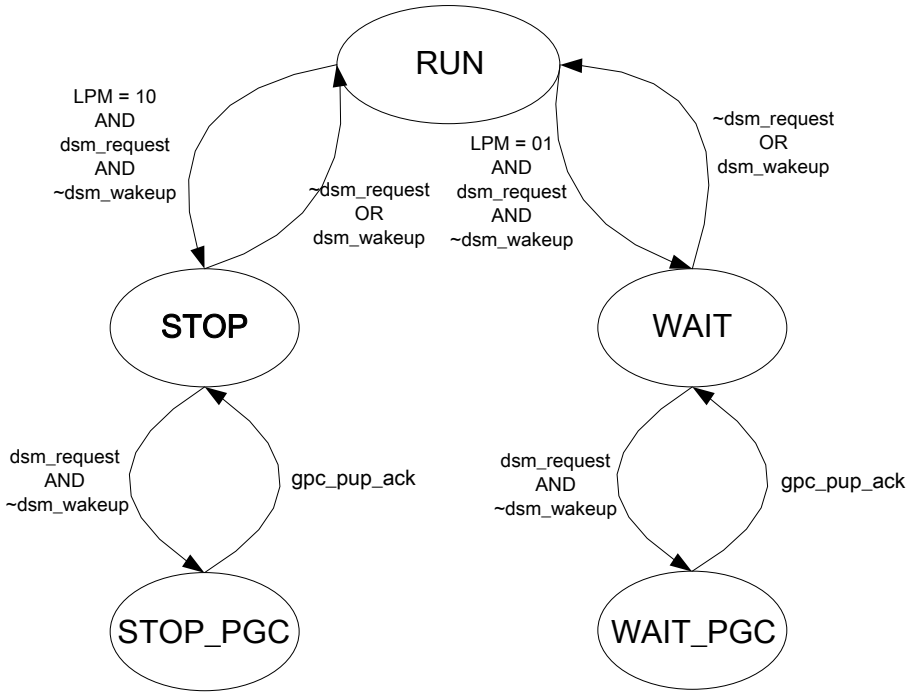

Figure 5-11. LPM transition inside CPU platform

System will go to DSM under the following conditions:

- Both A53 and M4 are STOP mode.
- Both GPC_SLPCR[EN_A53_FASTWUP_STOP_MODE] and GPC_SLPCR[EN_M4_FASTWUP_STOP_MODE] are not set.
- GPC_SLPCR[EN_DSM] is set.

NOTE

If GPC_LPCR_M4[MASK_DSM_TRIGGER] is set, the system will go to DSM when A53 goes STOP mode and GPC_SLPCR[EN_A53_FASTWUP_STOP_MODE] is not set. If GPC_LPCR_A53_BSC[MASK_DSM_TRIGGER] is set, the system will go to DSM when M4 goes to STOP mode and GPC_SLPCR[EN_M4_FASTWUP_STOP_MODE] not set. GPC_LPCR_M4[MASK_DSM_TRIGGER] and GPC_LPCR_A53_BSC[MASK_DSM_TRIGGER] cannot be set at the same time.

5.2.4.5 LPM Wake Up Process

DSM, STOP, WAIT mode will be woken up by interrupts:

- The CPU platforms share the same IRQ sources in this chip. Software can use GPC_IMRn_CORE0_A53, GPC_IMRn_CORE1_A53, GPC_IMRn_CORE2_A53, GPC_IMRn_CORE3_A53, and GPC_IMRn_M4 to separate the 128 bits IRQ sources to A53 core0, core1, core2, and core3, and M4 platform.
- The A53 core0, core1, core2, and core3 IRQ can also be from GIC source (defined by GPC_LPCR_A53_BSC[IRQ_SRC_C3], GPC_LPCR_A53_BSC[IRQ_SRC_C2], GPC_LPCR_A53_BSC[IRQ_SRC_C1], and GPC_LPCR_A53_BSC[IRQ_SRC_C0]) and if it is chosen from GIC source the GPC_IMRn_x_A53 will lose its function. See Power control for A53 Platform for more information.
- Interrupts for both A53 and M4 will cause the system wake up from DSM, A53 interrupt will wake up A53 from LPM, M4 interrupt will wake up M4 from LPM.

5.2.5 Power Gating Controller (PGC) Overview

The Power Gating Controller (PGC) is a power management component that controls the power-down and power-up sequencing of individual subsystems. For subsystems to be completely powered down in low power modes, a specific sequence of power control signals must be followed. The sequence timing is programmable using the PGC control registers.

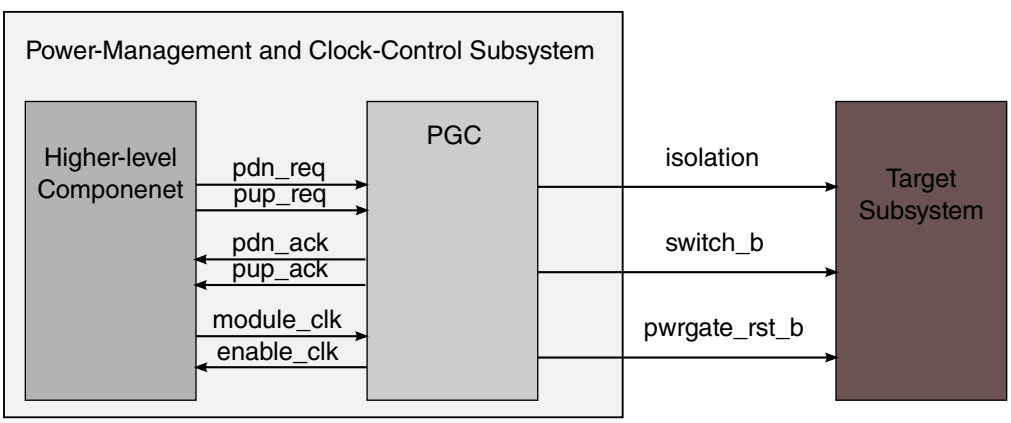

Figure 5-12. Power Gating Controller (PGC)

5.2.5.1 PGC power domains

The following table lists the PGCs in the chip and the corresponding power domain.

PGC type	Power domain
PGC_C0	Core0 of A53 platform
PGC_C1	Core1 of A53 platform
PGC_C2	Core2 of A53 platform
PGC_C3	Core3 of A53 platform
PGC_SCU	SCU/L2 cache RAM of A53 platform
PGC_NOC	NOC
PGC_PCIE	PCIE PHY
PGC_OTG1	USB OTG1 PHY
PGC_OTG2	USB OTG2 PHY
PGC_DDR1	DDR1
PGC_DISPMIX	DISPMIXMIX
GPC_MIPI	MIPI PHY
PGC_GPUMIX	GPUMIX
PGC_GPU_3D	GPU_3D
PGC_GPU_2D	GPU_2D
PGC_VPUMIX	VPUMIX
PGC_VPU_G1	VPU_G1
PGC_VPU_G2	VPU_G2
PGC_VPU_H1	VPU_H1

5.2.5.2 Trigger to PGC: Hardware and Software Requests

All PGCs can be power up/down by hardware or software request.

The LPM controller for each platform can generate hardware power down or power up request. All hardware requests will be mapped to “timeslot controller” before they goes to relevant PGC (see “Time slot control for PGCs” for more information).

The CPU can also generate software power up or power down request to relevant PGCs. The software trigger will not be mapped to timeslot control. If there are PGCs in software PDN/PUP sequence the request from LPM will be masked. The software trigger will also be failed if the timeslot control is in “busy” state.

All power up/down request to PGCs will be mapped to domain control module (see “Domain control for PGCs ”).

PGC_C0, PGC_C1, PGC_C2, and PGC_C3 can be triggered by its own “WFI/IRQ” without LPM trigger and time slot. See Power control for A53 Platform for more information.

5.2.5.3 Time slot control mechanism for PGCs

GPC uses a time slot controller to control the PGC sub-systems, such as the PGC in CPU0, CPU1,CPU2, CPU3, MIX, PCIE PHY, etc. We use it for below reasons when system wakes from low power mode.

1. Support flexible power down/up sequence for different sub-system
2. Sub-system can be power up in different slot to avoid large ramping up current in case they start ramping up at the same time

There are a total of 20 time slots used in the chip, one or more PGCs are used for power up or power down in each of these slots. The time slot controller will sample power up/down requests at slot0. If there are power up/down requests from SMC, it will scan from slot0 to slot19. When the scan process comes to one slot which has a defined power up or power down for one or more PGCs (defined by “SLTn_CFG”), the power up/down sequence of relevant PGCs will happen in that slot. Otherwise, the relevant slot will be skipped.

The next slot will not begin until the all PGCs finish their power up or power down process in current time slot. When all the 20 slots are finished, slot controller will jump to IDLE state and monitor new request from SMC.

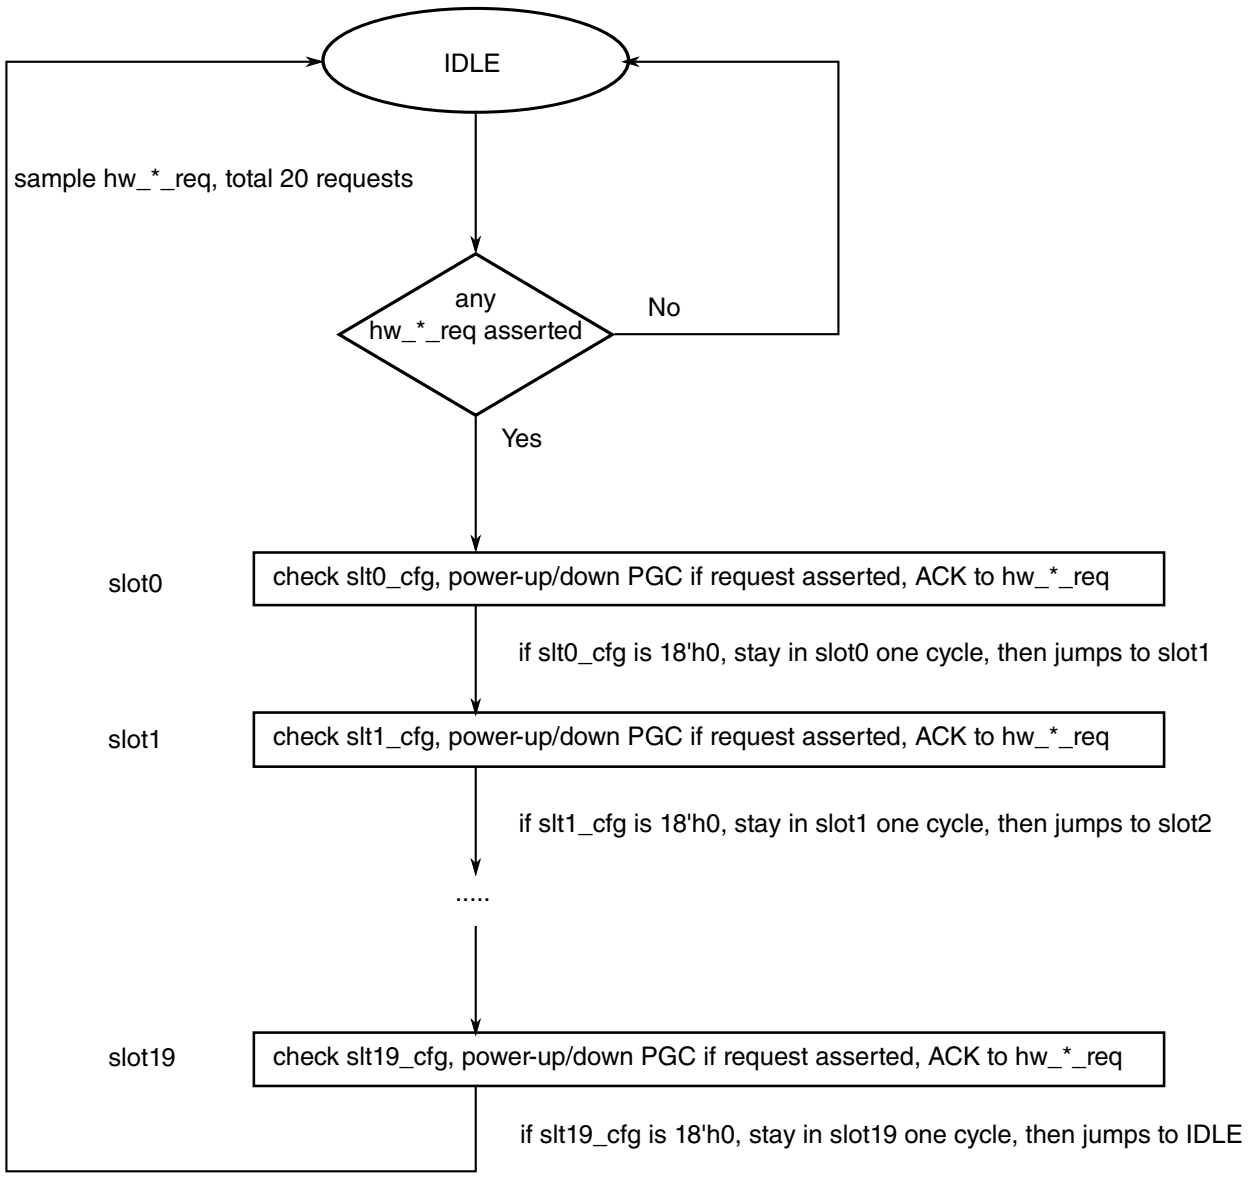

Figure 5-13. Slot controller processing flow

NOTE

PGC_SCU should be “always-on” to PGC_C0 PGC_C1, PGC_C2, and PGC_C3. This means PGC_SCU should be power up earlier than PGC_C0/PGC_C1/PGC_C2/PGC_C3 and should be power down later than PGC_C0/PGC_C1/ PGC_C2/PGC_C3 (see example code 1 and 2). If we arrange A53 Cx/A53 SCU power down/up in same slot, special setting is required (see example code 2).

NOTE

When the system enters/exists ALL_OFF or L2_RETENTION mode, PGC_MF should be power up earlier than PGC_C0/ PGC_C1/PGC_C2/PGC_C3/PGC_SCU. We can arrange MIX PGC power up in earlier slot than A53 Cx/SCU power up slot (See example code 1 and 2).

5.2.5.4 Handshake between LPM controller and time slot controller

The figure below shows an example of A53 “into” LPM sequence. We want to power up A53 SCU and A53 core0 in time slot0 /slot1/slot2 respectively. Request from low power mode controller will be mapped to relevant PGCs according to the rules listed above. We choose acknowledge from PGC_core0 as the acknowledge for A53 LPM power down request (relevant register bits are defined in “PGC_ACK_SEL_A53”). The A53 LPM will regard the three PGCs as a virtual big PGC and it will cancel all power up request when it receive the acknowledge signals from PGC_core0.

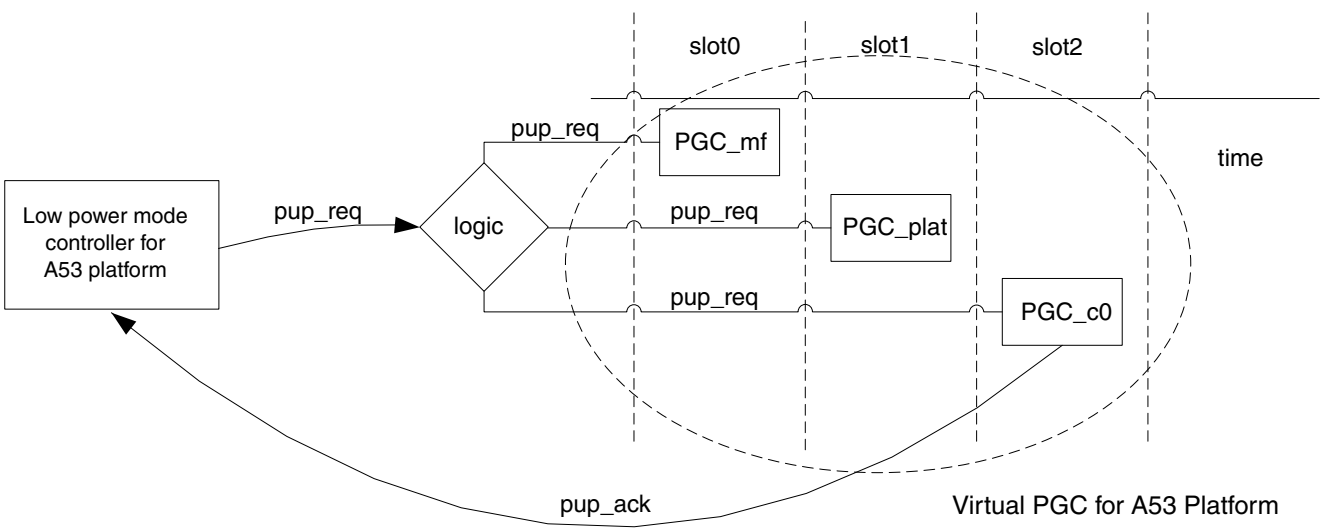

Figure 5-14. A53 into LPM sequence

NOTE

If a PGC is mapped to two CPU domain (refer to “Domain control for PGCs ”for more information), it cannot be selected as the power down acknowledge for both of the CPU platform. “PGC_ACK_SEL_A53”, "PGC_ACK_SEL_A53_PU", and “PGC_ACK_SEL_M4” are should be chosen for the last PGC in power up or power down sequence in the time slot. If there is no PGC be power up/power down with LPM sequence, the “dummy” acknowledge should be selected. Only one PGC

should be selected for power down or power up acknowledge for one CPU platform.

5.2.6 Power control for A53 Platform

5.2.6.1 A53 Platform power domains and power modes

There are four power domains inside SEC dual core Cortex A53 platform: Core0, Core1, Core2, Core3, SCU, and L2 RAM. There are six power states in A53 platform:

Power State	PDCPU0	PDCPU1	PDCPU2	PDCPU3	PDPLAT	PDL2	VDD_ARM
ALL_ON	ON	ON	ON	ON	ON	ON	ON
THREE_CPU_ON	3 CPUs are ON, 1 CPU is OFF				ON	ON	ON
TWO_CPU_ON	2 CPUs are ON, 2 CPUs are OFF				ON	ON	ON
ONE_CPU_ON	1 CPU is ON, 3 CPUs are OFF				ON	ON	ON
ALL_CPU_OFF	OFF	OFF	OFF	OFF	ON	ON	ON
L2_RETENTION	OFF	OFF	OFF	OFF	OFF	RET	ON
ALL_OFF	OFF	OFF	OFF	OFF	OFF	OFF	ON
POWER_DOWN	OFF	OFF	OFF	OFF	OFF	OFF	OFF

NOTE

In all six power states, “ALL_ON”, “THREE_CPU_ON", "TWO_CPU_ON", and "ONE_CPU_ON" can exist in all RUN, WAIT or STOP mode of A53 platform. “L2_RETENTION” and “ALL_OFF” can only exist in WAIT or STOP mode of A53 platform.

5.2.6.2 Power down process for the A53 Platform

5.2.6.2.1 Power down of Core0, Core1, Core2, and Core3 in the A53 Platform

The power of core0, core1, core2, and core3 can be shut off along with the LPM process, as show in the following figure:

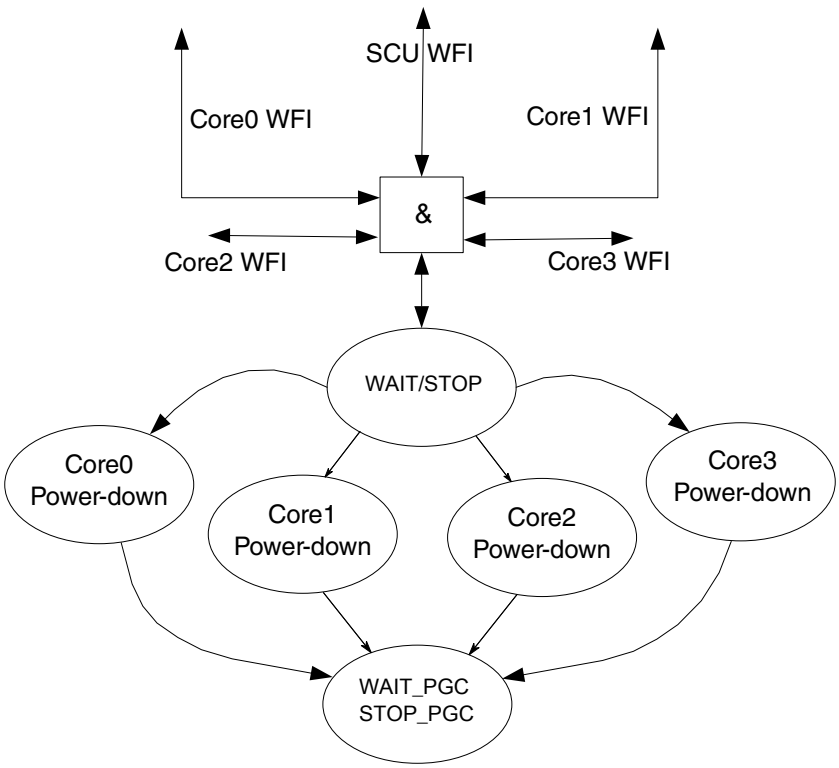

Figure 5-15. Power down of Core0, Core1, Core2, and Core3

WFIs from A53 platform will trigger the A53 platform LPM and the power of core0, core1, core2, or core3 will be shut off when “lpcr_a53_ad.en_c0_pdn”, “lpcr_a53_ad.en_c1_pdn”, “lpcr_a53_ad.en_c2_pdn”, or “lpcr_a53_ad.en_c3_pdn” enabled in this process. This mode should be used when core0 is used as the leading core of A53 platform.

The power of core0, core1, core2, and core3 can also be shut off in RUN mode: in this mode “LPCR_A53_AD.en_c0_wfi_pdn”, “LPCR_A53_AD.en_c1_wfi_pdn”, “LPCR_A53_AD.en_c2_wfi_pdn”, and “LPCR_A53_AD.en_c3_wfi_pdn” should be set and the condition to trigger A53 LPM will be some different:

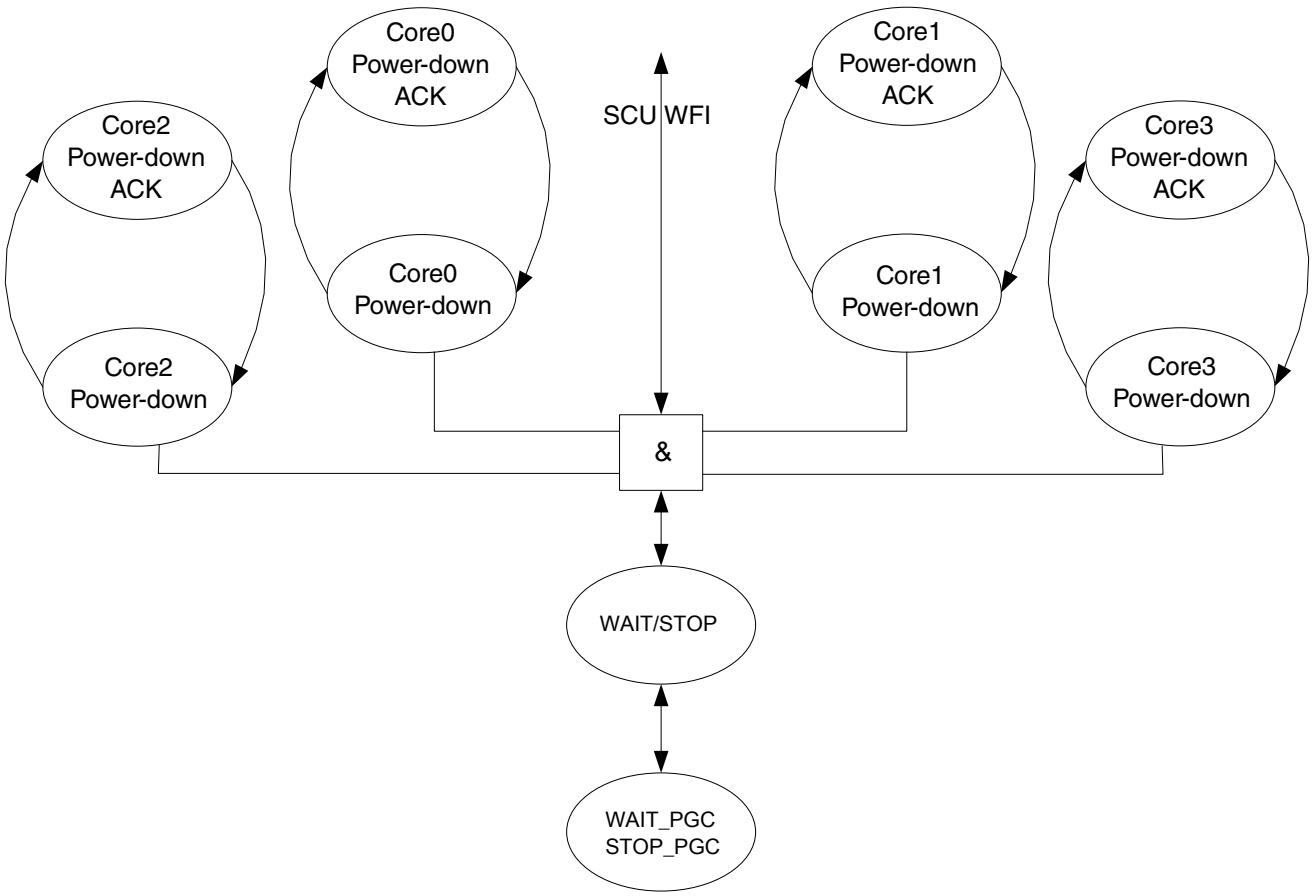

Figure 5-16. Power down of Core0, Core1, Core2, and Core3 in RUN mode

In this mode, core0/core1/core2/core3 power down process should not be disturbed by IRQs.

5.2.6.2.2 Power down of SCU and L2 Cache RAM

Power domain SCU and L2 cache RAM is controlled by one PGC – "PGC_PLAT" and they can only be power down in LPM process (when "LPCR_A53_AD.en_plat_pdn" is set). There is another bit "LPCR_A53_AD.l2pge" which will decide if L2 cache RAM need to be in retention mode when SCU domain is power down.

5.2.6.3 Power up process for the A53 Platform

- The core0, core1, core2, and core3 can be powered up with the exit of A53 LPM. The relevant bits are "LPCR_A53_AD.en_c0_pup", "LPCR_A53_AD.en_c1_pup", "LPCR_A53_AD.en_c2_pup", and "LPCR_A53_AD.en_c3_pup".
- The core0, core1, core2, and core3 can also be powered up by interrupt signal in RUN mode.

- The relevant bit are “LPCR_A53_AD.en_c0_irq_pup”, “LPCR_A53_AD.en_c1_irq_pup”, “LPCR_A53_AD.en_c2_irq_pup”, and “LPCR_A53_AD.en_c3_irq_pup”.
- The interrupt signal can be chosen from GIC or directly from IRQ with mask in GPCv2.
- The relevant select bits are “LPCR_A53_BSC.irq_src_c0”, “LPCR_A53_BSC.irq_src_c1”, “LPCR_A53_BSC.irq_src_c2”, “LPCR_A53_BSC.irq_src_c3”, and “LPCR_A53_BSC.irq_src_a53_wup”. (LPCR_A53_BSC[30],LPCR_A53_BSC[23:22],LPCR_A53_BSC.)

{LPCR_A53_BSC[30],LPCR_A53_BSC[23:22],LPCR_A53_BSC[29:28]}	Usage	Restriction
5'b00000	Use IRQ trigger A53 LPM and use IRQ to power up core0 to core3	None
5'b01111	Use GIC trigger A53 LPM and GIC to power up core0 to core3	SCU cannot power down in LPM, CPU clock cannot stop in LPM
5'b11111	Use IRQ trigger A53 LPM and GIC to power up core0 to core3	SCU cannot power down in LPM

As show in the table above, core0/core1/core2/core3 can only be power up by its own interrupt in RUN mode of A53 platform.

There are three combination of {LPCR_A53_BSC[30],LPCR_A53_BSC[23:22],LPCR_A53_BSC[29:28]}:

1. In the first case, “IMRn_CORE0_A53, IMRn_CORE1_A53, IMRn_CORE2_A53, IMRn_CORE3_A53“ are used to separate the 128 bits interrupts for core0, core1, core2, and core3 of A53 platform and also used as the interrupt mask for A53 LPM.
2. In the second case, “IMRn_CORE0_A53, IMRn_CORE1_A53, IMRn_CORE2_A53, IMRn_CORE3_A53” are not used, GIC setting are used to separate interrupts for core0, core1, core2, and core3 of A53 platform and also used as the interrupt mask for A53 LPM.
3. In the third case, “IMRn_CORE0_A53, IMRn_CORE1_A53, IMRn_CORE2_A53, IMRn_CORE3_A53” is used as the mask for interrupt for A53 LPM, GIC setting are used to separate interrupts for core0, core1, core2, and core3.

5.2.7 Power control for the M4 Platform

M4 LPM is same as A53 LPM. M4 platform doesn’t have its own power domain. There is a virtual PGC reserved for M4, the virtual PGC will do nothing else except generating an acknowledge signal and this signal can be chosen as the acknowledge signal for M4 platform.

5.2.8 Domain control for PGCs

The following rules are used for PGC power up/down with domain mapping control:

1. For PGCs inside CPU platform (since M4 doesn't have its own power domain, only PGCs in A53 platform are referred): for hardware trigger (including both power up and power down) only the LPM request from its own platform will take effect; for software trigger (including both power up and power down) (the relevant register bit are "CPU_PGC_SW_PUP_REQ" and "CPU_PGC_SW_PDN_REQ"), only the software running in its own platform will take effect.
2. For PGCs outside CPU platform(MIX and PU PGCs), register bits "PGC_CPU_MAPPING" will map MIX and PU PGCs to A53 or M4 CPU domain:
   - One PGC can be mapped to one or both of A53 and M4 domain;
   - For hardware power up request, if a PGC is mapped to any CPU domain, the PGC will be powered up when the corresponding CPU platform sends out its power up request.
   - For software power up, if a PGC is mapped any CPU platform, the PGC can be powered up by software running in corresponding CPU.(the relevant register bits are "MIX_PGC_SW_PUP_REQ" and "PU_PGC_SW_PUP_REQ")
   - For hardware power down, if a power domain is mapped to only one CPU domain, the relevant PGC can be powered down when the corresponding CPU platform sends out its power down request; If a power domain is mapped to both two CPU domain, when one CPU platform sends out its hardware power down request, the relevant PGC will power down with any of the following condition satisfied: the other CPU already in LPM; the other CPU want to power down relevant PGC (the relevant register are "A53_MIX_PDN_FLG, M4_MIX_PDN_FLG, A53_PU_PDN_FLG, M4_PU_PDN_FLG")
   - For software power down, if a power domain is mapped to only one CPU domain, the PGC can be powered down by software running in corresponding CPU. (the relevant register bits are "MIX_PGC_SW_PUP_REQ" and "PU_PGC_SW_PUP_REQ"). If a power domain is mapped to both two CPU domain, when one CPU platform sends out its software power down request, the relevant PGC will power down with any of the following condition satisfied: the other CPU already in LPM; the other CPU want to power down relevant PGC (the relevant register are "A53_MIX_PDN_FLG, M4_MIX_PDN_FLG, A53_PU_PDN_FLG, M4_PU_PDN_FLG")
   - The access of "PGC_CPU_MAPPING" is controlled by domain information from RDC

5.2.9 Example Code

Below are code examples for entering specific power scenarios

5.2.9.1 Example Code 1

```
//ARM enters into ALL_OFF(STOP) mode and enable DSM :
//after "wfi", MIX/C0/C1/C2/C3 power down in SLOT0, SCU power down in SLOT1 when
//after "GPT1_INT" arrived, MIX power up in SLOT2, SCU power up in SLOT3, C0 power up in
SLOT4
//IMRx_CORE0_A53

5.2.10 GPC Memory Map/Register Definition

Detailed descriptions of each register can be found below.

The total GPC memory map is 4KB

Table 5-10. Memory Regions

Address Range(offset)	Region
0x000 - 0x3FF	GPC configuration register
0x400 - 0x7FF	Reserved
0x800 - 0x9FF	CPU and SCU type PGC register base address
0xA00 - 0xBFF	MIX type PGC register base address
0xC00 - 0xFFF	PU type PGC register base address

Each PGC (CPU type, MIX type, PU type) will occupy 64 Bytes address space, the specific base address of each PGC are listed as below.

- 0x800 ~ 0x83F : PGC for A53 core0
- 0x840 ~ 0x87F: PGC for A53 core1
- 0x880 ~ 0x8BF: PGC for A53 core2
- 0x8C0 ~ 0x8FF: PGC for A53 core3
- 0x900 ~ 0x93F: PGC for A53 SCU
- 0xA00 ~ 0xA3F: Reserved
- 0xA40 ~ 0xA7F: PGC for NOC mix
- 0xC00 ~ 0xC3F: PGC for MIPI DSI PHY
- 0xC40 ~ 0xC7F: PGC for PCIE1 PHY
- 0xC80 ~ 0xCBF: USB_OTG1
- 0xCC0 ~ 0xCFF: USB_OTG2
- 0xD00 ~ 0xD3F: Reserved
- 0xD40 ~ 0xD7F: DDR1
- 0xD80 ~ 0xDBF: GPU_2D
- 0xDC0 ~ 0xDFF: GPUMIX
- 0xE00 ~ 0xE3F: VPUMIX
- 0xE40 ~ 0xE7F: GPU_3D
- 0xE80 ~ 0xEBF: DISPMIX
- 0xEC0 ~ 0xEFF: VPU_G1
- 0xF00 ~ 0xF3F: VPU_G2
- 0xF40 ~ 0xF7F: VPU_H1

For more specific information about PGC register definition, please see the register definition for each PGC.

GPC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
303A_0000	Basic Low power control register of A53 platform (GPC_LPCR_A53_BSC)	32	R/W	0000_3FF0h	5.2.10.1/ 609
303A_0004	Advanced Low power control register of A53 platform (GPC_LPCR_A53_AD)	32	R/W	0000_0020h	5.2.10.2/ 612
303A_0008	Low power control register of CPU1 (GPC_LPCR_M4)	32	R/W	0000_3FF0h	5.2.10.3/ 615
303A_0014	System low power control register (GPC_SLPCR)	32	R/W	E000_FF82h	5.2.10.4/ 617
303A_0018	MASTER LPM Handshake (GPC_MST_CPU_MAPPING)	32	R/W	0000_00FFh	5.2.10.5/ 620
303A_0020	Memory low power control register (GPC_MLPCR)	32	R/W	0101_0100h	5.2.10.6/ 621
303A_0024	PGC acknowledge signal selection of A53 platform (GPC_PGC_ACK_SEL_A53)	32	R/W	8000_8000h	5.2.10.7/ 622
303A_0028	PGC acknowledge signal selection of M4 platform (GPC_PGC_ACK_SEL_M4)	32	R/W	8000_8000h	5.2.10.8/ 624
303A_002C	GPC Miscellaneous register (GPC_MISC)	32	R/W	0000_0021h	5.2.10.9/ 625
303A_0030	IRQ masking register 1 of A53 core0 (GPC_IMR1_CORE0_A53)	32	R/W	0000_0000h	5.2.10.10/ 626

5.2.10.1 Basic Low power control register of A53 platform (GPC_LPCR_A53_BSC)

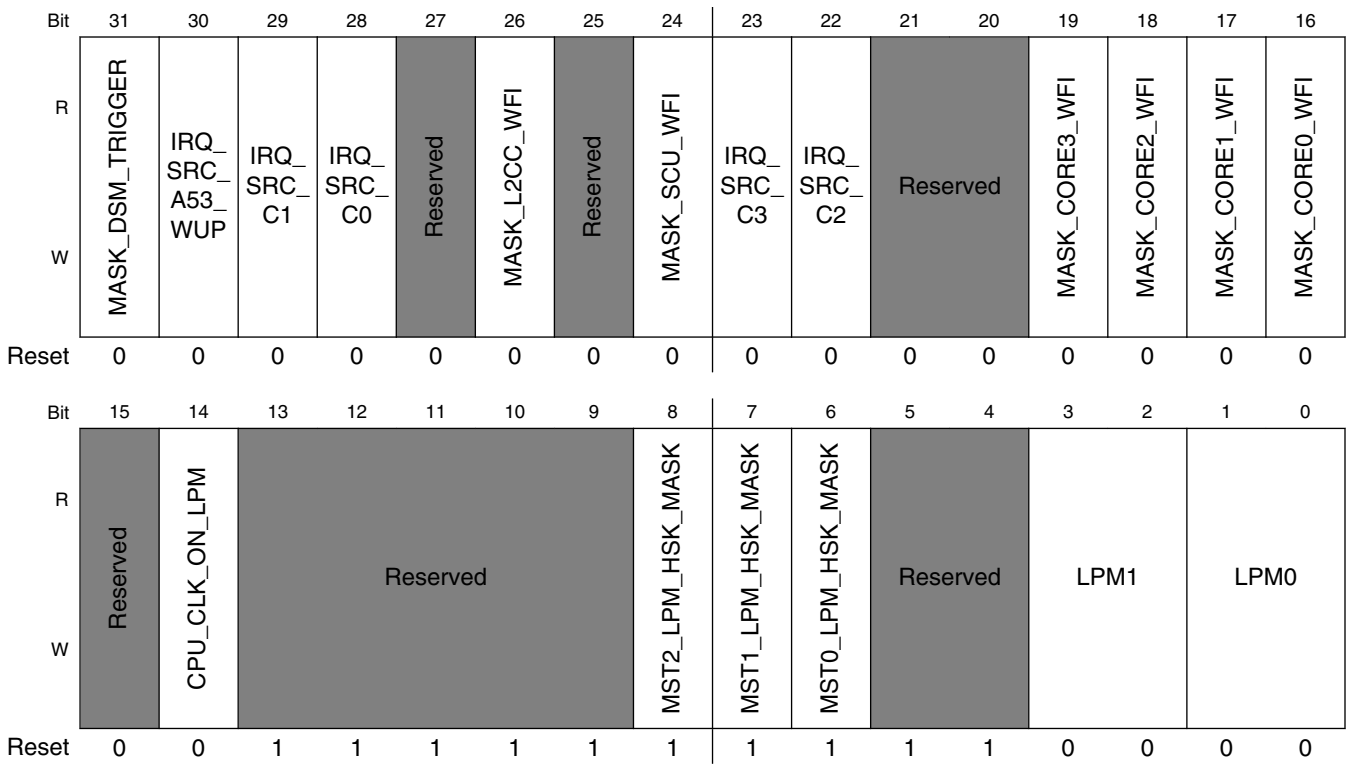
NOTE

LPCR_A53_BSC[CPU_CLK_ON_LPM] should be set 1'b1 when using A53 low power debug feature

NOTE

Always set LPM1/LPM0 with same value

Address: 303A_0000h base + 0h offset = 303A_0000h



GPC_LPCR_A53_BSC field descriptions

Field	Description
31 MASK_DSM_TRIGGER	DSM Trigger Mask 0 DSM trigger of A53 platform will not be masked 1 DSM trigger of A53 platform will be masked
30 IRQ_SRC_A53_WUP	LPCR_A53_BSC[IRQ_SRC_C0], LPCR_A53_BSC[IRQ_SRC_C1], LPCR_A53_BSC[IRQ_SRC_C2], LPCR_A53_BSC[IRQ_SRC_C3], and LPCR_A53_BSC[IRQ_SRC_A53_WUP] work together to decide the wake up source for A53 LPM and core0/core1/core2/core3 power. See "Power up process for A53 platform" for more specific information.

Table continues on the next page...

GPC_LPCR_A53_BSC field descriptions (continued)

Field	Description
	0 LPM wakeup source be “OR” result of LPCR_A53_BSC[IRQ_SRC_C0]/ LPCR_A53_BSC[IRQ_SRC_C1]/LPCR_A53_BSC[IRQ_SRC_C2]/LPCR_A53_BSC[IRQ_SRC_C3] setting 1 LPM wakeup source from external INT[127:0], masked by IMR0
29 IRQ_SRC_C1	LPCR_A53_BSC[IRQ_SRC_C0], LPCR_A53_BSC[IRQ_SRC_C1], LPCR_A53_BSC[IRQ_SRC_C2], LPCR_A53_BSC[IRQ_SRC_C3], and LPCR_A53_BSC[IRQ_SRC_A53_WUP] work together to decide the wake up source for A53 LPM and core0/core1/core2/core3 power. See “Power up process for A53 platform” for more specific information. 0 core1 wakeup source from external INT[127:0], masked by IMR1 refer to “Power up process for A53 platform” for more specific information 1 core1 wakeup source from GIC(nFIQ[1]/nIRQ[1]), SCU should not be power down during low power mode when this bit is set to 1’b1
28 IRQ_SRC_C0	LPCR_A53_BSC[IRQ_SRC_C0], LPCR_A53_BSC[IRQ_SRC_C1], LPCR_A53_BSC[IRQ_SRC_C2], LPCR_A53_BSC[IRQ_SRC_C3], and LPCR_A53_BSC[IRQ_SRC_A53_WUP] work together to decide the wake up source for A53 LPM and core0/core1/core2/core3 power. Reset	1	1	1	1	1	1	1	1	1	0	0	0	0	0	1	0

GPC_SLPCR field descriptions

Field	Description
31 EN_DSM	DSM enable 0 DSM disabled 1 DSM enabled
30 RBC_EN	Enable for REG_BYPASS_COUNTER. If enabled, REG_BYPASS signal will be asserted after REG_BYPASS_COUNT clocks of CKIL, after standby voltage is requested. If standby voltage is not requested REG_BYPASS won't be asserted, even if counter is enabled. 0 REG_BYPASS_COUNTER disabled 1 REG_BYPASS_COUNTER enabled
29–24 REG_BYPASS_COUNT	Counter for REG_BYPASS signal assertion after standby voltage request by PMIC_STBY_REQ. **NOTE:** When RBC enabled, interrupt will be masked until the counter counts to the value set in GPC_SLPCR[REG_BYPASS_COUNT], this can ignore the unexpected interrupts before CPU enter LPM mode, avoid the process interruption.

Table continues on the next page...

GPC_SLPCR field descriptions (continued)

Field	Description
	000000 no delay 000001 1 CKIL clock period delay 111111 63 CKIL clock period delay
23 DISABLE_A53_IS_DSM	0 Enable A53 isolation signal in DSM 1 Disable A53 isolation signal in DSM
22–20 -	This field is reserved. Reserved
19 EN_M4_FASTWUP_STOP_MODE	Enable M4 fast wake up stop mode, relevant PLLs will not be closed in this mode.
18 EN_M4_FASTWUP_WAIT_MODE	Enable M4 fast wake up wait mode, relevant PLLs will not be closed in this mode.
17 EN_A53_FASTWUP_STOP_MODE	Enable A53 fast wake up stop mode, relevant PLLs will not be closed in this mode.
16 EN_A53_FASTWUP_WAIT_MODE	Enable A53 fast wake up wait mode, relevant PLLs will not be closed in this mode.
15–8 OSCCNT	Oscillator ready counter value. These bits define value of 32KHz counter, that serve as counter for oscillator lock time. This is used for oscillator lock time. Current estimation is ~5ms. This counter will be used in sequence out of DSM and if sbyos bit was defined. GPC will wait the “OSCCNT” number of cycles before it notify CCM to open the relevant PLLs. 00000000 count 1 ckil 11111111 count 256 ckils
7 COSC_EN	On-chip oscillator enable bit - this bit value is reflected on the output cosc_en. The system will start with on-chip oscillator enabled to supply source for the PLLs. Software can change this bit if a transition to the bypass PLL clocks was performed for all the PLLs. In cases that this bit is changed from ‘0’ to ‘1’ then GPC will enable the on-chip oscillator and after counting oscnt ckil clock cycles before it notify CCM to open the relevant PLLs . The cosc_en bit should be changed only when on-chip oscillator is not chosen as the clock source. 0 Disable on-chip oscillator 1 Enable on-chip oscillator
6 COSC_PWRDOWN	In run mode, software can manually control powering down of on chip oscillator, i.e. generating ‘1’ on cosc_pwrdown signal. If software manually powered down the on chip oscillator, then sbyos functionality for on-chip oscillator will be bypassed. The manual closing of on-chip oscillator should be performed only in case the reference oscillator is not the source of all the clocks generation. 0 On-chip oscillator will not be powered down, i.e. cosc_pwrdown = 0 1 On-chip oscillator will be powered down, i.e. cosc_pwrdown = 1

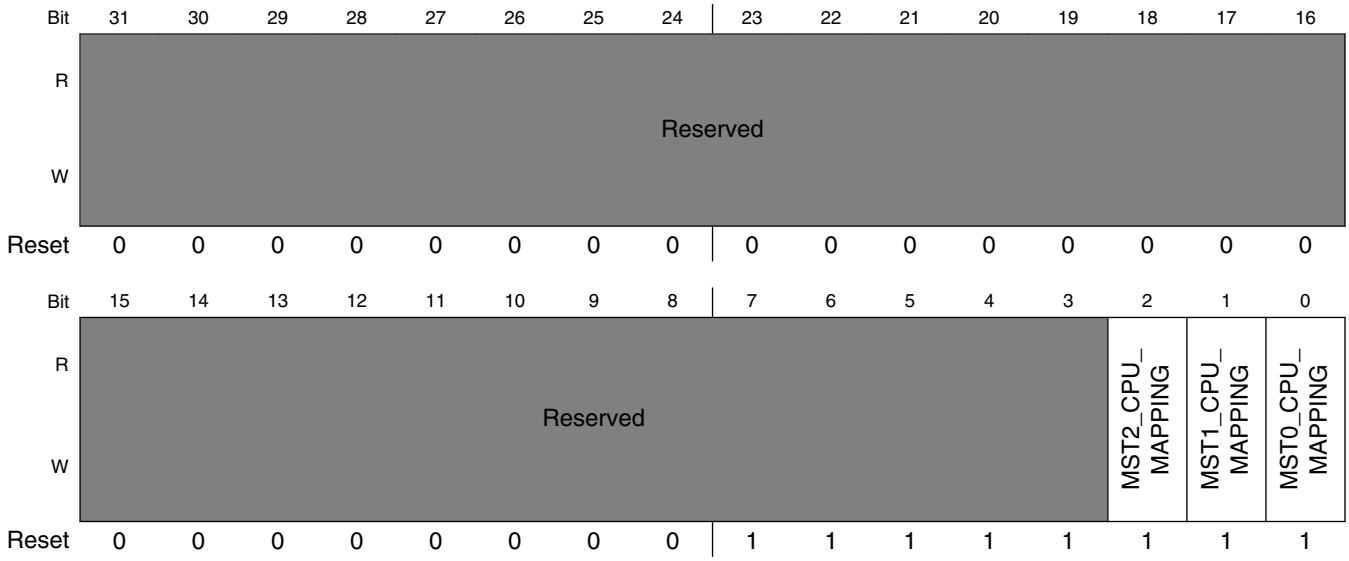
Table continues on the next page...

GPC_SLPCR field descriptions (continued)

Field	Description
5–3 STBY_COUNT	Standby counter definition. These two bits define, in the case of stop exit (if VSTBY bit was set), the amount of time GPC will wait between PMIC_STBY_REQ negation and the check of assertion of PMIC_READY. 000 GPC will wait 4 ckil clock cycles 001 GPC will wait 8 ckil clock cycles 010 GPC will wait 16 ckil clock cycles 011 GPC will wait 32 ckil clock cycles 100 GPC will wait 64 ckil clock cycles 101 GPC will wait 128 ckil clock cycles 110 GPC will wait 256 ckil clock cycles 111 GPC will wait 512 ckil clock cycles
2 VSTBY	Voltage standby request bit. This bit defines if PMIC_STBY_REQ pin, which notifies external power management IC to move from functional voltage to standby voltage, will be asserted in stop mode. 0 Voltage will not be changed to standby voltage after next entrance to stop mode. (PMIC_STBY_REQ will remain negated - ‘0’) 1 Voltage will be changed to standby voltage after next entrance to stop mode.
1 SBYOS	Standby clock oscillator bit. This bit defines if cosc_pwrdown, which power down the on chip oscillator, will be asserted in DSM. 0 On chip oscillator will not be powered down, after next entrance to DSM. 1 On chip oscillator will be powered down, after next entrance to DSM. When returning from DSM, external oscillator will be enabled again, on chip oscillator will return to oscillator mode , and after oscnt count GPC will continue with the exit from DSM process.
0 BYPASS_PMIC_READY	By asserting this bit GPC will bypass waiting for PMIC_READY signal when coming out of DSM. This should be used for PMIC’s that don’t support the PMIC_READY signal. 0 Don’t bypass the PMIC_READY signal - GPC will wait for its assertion during exit of low power mode if standby voltage was enabled 1 Bypass the PMIC_READY signal - GPC will wait for its assertion during exit of low power mode if standby voltage was enabled

5.2.10.5 MASTER LPM Handshake (GPC_MST_CPU_MAPPING)

Address: 303A_0000h base + 18h offset = 303A_0018h



GPC_MST_CPU_MAPPING field descriptions

Field	Description
31–3 -	This field is reserved. Reserved
2 MST2_CPU_MAPPING	MASTER2 CPU Mapping noc2supermix ADB LPM handshake mask. This bit should be used together with LPCR_A53_BSC[8]. If you want power of SCU, use this setting: LPCR_A53_BSC[8]=0; MST_CPU_MAPPING[2]=1 Otherwise, use this: LPCR_A53_BSC[8]=1; MST_CPU_MAPPING[2]=0 0 GPC will not send out power off requirement 1 GPC will send out power off requirement

1 A53_C1_PGC_PDN_ACK	Select power down acknowledge signal of A53 CORE1 PGC as the power down acknowledge for A53 LPM.
0 A53_C0_PGC_PDN_ACK	Select power down acknowledge signal of A53 CORE0 PGC as the power down acknowledge for A53 LPM.

5.2.10.8 PGC acknowledge signal selection of M4 platform (GPC_PGC_ACK_SEL_M4)

This register can only be accessed by the M4 platform.

NOTE

"dummy" PGC cannot be mapped to time slot control. "virtual" PGC can be mapped to time slot control. When virtual PGC is used, below setting is required - GPC_MISC[M4_PDN_REQ_MASK] should be set to 1'b1 and arrange virtual GPC in same slot with MIX. power/up slot (See example code 3). MIX PGC may possibly power down later than A53 platform power down when virtual PGC is used.

5.2.10.30 Slot configure register for A53 core (GPC_SLT*n*_CFG)

There are 20 slots in each SLTn_CFG(n = 0~19) will define the power up or power down behavior of one or more A53 CORE or SCU PGC in that each slot.

In each “SLTn_cfg”, 2 bits (slt_cfg[1:0])are reserved for each PGC:

- 2’b01 (slot controller will power down relevant PGC in corresponding slot if hardware power down request asserted)
- 2’b10 (slot controller will power up relevant PGC in corresponding slot if hardware power up request asserted)
- 2’b00 or 2’b11 (not power down or power up behavior in relevant slot)

The specific bits assignment for each PGC is shown in the table below.

	PGCx	PGCx-1	..	PGC2	PGC1	PGC0
SLT0_CFG	slt_cfg[1:0]	slt_cfg[1:0]	slt_cfg[1:0]	slt_cfg[1:0]	slt_cfg[1:0]	slt_cfg[1:0]

5.2.10.39 CPU PGC software up trigger status1 (GPC_CPU_PGC_PUP_STATUS1)

CPU_PGC_PUP_STATUS1 is a read only register, represents the results for power up software trigger for CPU type PGCs.

The field description is show in table below, the value of “1’b1” represent the software power up trigger failed because the relevant PGC is in a power down process. The relevant bit will be cleared after a success operation of power up software trigger for CPU type PGCs.

Address: 303A_0000h base + 130h offset = 303A_0130h

5.2.10.48 M4 PU PGC software down trigger status (GPC_M4_PU_PGC_PDN_STATUS*n*)

M4_PU_PGC_PDN_STATUSn (n = 0,1,2) are a read only register, represents the results for power DN software trigger from M4 platform to PU type PGCs.

M4_PU_PGC_PDN_STATUS0: value of “1’b1” represent the software power DN trigger failed because domain control condition. The relevant bit will be cleared after a success operation of power DN software trigger for PU type PGCs.

M4_PU_PGC_PDN_STATUS1: value of “1’b1” represent the software power DN trigger failed because the relevant PGC is in a power DN process. The relevant bit will be cleared after a success operation of power DN software trigger for PU type PGCs.

M4_PU_PGC_PDN_STATUS2: value of “1’b1” represent the software power DN trigger failed because time slot control is busy. The relevant bit will be cleared after a success operation of power DN software trigger for PU type PGCs.

Address: 303A_0000h base + 198h offset + (4d × i), where i=0d to 2d

5.2.10.63 Slot configure register for A53 core (GPC_SLT*n*_CFG)

There are 20 slots in each SLTn_CFG(n = 0~19) will define the power up or power down behavior of one or more A53 CORE or SCU PGC in that each slot.

In each “SLTn_cfg”, 2 bits (slt_cfg[1:0])are reserved for each PGC:

- 2’b01 (slot controller will power down relevant PGC in corresponding slot if hardware power down request asserted)
- 2’b10 (slot controller will power up relevant PGC in corresponding slot if hardware power up request asserted)
- 2’b00 or 2’b11 (not power down or power up behavior in relevant slot)

The specific bits assignment for each PGC is shown in the table below.

	PGCx	PGCx-1	..	PGC2	PGC1	PGC0

5.2.11 GPC PGC Memory Map/Register Definition

There are 14 PGC inside GPCv2, with 4 different types: CPU/SCU/MIX/PU. PCIE/ MIPI/USB OTGx PGC belongs to PU type PGC. Each type PGC has 4 different control words PGC_CTRL,PGC_PUPSCR,PGC_PDNSCR and PGC_SR. Different types PGC may have different field definition in these four registers. There is another extra control word PGC_AUXSW for SCU type PGC.

The total GPC memory map is 4KB

Table 5-11. Memory Regions

Address Range(offset)	Region
0x000 - 0x3FF	GPC configuration register
0x400 - 0x7FF	Reserved
0x800 - 0x9FF	CPU and SCU type PGC register base address
0xA00 - 0xBFF	MIX type PGC register base address
0xC00 - 0xFFF	PU type PGC register base address

Each PGC (CPU type, MIX type, PU type) will occupy 64 Bytes address space, the specific base address of each PGC are listed as below.

- 0x800 ~ 0x83F: PGC for A53 core0
- 0x840 ~ 0x87F: PGC for A53 core1
- 0x880 ~ 0x8BF: PGC for A53 core2
- 0x8C0 ~ 0x8FF: PGC for A53 core3
- 0x900 ~ 0x93F: PGC for A53 SCU
- 0xA40 ~ 0xA7F: PGC for NOC mix
- 0xC00 ~ 0xC3F: PGC for MIPI PHY (PU0)
- 0xC40 ~ 0xC7F: PGC for PCIE1 PHY (PU1)
- 0xC80 ~ 0xCBF: USB_OTG1 (PU2)
- 0xCC0 ~ 0xCFF: USB_OTG2 (PU3)
- 0xD00 ~ 0xD3F: Reserved (PU4)
- 0xD40 ~ 0xD7F: DDR1 (PU5)
- 0xD80 ~ 0xDBF: GPU_2D (PU6)
- 0xDC0 ~ 0xDFF: GPUMIX (PU7)
- 0xE00 ~ 0xE3F: VPUMIX (PU8)
- 0xE40 ~ 0xE7F: GPU_3D (PU9)
- 0xE80 ~ 0xEBF: DISPMIX (PU10)
- 0xEC0 ~ 0xEFF: VPU_G1 (PU11)
- 0xF00 ~ 0xF3F: VPU_G2 (PU12)
- 0xF40 ~ 0xF7F: VPU_H1 (PU13)

GPC_PGC_*n*CTRL field descriptions

Field	Description
31–30 -	This field is reserved. Reserved
29–24 MEMPWR_ TCD1_TDR_ TRM	After scu pdn_req, count this value to assert A53 mempwr to 1'b1 **NOTE:** Can't be programmed to zero (This register control only for SCU Type PGC)
23–22 -	This field is reserved. Reserved
21–16 L2RETN_TCD1_ TDR	After scu pdn_req, count this value to assert A53 l2retn to 1'b0 **NOTE:** Can't be programmed to zero (This register control only for SCU Type PGC)
15–14 -	This field is reserved. Reserved
13–8 DFTRAM_TCD1	After scu pdn_req, count this value to assert A53 dftram to 1'b1

Table continues on the next page...

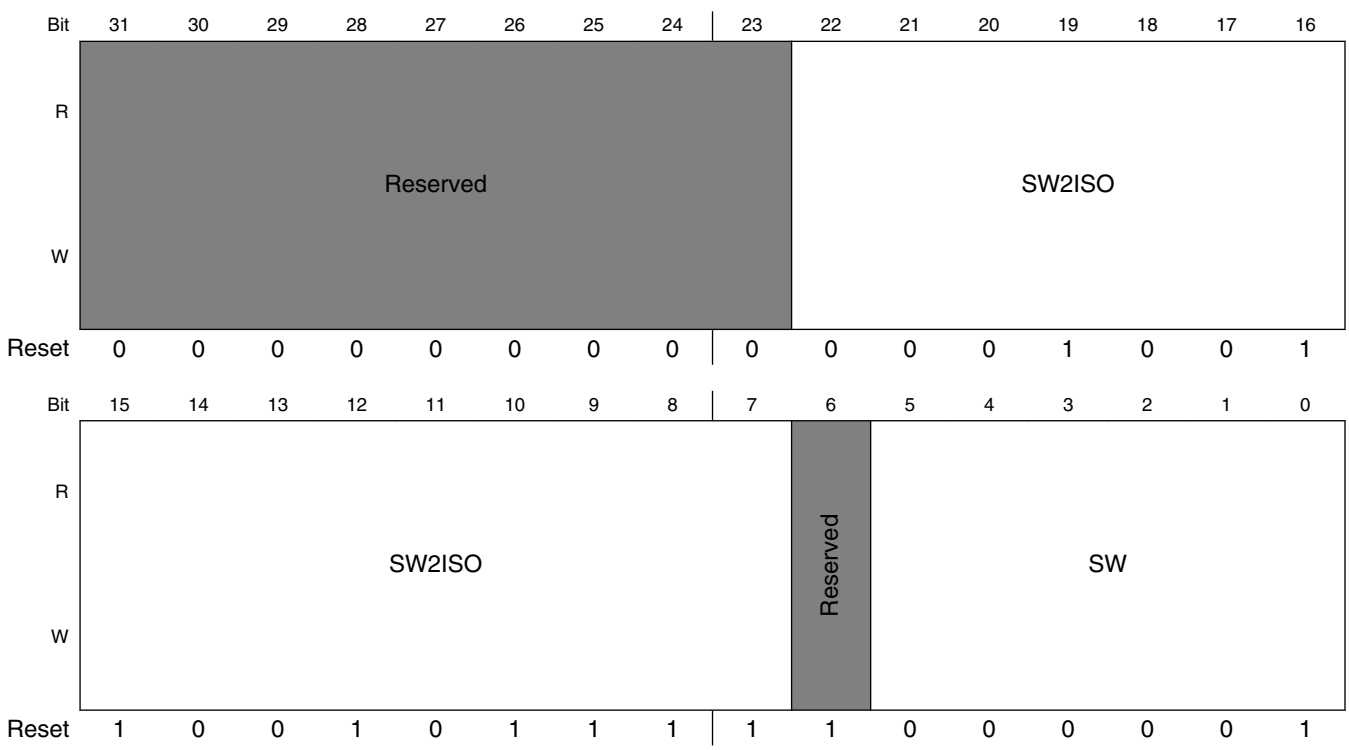
GPC_PGC_*n*CTRL field descriptions (continued)

Field	Description
	NOTE: Can't be programmed to zero (This register control only for SCU Type PGC)
7 -	This field is reserved. Reserved
6–1 L2RSTDIS	After scu pdn_req, count this value to assert A53 l2rstdis to 1'b1, it will be clear automatically once any of A53 core0/core1/core2/core3 is wakeup **NOTE:** Can't be programmed to zero (This register control only for SCU Type PGC)
0 PCR	Power Control **NOTE:** PCR must not change from power-down request (pdn_req) assertion until the target subsystem is completely powered up. 0 Do not switch off power even if pdn_req is asserted. 1 Switch off power when pdn_req is asserted.

5.2.11.2 GPC PGC Up Sequence Control Register (GPC_PGC_*n*PUPSCR)

GPC PGC Up Sequence Control Register

Address: 303A_0000h base + 804h offset + (64d × i), where i=0d to 4d



GPC_PGC_*n*PUPSCR field descriptions

Field	Description
31–23 -	This field is reserved. Reserved
22–7 SW2ISO	After asserting switch_b, the PGC waits a number of clocks equal to the value of SW2ISO before negating isolation.
6 -	This field is reserved. Reserved
SW	After a power-up request (pup_req assertion), the PGC waits a number of clocks equal to the value of SW before asserting switch_b **NOTE:** SW must not be programmed to zero.

5.2.11.3 GPC PGC Down Sequence Control Register (GPC_PGC_*n*PDNSCR)

GPC PGC Down Sequence Control Register

Address: 303A_0000h base + 808h offset + (64d × i), where i=0d to 4d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	1	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved		ISO2SW						Reserved		ISO					
Reset	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1

GPC_PGC_*n*PDNSCR field descriptions

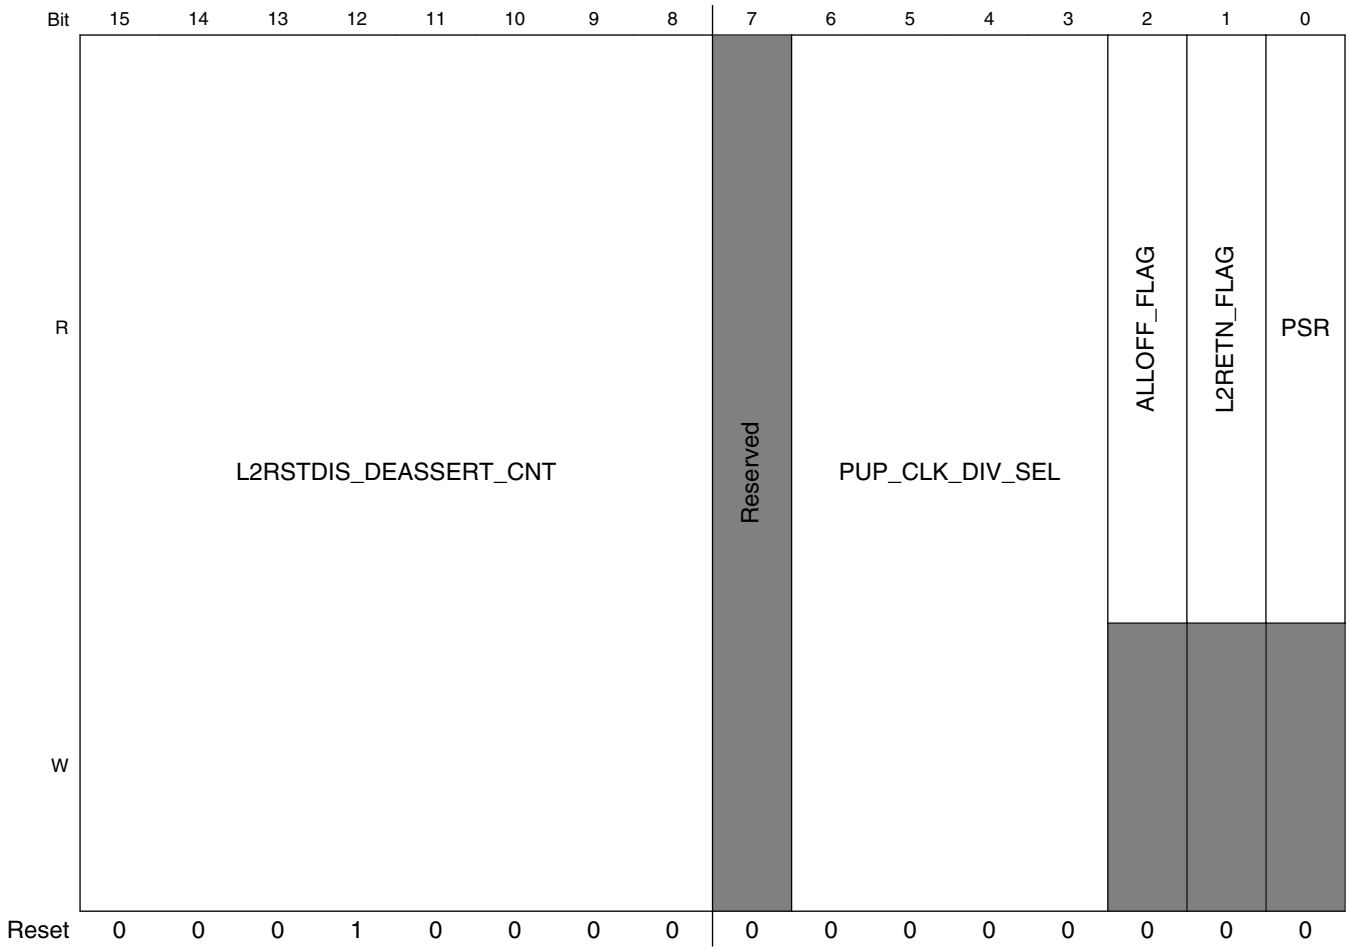
Field	Description
31–14 -	This field is reserved. Reserved
13–8 ISO2SW	After asserting isolation(by pdn_req assertion), the PGC waits a number of clocks equal to the value of ISO2SW before negating switch_b **NOTE:** ISO2SW must not be programmed to zero.
7–6 -	This field is reserved. Reserved
ISO	After a power-down request (pdn_req assertion), the PGC waits a number of clocks equal to the value of ISO before asserting isolation **NOTE:** ISO must not be programmed to zero.

5.2.11.4 GPC PGC Status Register (GPC_PGC_*n*SR)

GPC PGC Status Register

Address: 303A_0000h base + 80Ch offset + (64d × i), where i=0d to 4d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved														L2RSTDIS_DEASSERT_CNT	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



GPC_PGC_*n*SR field descriptions

Field	Description
31–18 -	This field is reserved. Reserved
17–8 L2RSTDIS_ DEASSERT_ CNT	Count this value to de-assert L2RSTDISABLE to LOW after CPU0 or CPU1 power up **NOTE:** This value can't be programmed to zero (This register control only for SCU Type PGC)
7 -	This field is reserved. Reserved
6–3 PUP_CLK_DIV_ SEL	Clock divider select for the clock of power up counter(count_clk is 32KHz for CPU/SCU type PGC, ipg_clk(66MHz) for MIX/PU Type PGC) 0000 1 0001 1/2 count_clk 0010 1/4 count_clk 0011 1/8 count_clk 0100 1/16 count_clk 0101 1/32 count_clk 0110 1/64 count_clk 0111 1/128 count_clk

Table continues on the next page...

GPC_PGC_*n*SR field descriptions (continued)

Field	Description
	1000 1/256 count_clk 1001 1/512 count_clk 1010 1/1024 count_clk 1011 1/2056 count_clk 1100 1/4096 count_clk 1101 1/8192 count_clk 1110 1/16384 count_clk 1111 1/32768 count_clk
2 ALLOFF_FLAG	All-off flag. **NOTE:** Software should write “1” to clear this flag after A53 is wakeup from ALL_OFF mode, otherwise, it will always keep to 1 (This register control only for SCU Type PGC) 0 A53 is not wakeup from ALL_OFF mode. 1 A53 is wakeup from ALL_OFF mode.
1 L2RETN_FLAG	L2 Retention Flag **NOTE:** Software should write “1” to clear this flag after A53 is wakeup from L2 retention mode, otherwise it will always keep to 1 (This register control only for SCU Type PGC) 0 A53 is not wakeup from L2 retention mode. 1 A53 is wakeup from L2 retention mode.
0 PSR	Power status. When in functional (or software-controlled debug) mode, PGC hardware sets PSR as soon as any of the power control output changes its state to one. Write one to clear this bit. Software should clear this bit after power up; otherwise, PSR continues to reflect the power status of the initial power down. 0 The target subsystem was not powered down for the previous power-down request. 1 The target subsystem was powered down for the previous power-down request.

5.2.11.5 GPC PGC Auxiliary Power Switch Control Register (GPC_PGC_A53SCU_AUXSW)

GPC PGC Auxiliary Power Switch Control Register.

Address: 303A_0000h base + 910h offset = 303A_0910h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

GPC_PGC_*n*SR field descriptions (continued)

Field	Description
	1000 1/256 count_clk 1001 1/512 count_clk 1010 1/1024 count_clk 1011 1/2056 count_clk 1100 1/4096 count_clk 1101 1/8192 count_clk 1110 1/16384 count_clk 1111 1/32768 count_clk
2 ALLOFF_FLAG	All-off flag. **NOTE:** Software should write “1” to clear this flag after A53 is wakeup from ALL_OFF mode, otherwise, it will always keep to 1 (This register control only for SCU Type PGC) 0 A53 is not wakeup from ALL_OFF mode. 1 A53 is wakeup from ALL_OFF mode.
1 L2RETN_FLAG	L2 Retention Flag **NOTE:** Software should write “1” to clear this flag after A53 is wakeup from L2 retention mode, otherwise it will always keep to 1 (This register control only for SCU Type PGC) 0 A53 is not wakeup from L2 retention mode. 1 A53 is wakeup from L2 retention mode.
0 PSR	Power status. When in functional (or software-controlled debug) mode, PGC hardware sets PSR as soon as any of the power control output changes its state to one. Write one to clear this bit. Software should clear this bit after power up; otherwise, PSR continues to reflect the power status of the initial power down. 0 The target subsystem was not powered down for the previous power-down request. 1 The target subsystem was powered down for the previous power-down request.

5.3 Crystal Oscillator (XTALOSC)

5.3.1 Overview

The chip has two XTAL modules, 24MHz XTAL module and 32KHz XTAL module. The 24MHz XTAL module is instantiated from the XTAL IP, which includes:

- 24MHz crystal oscillator to generate reference clock
- Digital control logics for the XTAL

The 32KHz XTAL module uses a different IP and it is used as the clock source for the RTC, located in the SNVS.

The 24MHz oscillator will be used as the primary clock source for the PLLs to generate the clock for CPU, BUS, and high-speed interfaces. For all PLLs, the 24MHz clock from the oscillator can be used as the PLL reference clock directly.

The OSC IP used by the 24MHz XTAL module has three modes, Internal clock generation mode, External clock receive mode and Retention mode. The figure below shows the OSC IP integration diagram:

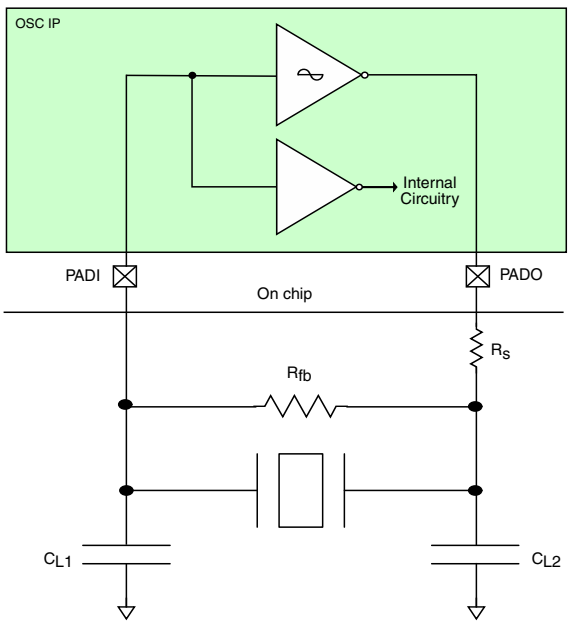

Figure 5-17. OSC IP Integration Diagram

During internal clock generation mode, a suitable quartz crystal is connected between PADI and PADO to generate the clock signal at the CK pin.

During external clock generation mode, the cell acts like a buffer, reflecting the PADI signal at CK.

The RTO (retention enable) signal retains the previous state of all the core input control signals. Logic at the RTO signal enables the retention operation.

Each XTAL module supports the following modes through register configuration:

- Normal oscillator mode - In normal mode, the XTAL IP generates stable square wave based on the crystal oscillator input.
- Bypass mode - In bypass mode, an external clock can be input through the XTAL pad.

5.4 Thermal Monitoring Unit (TMU)

5.4.1 Overview

The chip uses a temperature sensor to monitor the die temperature. The temperature sensor has a digitizer and local probe, and has the resolution of 1°C.

5.4.2 Features

- Junction temperature sensor function
- 1°C of sensing resolution
- 8-bit output codes with software calibration

5.4.3 Block Diagram

The TMU consists of a reference generation block, a positive TC voltage generator and a digitizer to convert the sensed voltage to 8-bit output codes.

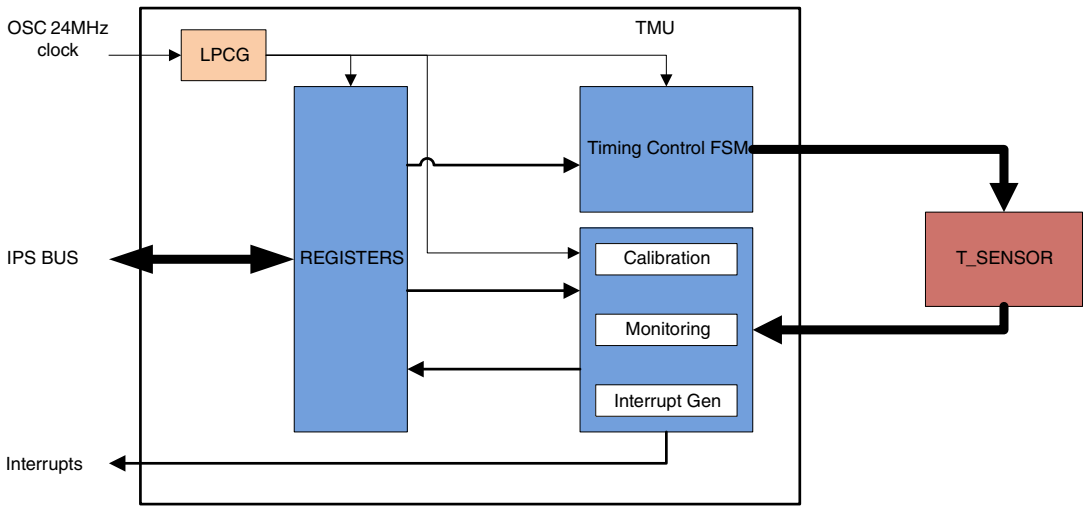

Figure 5-18. Block Diagram

5.4.4 Timing control FSM

The finite-state machine below describes the 8-bit clock input flow.

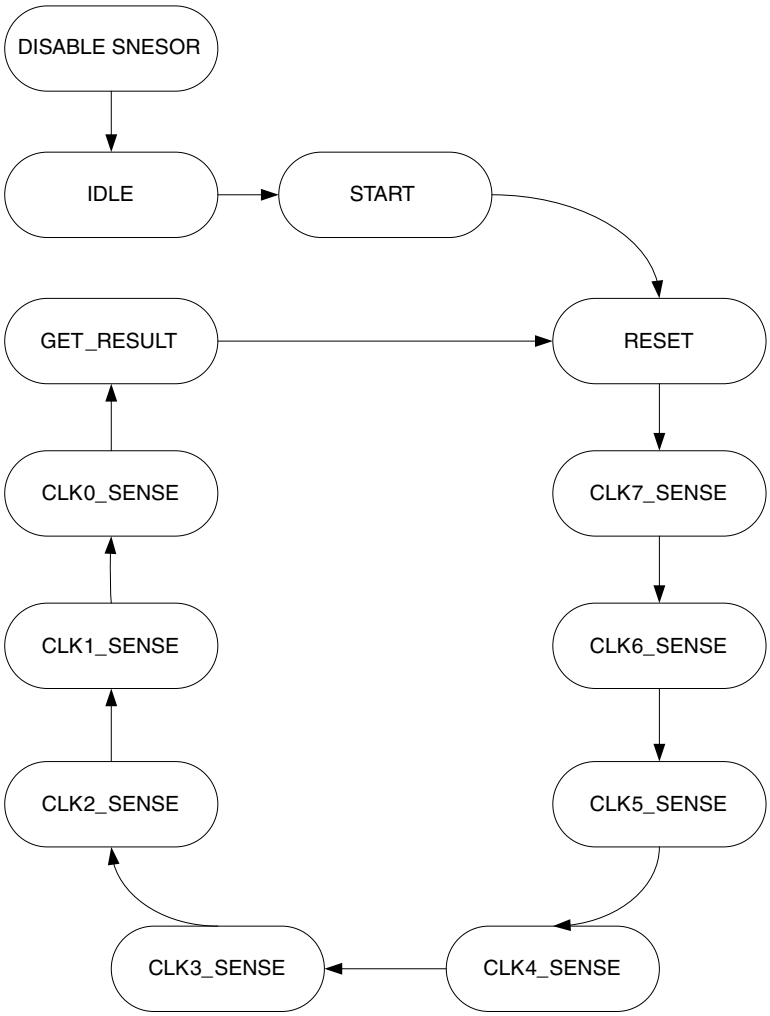

Figure 5-19. Timing Control FSM Diagram

5.4.5 Temperature Sensor Error Correction Method

The following figure shows an example of the difference between a reference curve and a real measured curve. The reference curve is based on ideal output codes vs. temperature, and the real measured curve is a waveform with process and mismatch error terms to the reference curve. There is DC offset between the real measured curve and the reference curve. In order to correct the error term, the temperature sensor uses software calibration method.

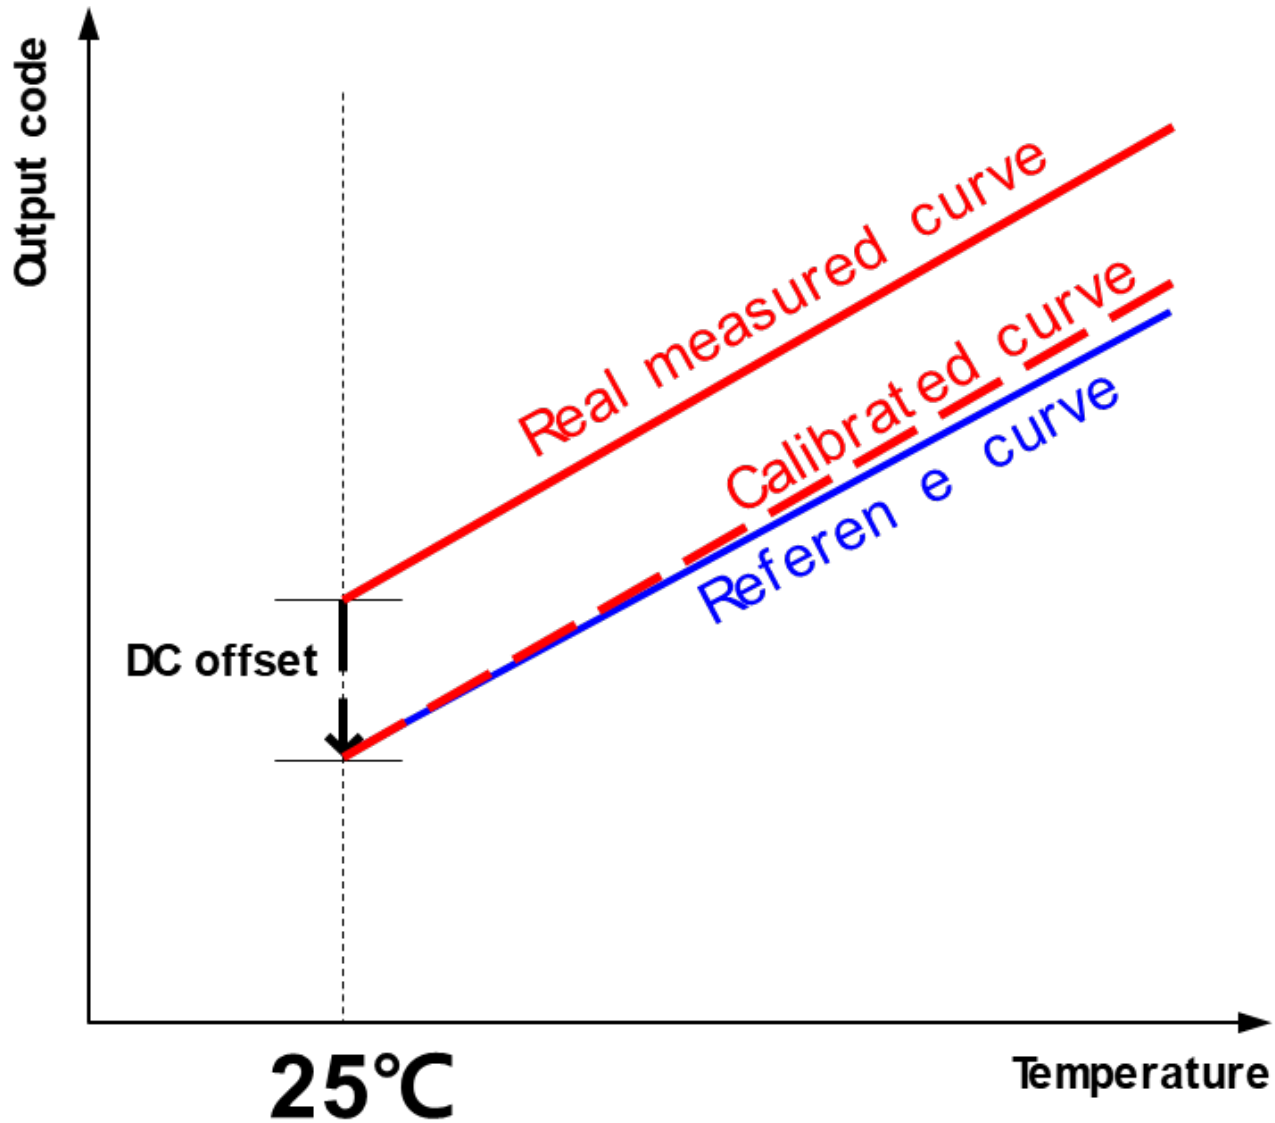

Figure 5-20. Reference Curve vs. Real Measured Curve

The software calibration method works as follows.

First, the temperature sensor senses die temperature at 25°C, and then 8-bit output codes are stored in the 8-bit OTP cells. With 8-bit data stored in OTP cells, the logic block (from the outside of the temperature sensor) is able to compensate DC offset.

Below equation shows the 1-point calibration method at 25°C.

$$T_{calib} = T_{sense} - (T_{E1} - 25)$$

Next equation shows the 1-point calibration method at 85°C.

$$T_{calib} = T_{sense} - (T_{E2} - 85)$$

where Tsense is the real measured output code including the DC offset, Tcalib is the calibrated output code of Tsense, TE1 (TE2) is the stored code in the first 8-bit OTP cell at 25°C (85°C) , and T25 (T85) is the ideal output code at 25°C (85°C). In other words, the DC offset is the difference between TE1 and T25. When the above equation is programmed in the glue logic block, the calibrated data is simply obtained by applying measured Tsense value.

Next equation shows the 2-point calibration method.

$$T_{calib} = (T_{sense} - T_{E1}) \times \frac{85-25}{T_{E2}-T_{E1}} + T_{E1} - (T_{E1} - 25)$$

where TE1 and TE2 are the temperature values stored in the 8-bit OTP cells from the 25°C and 85°C measurement, respectively. Units of all terms are degree (°C).

According to the above equation, (TE1 – 25) represents DC offset term and

$$(T_{sense} - T_{E1}) \times \frac{85 - 25}{T_{E2} - T_{E1}} + T_{E1}$$

represents slope compensation term. DC offset is simply difference between 25°C and TE1. Slope compensation term is reciprocal of temperature slope, (85 – 25)/(TE2 – TE1) times (Tsense – TE1). To obtain calibrated data, TE1 is added to slope compensation term for the slope error correction and DC offset tem is finally subtracted. If the above equation is programmed in the software, the calibrated data is simply obtained by applying measured Tsense value.

By using software slope calibration, it is possible to control a temperature slope of Tcalib. The software calibration method is below.

$$T_{calib\_SW} = \alpha \times (T_{sense} - T_{E1}) + 25$$

$$\alpha = \frac{(85 - 25)}{(Tcalib - T_{E1})}$$

5.4.6 Temperature Result Process

When the new sensor result is received, hardware will do 1 point calibration (software can do 2 points calibration). The calculated results and temperature value will then be transferred to registers, based on the calibration result and sensor-temperature mapping relationship. The hardware monitor checks the result effectiveness every time it gets the new sensor result. Hardware can also generate a normal interrupt or critical interrupt to the system when one of the three sensors reports a temperature value higher than the threshold value programmed in the registers

5.4.7 TMU Memory Map/Register Definition

This section provides a detailed description of all accessible TMU memory and registers. The table below lists the TMU registers. Note that the full register address is comprised of the programmable CCSRBAR together with the offset listed.

NOTE

The EN bit field of the TMU Enable Register (TMU_TER[EN]) must always be enabled for the part to operate correctly.

TMU memory map

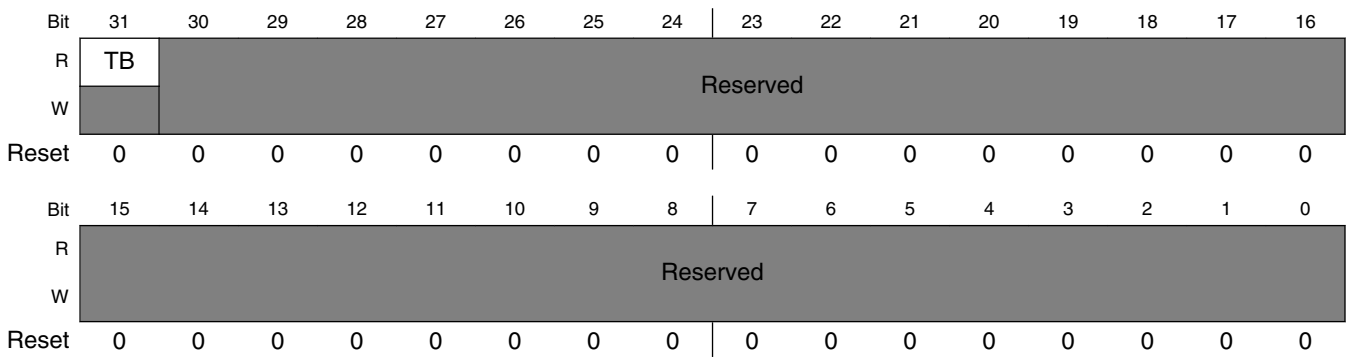
TMU_TER field descriptions

Field	Description
31 EN	Enable monitoring the temperature sensor **NOTE:** The POR value is disabled, but is enabled in boot. To ensure proper operation, this field must be enabled. 0 No monitoring 1 Enable monitoring
30–2 -	This field is reserved. Reserved
ALPF	Average low pass filter setting. The average temperature is calculated as: ALPF x Current_Temp + (1 - ALPF) x Average_Temp. If no previous (average) temperature is valid, current temperature is used. For proper operation, this field should only change when monitoring is disabled. 00 1.0 01 0.5 10 0.25 11 0.125

5.4.7.2 TMU Status register (TMU_TSR)

The TMU status register reports the monitoring status during operation.

Address: 3026_0000h base + 4h offset = 3026_0004h



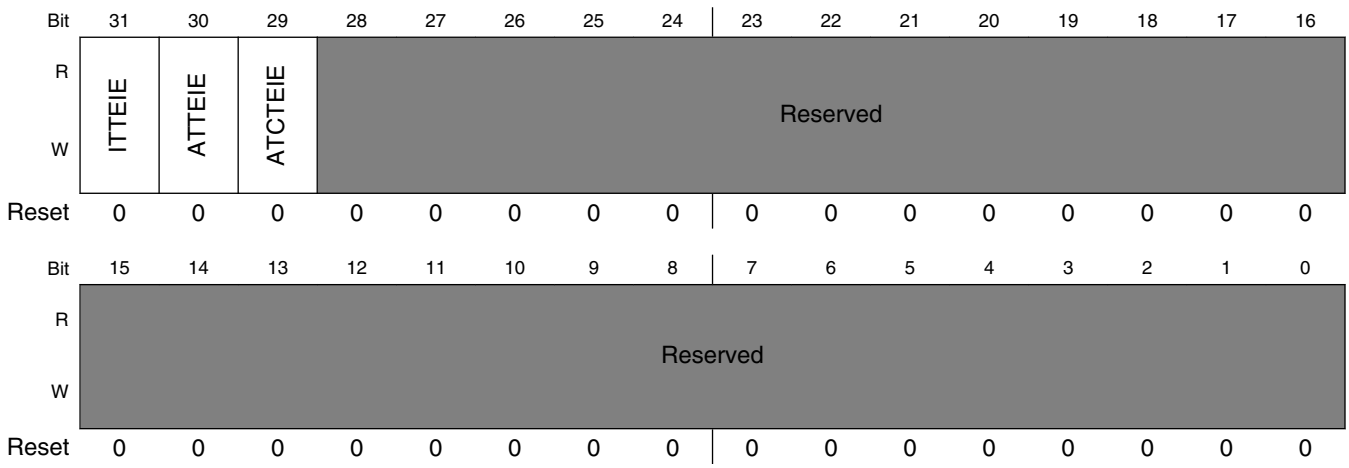
TMU_TSR field descriptions

Field	Description
31 TB	TMU busy. 0 TMU idle. 1 TMU busy. In monitoring mode this indicates a temperature measurement is pending. In calibration mode, sensor result has not yet been determined based on last given ambient temperature.
-	This field is reserved. Reserved

5.4.7.3 TMU Interrupt Enable register (TMU_TIER)

The TMU interrupt enable register determines if a detected status condition should cause a system interrupt. A system interrupt occurs if a bit in this register is set and the corresponding bit in the interrupt detect register is also set. To clear the interrupt, write a 1 to the interrupt detect register.

Address: 3026_0000h base + 8h offset = 3026_0008h



TMU_TIER field descriptions

Field	Description
31 ITTEIE	Immediate temperature threshold exceeded interrupt enable. 0 Disabled. 1 Interrupt enabled. Generate an interrupt if TIDR[ITTE] is set. Write 1 to this bit will clear bit TIDR[ITTE].
30 ATTEIE	Average temperature threshold exceeded interrupt enable. 0 Disabled. 1 Interrupt enabled. Generate an interrupt if TIDR[ATTE] is set. Write 1 to this bit will clear bit TIDR[ATTE].
29 ATCTEIE	Average temperature critical threshold exceeded interrupt enable. 0 Disabled. 1 Interrupt enabled. Generate an interrupt if TIDR[ATCTE] is set. Write 1 to this bit will clear bit TIDR[ATCTE].
-	This field is reserved. Reserved

5.4.7.4 TMU Interrupt Detect register (TMU_TIDR)

The TMU interrupt detect register indicates if an status condition was detected that could generate an interrupt. Write 1 to clear the detected condition and the interrupt, if enabled.

Address: 3026_0000h base + Ch offset = 3026_000Ch

TMU_TMHTACTR field descriptions

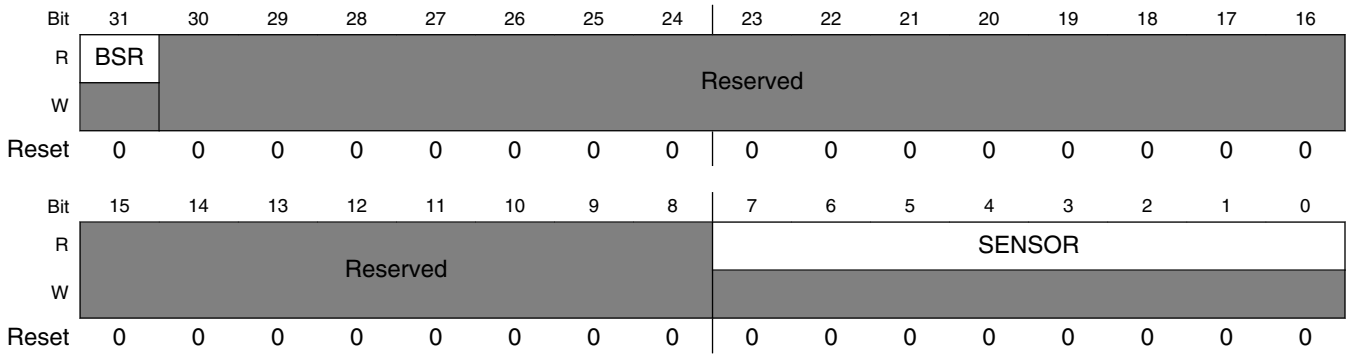
Field	Description
31 EN	Enable threshold. 0 Disabled. 1 Threshold enabled.
30–8 -	This field is reserved. Reserved
TEMP	High temperature average critical threshold value. Determines the average upper critical temperature threshold when EN=1. 10-125 °C Sensor range 0-9 and 126-255 °C Reserved

5.4.7.8 TMU Sensor Calibration register (TMU_TSCR)

The TMU sensor calibration register, in conjunction with the temperature calibration register, is used to build the internal sensor translation table used during monitoring.

During the calibration phase, TMR[CE]=1, reading this register will return the sensor reading. After writing the temperature calibration register, user should poll the TSR[TB] bit to determine when the sensor reading is complete and then read the register. If BSR=1 the sensor reading could not be established due to temperature outside sensor range.

Address: 3026_0000h base + 1Ch offset = 3026_001Ch



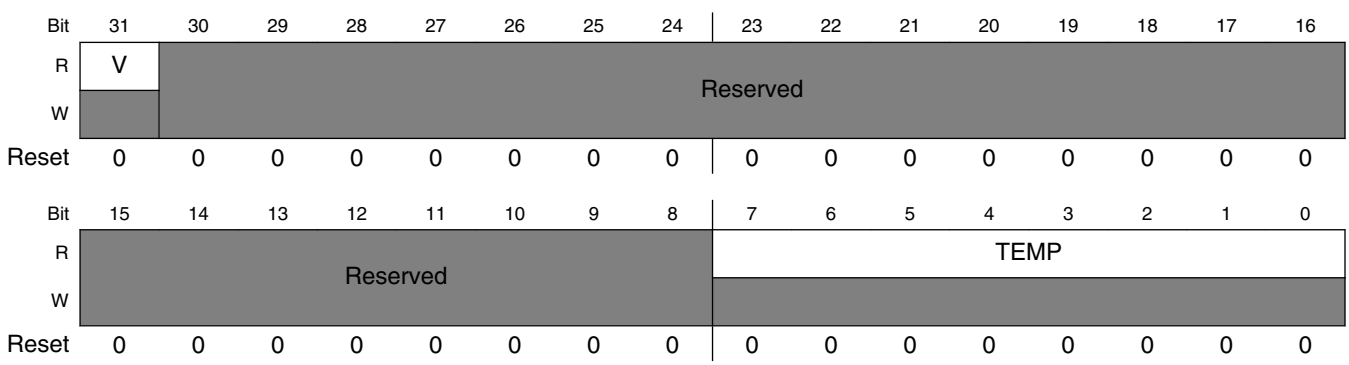
TMU_TSCR field descriptions

Field	Description
31 BSR	Beyond temperature sensor range of 10-125 °C. The sensor reading is invalid. Read-only.
30–8 -	This field is reserved. Reserved
SENSOR	Sensor reading. Read only.

5.4.7.9 TMU Report Immediate Temperature Site register n (TMU_TRITSR)

This TMU report register returns the last measured temperature at site. The site must be part of the list of enabled monitored sites as defined by TMR[MSITE].

Address: 3026_0000h base + 20h offset = 3026_0020h



TMU_TRITSR field descriptions

Field	Description
31 V	Valid measured temperature.

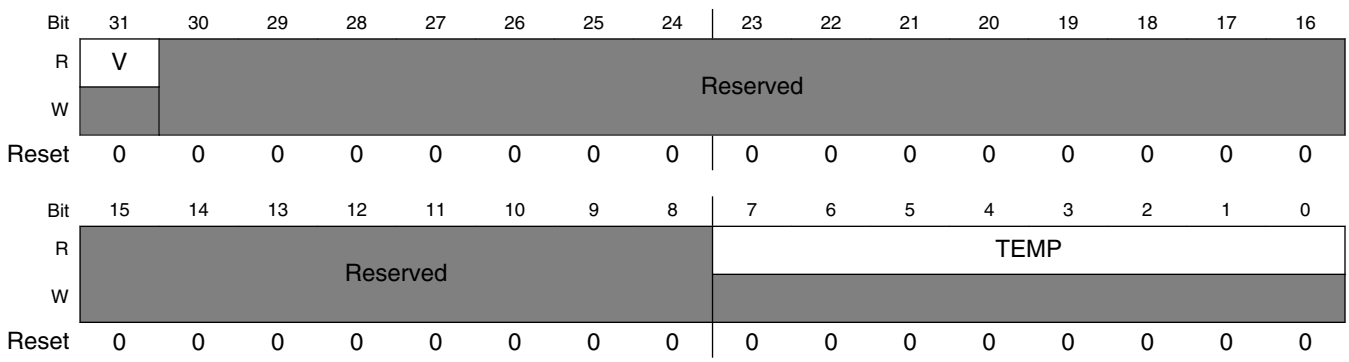
5.4.7.10 TMU Report Average Temperature Site register n (TMU_TRATSR)

This TMU report register returns the average measured temperature at site.

Address: 3026_0000h base + 24h offset = 3026_0024h



TMU_TRATSR field descriptions

Field	Description
31 V	Valid measured temperature. 0 Not valid. Temperature out of sensor range or first measurement still pending. 1 Valid.
30–8 -	This field is reserved. Reserved
TEMP	Average temperature reading at site0 when V=1.

Chapter 6
SNVS, Reset, Fuse, and Boot

6.1 System Boot

6.1.1 Overview

The boot process begins at the Power-On Reset (POR) where the hardware reset logic forces the Arm core to begin the execution starting from the on-chip boot ROM.

The boot ROM code uses the state of the internal register BOOT_MODE[1:0] as well as the state of various eFUSEs and/or GPIO settings to determine the boot flow behavior of the device.

The main features of the ROM include:

- Support for booting from various boot devices
- Serial downloader support (USB OTG)
- Device Configuration Data (DCD) and plugin
- Wake-up from the low-power modes

The boot ROM supports these boot devices:

- Serial NOR Flash via FlexSPI
- NAND flash
- SD/MMC
- Serial (SPI) NOR

The boot ROM uses the state of the BOOT_MODE and eFUSEs to determine the boot device. For development purposes, the eFUSEs used to determine the boot device may be overridden using the GPIO pin inputs.

The boot ROM code also allows to download the programs to be run on the device. The example is a provisioning program that can make further use of the serial connection to provide a boot device with a new image. Typically, the provisioning program is

downloaded to the internal RAM and allows to program the boot devices, such as the SD/MMC flash. The ROM serial downloader uses a high-speed USB in a non-stream mode connection.

The Device Configuration Data (DCD) feature allows the boot ROM code to obtain the SOC configuration data from an external program image residing on the boot device. As an example, the DCD can be used to program the DDR controller for optimal settings, improving the boot performance. The DCD is restricted to the memory areas and peripheral addresses that are considered essential for the boot purposes (see Write data command).

A key feature of the boot ROM is the ability to perform a secure boot, also known as a High-Assurance Boot (HAB). This is supported by the HAB security library which is a subcomponent of the ROM code. The HAB uses a combination of hardware and software together with the Public Key Infrastructure (PKI) protocol to protect the system from executing unauthorized programs. Before the HAB allows the user image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and the signatures are then included as a part of the final program image. If configured to do so, the ROM verifies the signatures using the public keys included in the program image. A secure boot with HAB can be performed on all boot devices supported on the chip in addition to the serial downloader. The HAB library in the boot ROM also provides the API functions, allowing the additional boot chain components (bootloaders) to extend the secure boot chain. The out-of-fab setting for the SEC_CONFIG is the open configuration, in which the ROM/HAB performs the image authentication, but all authentication errors are ignored and the image is still allowed to execute.

6.1.2 Boot modes

During reset, the chip checks the power gating controller status register.

During boot, the core's behavior is defined by the boot mode pin settings, as described in Boot mode pin settings. When waking up from the low-power boot mode, the core skips the clock settings. The boot ROM checks that the PERSISTENT_ENTRY0 (see Persistent bits) is a pointer to a valid address space (OCRAM, DDR, or EIM). If the PERSISTENT_ENTRY0 is a pointer to a valid range, it starts the execution using the entry point from the PERSISTENT_ENTRY0 register. If the PERSISTENT_ENTRY0 is a pointer to an invalid range, the core performs the system reset.

6.1.2.1 Boot mode pin settings

The device has four boot modes (one is reserved for NXP use). The boot mode is selected based on the binary value stored in the internal BOOT_MODE register.

The BOOT_MODE is initialized by sampling the BOOT_MODE0 and BOOT_MODE1 inputs on the rising edge of the POR_B. After these inputs are sampled, their subsequent state does not affect the contents of the BOOT_MODE internal register. The state of the internal BOOT_MODE register may be read from the BMOD[1:0] field of the SRC Boot Mode Register (SRC_SBMR2). The available boot modes are: Boot From Fuses, serial boot via USB, and Internal Boot. See this table for settings:

Table 6-1. Boot MODE pin settings

BOOT_MODE[1:0]	Boot Type
00	Boot From Fuses
01	Serial Downloader
10	Internal Boot
11	Reserved

6.1.2.2 High-level boot sequence

The figure found here show the high-level boot ROM code flow.

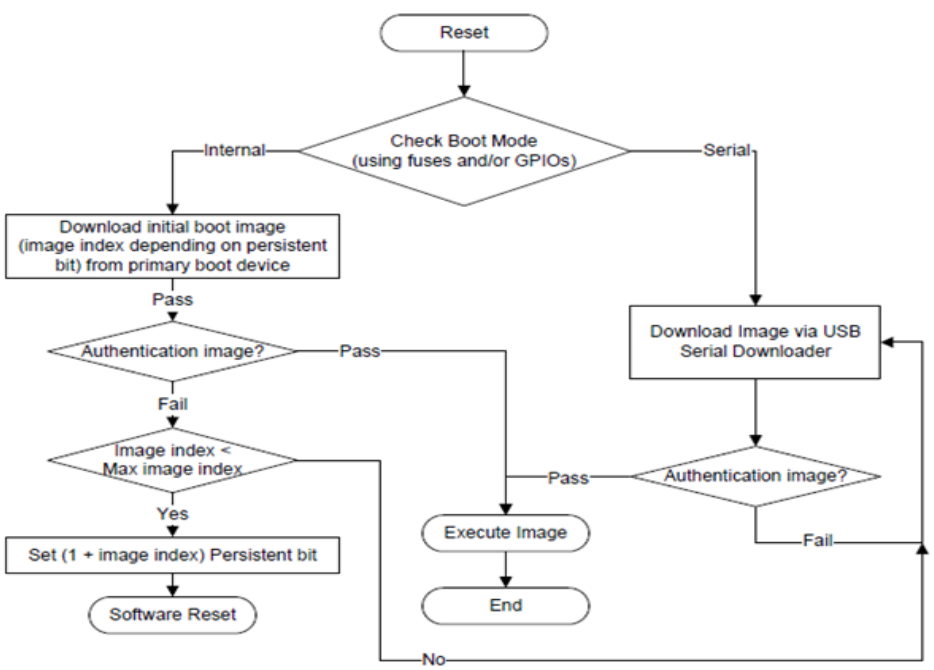


Figure 6-1. Boot flow

6.1.2.3 Boot From Fuses mode (BOOT_MODE[1:0] = 00b)

A value of 00b in the BOOT_MODE[1:0] register selects the Boot From Fuses mode.

This mode is similar to the Internal Boot mode described in Internal Boot mode (BOOT_MODE[1:0] = 0b10) with one difference. In this mode, the GPIO boot override pins are ignored. The boot ROM code uses the boot eFUSE settings only. This mode also supports a secure boot using HAB.

If set to Boot From Fuses, the boot flow is controlled by the BT_FUSE_SEL eFUSE value. If BT_FUSE_SEL = 0, indicating that the boot device (for example, flash, SD/MMC) was not programmed yet, the boot flow jumps directly to the Serial Downloader. If BT_FUSE_SEL = 1, the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default eFUSEs may be configured incorrectly for the hardware on the platform. In such case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using the Boot From Fuses mode addresses this problem.

Setting the BT_FUSE_SEL=0 forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a program image and blow the BT_FUSE_SEL and the other boot configuration eFUSEs. After the reset, the boot ROM code determines that the BT_FUSE_SEL is blown (BT_FUSE_SEL = 1) and the ROM code performs an internal boot according to the new eFUSE settings. This allows the user to set BOOT_MODE[1:0]=00b on a production device and burn the fuses on the same device (by forcing the entry to the Serial Downloader), without changing the value of the BOOT_MODE[1:0] or the pullups/pulldowns on the BOOT_MODE pins.

6.1.2.4 Serial Downloader

The Serial Downloader provides a means to download a program image to the chip over the USB serial connection.

In this mode, the ROM programs the WDOG1 for a time-out specified by the fuse WDOG Time-out Select (See fusemap for details) if the WDOG_ENABLE eFuse is 1 and continuously polls for the USB connection. If no activity is found on the USB OTG1 and the watchdog timer expires, the Arm core is reset.

NOTE

After the downloaded image is loaded, it is responsible for managing the watchdog resets properly.

This figure shows the USB boot flow:

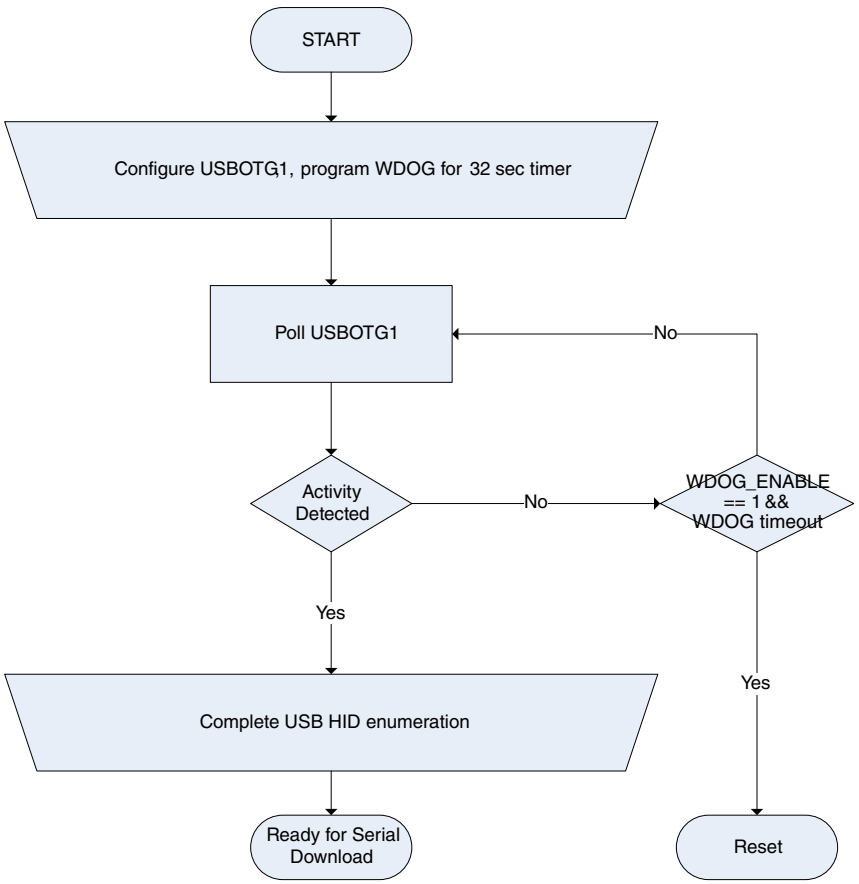

Figure 6-2. Serial Downloader boot flow

NOTE

Before going into USB serial mode, Boot ROM detect SD/MMC card on USDHC2 port. If a card is inserted, ROM will try to boot from it. This is the so-called Manufacture SD/MMC boot. This feature can be disabled by blowing fuse “Disable SD/MMC Manufacture Mode”. See SD/MMC manufacture mode for details.

6.1.2.5 Internal Boot mode (BOOT_MODE[1:0] = 0b10)

A value of 0b10 in the BOOT_MODE[1:0] register selects the Internal Boot mode. In this mode, the processor continues to execute the boot code from the internal boot ROM.

The boot code performs the hardware initialization, loads the program image from the chosen boot device, performs the image validation using the HAB library (see Boot security settings), and then jumps to an address derived from the program image. If an error occurs during the internal boot, the boot code jumps to the Serial Downloader (see Serial Downloader). A secure boot using the HAB is possible in all the three boot modes.

When set to the Internal Boot, the boot flow may be controlled by a combination of eFUSE settings with an option of overriding the fuse settings using the General Purpose I/O (GPIO) pins. The GPIO Boot Select FUSE (BT_FUSE_SEL) determines whether the ROM uses the GPIO pins for a selected number of configuration parameters or eFUSEs in this mode.

- If BT_FUSE_SEL = 1, all boot options are controlled by the eFUSEs described in Table 6-2.
- If BT_FUSE_SEL = 0, the specific boot configuration parameters may be set using the GPIO pins rather than eFUSEs. The fuses that can be overridden when in this mode are indicated in the GPIO column of Table 6-2. Table 6-3 provides the details of the GPIO pins.

The use of the GPIO overrides is intended for development since these pads are used for other purposes in the deployed products. NXP recommends controlling the boot configuration by the eFUSEs in the deployed products and reserving the use of the GPIO mode for the development and testing purposes only.

6.1.2.6 Boot security settings

The internal boot modes use one of three security configurations.

- Closed: This level is intended for use with shipping-secure products. All HAB functions are executed and the security hardware is initialized (the Security Controller or SNVS enters the Secure state), the DCD is processed if present, and the program image is authenticated by the HAB before its execution. All detected errors are logged, and the boot flow is aborted with the control being passed to the serial downloader. At this level, the execution does not leave the internal ROM unless the target executable image is authenticated.
- Open: This level is intended for use in non-secure products or during the development phases of a secure product. All HAB functions are executed as for a closed device. The security hardware is initialized (except for the SNVS which is left

in the Non-Secure state), the DCD is processed if present, and the program image is authenticated by the HAB before its execution. All detected errors are logged, but have no influence on the boot flow which continues as if the errors did not occur. This configuration is useful for a secure product development because the program image runs even if the authentication data is missing or incorrect, and the error log can be examined to determine the cause of the authentication failure.

- Field Return: This level is intended for the parts returned from the shipped products.

6.1.3 Device configuration

This section describes the external inputs that control the behavior of the Boot ROM code.

This includes the boot device selection (SD, MMC, and so on), boot device configuration (SD bus width, speed, and so on), and other. In general, the source for this configuration comes from the eFUSEs embedded inside the chip. However, certain configuration parameters can be sourced from the GPIO pins, allowing further flexibility during the development process.

6.1.3.1 Boot eFUSE descriptions

This table is a comprehensive list of the configuration parameters that the ROM uses.

Table 6-2. Boot eFUSE descriptions

Fuse	Configuration	Definition	GPIO[1]	Shipped value	Settings[2]
BT_FUSE_SEL	OEM	In the Internal Boot mode BOOT_MODE[1:0] = 10, the BT_FUSE_SEL fuse determines whether the boot settings indicated by a Yes in the GPIO column are controlled by the GPIO pins or the eFUSE settings in the On-Chip OTP Controller (OCOTP). In the Boot From Fuse mode BOOT_MODE[1:0] = 00, the BT_FUSE_SEL fuse indicates whether the bit configuration eFuses are programmed.	NA	0	If BOOT_MODE[1:0] = 0b10: • 0—The bits of the SBMR are overridden by the GPIO pins. • 1—The specific bits of the SBMR are controlled by the eFUSE settings. If BOOT_MODE[1:0] = 0b00 • 0—The BOOT configuration eFuses are not programmed yet. The boot flow jumps to the serial downloader. • 1—The BOOT configuration eFuses are programmed. The regular boot flow is performed.

Table continues on the next page...

Table 6-2. Boot eFUSE descriptions (continued)

Fuse	Configuration	Definition	GPIO[1]	Shipped value	Settings[2]
SEC_CONFIG[1:0]	SEC_CONFIG[0] - NXP SEC_CONFIG[1] - OEM	Security Configuration, as defined in Boot security settings	NA	01	00—Reserved 01—Open (allows any program image, even if the authentication fails) 1x—Closed (The program image executes only if authenticated)
FIELD_RETURN	OEM	Configure device for field return testing. Fuse burning is protected by CSF command, with proper parameter passed. Non-lockable.			0—Device is in functional/secure mode. 1—Device is open for "field-return" testing.
SRK_HASH[255:0]	OEM	256-bit hash value of the super root key (SRK_HASH)	NA	0	Settings vary—used by HAB
BT_MMU_DISABLE (BOOT_CFG[16])	OEM	The MMU/L1 D Cache disable bit used by the boot ROM for fast HAB processing.	No	0	0—MMU/L1 D Cache is enabled by the ROM during the boot. 1—MMU/L1 D Cache is disabled by the ROM during the boot.
L1 I-Cache DISABLE	OEM	L1 I Cache disable bit used by the boot during the entire execution.	No	0	0—L1 I Cache is enabled by the ROM during the boot. 1—L1 I Cache is disabled by the ROM during the boot.
LPB_BOOT	OEM	USB Low-Power Boot	No	0	0x—LPB Disable 10—Divide by 2 11—Divide by 4
BT_LPB_POLARITY	OEM	USB Low-Power Boot GPIO polarity	No	0	0—Low on the GPIO pad indicates the low-power condition. 1—High on the GPIO pad indicates the low-power condition.
WDOG_ENABLE	OEM	Watchdog reset counter enable	No	0	0—The watchdog reset counter is disabled during the serial downloader. 1—The watchdog reset counter is enabled during the serial downloader.
Recovery Boot Enable	OEM	SPI recovery boot enable	No	0	0—Disabled 1—Enabled
MMC_DLL_DLY[6:0]	OEM	uSDHC Delay Line settings	No	0	uSDHC Delay Line settings
SRK_REVOKE[2:0]	OEM	SRK revocation mask	No	0	SRK revocation mask
DISABLE_SDMMC_MFG	OEM	Disable the SDMMC manufacture mode	Yes	0	0—enable the SD/MMC MFG mode 1—disable the SD/MMC MFG mode

Table continues on the next page...

Table 6-2. Boot eFUSE descriptions (continued)

Fuse	Configuration	Definition	GPIO[1]	Shipped value	Settings[2]
USDHC_PAD_SETTINGS NAND_PAD_SETTINGS	OEM	Override values for the SD/MMC and NAND boot modes	No	0	Override the following IO PAD settings: [1:0] Driver Strength [2] Slew Rate [3] Hysteresis > [4] Pull/Keeper select [6:5] Pull up/down config .
OVERRIDE_HYS_SDMMC_PADS	OEM	Overrides the HYS bit for the SD pads	No	0	Override the IO PAD setting HYS to 1 for the SD pads.
eMMC_4.4_RESET_TO_PRE-IDLE_STATE	OEM	ROM resets the boot device in the pre-idle state using the eMMC 4.4 feature, CMD0 with the argument value 0xf0f0f0f0.	No	0	Applicable for booting from the eMMC 4.4 spec or greater version devices. The fuse must not be blown for the eMMC 4.3 or lesser spec version devices.

1. This setting can be overridden by the GPIO settings when the BT_FUSE_SEL fuse is intact. See GPIO Boot Overrides for the corresponding GPIO pin.
2. 0 = intact fuse and 1= blown fuse

6.1.3.2 GPIO boot overrides

This table provides a list of the GPIO boot overrides:

Table 6-3. GPIO override contact assignments

Package pin	Direction on reset	eFuse
BOOT_MODE1	Input	Boot mode selection
BOOT_MODE0	Input	
SAI1_RXD0	Input	BOOT_CFG[0]
SAI1_RXD1	Input	BOOT_CFG[1]
SAI1_RXD2	Input	BOOT_CFG[2]
SAI1_RXD3	Input	BOOT_CFG[3]
SAI1_RXD4	Input	BOOT_CFG[4]
SAI1_RXD5	Input	BOOT_CFG[5]
SAI1_RXD6	Input	BOOT_CFG[6]
SAI1_RXD7	Input	BOOT_CFG[7]
SAI1_TXD0	Input	BOOT_CFG[8]

Table continues on the next page...

Table 6-3. GPIO override contact assignments (continued)

Package pin	Direction on reset	eFuse
SAI1_TXD1	Input	BOOT_CFG[9]
SAI1_TXD2	Input	BOOT_CFG[10]
SAI1_TXD3	Input	BOOT_CFG[11]
SAI1_TXD4	Input	BOOT_CFG[12]
SAI1_TXD5	Input	BOOT_CFG[13]
SAI1_TXD6	Input	BOOT_CFG[14]
SAI1_TXD7	Input	BOOT_CFG[15]

The input pins provided are sampled at boot, and can be used to override the corresponding eFUSE values, depending on the setting of the BT_FUSE_SEL fuse.

6.1.3.3 Device Configuration Data (DCD)

The DCD is the configuration information contained in the program image (external to the ROM) that the ROM interprets to configure various on-chip peripherals. See Device Configuration Data (DCD) for more details on DCD.

6.1.4 Device initialization

This section describes the details of the ROM and provides the initialization details.

This includes details on:

- The ROM memory map
- The RAM memory map
- On-chip blocks that the ROM must use or change the POR register default values
- Clock initialization
- Enabling the cache
- Exception handling and interrupt handling

6.1.4.1 Internal ROM/RAM memory map

These figures show the iROM memory map:

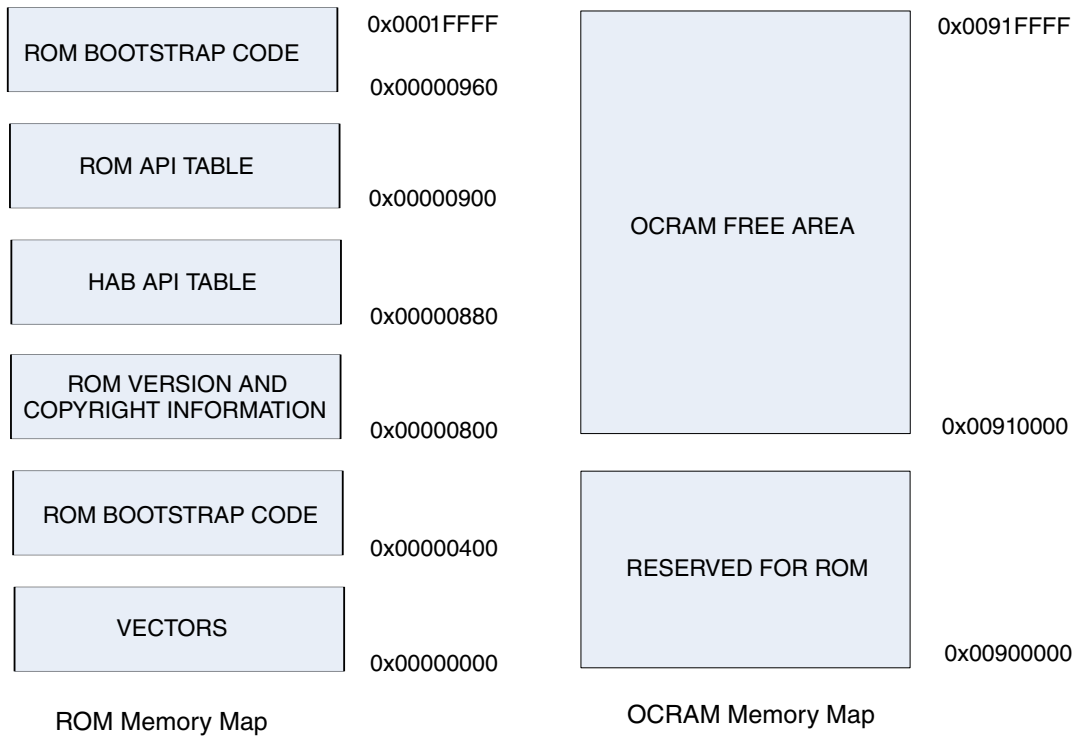

Figure 6-3. Internal ROM and RAM memory map

NOTE

The entire OCRAM region can be used freely after the boot.

6.1.4.2 Boot block activation

The boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow.

The ROM configures and uses the following blocks (listed in an alphabetical order) during the boot process. Note that the blocks actually used depend on the boot mode and the boot device selection:

- APBH—the DMA engine to drive the GPMI module
- BCH—62-bit error correction hardware engine with the AXI bus master and a private connection to the GPMI
- CCM—Clock Control Module
- ECSPI—Enhanced Configurable Serial Peripheral Interface
- FlexSPI—Flexible SPI Interface which supports serial NOR devices
- GPMI—NAND controller pin interface
- OCOTP_CTRL—On-Chip OTP Controller; the OCOTP contains the eFUSEs

- IOMUXC—I/O Multiplexer Control which allows the GPIO use to override the eFUSE boot settings;
- IOMUXC GPR—I/O Multiplexer Control General-Purpose Registers
- CAAM—Cryptographic Acceleration and Assurance Module
- SNVS—Secure Non-Volatile Storage
- SRC—System Reset Controller
- USB—used for the serial download of a boot device provisioning program
- USDHC—Ultra-Secure Digital Host Controller
- WDOG-1—Watchdog timer

6.1.4.3 Clocks at boot time

The table below show the various clocks and their sources used by the ROM.

After the reset, each Arm core has access to all peripherals. The ROM code disables the clocks listed in the following table, except for the boot devices listed in the second column.

Table 6-4. PLL setting by ROM

PLL name	Frequency	Comment
ARM_PLL	800 MHz	
SYS_PLL1	800 MHz	
SYS_PLL2	1000 MHz	
SYS_PLL3	1000 MHz	

NOTE

All other PLLs are in the default status.

Table 6-5. Clock root setting by ROM

Clock Name	Frequency (MHz)	Source	Enable
ARM_A53_ROOT	800	arm_pll_clk	Yes
ARM_M4_CLK_ROOT	200	system_pll2_200m_clk	
AHB_CLK_ROOT	133	system_pll1_133m_clk	Yes
MAIN_AXI_CLK_ROOT	333	system_pll2_333m_clk	Yes
VPU_A53_CLK_ROOT	800	arm_pll_clk	No
DRAM_ALT_CLK_ROOT	800	system_pll1_800m_clk	yes
NAND_CLK_ROOT	500	system_pll2_500m_clk	Enabled by driver
NAND_USDHC_BUS_CLK_ROOT	266	system_pll1_266m_clk	Enabled by driver
USB_BUS_CLK_ROOT		system_pll2_500m_clk	Enabled by driver

Table continues on the next page...

Table 6-5. Clock root setting by ROM (continued)

Clock Name	Frequency (MHz)	Source	Enable
NOC_CLK_ROOT	400	system_pll1_800m_clk	Yes
USDHC1_CLK_ROOT	200	system_pll1_400m_clk	Enabled by driver
USDHC2_CLK_ROOT	200	system_pll1_400m_clk	Enabled by driver
USB_PHY_REF_CLK_ROOT		system_pll1_100m_clk	Enabled by driver
ECSPI1_CLK_ROOT	50	system_pll2_200m_clk	No
ECSPI2_CLK_ROOT	50	system_pll2_200m_clk	No
ECSPI3_CLK_ROOT	50	system_pll2_200m_clk	No
WRCLK_CLK_ROOT		system_pll1_40m_clk	No

NOTE

All other clock roots are in the default status.

Table 6-6. NAND_CLK_ROOT setting

NAND data rate	NAND_CLK_ROOT source	Frequency
Async/Legacy NAND	system_pll1_400m_clk	25 MHz
Sync 40M	system_pll1_400m_clk	40 MHz
Toggle/Sync 66M	system_pll1_400m_clk	66 MHz
Toggle 80M	system_pll1_400m_clk	80 MHz
Sync 100M	system_pll1_400m_clk	100 MHz
Toggle/Sync 133M	system_pll1_400m_clk	133 MHz
Sync 160M	system_pll1_400m_clk	133 MHz
Toggle/Sync 200M	system_pll1_400m_clk	200 MHz

NOTE

The NAND_CLK_ROOT source depends on the NAND data rate.

The ROM code disables the clocks listed in the following table, except for the boot devices listed in the "Enabled for boot device" column below.

Table 6-7. CCGR setting by ROM

CCGR Register	LPCG Enable	Enabled for boot device

6.1.4.4 Enabling MMU and caches

The boot ROM includes a feature that enables the Memory Management Unit (MMU) and the caches to improve the boot speed.

The L1 instruction cache is enabled at the start of the image download. The L1 data cache, L2 cache, and MMU are enabled during the image authentication. When the HAB authentication completes, the ROM disables the L1 data cache, L2 cache, and MMU.

The L1 Instruction cache, L1 data cache, L2 cache, and MMU is controlled by eFuse. By default, these features are enabled.

Enabling the MMU when booting non-securely with SEC_CONFIG=Open and setting the CSF pointer in the Image Vector Table to NULL has no impact on the boot performance. With this configuration, it is recommended to blow the BT_MMU_DISABLE fuse.

6.1.4.5 Exception handling

The exception vectors located at the start of the ROM are used to map all the Arm exceptions (except the reset exception) to a duplicate exception vector table in the internal RAM.

During the boot phase of CPU0, the RAM vectors point to the serial downloader in the ROM.

After the boot, the program image can overwrite the vectors as required. The code shown below is used to map the ROM exception vector table to the duplicate exception vector table in the RAM.

Mapping ROM Exception Vector Table

```
;; Define linker area for ROM exception vector table
AREA IROM_VECTORS, CODE, READONLY
LDR     PC, Reset_Addr
LDR     PC, Undefined_Addr
LDR     PC, SWI_Addr
LDR     PC, Prefetch_Addr
LDR     PC, Abort_Addr
NOP                         ; Reserved vector
LDR     PC, IRQ_Addr
LDR     PC, FIQ_Addr

;; Define exception vector table
Reset_Addr      DCD     start_address
Undefined_Addr  DCD     iRAM_Undefined_Handler
SWI_Addr        DCD     iRAM_SWI_Handler
Prefetch_Addr   DCD     iRAM_Prefetch_Handler
Abort_Addr      DCD     iRAM_Abort_Handler
                DCD     0               ; Reserved vector
IRQ_Addr        DCD     iRAM_IRQ_Handler
FIQ_Addr        DCD     iRAM_FIQ_Handler

start_address DCD start ;reset handler vector
```

6.1.4.6 Interrupt handling during boot

No special interrupt-handling routines are required during the boot process. The interrupts are disabled during the boot ROM execution and may be enabled in a later boot stage.

6.1.4.7 Persistent bits

Some modes of the boot ROM require the registers that keep their values after a warm reset. The SRC General-Purpose registers are used for this purpose.

See this table for persistent bits list and description:

Table 6-8. Persistent bits

Bit name	Bit location	Description
PERSIST_SECONDARY_BOOT	SRC_GPR10[30]	This bit identifies which image must be used—primary and secondary. Used only for the boot modes that support redundant boot.
PERSIST_BLOCK_REWRITE	SRC_GPR10[29]	This bit is used as a warning. It identifies that there are errors in the NAND blocks that hold the application image. See NAND flash for more details.
PERSISTENT_ENTRY0[31:0]	SRC_GPR1[31:0]	Holds the entry function for the CPU0 to wake up from the low-power mode.
PERSISTENT_ARG0[31:0]	SRC_GPR2[31:0]	Holds the argument of entry function for the CPU0 to wake up from the low-power mode.
PERSISTENT_ENTRY1[31:0]	SRC_GPR3[31:0]	Holds the entry function for the CPU1 to wake up from the low-power mode.
PERSISTENT_ARG1[31:0]	SRC_GPR4[31:0]	Holds the argument of the entry function for the CPU1 to wake up from the low-power mode.

6.1.5 Boot devices (internal boot)

The chip supports these boot flash devices:

- Serial NOR flash via FlexSPI interface
- Raw NAND (MLC and SLC), and Toggle-mode NAND flash through GPMI-2 interface, located at CS0. Page sizes of 2 KB, 4 KB, and 8 KB. The bus widths of 8-bit with 2 through 62-bit BCH hardware ECC (Error Correction) are supported.
- SD/MMC/eSD/SDXC/eMMC4.4 via USDHC interface, supporting high capacity cards.
- EEPROM boot via SPI (serial flash).
- EEPROM boot via SPI (serial flash)

The selection of the external boot device type is controlled by the BOOT_CFG eFUSEs. See this table for more details:

Table 6-9. Boot device selection

BOOT_CFG[14:12]	Boot device
001	SD/eSD
010	MMC/eMMC
011	NAND
100	Serial NOR boot via FlexSPI
110	Serial (SPI) NOR

6.1.5.1 Serial NOR Flash Boot via FlexSPI

6.1.5.1.1 Serial NOR eFUSE Configuration

Table 6-10. Fuse definition for Serial NOR over FlexSPI

Fuse Config	Config	Definitions	GPIO	Shipped Value	Settings
BOOT_CFG[3:0]	OEM	xSPI FLASH Dummy Cycle	Yes	0	0 – Dummy cycles is auto-probed Others – Actual dummy cycles for Read command
BOOT_CFG[5:4]	OEM	xSPI FLASH Auto Probe Type	Yes	0	0 – QuadSPI NOR 1 – MXIC Octal 2 – Micron Octal 3 – Adesto Octal
BOOT_CFG[7:6]	OEM	Hold time before read from device	Yes	0	0 – 500us 1 – 1ms 2 – 3ms 3 – 10ms
BOOT_CFG[10:8]	OEM	Flash Type	Yes	0	000b–Device supports 3B read by default 001b–Device supports 4B read by default 010b–HyperFlash 1V8 011b–HyperFlash 3V3 100b–MXIC Octal DDR
BOOT_CFG[11]	OEM	xSPI FLASH Auto Probe	Yes	0	0 – Disabled 1 – Enabled
BOOT_CFG[14:12]	OEM	Boot device selection	Yes	0	100 – Serial NOR device is selected as boot device.
0x480[2:0] (BOOT_CFG_PARAMETER)	OEM	xSPI FLASH Frequency	No	0	0 - 100 MHz 1 - 133 MHz 2 - 166 MHz 3 - 200 MHz 4 - 80 MHz 5 - 20 MHz Others – Reserved

NOTE

If the xSPI FLASH Auto Probe feature is enabled, the following is the logic how this feature works with other fuse combinations:

- Flash Type - If Flash type is 0, the "xSPI FLASH Auto Probe Type" takes effect for the Flash type selection. If Flash Type is greater than 1, the "Flash Type" Fuse is used for Flash type selection, ROM will issue specific command to probe the presence of Serial NOR FLASH.
- xSPI FLASH Frequency - This field is used for specifying the Flash working frequency.

6.1.5.1.2 FlexSPI Serial NOR Flash Boot Operation

The Boot ROM attempts to boot from Serial NOR flash if the BOOT_CFG [7:6] fuses are programmed to 0b’00 as shown in the Serial NOR eFUSE Configuration table, then the ROM will initialize FlexSPI1 interface. FlexSPI interface initialization is a two-step process.

The ROM expects the 512-byte FlexSPI NOR configuration parameters as explained in next section to be present at offset 0 in Serial NOR flash. The ROM reads these configuration parameters using the read command specified by BOOT_CFG [5:3] with Serial clock operating at 30 MHz.

In the second step, ROM configures FlexSPI1 interface with the parameters provided in configuration block read from Serial NOR flash and starts the boot procedure. Refer to Table 25-14 for details regarding FlexSPI configuration parameters and to the FlexSPI NOR boot flow chart for detailed boot flow chart of FlexSPI NOR.

Both booting an XIP and non XIP image are supported from Serial NOR Flash. For XIP boot, the image has to be built for FlexSPI address space and for non XIP the image can be built to execute from Internal RAM.

6.1.5.1.3 FlexSPI NOR boot flow chart

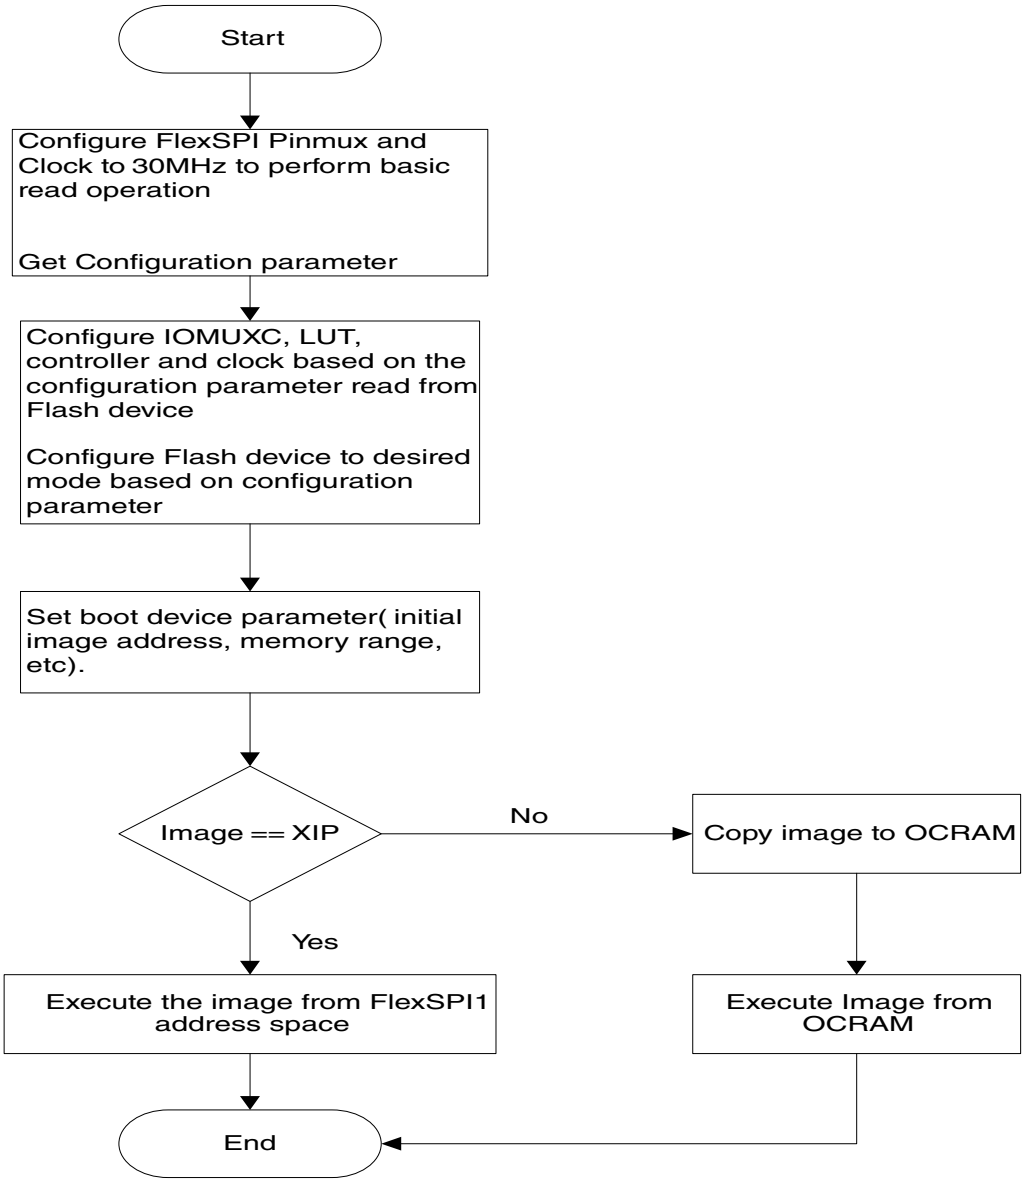

Figure 6-4. FlexSPI NOR boot flow

6.1.5.2 Serial NOR configuration based on FlexSPI interface

The ROM SW supports Serial NOR based on FlexSPI module, using a 448-bytes common FlexSPI configuration block and several specified parameters for Serial NOR respectively. See below sections for more details.

6.1.5.2.1 FlexSPI Configuration Block

FlexSPI Configuration block consists of parameters regarding specific Flash devices including read command sequence, quad mode enablement sequence (optional), etc.

Table 6-11. FlexSPI Configuration block

Name	Offset	Size(bytes)	Description
Tag	0x000	4	0x42464346, ascii:" FCFB"
Version	0x004	4	0x56010000 [07:00] bugfix = 0 [15:08] minor = 0 [23:16] major = 1 [31:24] ascii 'V'
-	0x008	4	Reserved
readSampleClkSrc	0x00C	1	0 – internal loopback 1 – loopback from DQS pad 3 – Flash provided DQS
dataHoldTime	0x00D	1	Serial Flash CS Hold Time Recommend default value is 0x03
dataSetupTime	0x00E	1	Serial Flash CS setup time Recommended default value is 0x03
columnAdressWidth	0x00F	1	3 – For HyperFlash 12/13 – For Serial NAND, see datasheet to find correct value 0 – Other devices
deviceModeCfgEnable	0x010	1	Device Mode Configuration Enable feature 0 – Disabled 1 – Enabled
-	0x011	3	Reserved
deviceModeSeq	0x014	4	Sequence parameter for device mode configuration
deviceModeArg	0x018	4	Device Mode argument, effective only when deviceModeCfgEnable = 1
configCmdEnable	0x01C	1	Config Command Enable feature 0 – Disabled 1 – Enabled
-	0x01D	3	Reserved
configCmdSeqs	0x020	16	Sequences for Config Command, allow 4 separate

Table continues on the next page...

Table 6-11. FlexSPI Configuration block (continued)

Name	Offset	Size(bytes)	Description
			configuration command sequences.
cfgCmdArgs	0x030	16	Arguments for each separate configuration command sequence.
controllerMiscOption	0x040	4	Bit0 – differential clock enable Bit1 – CK2 enable, must set to 0 in this silicon Bit2 – ParallelModeEnable, must set to 0 for this silicon Bit3 – wordAddressableEnable Bit4 – Safe Configuration Frequency enable set to 1 for the devices that support DDR Read instructions Bit5 – Pad Setting Override Enable Bit6 – DDR Mode Enable, set to 1 for device supports DDR read command
deviceType	0x044	1	1 – Serial NOR 2 – Serial NAND
sflashPadType	0x045	1	1 – Single pad 2 – Dual pads 4 – Quad pads 8 – Octal pads
serialClkFreq	0x046	1	Chip specific value, for this silicon 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 75 MHz 5 – 80 MHz 6 – 100 MHz 7 – 133 MHz 8 – 166 MHz Other value: 30 MHz
lutCustomSeqEnable	0x047	1	0 – Use pre-defined LUT sequence index and number 1 - Use LUT sequence parameters provided in this block

Table continues on the next page...

Table 6-11. FlexSPI Configuration block (continued)

Name	Offset	Size(bytes)	Description
-	0x048	8	Reserved
sflashA1Size	0x050	4	For SPI NOR, need to fill with actual size For SPI NAND, need to fill with actual size * 2
sflashA2Size	0x054	4	The same as above
sflashB1Size	0x058	4	The same as above
sflashB2Size	0x05C	4	The same as above
csPadSettingOverride	0x060	4	Set to 0 if it is not supported
sclkPadSettingOverride	0x064	4	Set to 0 if it is not supported
dataPadSettingOverride	0x068	4	Set to 0 if it is not supported
dqsPadSettingOverride	0x06C	4	Set to 0 if it is not supported
timeoutInMs	0x070	0	Maximum wait time during read busy status 0 – Disabled timeout checking feature Other value – Timeout if the wait time exceeds this value.
commandInterval	0x074	4	Unit: ns Currently, it is used for SPI NAND only at high frequency
dataValidTime	0x078	4	Time from clock edge to data valid edge, unit ns. This field is used when the FlexSPI Root clock is less than 100 MHz and the read sample clock source is device provided DQS signal without CK2 support. [31:16] data valid time for DLLB in terms of 0.1 ns [15:0] data valid time for DLLA in terms of 0.1 ns
busyOffset	0x07C	2	busy bit offset, valid range : 0-31
busyBitPolarity	0x07E	2	0 – busy bit is 1 if device is busy 1 – busy bit is 0 if device is busy
lookupTable	0x080	256	Lookup table
lutCustomSeq	0x180	48	Customized LUT sequence, see below table for details.
	0x1B0	16	Reserved for future use

Note:

1. To customize the LUT sequence for some specific device, users need to enable “lutCustomSeqEnable” and fill in corresponding “lutCustomSeq” field specified by command index below.
2. For Serial (SPI) NOR, the pre-defined LUT index is as follows:

Table 6-12. LUT sequence definition for Serial NOR

Command Index	Name	Index in lookup table	Description
0	Read	0	Read command Sequence
1	ReadStatus	1	Read Status command
2	WriteEnable	3	Write Enable command sequence
3	EraseSector	5	Erase Sector Command
4	PageProgram	9	Page Program Command
5	ChipErase	11	Full Chip Erase
6	Dummy	15	Dummy Command as needed
	Reserved	2,4,6,7,8,10,12,13,14	All reserved indexes can be freely used for other purpose

6.1.5.2.2 Serial NOR configuration block (512 bytes)

Table 6-13. Serial NOR configuration block

Name	Offset	Size (Bytes)	Description
memCfg	0	448	The common memory configuration block, see FlexSPI configuration block for more details
pageSize	0x1C0	4	Page size in terms of bytes, not used by ROM
sectorSize	0x1C4	4	Sector size in terms of bytes, not used by ROM
ipCmdSerialClkFreq	0x1C8	4	Chip specific value, not used by ROM For Ultra 0 – No change, keep current serial clock unchanged 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 75 MHz

6.1.5.3 NAND flash

The boot ROM supports a number of MLC/SLC NAND flash devices from different vendors and LBA NAND flash devices. The Error Correction and Control (ECC) subblock (BCH) is used to detect the errors.

6.1.5.3.1 NAND eFUSE configuration

The boot ROM determines the configuration of the external NAND flash by parameters, either provided by the eFUSE, or sampled on the GPIO pins during boot. See Table 6-14 for parameters details.

NOTE

BOOT_CFGx sampled on the GPIO pins depends on the BT_FUSE_SEL setting. See Boot Fusemap for details.

Table 6-14. NAND boot eFUSE descriptions

Fuse	Config	Definition	GPIO[1]	Shipped value	Settings
BOOT_CFG[15:12]	OEM	Boot device selection	Yes	0	0011—boot from the NAND interface
BOOT_CFG[7]	OEM	BT_TOGGLEMODE	Yes	0	0—raw NAND 1—toggle mode NAND
BOOT_CFG[11:10]	OEM	Pages in block	Yes	0	00—128 01—64 10—32 11—256
BOOT_CFG[9:8]	OEM	Row address cycles	Yes	00	00—3 01—2 10—4 11—5

1. The setting can be overridden by the GPIO settings when the BT_FUSE_SEL fuse is intact. See Table 1 for the corresponding GPIO pin.

6.1.5.3.2 NAND flash boot flow and Boot Control Blocks (BCB)

There are two BCB data structures:

- FCB
- DBBT

As a part of the NAND media initialization, the ROM driver uses safe NAND timings to search for the Firmware Configuration Block (FCB) that contains the optimum NAND timings, the page address of the Discovered Bad Block Table (DBBT) Search Area, and the start page address of the primary and secondary firmware.

The hardware ECC level to use is embedded inside the FCB block. The FCB data structure is also protected using the ECC. The driver reads raw 2112 bytes of the first sector and runs through the software ECC engine that determines whether the FCB data is valid or not.

If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments the page number to the Search Stride number of pages to read for the next BCB until the SearchCount pages have been read.

If the search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM enters the serial download mode.

The FCB contains the page address of the DBBT Search Area, and the page address for primary and secondary boot images. The DBBT is searched in the DBBT Search Area, just like the FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using the starting page address from the FCB.

This figure shows the state diagram of the FCB search:

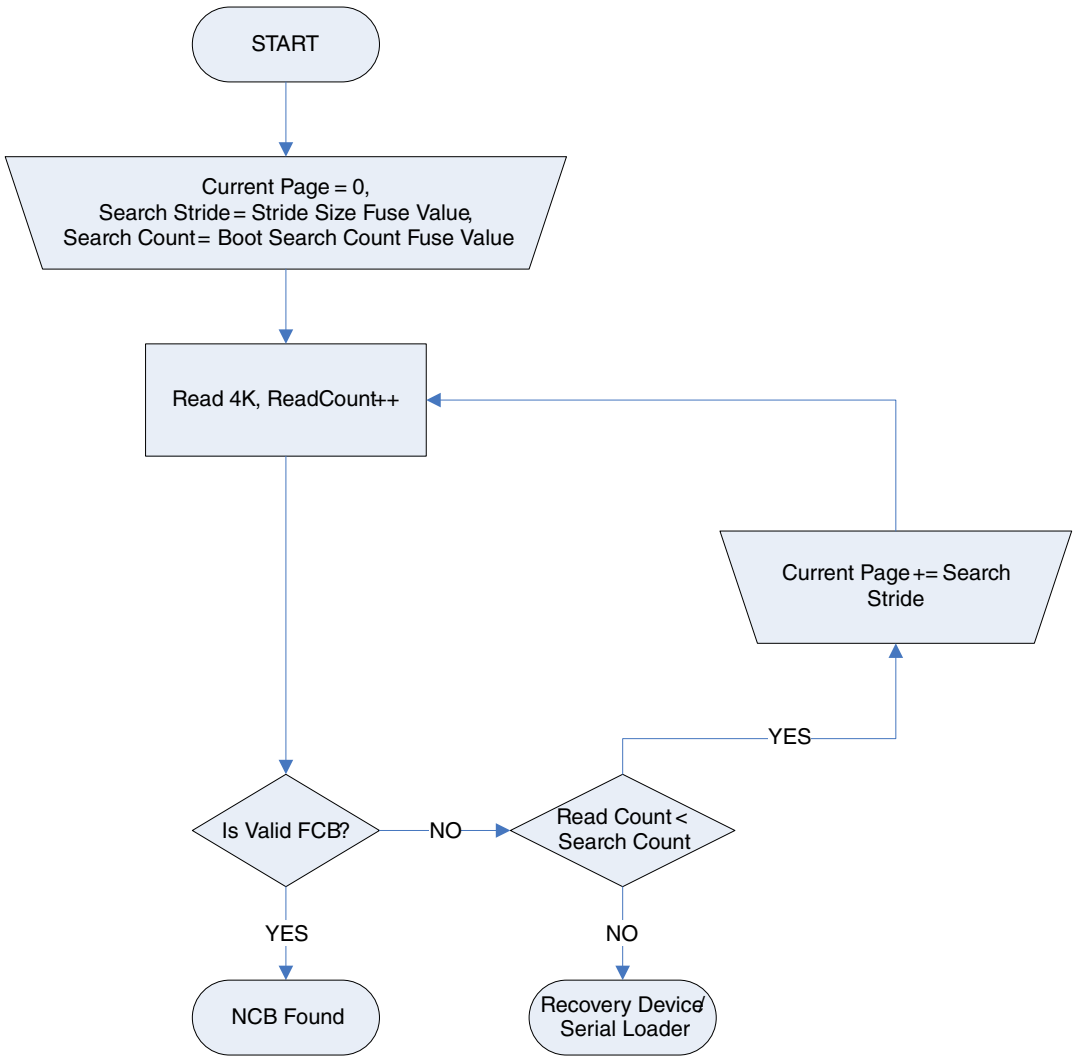

Figure 6-5. FCB search flow

When the FCB is found, the boot ROM searches for the Discovered Bad Blocks Table (DBBT). If the DBBT Search Area is 0 in the FCB, the ROM assumes that there are no bad blocks on the NAND device boot area. See this figure for the DBBT search flow:

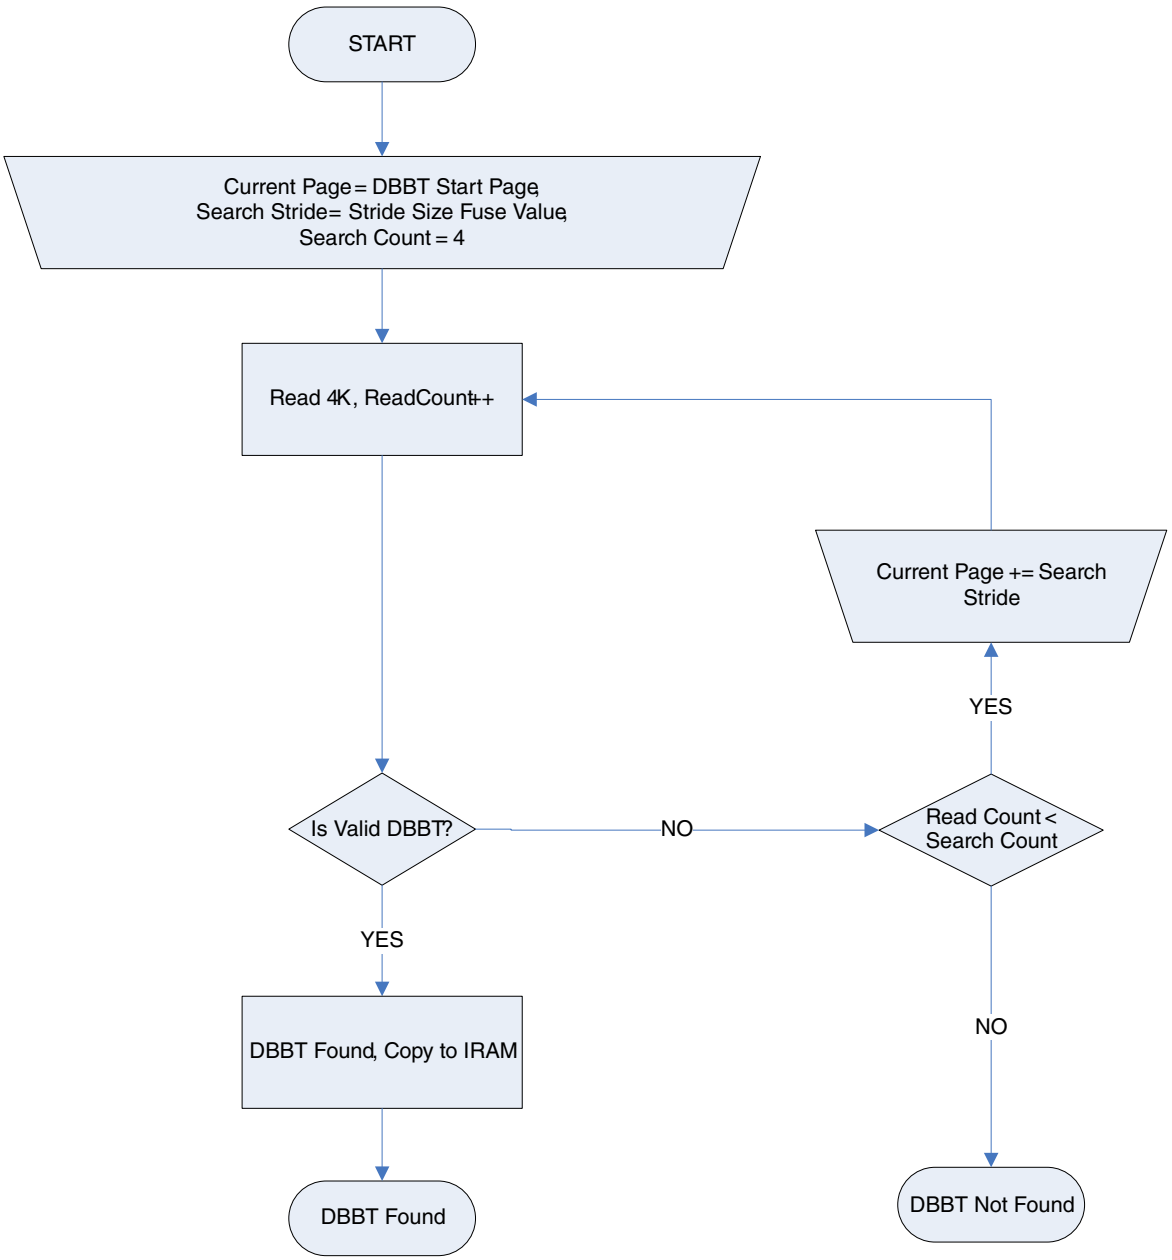

Figure 6-6. DBBT search flow

The BCB search and load function also monitors the ECC correction threshold and sets the PERSIST_BLOCK_REWRITE persistent bit if the threshold exceeds the maximum ECC correction ability.

If there is a page with a number of errors higher than ECC can correct during the primary image read, the boot ROM turns on the PERSIST_SECONDARY_BOOT bit and performs the software reset (After the software reset, the secondary image is used).

If there is a page with number of errors higher than ECC can correct during secondary image read, the boot ROM goes to the serial loader.

6.1.5.3.3 Firmware configuration block

The FCB is the first sector in the first good block. The FCB must be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance, so, in case the first NAND block becomes corrupted, the ROM finds its copy in the next NAND block. The search area must span over at least two NAND blocks. The location information for the DBBT search area, FW1, and FW2 are all specified in the FCB. This table shows the flash control block structure:

Table 6-15. Flash control block structure

Name	Start byte	Size in bytes	Description
Reserved	0	4	Reserved for Fingerprint #1(Checksum)
FingerPrint	4	4	32-bit word with a value of 0x20424346, in ascii "FCB"
Version	8	4	32-bit version number; this version of FCB is 0x00000001
m_NANDTiming	12	8	8 B of data for eight NAND timing parameters from the NAND datasheet. The eight parameters are: m_NandTiming[0]=data_setup, m_NandTiming[1]=data_hold, m_NandTiming[2]=address_setup, m_NandTiming[3]=dsample_time, m_NandTiming[4]=nand_timing_state, m_NandTiming[5]=REA, m_NandTiming[6]=RLOH, m_NandTiming[7]=RHOH. The ROM only uses the first four parameters, but the FCB provides space for other four parameters to be used by the bootloader or other applications.
PageDataSize	20	4	The number of bytes of data in a page. Typically, this is 2048 bytes for 2112 bytes page size or 4096 bytes for 4314/4224 bytes page size or 8192 for 8568 bytes page size.
TotalPageSize	24	4	The total number of bytes in a page. Typically, 2112 for 2-KB page or 4224 or 4314 for 4-KB page or 8568 for 8-KB page.
SectorsPerBlock	28	4	The number of pages per block. Typically 64 or 128 or depending on the NAND device type.

Table continues on the next page...

Table 6-15. Flash control block structure (continued)

Name	Start byte	Size in bytes	Description
NumberOfNANDs	32	4	Not used by ROM
TotalInternalDie	36	4	Not used by ROM
CellType	40	4	Not used by ROM
EccBlockNEccType	44	4	Value from 0 to is used to set the BCH Error Corrrection level 0, 2, 4, .. or 62 for Block BN of ECC page, used in configuring the BCH62 page layout registers.
EccBlock0Size	48	4	Size of block B0 used in configuring the BCH62 page-layout registers.
EccBlockNSize	52	4	Size of block BN used in configuring the BCH62 page-layout registers.
EccBlock0EccType	56	4	Value from 0 to used to set the BCH Error Corrrection level 0, 2, 4, .. or 62 for Block BN of ECC page, used in configuring the BCH62 page layout registers.
MetadataBytes	60	4	Size of metadata bytes used in configuring the BCH62 page-layout registers.
NumEccBlocksPerPage	64	4	Number of the ECC blocks BN not including B0. This value is used in configuring the BCH62 page-layout registers.
EccBlockNEccLevelSDK	68	4	Not used by ROM
EccBlock0SizeSDK	72	4	Not used by ROM
EccBlockNSizeSDK	76	4	Not used by ROM
EccBlock0EccLevelSDK	80	4	Not used by ROM
NumEccBlocksPerPageSDK	84	4	Not used by ROM
MetadataBytesSDK	88	4	Not used by ROM
EraseThreshold	92	4	Not used by ROM
Firmware1_startingPage	104	4	Page number address where the first copy of bootable firmware is located.
Firmware2_startingPage	108	4	Page number address where the second copy of bootable firmware is located.
PagesInFirmware1	112	4	Size of the first copy of firmware in pages.
PagesInFirmware2	116	4	Size of the second copy of firmware in pages.
DBBTSearchAreaStartAddress	120	4	Page address for the bad block table search area.
BadBlockMarkerByte	124	4	This is an input offset in the BCH page for the ROM to swap with the first byte of metadata after reading a page using the BCH62. The ROM supports the restoration of manufacturer-marked bad block markers in the page and this offset is the bad block marker offset location.
BadBlockMarkerStartBit	128	4	This is an input bit offset in the BadBlockMarkerByte for the ROM to use when swapping eight bits with the first byte of metadata.

Table continues on the next page...

Table 6-15. Flash control block structure (continued)

Name	Start byte	Size in bytes	Description
BBMarkerPhysicalOffset	132	4	This is the offset where the manufacturer leaves the bad block marker on a page.
BCHType	136	4	0 for BCH20 and 1 for BCH62. The chip is backwards compatible to BCH20 and this field tells the ROM to use the BCH20 or BCH62 block.
TMTiming2_ReadLatency	140	4	Toggle mode NAND timing parameter read latency, the ROM uses this value to configure the timing2 register of the GPMI.
TMTiming2_PreambleDelay	144	4	Toggle mode NAND timing parameter Preamble Delay. The ROM uses this value to configure the timing2 register of the GPMI.
TMTiming2_CEDelay	148	4	Toggle mode NAND timing parameter CE Delay. The ROM uses this value to configure the timing2 register of the GPMI.
TMTiming2_PostambleDelay	152	4	Toggle mode NAND timing parameter Postamble Delay. The ROM uses this value to configure the timing2 register of the GPMI.
TMTiming2_CmdAddPause	156	4	Toggle mode NAND timing parameter Cmd Add Pause. The ROM uses this value to configure the timing2 register of the GPMI.
TMTiming2_DataPause	160	4	Toggle mode NAND timing parameter Data Pause. The ROM uses this value to configure the timing2 register of the GPMI.
TMSpeed	164	4	This is the toggle mode speed for the ROM to configure the gpmi clock. 0 for 33 MHz, 1 for 40 MHz, and 2 for 66 MHz.
TMTiming1_BusyTimeout	168	4	Toggle mode NAND timing parameter Busy Timeout. The ROM uses this value to configure the timing1 register of the GPMI.
DISBBM	172	4	If 0, the ROM swaps the BadBlockMarkerByte with metadata[0] after reading a page using the BCH62. If the value is 1, the ROM does not swap.
BBMark_spare_offset	176	4	The offset in the metadata place which stores the data in the bad block marker place.
Onfi_sync_enable	180	4	Enable the Onfi nand sync mode support.
Onfi_sync_speed	184	4	Speed for the Onfi nand sync mode: 0 - 24 MHz, 1 - 33 MHz, 2 - 40 MHz, 3 - 50 MHz, 4 - 66 MHz, 5 - 80 MHz, 6 - 100 MHz, 7 - 133 MHz, 8 - 160 MHz, 9 - 200 MHz
Onfi_syncNANDData	188	28	The parameters for the Onfi nand sync mode timing. They are read latency, ce_delay, preamble_delay, postamble_delay, cmdadd_pause, data_pause, and busy_timeout.
DISBB_Search	216	4	Disable the bad block search function when reading the firmware, only using DBBT.

The FCB data structure is protected using a 62-bit ECC. The layout of the FCB page is illustrated in this figure:

Figure 6-7. Layout of the FCB page

The detailed parameters of the FCB pages are listed in this table:

Table 6-16. Parameters setting for FCB page

Parameter	Value
TotalPageSize	2048+64=2112
MetadataBytes	32
EccBlock0Size	128
EccBlock0EccType	31
BCHType	0
EccBlockNSize	128
EccBlockNEccType	31
NumEccBlocksPerPage	7

To reduce the disturbances caused by a neighboring cell in the FCB page in the NAND chip, a randomizer is enabled when reading the FCB page. BCH ECC has a Randomizer module that is interfaced through the GPMI APBHDMA chain. The Randomizer can generate random data based on BCH ECC encoded/decoded data. It can be employed to reduce the disturbances caused by a neighboring cell in the NAND chip, thus reducing bit errors. The randomizer is used to reduce the bit errors in the FCB. Ensure that the randomizer is enabled when burning the FCB pages in the NAND flash. To control the randomizer for the pages (except for FCB), a new field called Randomizer_Enable is added into the FCB structure. If the Randomizer_Enable field is set to 0, the randomizer is disabled. Reading the pages (except for FCB) being set to a non-zero value enables the randomizer. For detailed randomizer information, see Randomizer.

6.1.5.3.4 Discovered Bad Block Table (DBBT)

See this table for the DBBT format:

Table 6-17. DBBT structure

Name	Start byte	Size in bytes	Description
reserved	0	4	-
FingerPrint	4	4	32-bit word with a value of 0x44424254,in ascii "DBBT"
Version	8	4	32-bit version number; this version of DBBT is 0x00000001
reserved	12	4	-
DBBT_NUM_OF_PAGES	16	4	Size of the DBBT in pages
reserved	20	4*PageSize-20	-
reserved	4*PageSize	4	-
Number of Entries	4*PageSize + 4	4	Number of bad blocks
Bad Block Number	4*PageSize + 8	4	First bad block number
Bad Block Number	4*PageSize + 12	4	Second bad block number
-	-	-	Next bad block number
-	-	-	-
Last bad block number	-	-	Last bad block number

6.1.5.3.5 Bad block handling in ROM

During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block.

If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

If the Bad Block table start page is null, check the manufactory made Bad Block marker. The location of the Bad Block maker is at the first three or last three pages in every block of the NAND flash. The NAND manufacturers normally use one byte in the spare area of certain pages within a block to mark that a block is bad or not. A value of 0xFF means good block, non-FF means bad block.

To preserve the BI (bad block information), the flash updater or gang programmer applications must swap the Bad Block Information (BI) data to byte 0 of the metadata area for every page before programming the NAND flash. When the ROM loads the firmware, it copies back the value at metadata[0] to the BI offset in the page data. This figure shows how the factory bad block marker is preserved:

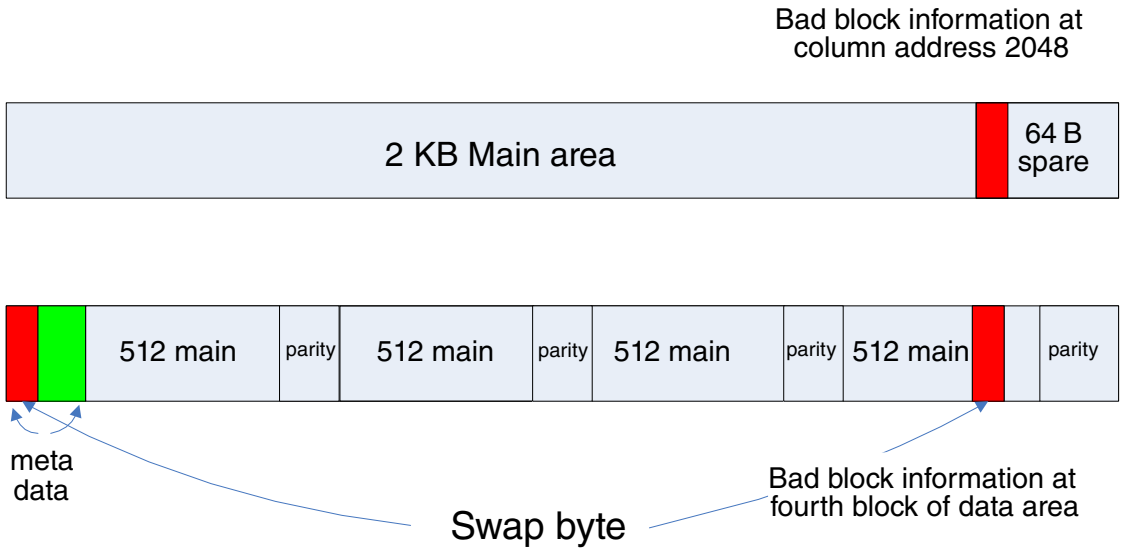

Figure 6-8. Factory bad block marker preservation

In the FCB structure, there are two elements (m_u32BadBlockMarkerByte and m_u32BadBlockMarkerStartBit) to indicate the byte and bit place in the page data that the manufacturer marked the bad block marker.

6.1.5.3.6 Toggle mode DDR NAND boot

If the BT_TOGGLEMODE efuse is blown, the ROM does the following to boot from the Samsung's toggle mode DDR NAND.

6.1.5.3.6.1 GPMI and BCH clocks configuration

The ROM sets the clock source and the dividers in the CCM registers.

If the BOOT_CFG is set (toggle mode), the GPMI/BCH CLK source is PLL2PFD4, and running at 66 MHz, otherwise the GPMI/ BCH CLK souce is PLL3, running at 24 MHz. The ROM sets the default values to timing0, timing1, and timing2 gpmi registers for 24 MHz clock speed. It uses the BOOT_CFG fuse to configure the GPMI timing2 register parameters preamble delay and read latency. The default value for these parameters is 2 when the fuses are not blown.

The default timing parameter values used by the ROM for the toggle-mode device are:

- Timing0.ADDRESS_SETUP = 5
- Timing0.DATA_SETUP = 10
- Timing0.DATA_HOLD = 10
- Timing1.DEVICE_BUSY_TIMEOUT = 0 x 500

- Timing2.READ_LATENCY = BOOT_CFG if blown, otherwise 2
- Timing2.CE_DELAY = 2
- Timing2.PREAMBLE_DELAY = BOOT_CFG if blown, otherwise 2
- Timing2.POSTAMBLE_DELAY = 3
- Timing2.CMDADD_PAUSE = 4
- Timing2.DATA_PAUSE = 6

The default timing parameters can be overriden by the TMTiming2_ReadLatency, TMTiming2_PreambleDelay, TMTiming2_CEDelay, TMTiming2_PostambleDelay, TMTiming2_CmdAddPause, and TMTiming2_DataPause parameters of the FCB.

6.1.5.3.6.2 Setup DMA for DDR transfers

In the DMA descriptors, the GPMI is configured to read the page data at a double data rate, the word length is set to 16, and the transfer count to a half of the page size.

6.1.5.3.6.3 Reconfigure timing and speed using values in FCB

After reading the FCB page with the GPMI set to default timings and a speed of 33 MHz, the ROM reconfigures the CCM dividers to run the gpmi/bch clks to a desired speed specified in the FCB for the rest of the boot process. The GPMI timing registers are also reconfigured to the values specified in the FCB.

The GPMI speed can be configured using the FCB parameter TMSpeed:

- 0—25 MHz
- 1—33 MHz
- 2—40 MHz
- 3—50 MHz
- 4—66 MHz
- 5—80 MHz
- 6—100 MHz
- 7—133 MHz
- 8—133 MHz
- 9—200 MHz

The GPMI timing0 register fields data_setup, data_hold, and address_setup are set to the values specified for the data_setup and data_hold and address_setup in the FCB member m_NANDTiming.

The GPMI timing1.DEVICE_BUSY_TIMEOUT is set to the value specified in the FCB member TMTiming1_BusyTimeout.

The GPMI timing2 register values are set using the FCB members TMTiming2.READ_LATENCY, CE_DELAY, PREAMBLE_DELAY, POSTAMBLE_DELAY, CMDADD_PAUSE, and DATA_PAUSE.

6.1.5.3.7 Typical NAND page organization

6.1.5.3.7.1 BCH ECC page organization

The first data block is called block 0 and the rest of the blocks are called block N. A separate ECC level scan is used for block 0 and block N.

The metadata bytes must be located at the beginning of a page, starting at byte 0, followed by the data block 0, the ECC bytes for data block 0, the block 1 and its ECC bytes, and so on, up until the N data blocks. The ECC level for the block 0 can be different from the ECC level for the rest of the blocks.

For the NAND boot with page-size restrictions and the data block size restricted to 512 B, only few combinations of the ECC for block 0 and block N are possible.

This figure shows the valid layout for 2112-byte sized page.

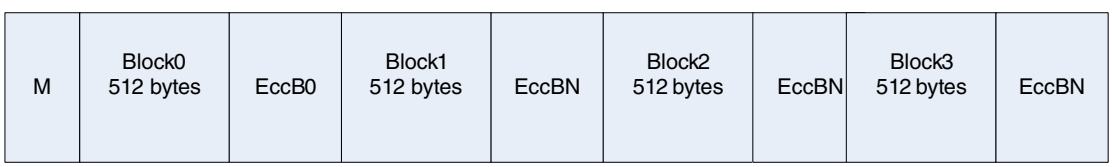

Figure 6-9. Valid layout for 2112-byte sized page

The example below is for 13 bits of parity (GF13). The number of ECC bits required for a data block is calculated using the (ECC_Correction_Level * 13) bits.

In the above layout, the ECC size for EccB0 and EccBN must be selected to not exceed a total page size of 2112 bytes. The EccB0 and EccBN can be one of the 2, 4, 6, 8, 10, 12, 14, 16, 18, and 20 bits on the ECC correction level. The total bytes are:

[M + (data_block_size x 4) + ([EccB0 + (EccBN x 3)] x 13) / 8] <= 2112;

M = metadata bytes and data_block_size is 512.

There are four data blocks of 512 bytes each in a page of 2-KB page sized NAND. The values of EccB0 and EccBN must be such that the above calculation does not result in a value greater than 2112 bytes.

M	Block0 512 bytes	EccB0	Block1 512 bytes	EccBN	Block2 512 bytes	EccBN	Block3 512 bytes	EccBN
	Block4 512 bytes	EccBN	Block5 512 bytes	EccBN	Block6 512 bytes	EccBN	Block7 512 bytes	EccBN

Figure 6-10. Valid layout for 4-KB sized page

Different NAND manufacturers have different sizes for a 4-KB page; 4314 bytes is typical.

[M + (data_block_size x 8) + ([EccB0 + (EccBN x 7)] x 13) / 8] <= 4314;

M= metadata bytes and data_block_size is 512.

There are eight data blocks of 512 bytes each in a page of a 4-KB page sized NAND. The values of the EccB0 and EccBN must be such that the above calculation does not result in a value greater than the size of a page in a 4-KB page NAND.

6.1.5.3.7.2 Metadata

The number of bytes used for the metadata is specified in the FCB. The metadata for the BCH encoded pages is placed at the beginning of a page. The ROM only cares about the first byte of metadata to swap it with a bad block marker byte in the page data after each page read; it is important to have at least one byte for the metadata bytes field in the FCB data structure.

6.1.5.3.8 IOMUX configuration for NAND

The following table shows the RawNAND IOMUX pin configuration.

Table 6-18. NAND IOMUX pin configuration

Signal	Pad name
NAND_CLE	SD3_CLK.alt1
NAND_ALE	SD3_CMD.alt1
NAND_WP_B	SAI1_MCLK.alt1
NAND_RE_B	SD3_STROBE.alt1

6.1.5.4 Expansion device

The ROM supports booting from the MMC/eMMC and SD/eSD compliant devices.

6.1.5.4.1 Expansion device eFUSE configuration

The SD/MMC/eSD/eMMC/SDXC boot can be performed using either the USDHC ports, based on the setting of the BOOT_CFG[11:10] (Port Select) fuse or it is associated to the GPIO input value at the boot.

All USDHC ports support the fast boot. See this table for details:

Table 6-19. USDHC boot eFUSE descriptions

Fuse	Config	Definition	GPIO[1]	Shipped value	Settings
BOOT_CFG[7]	OEM	Fast boot support	Yes	000	0 - Normal boot 1 - Fast boot
BOOT_CFG[6:4]	OEM	Bus width	Yes	000	0 - SD/eSD/SDXC 1 - MMC/eMMC

0x4A0[5:4]	OEM	uSDHC power cycle interval	No	0	00 - 20 ms 01 - 10 ms 10 - 5 ms 11 - 2.5 ms

1. The setting can be overridden by the GPIO settings when the BT_FUSE_SEL fuse is intact. See GPIO boot overrides for the corresponding GPIO pin.

The boot code supports these standards:

- MMCv4.4 or less
- eMMCv5.0 or less

- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST_BOOT
- SDXCv3.0

The MMC/SD/eSD/SDXC/eMMC can be connected to any of the USDHC blocks and can be booted by copying 4 KB of data from the MMC/SD/eSD/eMMC device to the internal RAM. After checking the Image Vector Table header value (0xD1) from program image, the ROM code performs a DCD check. After a successful DCD extraction, the ROM code extracts from the Boot Data Structure the destination pointer and length of image to be copied to the RAM device from where the code execution occurs.

The maximum image size to load into the SD/MMC boot is 32 MB. This is due to a limited number of uSDHC ADMA Buffer Descriptors allocated by the ROM.

NOTE

The initial 4 KB of the program image must contain the IVT, DCD, and the Boot Data structures.

Table 6-20. SD/MMC frequencies

	SD	MMC	MMC (DDR mode)
Identification (KHz)	347.22		
Normal-speed mode (MHz)	25	20	25
High-speed mode (MHz)	50	40	50
UHSI SDR50 (MHz)	100		
UHSI SDR104 (MHz)	200		

NOTE

The boot ROM code reads the application image length and the application destination pointer from the image.

6.1.5.4.2 MMC and eMMC boot

This table provides the MMC and eMMC boot details.

Table 6-21. MMC and eMMC boot details

Normal boot mode	During the initialization (normal boot mode), the MMC frequency is set to 347.22 KHz. When the MMC card enters the identification portion of the initialization, the voltage validation is performed, and the ROM boot code checks the high-voltage settings and the card capacity. The ROM boot code supports both the high-capacity and low-capacity MMC/ eMMC cards. After the initialization phase is complete, the ROM boot code switches to a higher frequency (20 MHz in

Table continues on the next page...

Table 6-21. MMC and eMMC boot details (continued)

	the normal boot mode or 40 MHz in the high-speed mode). The eMMC is also interfaced via the USDHC and follows the same flow as the MMC. The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD[179] to get the boot partition to be set. If there is no boot partition mentioned in the BOOT_PARTITION_ENABLE field or the user partition was mentioned, the ROM boots from the user partition.
eMMC4.3 or eMMC4.4 device supporting special boot mode	If using an eMMC4.3 or eMMC4.4 device that supports the special boot mode, it can be initiated by pulling the CMD line low. If the BOOT ACK is enabled, the eMMC4.3/eMMC4.4 device sends the BOOT ACK via the DATA lines and the ROM can read the BOOT ACK [S010E] to identify the eMMC4.3/eMMC4.4 device. If the BOOT ACK is enabled, the ROM waits 50 ms to get the BOOT ACK and if the BOOT ACK is received by the ROM. If BOOT ACK is disabled ROM waits 1 second for data. If the BOOT ACK or data was received, the eMMC4.3/eMMC4.4 is booted in the "boot mode", otherwise the eMMC4.3/eMMC4.4 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by the BOOT_CFG (fast boot) fuse. The BOOT ACK is selected by the .
eMMC4.4 device	If using the eMMC4.4 device, the Double Data Rate (DDR) mode can be used. This mode can be selected by the BOOT_CFG2[7:5] (bus width) fuse.

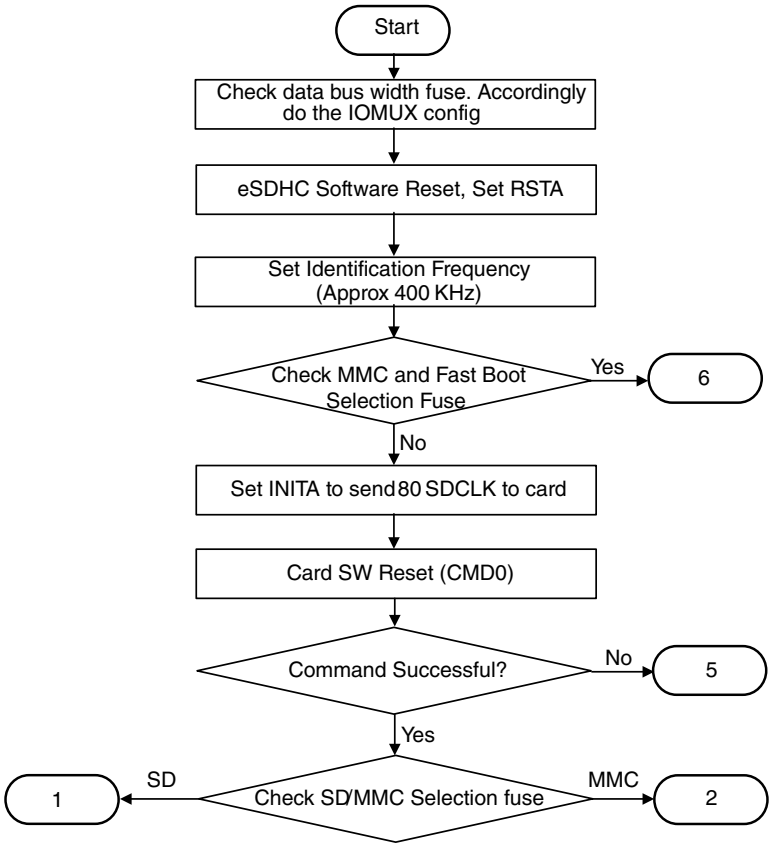

Figure 6-11. Expansion device boot flow (1 of 6)

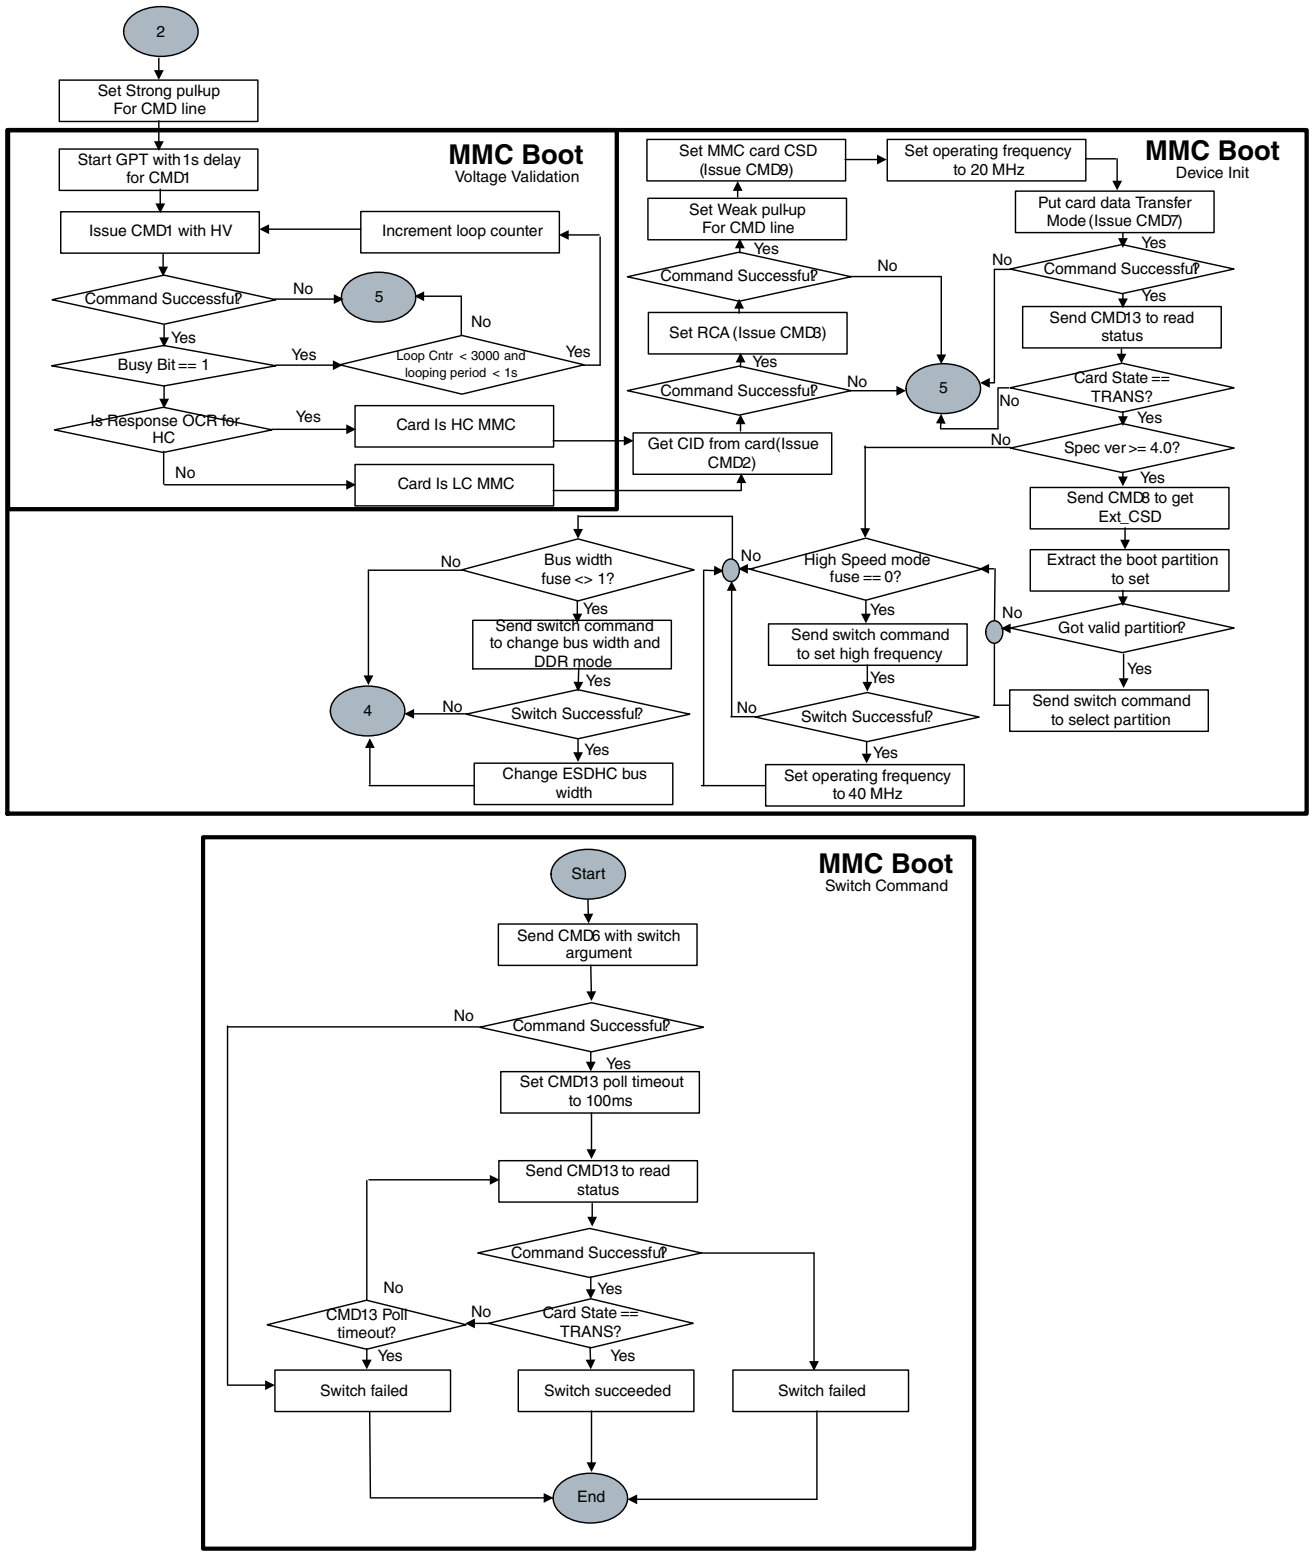

Figure 6-12. Expansion device (MMC) boot flow (2 of 6)

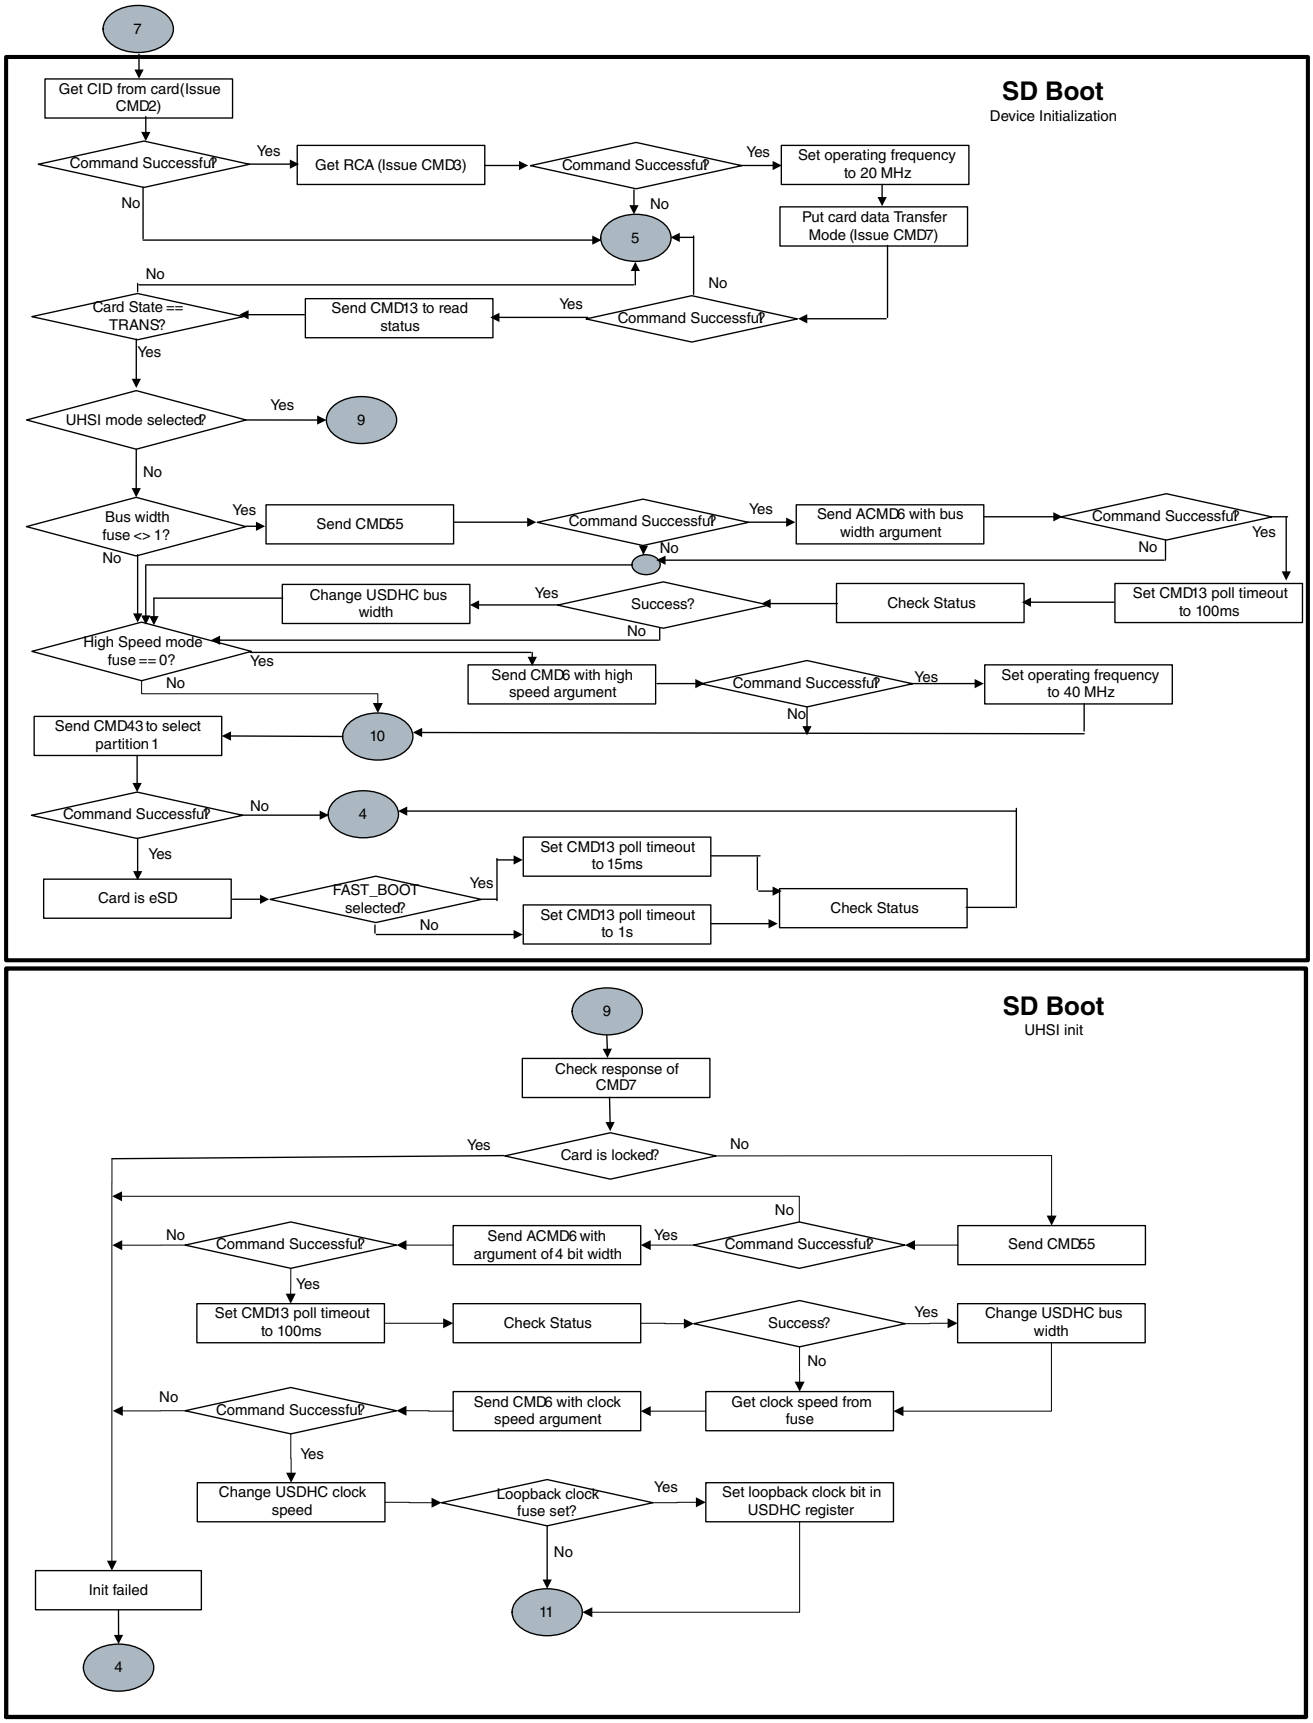

Figure 6-15. Expansion device (MMCSD/eSD/SDXC) boot flow (4 of 6)

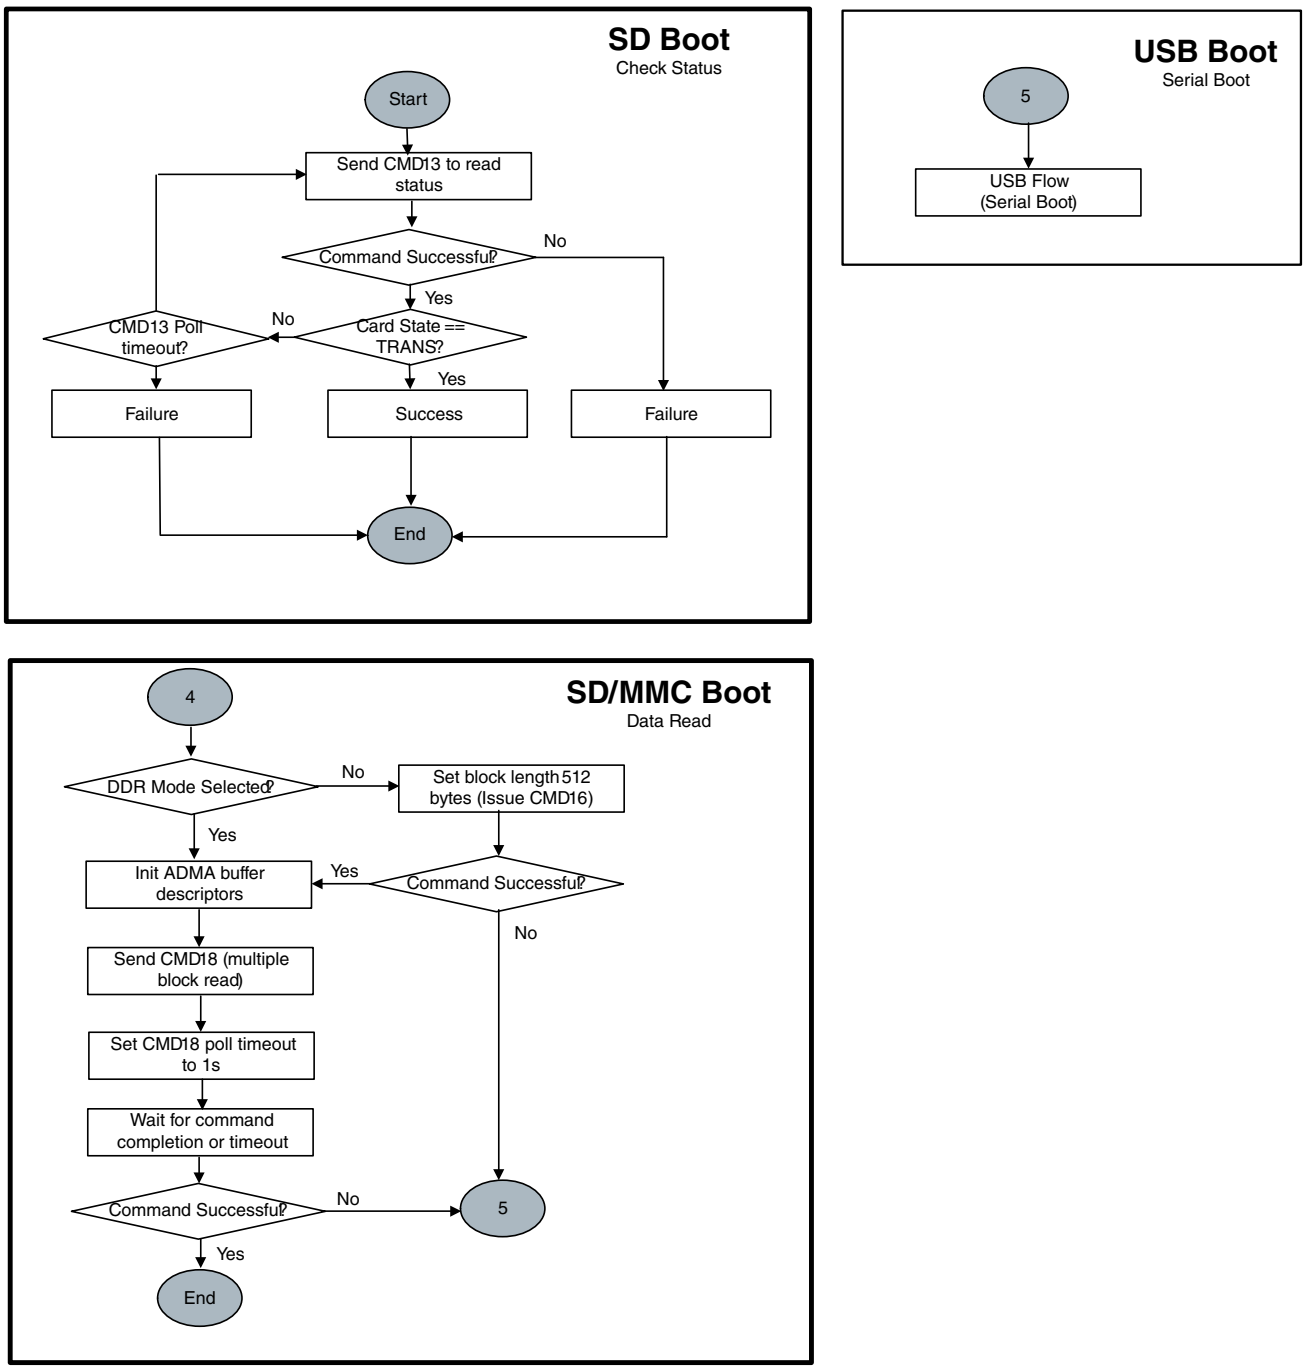

Figure 6-16. Expansion device (SD/eSD) boot flow (5 of 6)

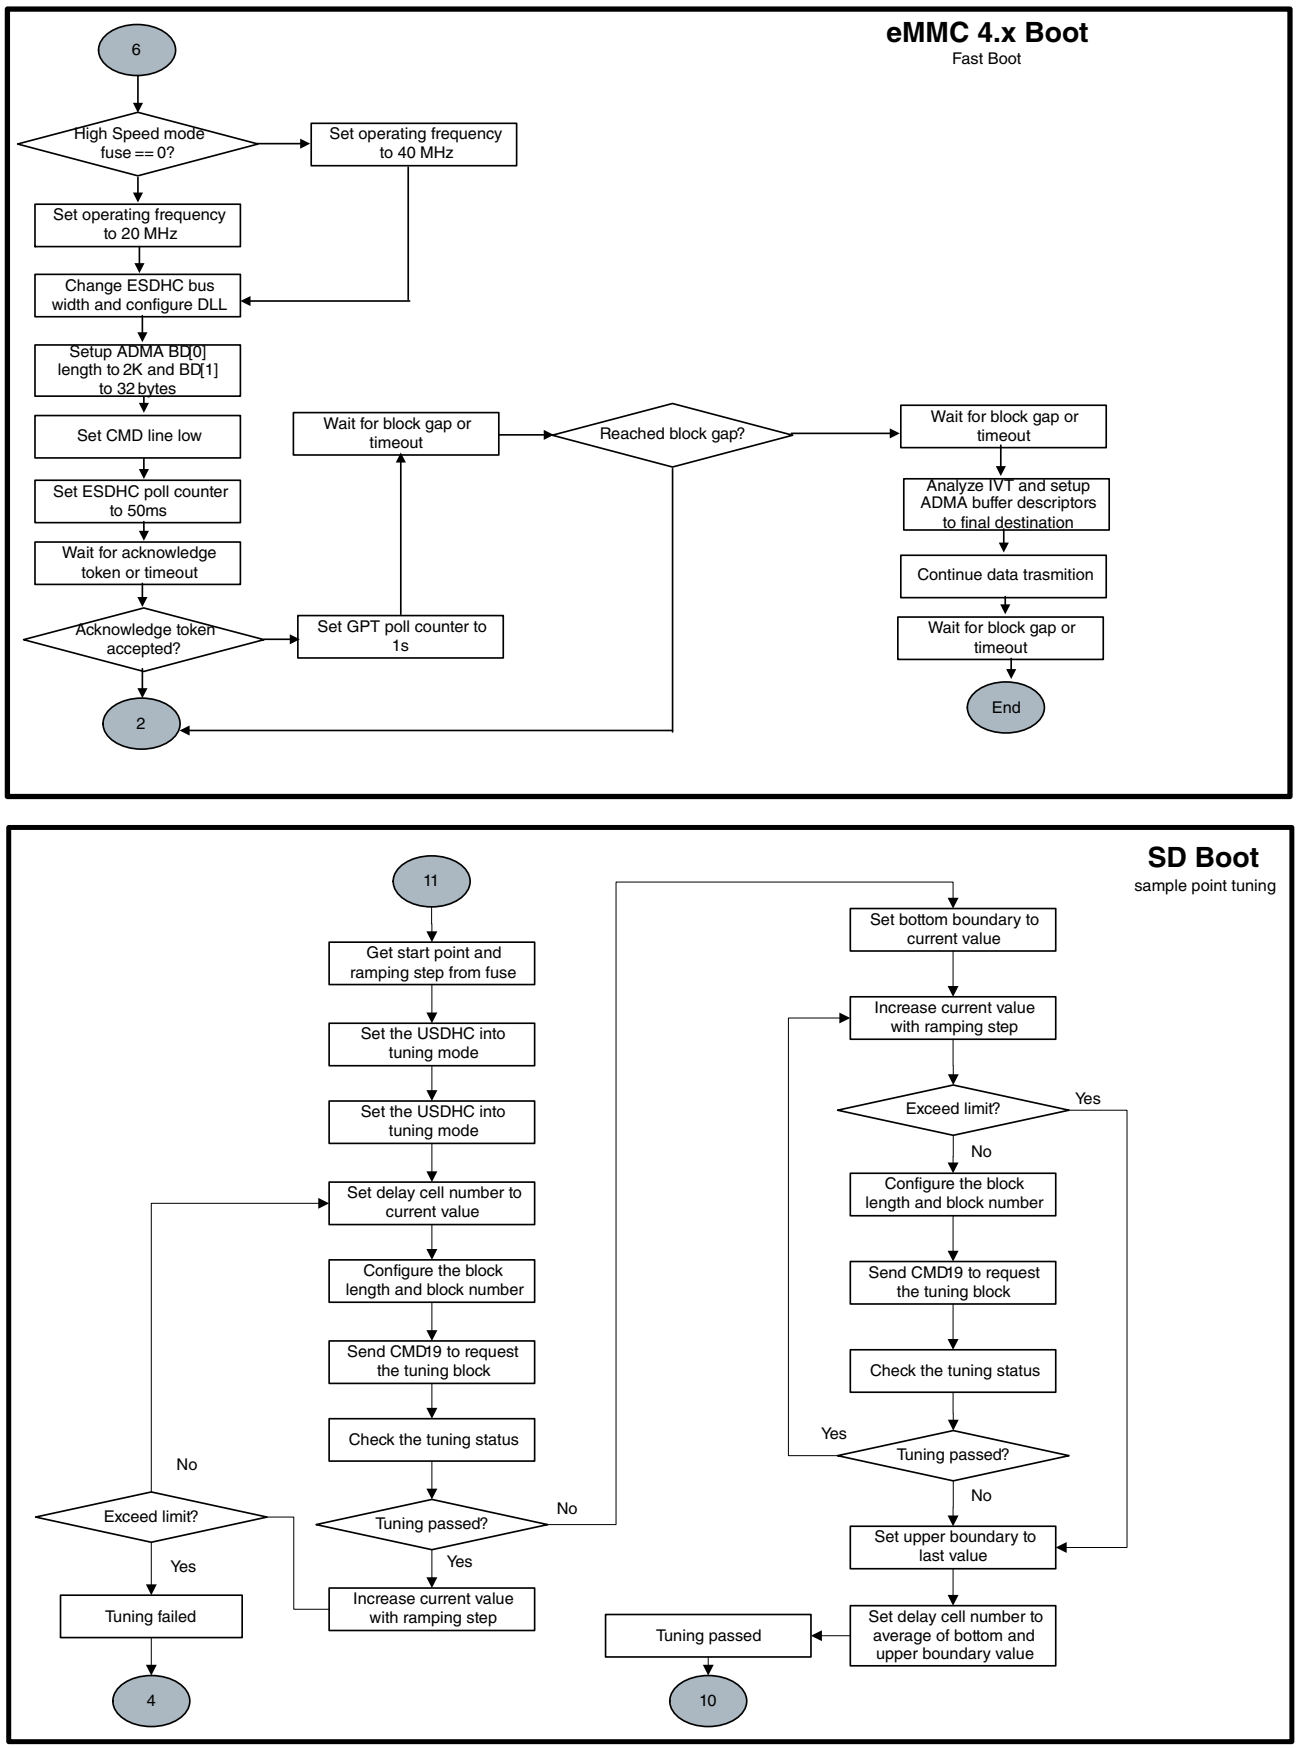

Figure 6-17. Expansion device boot flow (6 of 6)

6.1.5.4.3 SD, eSD, and SDXC

After the normal boot mode initialization begins, the SD/eSD/SDXC frequency is set to 347.22 kHz. During the identification phase, the SD/eSD/SDXC card voltage validation is performed. During the voltage validation, the boot code first checks with the high-voltage settings; if that fails, it checks with the low-voltage settings.

The capacity of the card is also checked. The boot code supports the high-capacity and low-capacity SD/eSD/SDXC cards after the voltage validation card initialization is done.

During the card initialization, the ROM boot code attempts to set the boot partition for all SD, eSD, and SDXC devices. If this fails, the boot code assumes that the card is a normal SD or SDXC card. If it does not fail, the boot code assumes it is an eSD card. After the initialization phase is over, the boot code switches to a higher frequency (25 MHz in the normal-speed mode or 50 MHz in the high-speed mode). The ROM also supports the FAST_BOOT mode booting from the eSD card. This mode can be selected by the BOOT_CFG[4] (Fast Boot) fuse described in .

For the UHSI cards, the clock speed fuses can be set to SDR50 or SDR104 on ports. This enables the voltage switch process to set the signaling voltage to 1.8 V during the voltage validation. The bus width is fixed at a 4-bit width and a sampling point tuning process is needed to calibrate the number of the delay cells. If the SD Loopback Clock eFuse is set, the feedback clock comes directly from the loopback SD clock, instead of the card clock (by default). The SD clock speed can be selected by the BOOT_CFG[3:2], and the SD Loopback Clock is selected by the BOOT_CFG[0].

The UHSI calibration start value (MMC_DLL_DLY[6:0]) and the step value can be set to optimize the sample point tuning process.

If the SD Power Cycle Enable eFuse is 1, the ROM sets the SD_RST pad low, waits for 5 ms, and then sets the SD_RST pad high. If the SD_RST pad is connected to the SD power supply enable logic on board, it enables the power cycle of the SD card. This may be crucial in case the SD logic is in the 1.8 V states and must be reset to the 3.3 V states.

6.1.5.4.4 IOMUX configuration for SD/MMC

Table 6-22. SD/MMC IOMUX pin configuration

6.1.5.4.5 Redundant boot support for expansion device

The ROM supports the redundant boot for an expansion device. The primary or secondary image is selected, depending on the PERSIST_SECONDARY_BOOT setting. (see Table 6-8).

If the PERSIST_SECONDARY_BOOT is 0, the boot ROM uses address 0x8400 for the primary image.

If the PERSIST_SECONDARY_BOOT is 1, the boot ROM reads the secondary image table from address 0x8200 on the boot media and uses the address specified in the table.

Table 6-23. Secondary image table format

Reserved (chipNum)
Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- The tag is used as an indication of the valid secondary image table. It must be 0x00112233.
- The firstSectorNumber is the first 512-byte sector number of the secondary image.

For the secondary image support, the primary image must reserve the space for the secondary image table. See this figure for the typical structures layout on an expansion device.

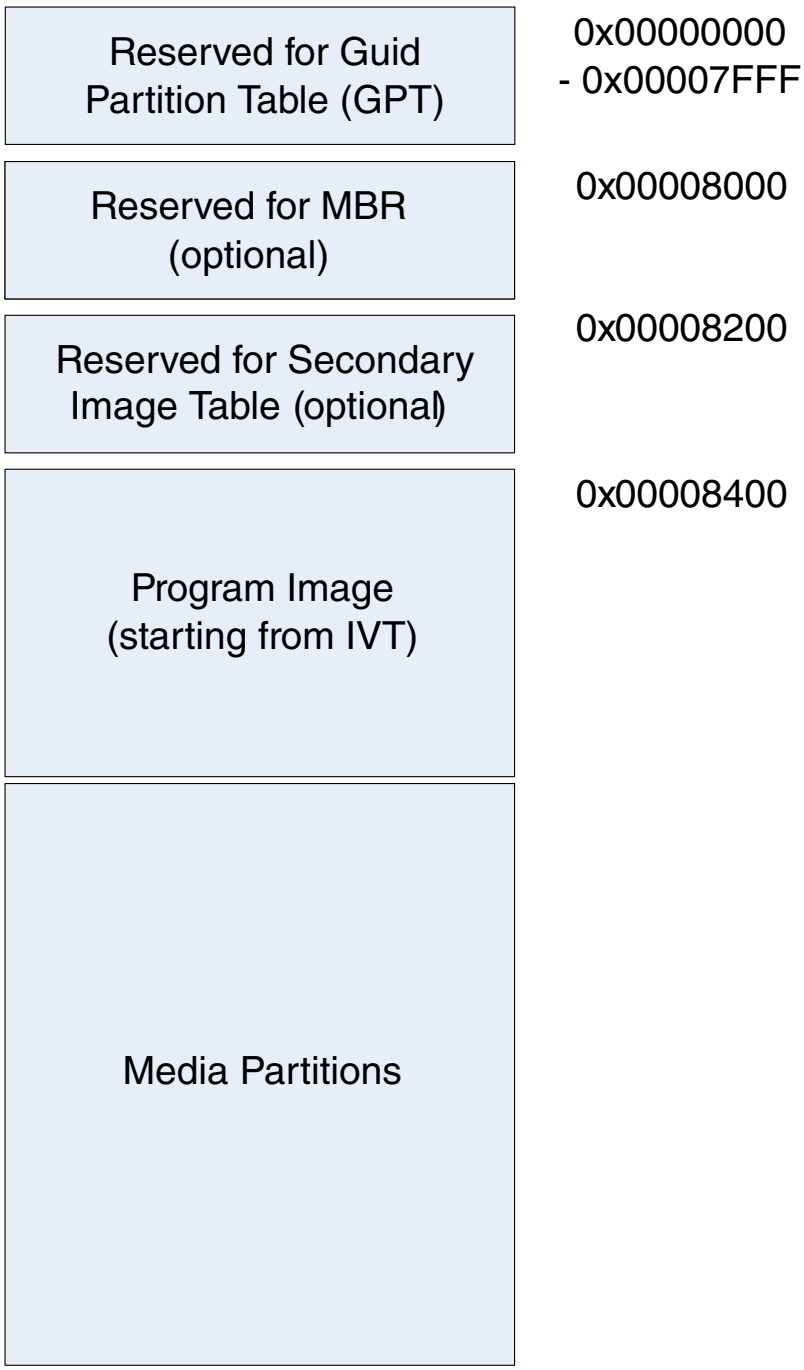

Figure 6-18. Expansion device structures layout

For the Closed mode, if there are failures during primary image authentication, the boot ROM turns on the PERSIST_SECONDARY_BOOT bit (see Table 6-8) and performs the software reset. (After the software reset, the secondary image is used.)

6.1.5.5 Serial NOR through SPI

The chip supports booting from serial memory devices, such as EEPROM and serial flash, using the SPI.

These ports are available for serial boot: eCSPI (eCSPI1, eCSPI2, eCSPI3) interfaces.

6.1.5.5.1 Serial(SPI) NOR eFUSE configuration

The boot ROM code determines the type of device using the following parameters, either provided by the eFUSE settings or sampled on the I/O pins, during boot.

See this table for details:

Table 6-24. Serial(SPI) NOR boot eFUSE descriptions

Fuse	Config	Definition	GPIO[1]	Shipped value	Settings
BOOT_CFG[14:12]	OEM	Boot device selection	Yes	0000	110 - Boot from the serial(SPI) NOR
BOOT_CFG[11:9]	OEM	ECSPI port selection	Yes	000	000 - eCSPI1 001 - eCSPI2 010 - eCSPI3
BOOT_CFG[8]	OEM	SPI addressing	Yes	0	0 - 3 B (24-bit) 1 - 2 B (16-bit)
0x480[25]	OEM	Recovery boot enable	No	0	0 – Disabled 1 – Enabled
BOOT_CFG[7:6]	OEM	CS selection (SPI only)	Yes	00	00 – CS#0
0x480[31:29]	OEM	Recovery port selection	No	000	000 - eCSPI1 001 - eCSPI2 010 - eCSPI3
0x480[28]	OEM	Recovery SPI addressing	No	0	0 - 3 B (24-bit) 1 - 2 B (16-bit)
0x480[27:26]	OEM	Recovery CS selection (SPI only)	No	00	00 - CS#0

1. The setting can be overridden by the GPIO settings when the BT_FUSE_SEL fuse is intact. See Table 1 for the corresponding GPIO pin.

The ECPSI-1/ECPSI-2/ECPSI-3 block can be used as a boot device using the ECSPI interface for the serial(SPI) NOR boot. The SPI interface is configured to operate at 12.5 MHz for 3-byte addressing devices and at 3.125 MHz for 2-byte addressing devices.

The boot ROM copies 4 KB of data from the serial ROM device to the internal RAM. After checking the Image Vector Table header value (0xD1) from the program image, the ROM code performs a DCD check. After a successful DCD extraction, the ROM code extracts the destination pointer and length of image from the Boot Data Structure to be copied to the RAM device from where the code execution occurs.

NOTE

The Initial 4 KB of program image must contain the IVT, DCD, and the Boot Data Structures.

6.1.6 Program image

This section describes the data structures that are required to be included in the user's program image. The program image consists of:

- Image vector table—a list of pointers located at a fixed address that the ROM examines to determine where the other components of the program image are located.
- Boot data—a table that indicates the program image location, program image size in bytes, and the plugin flag.
- Device configuration data—IC configuration data.
- User code and data.

6.1.6.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the program image containing the required data components to perform a successful boot.

The IVT includes the program image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process.The ROM locates the IVT at a fixed address that is determined by the boot device connected to the Chip. The IVT offset from the base address and initial load region size for each boot device type is defined in the table below. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

Table 6-25. Image Vector Table Offset and Initial Load Region Size

Boot Device Type	Image Vector Table Offset	Initial Load Region Size
NAND	1 Kbyte = 0x4000 bytes	8 Kbyte

Table continues on the next page...

Table 6-25. Image Vector Table Offset and Initial Load Region Size (continued)

Boot Device Type	Image Vector Table Offset	Initial Load Region Size
SD/eSD/MMC/eMMC normal boot	33 Kbyte = 0x8400 bytes	8 Kbyte
eMMC Fast boot	1 Kbyte = 0x400 bytes	8 Kbyte
FlexSPI	4 Kbyte = 0x1000 bytes	8 Kbyte
ECSPI	1 Kbyte = 0x400 bytes	8 Kbyte

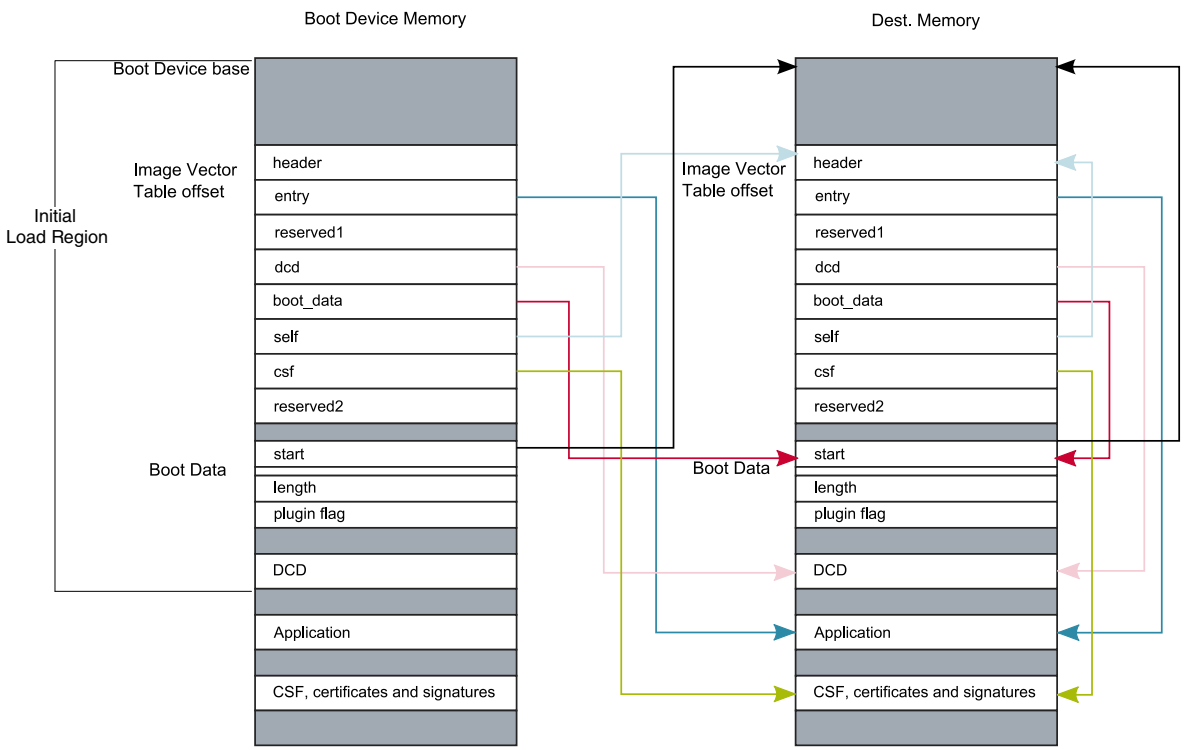

Figure 6-19. Image Vector Table

6.1.6.1.1 Image vector table structure

The IVT has the following format where each entry is a 32-bit word:

Table 6-26. IVT format

header
entry: Absolute address of the first instruction to execute from the image
reserved1: Reserved and should be zero
dcd: Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See Device Configuration Data (DCD) for further details on the DCD.

Table continues on the next page...

Table 6-26. IVT format (continued)

boot data: Absolute address of the boot data
self: Absolute address of the IVT. Used internally by the ROM.
csf: Absolute address of the Command Sequence File (CSF) used by the HAB library. See High-Assurance Boot (HAB) for details on the secure boot using HAB. This field must be set to NULL when not performing a secure boot
reserved2: Reserved and should be zero

Figure 6-20 shows the IVT header format:

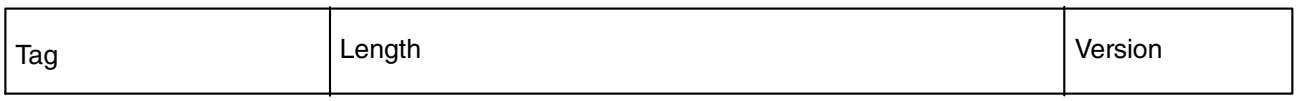

Figure 6-20. IVT header format

where:

```
Tag: A single byte field set to 0xD1
Length: a two byte field in big endian format containing the overall length of the IVT,
in bytes, including the header. (the length is fixed and must have a value of
32 bytes)
Version: A single byte field set to 0x40 or 0x41
```

6.1.6.1.2 Boot data structure

The boot data must follow the format defined in the table found here, each entry is a 32-bit word.

Table 6-27. Boot data format

start	Absolute address of the image
length	Size of the program image
plugin	Plugin flag (see Plugin image)

6.1.6.2 Device Configuration Data (DCD)

Upon reset, the chip uses the default register values for all peripherals in the system. However, these settings typically are not ideal for achieving the optimal system performance and there are even some peripherals that must be configured before they can be used.

The DCD is a configuration information contained in the program image (external to the ROM) that the ROM interprets to configure various peripherals on the chip.

For example, the EIM default settings allow the core to interface to a NOR flash device immediately after the reset. This allows the chip to interface with any NOR flash device, but has the disadvantage of slow performance. Additionally, some components (such as DDR) require some sequence of register programming as a part of the configuration before it is ready to be used. The DCD feature can be used to program the EIM registers and the DDR Controller registers to the optimal settings.

The ROM determines the location of the DCD table based on the information located in the Image Vector Table (IVT). See Image Vector Table and Boot Data for more details. The DCD table shown below is a big-endian byte array of the allowable DCD commands. The maximum size of the DCD is limited to 1768 B.

Figure 6-21. DCD data format

The DCD header is 4 B with the following format:

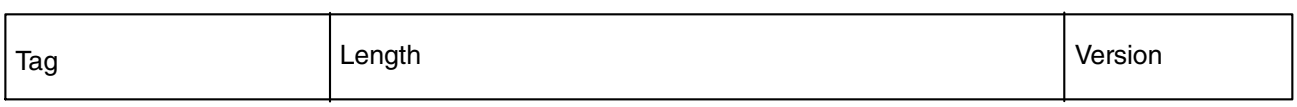

Figure 6-22. DCD header format

where:

```
Tag: A single-byte field set to 0xD2
Length: a two-byte field in the big-endian format containing the overall length of the DCD
(in bytes) including the header
Version: A single-byte field set to 0x41
```

6.1.6.2.1 Write data command

The write data command is used to write a list of given 1-, 2- or 4-byte values (or bitmasks) to a corresponding list of target addresses.

The format of the write data command (in a big-endian byte array) is shown in this table:

Table 6-28. Write data command format

Tag	Length	Parameter
Address		
Value/Mask		
[Address]		
[Value/Mask]		
...		
[Address]		
[Value/Mask]		

where:

```
Tag: a single-byte field set to 0xCC
Length: a two-byte field in a big-endian format, containing the length of the Write Data
Command (in bytes) including the header
Address: the target address to which the data must be written
Value/Mask: the data value (or bitmask) to be written to the preceding address
```

The parameter field is a single byte divided into the bitfields, as follows:

Table 6-29. Write data command parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: the width of the target locations in bytes (either 1, 2, or 4)
flags: control flags for the command behavior
Data Mask = bit 3: if set, only specific bits may be overwritten at the target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, the bits at the target address are overwritten with this flag
(otherwise it is ignored)
```

One or more target address and value/bitmask pairs can be specified. The same bytes' and flags' parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

Table 6-30. Interpretation of write data command flags

"Mask"	"Set"	Action	Interpretation
0	0	*address = val_msk	Write value
0	1	*address = val_msk	Write value
1	0	*address &= ~val_msk	Clear bitmask
1	1	*address |= val_msk	Set bitmask

NOTE

If any of the target addresses does not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values are larger or any of the bitmasks are wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within the allowed region, none of the values are written. The list of allowable blocks and target addresses for the chip are provided below.

6.1.6.2.2 Check data command

The check data command is used to test for a given 1-, 2-, or 4-byte bitmasks from a source address.

The check data command is a big-endian byte array with the format shown in this table:

Table 6-31. Check data command format

Tag	Length	Parameter
Address		
Mask		
[Count]		

where:

```
Tag: a single-byte field set to 0xCF
Length: a two-byte field in the big-endian format containing the length of the check data
command (in bytes) including the header
Address: the source address to test
Mask: the bit mask to test
Count: an optional poll count; If the count is not specified, this command polls
indefinitely
until the exit condition is met. If count = 0, this command behaves as for the NOP.
```

The parameter field is a single byte divided into bitfields, as follows:

Table 6-32. Check data command parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: the width of target locations in bytes (either 1, 2, or 4)
flags: control flags for the command behavior
Data Mask = bit 3: if set, only the specific bits may be overwritten at a target address
```

```
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, the bits at the target address are overwritten with this flag
(otherwise it is ignored)
```

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows:

Table 6-33. Interpretation of check data command flags

"Mask"	"Set"	Action	Interpretation
0	0	(*address & mask) == 0	All bits clear
0	1	(*address & mask) == mask	All bits set
1	0	(*address & mask)!= mask	Any bit clear
1	1	(*address & mask)!= 0	Any bit set

NOTE

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

6.1.6.2.3 NOP command

This command has no effect.

The format of the NOP command is a big-endian four-byte array, as shown in this table:

Table 6-34. NOP command format

Tag	Length	Undefined

where:

```
Tag: a single-byte field set to 0xC0
Length: a two-byte field in big endian containing the length of the NOP command in bytes
(fixed to a
value of 4)
Undefined: this byte is ignored and can be set to any value.
```

6.1.6.2.4 Unlock command

The unlock command is used to prevent specific engine features from being locked when exiting the ROM.

The format of the unlock command (in a big-endian byte array) is shown in this table:

Table 6-35. Unlock command format

Tag	Length	Eng
Value		
Value		
...		
Value		

where:

NOTE

This command may not be used in the DCD structure if the SEC_CONFIG is configured as closed.

6.1.7 Plugin image

The ROM supports a limited number of boot devices. When using other devices as a boot source (for example, Ethernet, CDROM, or USB), the supported boot device must be used (typically serial(SPI) NOR) as a firmware to provide the missing boot drivers. Additionally, the plugin can be customized to support boot drivers, which is more flexible when performing the device initialization, such as condition judging, delay assertion, or to apply custom settings to the boot device and memory system.

In addition to the standard images, the chip also supports plugin images. The plugin images return the execution to the ROM whereas the standard image does not.

The boot ROM detects the image type using the plugin flag of the boot data structure (see Boot data structure). If the plugin flag is 1, then the ROM uses the image as a plugin function. The function must initialize the boot device and copy the program image to the final location. At the end, the plugin function must return with the program image parameters. (See High-level boot sequence for details about the boot flow).

The boot ROM authenticates the plugin image before running the plugin function and then authenticates the program image.

The plugin function must follow the API described below:

typedef BOOLEAN (*plugin_download_f)(void **start, size_t *bytes, UINT32 *ivt_offset);

ARGUMENTS PASSED:

- start - the image load address on exit.

- bytes - the image size on exit.
- ivt_offset - the offset (in bytes) of the IVT from the image start address on exit.

RETURN VALUE:

- 1 - success
- 0 - failure

6.1.8 Serial Downloader

The Serial Downloader provides a means to download a program image to the chip over the USB serial connection.

In this mode, the ROM programs the WDOG1 for a time-out specified by the fuse WDOG Time-out Select (See fusemap for details) if the WDOG_ENABLE eFuse is 1 and continuously polls for the USB connection. If no activity is found on the USB OTG1 and the watchdog timer expires, the Arm core is reset.

NOTE

After the downloaded image is loaded, it is responsible for managing the watchdog resets properly.

This figure shows the USB boot flow:

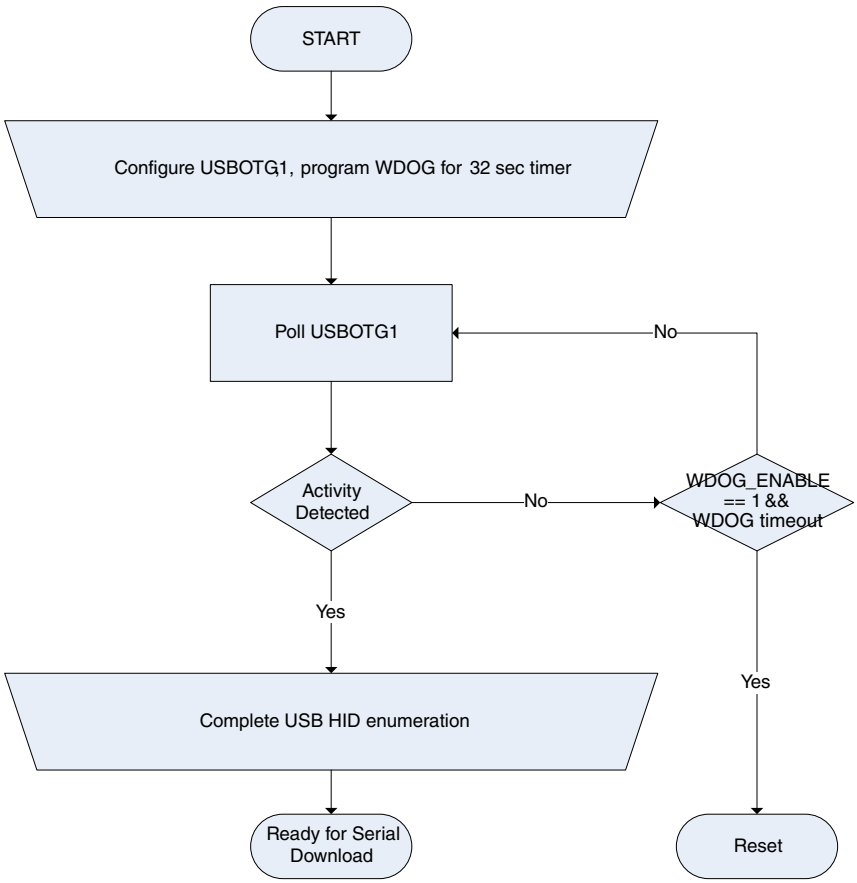

Figure 6-23. Serial Downloader boot flow

NOTE

Before going into USB serial mode, Boot ROM detect SD/MMC card on USDHC2 port. If a card is inserted, ROM will try to boot from it. This is the so-called Manufacture SD/MMC boot. This feature can be disabled by blowing fuse "Disable SD/MMC Manufacture Mode". See SD/MMC manufacture mode for details.

6.1.8.1 USB

The USB support is composed of the USB (core controller, compliant with the USB 2.0 specification) and the USBPHY (HS USB transceiver).

The ROM supports the USB OTG port for boot purposes. The other USB ports on the chip are not supported for boot purposes.

The USB Driver is implemented as a USB HID class. A collection of four HID reports are used to implement the SDP protocol for data transfers, as described in Table 6-36.

Table 6-36. USB HID reports

Report ID (first byte)	Transfer endpoint	Direction	Length	Description
1	control OUT	Host to device	17 B	SDP command from the host to the device.
2	control OUT	Host to device	Up to 1025 B	Data associated with the report 1 SDP command.
3	interrupt	Device to host	5 B	HAB security configuration. The device sends 0x12343412 in the closed mode and 0x56787856 in the open mode.
4	interrupt	Device to host	Up to 65 B	Data in response to the SDP command in report 1.

6.1.8.1.1 USB configuration details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for the are listed in the following table.

Table 6-37. VID/PID and strings for USB device driver

Descriptor	Value
VID	0x1FC9 (NXP vendor ID)
PID[1]	0x012B
String Descriptor1 (manufacturer)	NXP Semiconductors
String Descriptor2 (product)	SE Blank SP Blank NS Blank FR Blank
String Descriptor4	NXP Flash
String Descriptor5	NXP Flash

1. Allocation based on the BPN (Before Part Number)

6.1.8.1.2 IOMUX configuration for USB

The interface signals of the UTMI PHY are not configured in the IOMUX,, except for the USB_OTGn_ID pins. The USB ID pin function is configured using the USBNC_n_CTRL2[ID_DIG_SEL] and the IOMUXC_USB_OTGn_ID_SELECT_INPUT register. The remaining pins of the UTMI PHY interface use the dedicated contacts on the IC. See the chip data sheet for details.

6.1.8.2 Serial Download Protocol (SDP)

The 16-byte SDP command from the host to device is sent using the HID report 1.

This table describes the 16-byte SDP command data structure:

Table 6-38. 16-byte SDP command data structure

BYTE offset	Size	Name	Description
0	2	COMMAND TYPE	These commands are supported for the ROM: • 0x0101 READ_REGISTER • 0x0202 WRITE_REGISTER • 0x0404 WRITE_FILE • 0x0505 ERROR_STATUS • 0x0A0A DCD_WRITE • 0x0B0B JUMP_ADDRESS
2	4	ADDRESS	Only relevant for these commands: READ_REGISTER, WRITE_REGISTER, WRITE_FILE, DCD_WRITE, and JUMP_ADDRESS. For the READ_REGISTER and WRITE_REGISTER commands, this field is the address to a register. For the WRITE_FILE and JUMP_ADDRESS commands, this field is an address to the internal or external memory address.
6	1	FORMAT	Format of access, 0x8 for an 8-bit access, 0x10 for a 16-bit access, and 0x20 for a 32-bit access. Only relevant for the READ_REGISTER and WRITE_REGISTER commands.
7	4	DATA COUNT	Size of the data to read or write. Only relevant for the WRITE_FILE, READ_REGISTER, WRITE_REGISTER, and DCD_WRITE commands. For the WRITE_FILE and DCD_WRITE commands, the DATA COUNT is in the byte units.
11	4	DATA	The value to write. Only relevant for the WRITE_REGISTER command.
15	1	RESERVED	Reserved

6.1.8.2.1 SDP commands

The SDP commands are described in the following sections.

6.1.8.2.1.1 READ_REGISTER

The transaction for the READ_REGISTER command consists of these reports: Report1 for the command, Report3 for the security configuration, and Report4 for the response or the register value.

The register to read is specified in the ADDRESS field of the SDP command. The first device sends Report3 with the security configuration followed by the Report4 with the bytes read at a given address. If the count is greater than 64, multiple reports with the report id 4 are sent until the entire data requested by the host is sent. The STATUS is either 0x12343412 for the closed parts and 0x56787856 for the open or field return parts.

Report1, Command, Host to Device:

1	Valid values for the READ_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT

ID 16-byte SDP command

Report3, Response, Device to Host:

3	Four bytes indicating the security configuration

ID 4 bytes status

Report4, Response, Device to Host: first response report

4	Register value

ID 4 bytes of data containing the register value. If the number of bytes requested is less than 4, the remaining bytes must be ignored by the host.

Multiple reports of the report id 4 are sent until the entire requested data is sent.

Report4, Response, Device to Host: last response report

4	Register value

ID 64 bytes of data containing the register value. If the number of bytes requested is less than 64, the remaining bytes must be ignored by the host.

6.1.8.2.1.2 WRITE_REGISTER

The transaction for the WRITE_REGISTER command consists of these reports: Report1 for the command, Report3 for the security configuration and Report4 for the write status.

The host sends Report1 with the WRITE_REGISTER command. The register to write is specified in the ADDRESS field of the SDP command of Report1, with the FORMAT field set to the data type (number of bits to write, either 8, 16, or 32) and the value to write in the DATA field of the SDP command. The device writes the DATA to the register address and returns the WRITE_COMPLETE code using Report4 and the security configuration using Report3 to complete the transaction.

Report1, Command, Host to Device:

1	Valid values for WRITE_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT and DATA

ID 16-byte SDP command

Report3, Response, Device to Host:

3	4 bytes indicating the security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	WRITE_COMPLETE (0x128A8A12) status

ID 64 bytes data with the first 4 bytes to indicate that the write is completed with code 0x128A8A12. On failure, the device reports the HAB error status.

6.1.8.2.1.3 WRITE_FILE

The transaction for the WRITE_FILE command consists of these reports: Report1 for the command phase, Report2 for the data phase, Report3 for the HAB mode, and Report4 to indicate that the data are received in full.

The size of each Report2 is limited to 1024 bytes (limitation of the USB HID protocol). Hence, multiple Report2 packets are sent by the host in the data phase until the entire data is transferred to the device. When the entire data (DATA_COUNT bytes) is received, the device sends Report3 with the HAB mode and Report4 with 0x88888888, indicating that the file download completed.

Report1, Host to Device:

1	Valid values for WRITE_FILE COMMAND, ADDRESS, DATA_COUNT

ID 16-byte SDP command

==========Optional Begin==========

Host sends the ERROR_STATUS command to query if the HAB rejected the address

========== Optional End==========

Report2, Host to Device:

2	File data

ID Max 1024 bytes data per report

Report2, Host to Device:

2	File data

ID Max 1024 bytes data per report

Report3, Device to Host:

3	4 bytes indicating security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	COMPLETE (0x88888888) status

ID 64 bytes data with the first four bytes to indicate that the file download completed with code 0x88888888. On failure, the device reports the HAB error status.

6.1.8.2.1.4 ERROR_STATUS

The transaction for the SDP command ERROR_STATUS consists of three reports.

Report1 is used by the host to send the command; the device sends global error status in four bytes of Report4 after returning the security configuration in Report3. When the device receives the ERROR_STATUS command, it returns the global error status that is updated for each command. This command is useful to find out whether the last command resulted in a device error or succeeded.

Report1, Command, Host to Device:

1	ERROR_STATUS COMMAND

ID 16-byte SDP Command

Report3, Response, Device to Host:

3	Four bytes indicating the security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	Four bytes Error status

ID first 4 bytes status in 64 bytes Report4

6.1.8.2.1.5 DCD_WRITE

The SDP command DCD_WRITE is used by the host to send multiple register writes in one shot. This command is provided to speed up the process of programming the register writes (such as to configure an external RAM device).

The command goes with Report1 from the host with COMMAND TYPE set to DCD_WRITE, ADDRESS which is used as a temporary location of the DCD data, and DATA_COUNT to the number of bytes sent in the data out phase. In the data phase, the host sends the data for a number of registers using Report2. The device completes the transaction with Report3 indicating the security configuration and Report4 with the WRITE_COMPLETE code 0x12828212.

Report1, Command, Host to Device:

1	DCD_WRITE COMMAND, ADDRESS, DATA_COUNT

ID 16-byte SDP Command

Report2, Data, Host to Device:

2	DCD binary data

ID Max 1024 bytes per report

Report3, Response, Device to Host:

3	Four bytes indicating the security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	WRITE_COMPLETE (0x128A8A12) status

ID 64 bytes report with the first four bytes to indicate that the write completed with the code 0x128A8A12. On failure, the device reports the HAB error status.

See Device Configuration Data (DCD) for the DCD format description.

6.1.8.2.1.6 SKIP_DCD_HEADER

The SDP command SKIP_DCD_HEADER is used by the host to inform the device to skip the DCD configuration within the download image.

If the download image must be run on the DDR, the DCD configuration data must be built into the image. In case the host issued DCD_WRITE to push the DCD configuration data to the device for the DDR initialization, the image with the DCD information causes the ROM to initialize the DDR twice, and may cause the initialization processing to hang.

The SKIP_DCD_HEADER command informs the device to skip the DCD configuration within the download image and avoid this issue.

This command is typically sent after JUMP_ADDRESS. This command is sent by the host in the command-phase of the transaction using Report1, there is no data phase for this command. The device completes the transaction with Report3 indicating the security configuration and Report4 with the OK_ACK code 0x900DD009.

Report1, Command, Host to Device:

1	SKIP_DCD_HEADER

ID 16-byte SDP Command

Report3, Response, Device to Host:

3	Four bytes indicating the security configuration

ID 4 bytes status

Report4, Response, Device to Host:

4	OK_ACK (0x900DD009)

6.1.8.2.1.7 JUMP_ADDRESS

The SDP command JUMP_ADDRESS is the last command that the host can send to the device. After this command, the device jumps to the address specified in the ADDRESS field of the SDP command and starts to execute.

This command usually follows after the WRITE_FILE command. The command is sent by the host in the command-phase of the transaction using Report1. There is no data phase for this command, but the device sends the status Report3 to complete the transaction. If the authentication fails, it also sends Report4 with the HAB error status.

Report1, Command, Host to Device:

1	JUMP_ADDRESS COMMAND, ADDRESS

ID 16-byte SDP Command

Report3, Response, Device to Host:

3	Four bytes indicating the security configuration

ID 4 bytes status

This report is sent by the device only in case of an error jumping to the given address, or if the device reports error in Report4, Response, Device to Host:

4	Four bytes HAB error status

ID 4 bytes status, 64 bytes report length

6.1.9 Recovery devices

The chip supports recovery devices. If the primary boot device fails, the boot ROM tries to boot from the recovery device using the USDHC2 port.

6.1.10 Low-power boot

The ROM supports the low-power boot. If the LPB_BOOT fuses are blown, the chip checks if there is a low-power condition via the pad. If there is a low-power boot condition, the ROM applies division factors on the ARM, DDR, AXI, and AHB root clocks based on the LPB_BOOT fuses value (see the table below). The polarity of the low-power boot condition on the pad is set by the BT _LPB_POLARITY fuse (see the following figure).

Table 6-39. Low-power boot frequencies

LPB_BOOT	Boot Frequencies=0	Boot Frequencies=1
00	ARM_A53_CLK_ROOT= 800 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 333 MHz	ARM_A53_CLK_ROOT= 400 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 166 MHz
01	ARM_A53_CLK_ROOT= 800 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 333 MHz	ARM_A53_CLK_ROOT= 400 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 166 MHz
10	ARM_A53_CLK_ROOT= 400 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 166 MHz	ARM_A53_CLK_ROOT= 200 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 83.3 MHz
11	ARM_A53_CLK_ROOT= 200 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 83.3 MHz	ARM_A53_CLK_ROOT= 200 MHz AHB_CLK_ROOT= 133 MHz MAIN_AXI_CLK_ROOT= 41.67 MHz

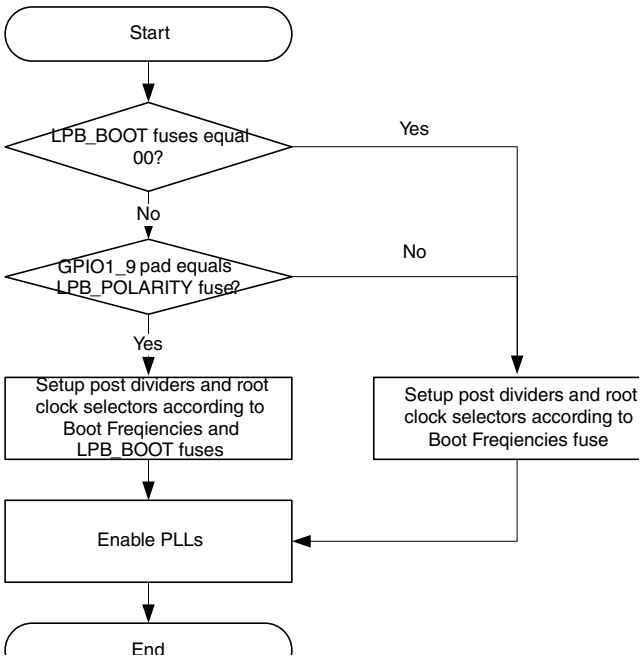

Figure 6-24. Low-power boot flow

6.1.11 SD/MMC manufacture mode

When the internal boot and recover boot (if enabled) failed , the boot goes to the SD/MMC manufacture mode before the serial download mode. In the manufacture mode, one bit bus width is used despite of the fuse setting.

By default, the SD/MMC manufacture mode is enabled. Blow the fuse of the DISABLE_SDMMC_MFG to disable it.

NOTE

A secondary boot is not supported in the SD/MMC manufacture mode.

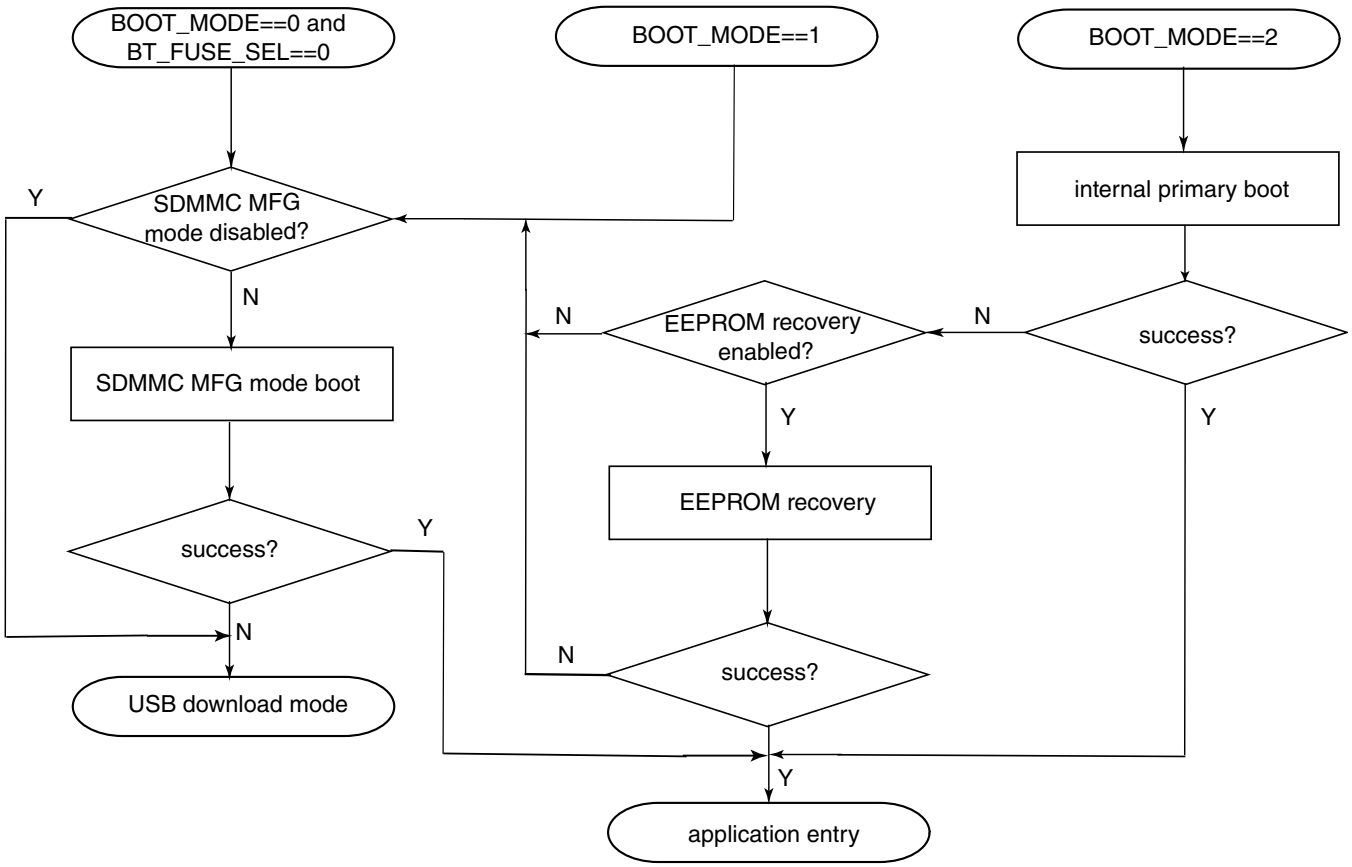

Figure 6-25. SD/MMC manufacture boot flow

6.1.12 High-Assurance Boot (HAB)

The High Assurance Boot (HAB) component of the ROM protects against the potential threat of attackers modifying the areas of code or data in the programmable memory to make it behave in an incorrect manner. The HAB also prevents the attempts to gain access to features which must not be available.

The integration of the HAB feature with the ROM code ensures that the chip does not enter an operational state if the existing hardware security blocks detected a condition that may be a security threat or if the areas of memory deemed to be important were modified. The HAB uses the RSA digital signatures to enforce these policies.

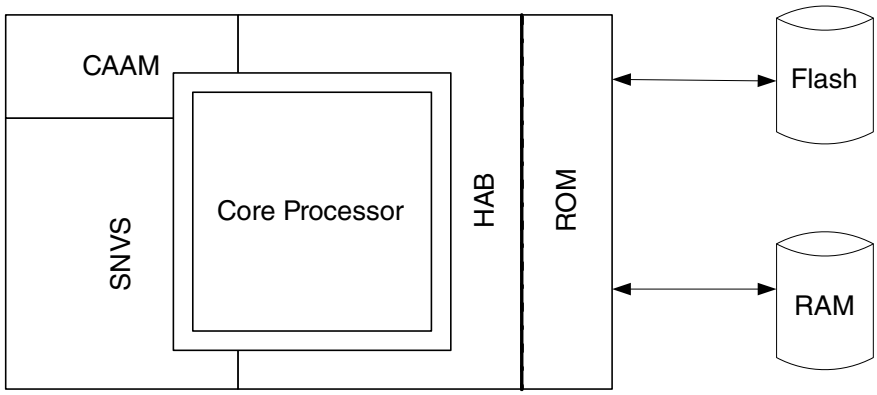

Figure 6-26. Secure boot components

The figure above illustrates the components used during a secure boot using HAB. The HAB interfaces with the SNVS to make sure that the system security state is as expected. The HAB also uses the CAAM hardware block to accelerate the SHA-256 message digest operations performed during the signature verifications and AES-128 operations for the encrypted boot operations. The HAB also includes a software implementation of SHA-256 for cases where a hardware accelerator can't be used. The RSA key sizes supported are 1024, 2048, 3072, and 4096 bits. The RSA signature verification operations are performed by a software implementation contained in the HAB library. The main features supported by the HAB are:

- X.509 public key certificate support
- CMS signature format support
- Proprietary encrypted boot support. Note that the encrypted boot depends on the CAAM hardware module. When the CAAM is disabled (when the EXPORT_CONTROL fuse is blown), the encrypted boot is not available.

NOTE

NXP provides the reference Code Signing Tool (CST) for key generation, certificate generation, and code signing for use with the HAB library. The CST can be found by searching for "IMX_CST_TOOL" at http://www.nxp.com.

NOTE

For further details on using the secure boot feature using HAB, refer to *Secure Boot on i.MX 50, i.MX 53, i.MX 6 and i.MX 7 Series using HABv4 (AN4581).*

6.1.12.1 HAB API vector table addresses

For devices that perform a secure boot, the HAB library may be called by the boot stages that execute after the ROM code.

NOTE

For additional information on the secure boot including the HAB API, refer to *HABv4 RVT Guidelines and Recommendations (AN12263)*.

6.1.13 Boot information for software

To address the requirement that the boot image may need to get the basic boot information when getting out of the boot process, the boot software information (Boot_SW_Info) is provisioned by the ROM.

The software must read the ROM address 0x9e8 to get the base address of the Boot_SW_Info data structure, and parse the Boot_SW_Info content to get the boot information.

Table 6-40. Boot_SW_Info structure

Offset	Byte3	Byte2	Byte1	Byte0
0x0	Reserved	Boot Device Type	Boot Device Instance	Reserved
0x4	Arm core frequency (in Hz)			
0x8	AXI bus frequency (in Hz)			
0xC	DDR frequency (in Hz)			
0x10	GPT1 input clock frequency (in Hz)			
0x14	Reserved			
0x18				
0x1C				

NOTE

The boot ROM sets the GPT1 in a free-running mode with a 32-kHz input clock.

Boot device type mapping:

- 0x1 - SD card or eSD chip
- 0x2 - MMC card or eMMC chip
- 0x3 - NAND chip

Boot device instance: The instance index of the boot device, starting from 0.

6.2 Fusemap

6.2.1 Boot Fusemap

The following section details the various modes and selection of the required boot devices. A separate map is given for each and every boot device. The device select is specified by BOOT_CFG[14:12] fuses listed below.

Table 6-41. Boot Device Select

Boot Device	BOOT_CFG[14]	BOOT_CFG[13]	BOOT_CFG[12]
SD/eSD	0	0	1
MMC/eMMC	0	1	0
NAND	0	1	1
FlexSPI	1	0	0
SPI/NOR	1	1	0

NOTE

Fuses marked as “Reserved” are reserved for NXP internal (and future) use only. Customers should not attempt to burn these, as the IC behavior may be unpredictable. The reserved fuses can be read as either 0 or 1.

Table 6-42. SD/eSD Boot Fusemap

6.2.3 Fusemap Descriptions Table

NOTE

Definitions for fuse settings are as follows:

- Unlock - The controlled field can be read, sensed, burned, or overridden in the corresponding OCOTP shadow register.
- Lock - The controlled field can't be read, overridden nor burned.
- Override Protect (OP) - The controlled field can be read, sensed, or burned in the corresponding OCOTP shadow register.
- Write Protect (WP) - The controlled field can be read, sensed, or overridden in the corresponding OCOTP shadow register.
- OP + WP - The controlled field can only be read or sensed in the corresponding OCOTP shadow register. It cannot be burned or overridden in the corresponding OCOTP shadow register.
- Lock - The controlled field cannot be read, burned, or overridden.

6.3 On-Chip OTP Controller (OCOTP_CTRL)

6.3.1 Overview

This section contains information describing the requirements for the on-chip eFuse OTP controller along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

6.3.1.1 Features

The OCOTP provides the following features:

- Loading and housing of fuse content into shadow registers.
- Generation of HWV_FUSE (hardware visible fuse bus) and the HWV_REG bus which is made up of volatile PIO register based "fuses". The HWV_REG bits come from the SCS (Software Controllable Signals) register.
- Generation of STICKY_REG which is consist of sticky register bits.
- Provide program-protect and read-protect eFuse.
- Provide override and read protection of shadow register.

6.3.2 Top-Level Symbol and Functional Overview

The figure found here shows the OCOTP system level diagram.

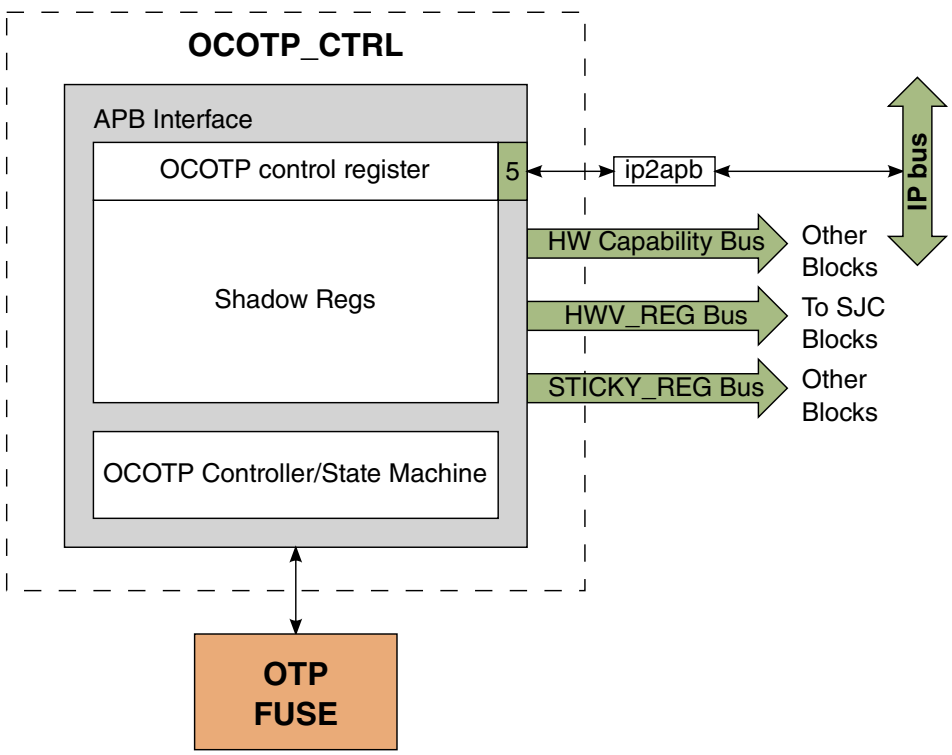

Figure 6-27. OCOTP System Level Diagram

6.3.2.1 Operation

The IP bus interface of the OCOTP provides two functions.

- Configure control registers for programming and reading fuse .
- Override and read shadow registers.

6.3.2.1.1 Shadow Register Reload

All fuse words in are shadowed. Therefore, fuse information is available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers (including HW_OCOTP_LOCK) without having to reset the device. To force a reload, complete the following steps:

1. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write , read or reload must be completed before a new access can be requested.
2. Set the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit. OCOTP will read all the fuse one by one and put it into corresponding shadow register.
3. Wait for HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[RELOAD_SHADOWS] to be cleared by the controller.

The controller will automatically clear the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

6.3.2.1.2 Fuse and Shadow Register Read

All shadow registers are always readable through the APB bus except some secret keys regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write , read or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

To read fuse words directly from correctly complete the following steps:

1. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
2. Write the requested to HW_OCOTP_CTRL[ADDR].

6.3.2.1.3 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The LOCK shadow register also has no shadow or fuse lock bits but it is always read only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank correctly complete the following steps:

1. Program HW_OCOTP_TIMING[STROBE_PROG] and fields with timing values to match the current frequency of the ipg_clk. OTP writes will work at maximum bus frequencies as long as the parameters are set correctly.
2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested to HW_OCOTP_CTRL[ADDR] and program the unlock code into HW_OCOTP_CTRL[WR_UNLOCK]. This must be programmed for each write access. The lock code is documented in the register description. Both the unlock code and address can be written in the same operation.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds. Write latencies is based on amount of bit filed which is 1. For example : program half fuse bits in one word need 10 us x 16.

For further details of OTP read/write operations see [eFUSE].

HW_OCOTP_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while HW_OCOTP_CTRL[RELOAD_SHADOWS] is set. In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed to from a shadow register which has been read locked.
- A program is performed to a fuse which has been .
- A read is performed to from a fuse which has been read locked.

6.3.2.1.4 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations following a write must be separated by 2 us after the clearing of HW_OCOTP_CTRL_BUSY following the write. This guarantees programming voltages on-chip to reach a steady state when exiting a write sequence. This includes reads, shadow reloads, or other writes.

A recommended software sequence to meet the postamble requirements is as follows:

- Issue the write and poll for BUSY (as per Fuse Shadow Memory Footprint).
- After BUSY is clear, wait an additional 2 us.
- Perform the next OTP operation.

6.3.2.2 Fuse Shadow Memory Footprint

The OTP memory footprint shows in the following figure. The registers are grouped by lock region. Their names correspond to the PIO register and fusemap names.

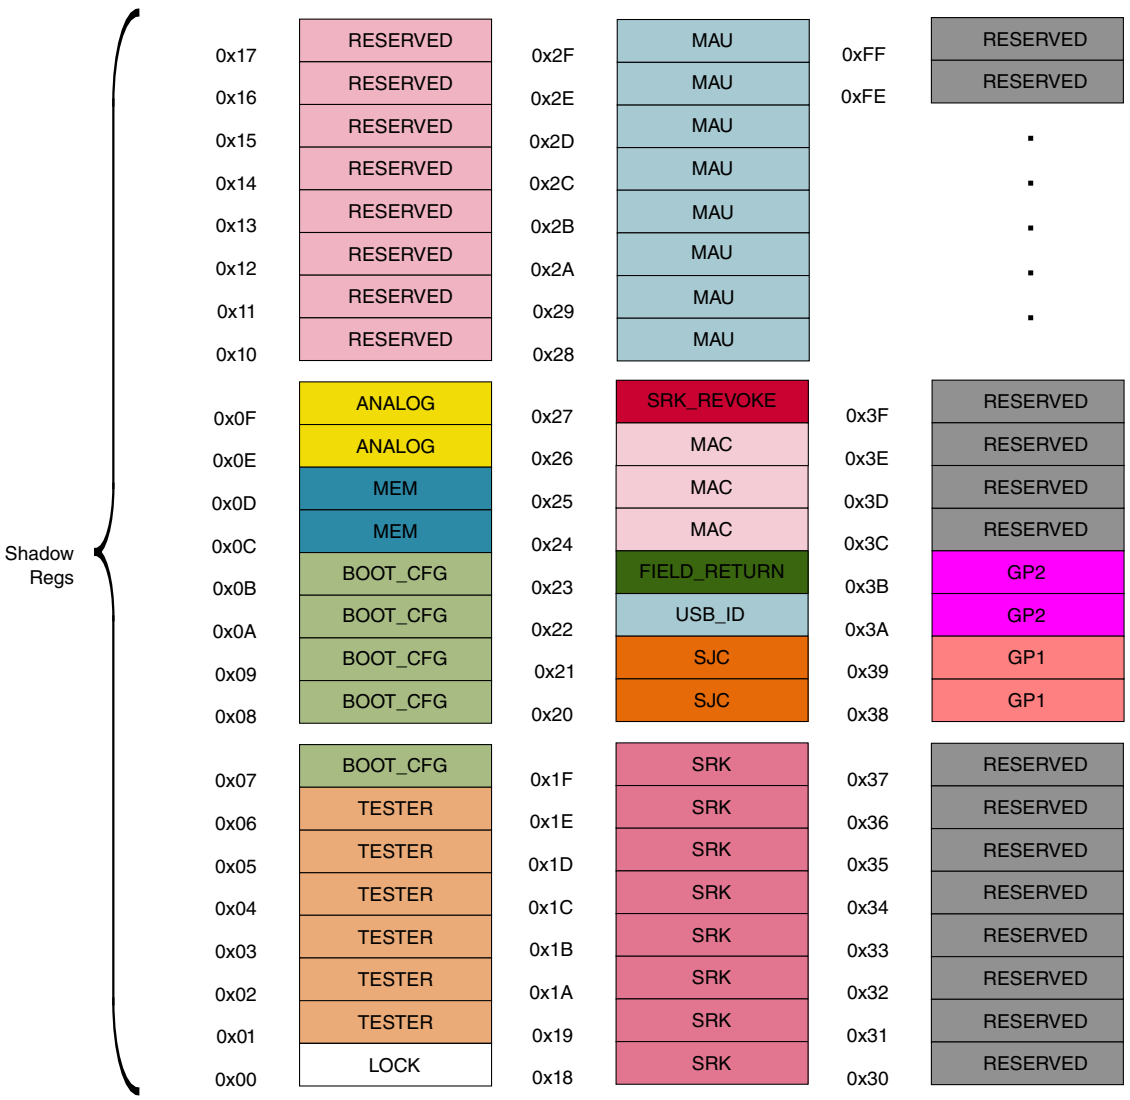

Figure 6-28. OTP Memory Footprint

6.3.2.3 OTP Read/Write Timing Parameters

There are timing fields contained in the HW_OCOTP_TIMING register that specify counter limit values, which are used to specify the signal timing.

Both two timing parameters are specified in ipg_clk cycles. Since the ipg_clk frequency can be set to a range of values, these parameters must be adjusted with the clock to yield the appropriate delay.

6.3.2.4 Hardware Visible Fuses

The hwv_fuse bus emanates from the OCOTP block and goes to various other blocks inside the chip. This bus is made up of the shadow register bits for .

Only a subset of these fuse bits are currently used by the hardware. The fuse bits are initially copied from the banks after reset is deasserted. When all fuse bits are loaded into their shadow registers, the OCOTP asserts the fuse_latched output signal.

The hwv_reg bus also comes from the OCOTP. Its source is the HW_OCOTP_SCS register. This register has 1 defined bit, the HAB_JDE bit, that is connected to the SJC block. The SCS bits are intended to be used as volatile fuse bits under software control. Additional bits will be defined as needed in future implementations.

The system-wide reset sequence must be coordinated by the system reset controller, so that the hwv_fuse and hwv_reg buses are stable and reflect the values of the fuses before they are used by the rest of the system.

6.3.2.5 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time HW_OCOTP_CTRL_BUSY is set. The load time is similar to that of a "reload shadow" operation.

6.3.2.6 Secure JTAG control

The JTAG control fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are envisioned, as shown in the table below.

Table 6-50. JTAG Security Level Control Bits

Security Mode	JTAG_SMODE	Description
No Debug	2'b11	The highest security level.
Secure JTAG	2'b01	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	Low Security, all JTAG features are enabled.

6.3.3 Fuse Map

See the Fusemap chapter of this reference manual for more information.

6.3.4 OCOTP Memory Map/Register Definition

NOTE

When write/read unimplemented register address in ocotp_ctrl, ocotp_ctrl will not send error and read data will be 0.

OCOTP Hardware Register Format Summary

OCOTP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

6.3.4.1 OTP Controller Control Register (OCOTP_HW_OCOTP_CTRL*n*)

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjuction with the HW_OCOTP_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and HW_OCOTP_READ_CTRL register. Read value is saved in HW_OCOTP_READ_FUSE_DATA register.

Address: 3035_0000h base + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	WR_UNLOCK															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved					RELOAD_SHADOWS	ERROR	BUSY	ADDR							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

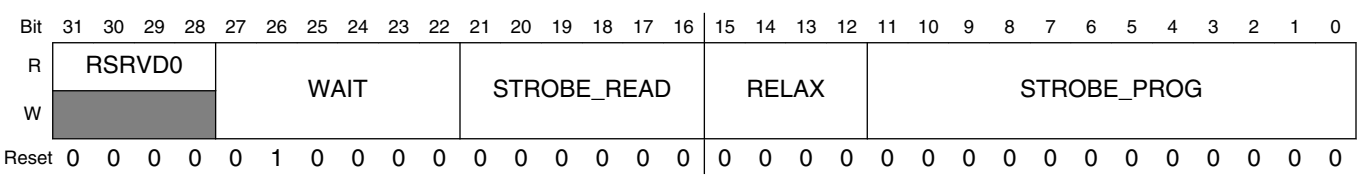
OCOTP_HW_OCOTP_CTRL*n* field descriptions

Field	Description
31–16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: This register must be unlocked on a write-by-write basis (a write is initiated when HW_OCOTP_DATA is written), so the UNLOCK bitfield must contain the correct key value during all writes to HW_OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY).
15–11 -	This field is reserved. Reserved
10 RELOAD_ SHADOWS	Set to force re-loading the shadow registers (HW/SW capability and LOCK). This operation will automatically set BUSY. Once the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 ERROR	Set by the controller when an access to a locked region(OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface is active and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a one to the SCT clear address space and not by a general write.
8 BUSY	OTP controller status bit. When active, no new write access or read access to OTP(including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
ADDR	OTP write and read access address register. Specifies one of 128 word address locations (0x00 - 0x7f). If a valid access is accepted by the controller, the controller makes an internal copy of this value. This internal copy will not update until the access is complete.

6.3.4.2 OTP Controller Timing Register (OCOTP_HW_OCOTP_TIMING)

This register specifies timing parameters for programming and reading the OCOTP fuse array.

Address: 3035_0000h base + 10h offset = 3035_0010h



OCOTP_HW_OCOTP_TIMING field descriptions

Field	Description
31–28 RSRVD0	These bits always read back zero.
27–22 WAIT	This count value specifies time interval between auto read and write access in one time program. It is given in number of ipg_clk periods.

Table continues on the next page...

OCOTP_HW_OCOTP_TIMING field descriptions (continued)

Field	Description
21–16 STROBE_READ	This count value specifies the strobe period in one time read OTP. Trd = ((STROBE_READ+1)- 2*(RELAX +1)) /ipg_clk_freq. It is given in number of ipg_clk periods.
15–12 RELAX	This count value specifies the time to add to all default timing parameters other than the Tpgm and Trd. It is given in number of ipg_clk periods.
STROBE_PROG	This count value specifies the strobe period in one time write OTP. Tpgm = ((STROBE_PROG+1)- 2*(RELAX+1)) /ipg_clk_freq. It is given in number of ipg_clk periods.

6.3.4.3 OTP Controller Write Data Register (OCOTP_HW_OCOTP_DATA)

This register is used in conjuction with HW_OCOTP_CTRL to perform one-time writes to the OTP.

Address: 3035_0000h base + 20h offset = 3035_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

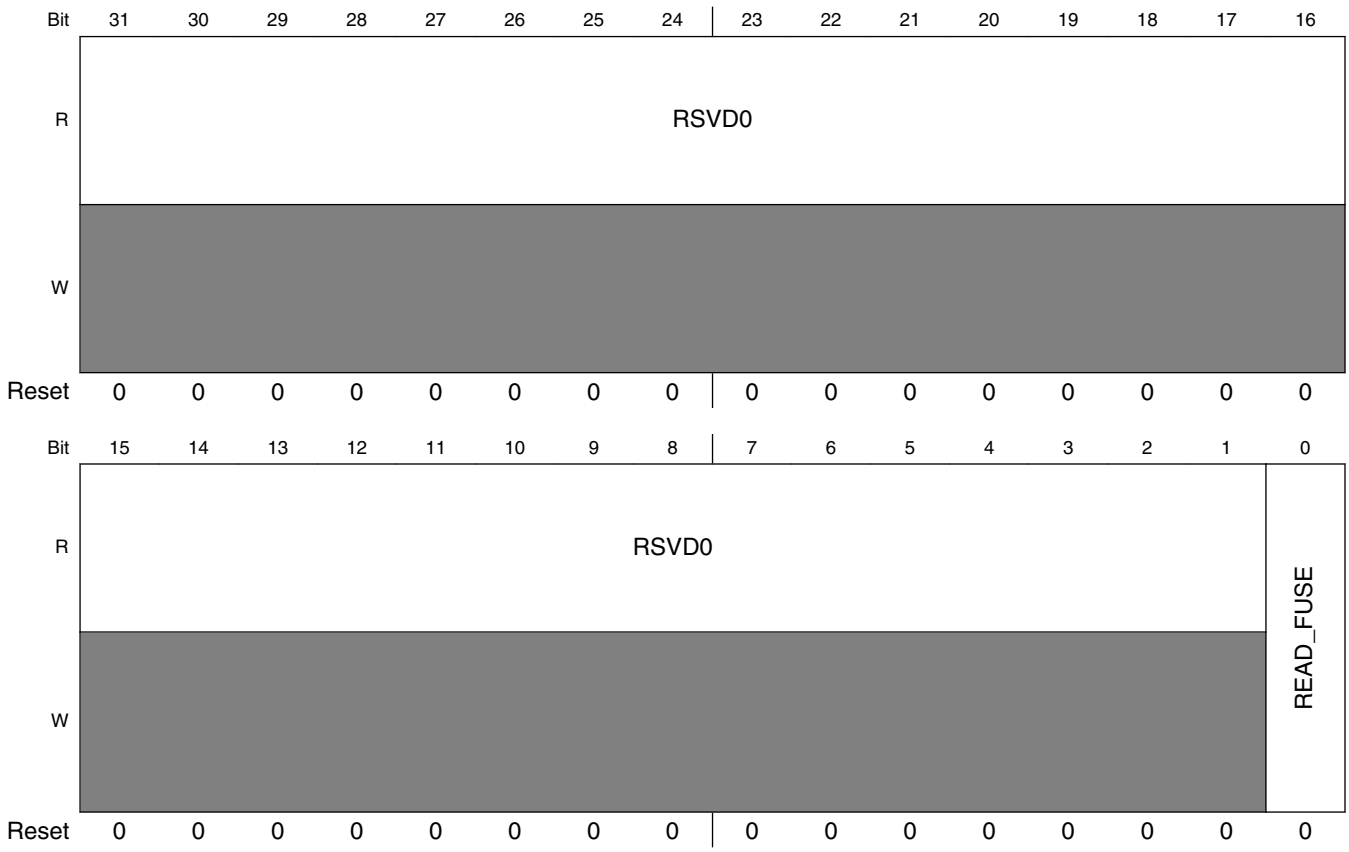
OCOTP_HW_OCOTP_DATA field descriptions

Field	Description
DATA	Used to initiate a write to OTP.

6.3.4.4 OTP Controller Write Data Register (OCOTP_HW_OCOTP_READ_CTRL)

This register is used in conjuction with HW_OCOTP_CTRL to perform one time read to the OTP.

Address: 3035_0000h base + 30h offset = 3035_0030h



OCOTP_HW_OCOTP_READ_CTRL field descriptions

Field	Description
31–1 RSVD0	Reserved
0 READ_FUSE	Used to initiate a read to OTP.

6.3.4.5 OTP Controller Read Data Register (OCOTP_HW_OCOTP_READ_FUSE_DATA)

The data read from OTP

Address: 3035_0000h base + 40h offset = 3035_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

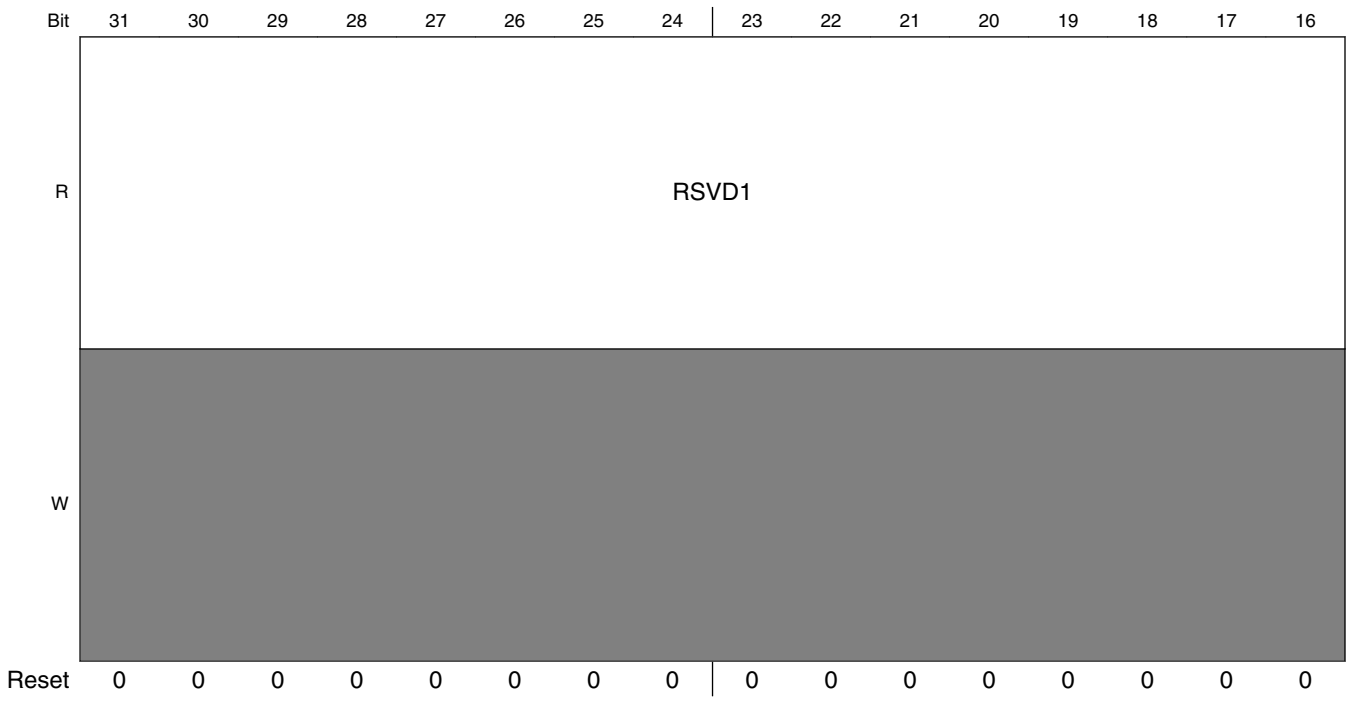
OCOTP_HW_OCOTP_READ_FUSE_DATA field descriptions

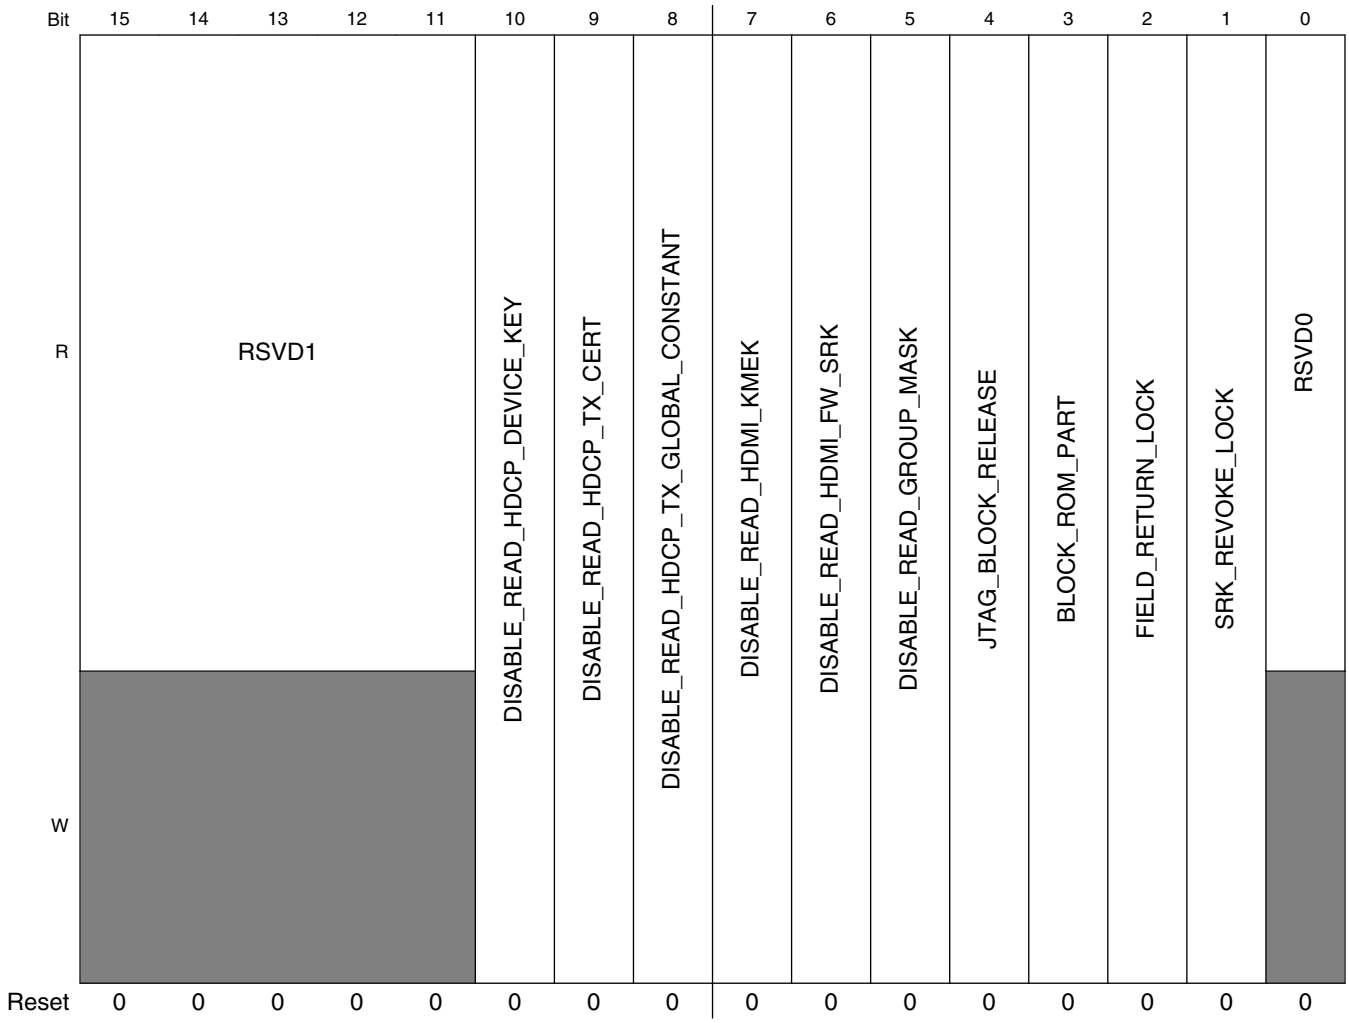
Field	Description
DATA	The data read from OTP

6.3.4.6 Sticky bit Register (OCOTP_HW_OCOTP_SW_STICKY)

Some sticky bits are used by SW to lock some fuse area , shadow registers and other features.

Address: 3035_0000h base + 50h offset = 3035_0050h





OCOTP_HW_OCOTP_SW_STICKY field descriptions

Field	Description
31–11 RSVD1	Reserved
10 DISABLE_ READ_HDCP_ DEVICE_KEY	Shadow register write and OTP write lock for HDCP_DEVICE_HDCP region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
9 DISABLE_ READ_HDCP_ TX_CERT	Shadow register write and OTP write lock for HDCP_TX_CERT region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
8 DISABLE_ READ_HDCP_ TX_GLOBAL_ CONSTANT	Shadow register write and OTP write lock for HDCP_TX_GLOBAL_CONSTANT region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.

Table continues on the next page...

OCOTP_HW_OCOTP_SW_STICKY field descriptions (continued)

Field	Description
7 DISABLE_ READ_HDMI_ KMEK	Shadow register write and OTP write lock for HDMI_KMEK region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
6 DISABLE_ READ_HDMI_ FW_SRK	Shadow register write and OTP write lock for HDMI_FW_SRK region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
5 DISABLE_ READ_GROUP_ MASK	Shadow register write and OTP write lock for GROUP_MASK region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
4 JTAG_BLOCK_ RELEASE	Set by Arm during Boot after DTCP is initialized and before test mode entry. * 0 (Default) - JTAG is blocked (subject to other conditions).* 1 - JTAG block is released (subject to other controls). Once this bit is set, it is always high unless a POR is issued.
3 BLOCK_ROM_ PART	Set by Arm during Boot after DTCP is initialized and before test mode entry, if ROM_PART_LOCK=1.* 0 (Default) - Secret part of Boot ROM is not hidden (subject to other conditions).* 1 - Secret part of Boot ROM is hidden.Once this bit is set, it is always high unless a POR is issued.
2 FIELD_ RETURN_LOCK	Shadow register write and OTP write lock for FIELD_RETURN region. When set, the writing of this region's shadow register and OTP fuse word are blocked.Once this bit is set, it is always high unless a POR is issued.
1 SRK_REVOKE_ LOCK	Shadow register write and OTP write lock for SRK_REVOKE region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
0 RSVD0	Reserved

6.3.4.7 Software Controllable Signals Register (OCOTP_HW_OCOTP_SCS*n*)

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their defualt values after POR.

Address: 3035_0000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK	SPARE														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SPARE															HAB_JDE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OCOTP_HW_OCOTP_SCS*n* field descriptions

Field	Description
31 LOCK	When set, all of the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a POR is issued.
30–1 SPARE	Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properlay signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by POR. 0: JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms). 1: JTAG debugging is enabled by the HAB (though this signal may be gated off).

6.3.4.8 OTP Controller Version Register (OCOTP_HW_OCOTP_VERSION)

This register indicates the RTL version in use.

Address: 3035_0000h base + 90h offset = 3035_0090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MAJOR								MINOR								STEP															
W																																
Reset	0	0	0	0	0	0	0	1	0	1	0	0	1	0	0	0	0	0	0	1	0	0	1	0	1	0	0	1	1	0	0	1

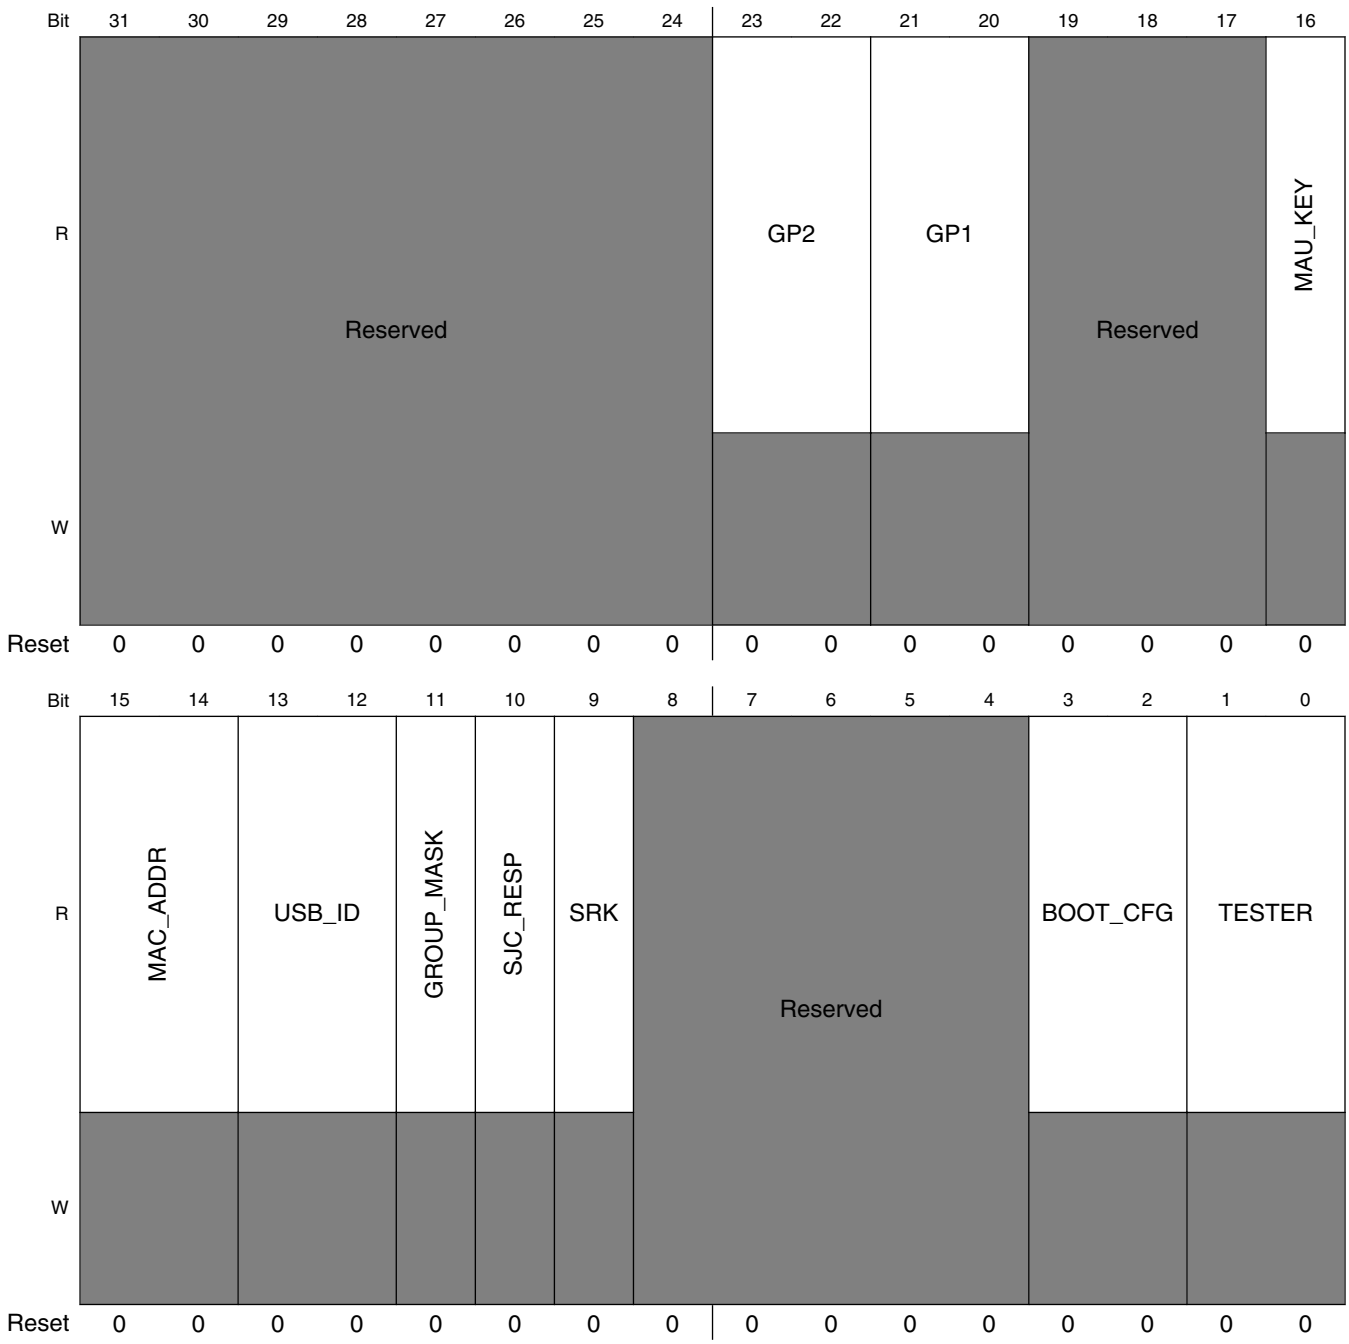
OCOTP_HW_OCOTP_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

6.3.4.9 Value of OTP Bank0 Word0 (Lock controls) (OCOTP_HW_OCOTP_LOCK)

Shadowed memory mapped access to OTP Bank 0, word 0.

Address: 3035_0000h base + 400h offset = 3035_0400h



OCOTP_HW_OCOTP_LOCK field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–22 GP2	Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
21–20 GP1	Status of shadow register and OTP write lock for gp1 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
19–17 -	This field is reserved. Reserved
16 MAU_KEY	Status of shadow register read and write, OTP read and write lock for manufacture_key region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
15–14 MAC_ADDR	Status of shadow register and OTP write lock for mac_addr region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
13–12 USB_ID	Status of shadow register and OTP write lock for usb_id region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
11 GROUP_MASK	Status of shadow register and OTP write lock for group mask region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
10 SJC_RESP	Status of shadow register read and write, OTP read and write lock for sjc_resp region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
9 SRK	Status of shadow register and OTP write lock for srk region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
8–4 -	This field is reserved. Reserved
3–2 BOOT_CFG	Status of shadow register and OTP write lock for boot_cfg region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
TESTER	Status of shadow register and OTP write lock for tester region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

6.3.4.10 Value of OTP Bank0 Word1 (Tester Info.) (OCOTP_HW_OCOTP_TESTER0)

Shadowed memory mapped access to OTP Bank 0, word 1.

Address: 3035_0000h base + 410h offset = 3035_0410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

6.4 Secure Non-Volatile Storage (SNVS)

6.4.1 SNVS introduction

SNVS is a companion module to the CAAM module.

SNVS incorporates both security and non-security functionality. The SNVS non-security functionality is described in this document, but the SNVS security functionality is described only in the Security Reference Manual.

SNVS non-security functions:

- Realtime Counter (RTC) - a software accessible realtime counter
  - RTC can be set to the value in the SRTC
- General Purpose Register - a set of registers used to hold 128 bits of data specified by software

  - If the SNVS_LP power input is connected to an uninterrupted power supply, the GPR value is maintained when main SoC is powered off
- Chip power-on/power-off - If the SNVS_LP power input is connected to an uninterrupted power supply and the Power On button input signal is connected to a power button external to the chip, logic within SNVS_LP can be used to wake the chip from a power down.

6.4.1.1 SNVS feature list

The following table summarizes the features of SNVS:

Table 6-51. SNVS feature list

Feature	Description	Links for Further Information
Real time counter (RTC)	• The RTC is driven by a dedicated clock, which is off when the system power is down. • Programmable time alarm interrupt	SNVS_HP Real Time Counter
General-purpose register	• The general-purpose register is available to software to store 128 bits of data. • The general-purpose register is zeroized when a security violation is detected. • If the SNVS_LP power input is connected to an uninterrupted power supply (see SNVS power domains), the general-purpose register value is retained even if the main chip is powered down.	Using the General-Purpose Register
Register access restrictions	• Some registers/values can be written only once per boot cycle.	privileged and non-privileged registers
Wakeup from power off	• Input signal from off chip requests SNVS_LP to power on the main SoC (Assuming that the SNVS_LP power input is connected to an uninterrupted power supply (see SNVS power domains). • Hardware debounces the input signal using software-specified signal bounce characteristics	LP Wake-Up Interrupt Enable

6.4.1.2 SNVS functional description

SNVS implements several non-security features that involve software interaction:

- reading or writing the Realtime Counter (RTC) (This is a non-privileged operation.) - software can also instruct SNVS to load the current SRTC value into the RTC
- reading or writing the General Purpose Register (GPR) (Note that there may be a significant delay when reading or writing registers in the LP section if the LP clock is different from the HP clock.)

The following sections describe in more detail the operation of SNVS.

6.4.2 SNVS Structure

SNVS is organized as two major sub-modules:

- Low-Power Section of SNVS (SNVS_LP)

  The SNVS_LP section provides hardware that enables secure storage and protection of sensitive data. The SNVS module is designed to safely hold security-related data such as cryptographic key, time counter, monotonic counter, and general purpose security information.

  The SNVS_LP block implements the following functional units:
  - Control and Status Registers
  - General Purpose Registers

  When the LP section is connected to an uninterrupted power supply the state of these registers is maintained even when the main chip power is off. (see SNVS power domains)

- High-Power Section of SNVS (SNVS_HP)

  The SNVS_HP section contains all SNVS status and configuration registers. It implements all features that enable system communication and provisioning of the SNVS_LP section.

  The SNVS_HP provides an interface between SNVS_LP and the rest of the system.

  The SNVS_HP block implements the following functional units:
  - IP Bus Interface
  - SNVS_LP Interface
  - Zeroizable Master Key Programming Mechanism
  - Real Time Counter with Alarm Control and Status Registers
  - Control and status registers

  SNVS_HP is in the chip's power supply domain and thus receives power along with the rest of the chip.

The following figure illustrates the structure of SNVS.

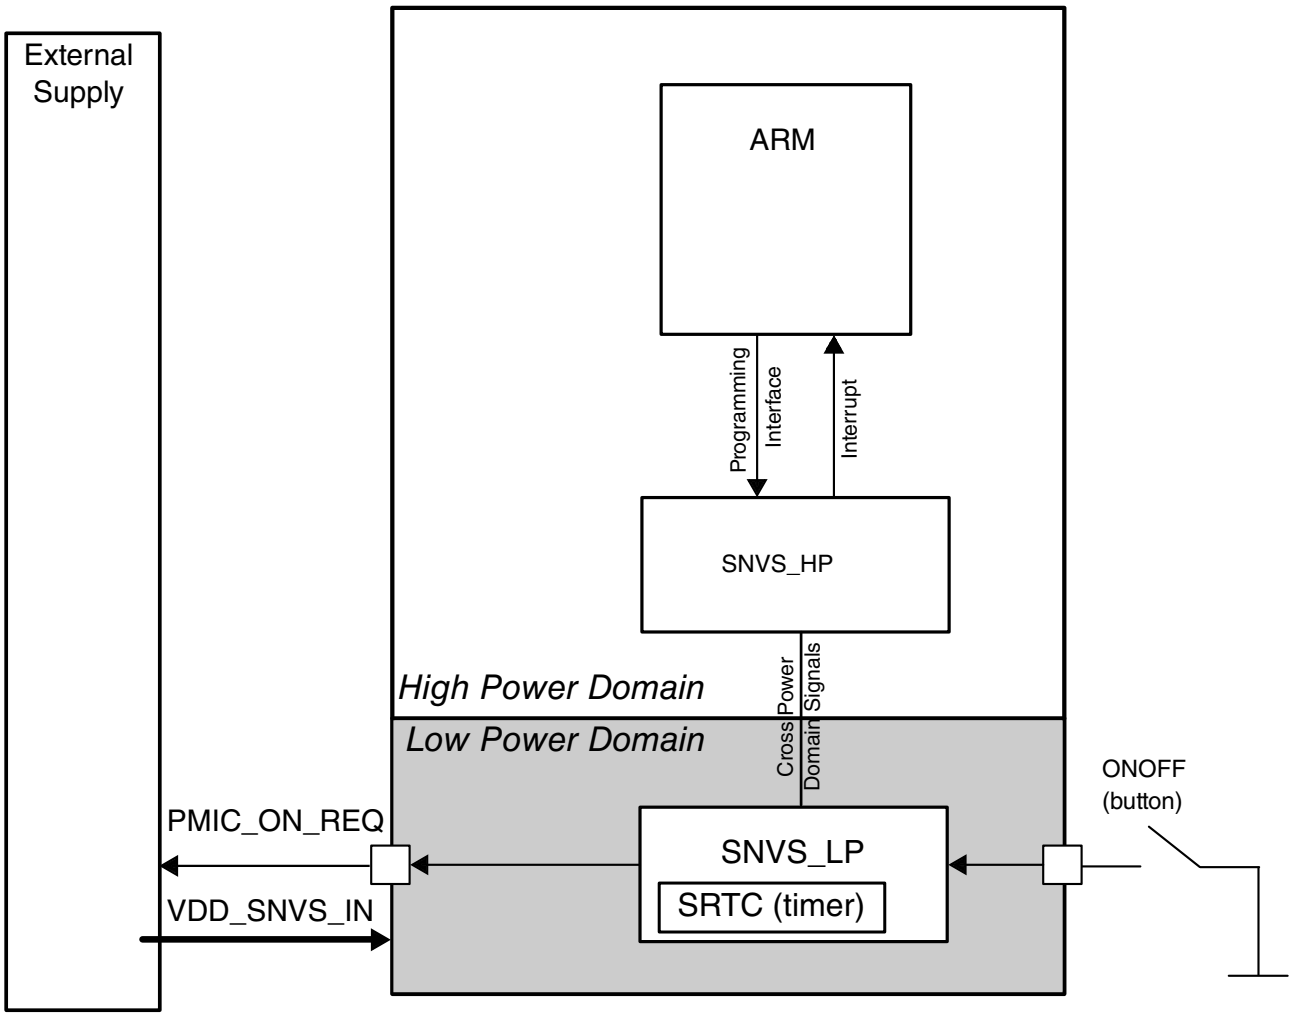

Figure 6-29. SNVS Block Diagram

6.4.2.1 SNVS power domains

In some versions of SNVS (including this version), the LP (Low Power) section is implemented in an independent power domain from the HP (High Power) section, and most other logic on the chip. Throughout the SNVS documentation whenever mention is made of "always-on" logic, this assumes a version of SNVS that implements an independent power domain for the LP section, and that the power for this section is supplied by an uninterrupted power supply. The purpose for the independent power domain is so that data can be retained and certain logic can remain functional even when the main chip logic is powered down. But this is possible only if the LP domain remains powered via an uninterrupted power supply when the main chip power domain is powered off. Usually this uninterrupted power supply would be a battery, with possibly some power management logic to power the LP section from main power (and perhaps

recharge the battery) when main power is on, and switch to battery power when the main power is off. In versions of SNVS with an independent LP power domain the LP section can be electrically isolated from the rest of the chip logic to ensure that its logic does not get corrupted when the main chip is powered down. If the battery runs down or is removed, an LP POR will occur when the LP section next powers up. Note that some OEMs may choose to connect LP power to HP/main chip power and dispense with a battery. In that case the SNVS will operate the same as an SNVS without an independent LP power domain. No state will be retained in the LP section when the chip is powered down, and an LP POR will occur whenever there is an HP POR.

6.4.2.2 Power glitch detector (PGD)

SNVS_LP incorporates a mechanism to detect glitches on the SNVS_LP power supply that might cause the LP control, status, and secure counter values to change. The mechanism works as follows:

1. The PGD register (LPPGDR) is loaded with the known specific value 4173_6166h as part of the SNVS initialization process.
2. Subsequently, this register's value is continuously compared to the hardwired value 4173_6166h.
3. If the comparison indicates that any bit has changed, a power glitch violation is asserted.

Power glitch detection is always enabled and cannot be disabled. At LP POR this register is reset to all 0's, so the hardwired comparison fails and a power glitch violation is reported. Therefore, before programming any feature in the SNVS the power glitch violation should be cleared. The initialization software should write the proper value (4173_6166h) into LPPGDR (see SNVS_LP Power Glitch Detector Register (LPPGDR)) and should then clear the power glitch record in the LP status register (see SNVS_LP Status Register (LPSR)).

The following figure shows the PGD mechanism.

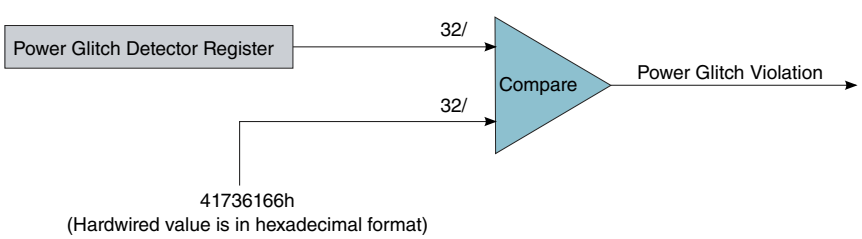

Figure 6-30. Power glitch detector

6.4.2.3 SNVS clock sources

The SNVS has the following clock sources:

- System peripheral clock input. This clock is used by the SNVS's internal logic, for example, the Security State Machine. This clock can be gated outside of the module when the SNVS indicates that it is not in use.
- HP RTC clock. This clock is used by SNVS_HP real-time counter. This clock does not need to be synchronous with other clocks.

6.4.3 Runtime Procedures

SNVS implements a number of features that are intended to be accessed by software at runtime (as opposed to accessed at boot time). These features include:

- Real Time Clock (see SNVS_HP Real Time Counter)
- General Purpose Register (see Using the General-Purpose Register)

Procedures for using these features are described in the following sections.

6.4.3.1 Using SNVS Timer Facilities

SNVS incorporates timer facilities that can optionally generate an interrupt at a specified time. As described in the following sections, SNVS_HP incorporates a Real Time Counter that is available for general use, and SNVS_LP incorporates a Secure Real Time Counter intended for security applications.

6.4.3.1.1 SNVS_HP Real Time Counter

SNVS_HP implements a real time counter that can be read or written by any application; it has no privileged software access restrictions. When the chip is powered down the RTC is not active and it is reset at chip POR. The RTC can be used to generate a functional interrupt request either at a specific time, or at a specific frequency, or both. To generate an interrupt request at a specific time HPTA_EN is set to 0, the desired time is written to HPTA_MS and HPTA_LS and then HPTA_EN is set to 1. HPTA_EN, HPTA_MS and HPTA_LS can be written by any software that has access to SNVS registers; there are no privileged access restrictions. The counter can be synchronized to the SNVS_LP SRTC by writing to the HP_TS bit of SNVS_HP Control Register. This is particularly useful if the SNVS_LP is powered from an uninterrupted power source because the RTC can then be set from a chip-internal time source.

6.4.3.1.2 RTC/SRTC control bits setting

All SNVS registers are programmed from the register bus, consequently any software-initiated changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC/SRTC clock after they are programmed. To avoid IP clock and RTC/SRTC clock synchronization issues, the following values can be changed only when the corresponding function is disabled.

Table 6-52. RTC/SRTC synchronized values list

Function	Value/register	Control bit setting
HP section		
HP Real Time Counter	HPRTCMR and HPRTCLR Registers	RTC_EN = 0 : HPRTCMR/HPRTCLR **can** be programmed RTC_EN = 1 : HPRTCMR/HPRTCLR **cannot** be programmed
HP Time Alarm	HPTAMR and HPTALR Registers	HPTA_EN = 0 : HPTAMR/HPTALR **can** be programmed HPTA_EN = 1 : HPTAMR/HPTALR **cannot** be programmed
LP section		
LP Secure Real Time Counter	LPRTCMR and LPRTCLR Registers	SRTC_ENV = 0 : LPRTCMR/LPRTCLR **can** be programmed SRTC_ENV = 1 : LPRTCMR/LPRTCLR **cannot** be programmed
LP Time Alarm	LPTAR Register	LPTA_EN = 0 : LPTAR **can** be programmed LPTA_EN = 1 : LPTAR **cannot** be programmed

Use the following steps to program synchronized values:

1. Check the enable bit value. If set, clear it.

2. Verify that the enable bit is cleared. There are two reasons to verify the enable bit's setting:

- Enable bit clearing does not happen immediately; it takes three IP clock cycles and two RTC/SRTC clock cycles to change the enable bit's value.
- If the enable bit is locked for programming, it cannot be cleared.

3. Program the desired value.

4. Set the enable bit; it takes three IP clock cycles and two RTC/SRTC clock cycles for the bit to set.

NOTE

Incrementing the value programmed into RTC/SRTC registers by two compensates for the two RTC/SRTC clock cycle delay that is required to enable the counter.

6.4.3.1.3 Reading RTC and SRTC values

Software should follow the following procedure to ensure that it has read correct data from the RTC (HPRTCMR and HPRTCLR) and SRTC (LPSRTCMR and LPSRTCLR) registers:

- Read the most-significant half and the least-significant half of the RTC/SRTC and then read both halves again. If the values read are the same both times, the value is correct.
- If the two consecutive pairs of reads yield different results, perform two more reads.

The worst case scenario may require three sessions of two consecutive pairs of reads. There are several reasons that the values may be incorrectly read initially:

- Synchronization issues between the RTC/SRTC clock and the system clock
- Since the counter continues to increment, there may be a carry from the least-significant 32-bits to the most-significant bits in between reading the two halves of the counter

6.4.3.2 Using Other SNVS Registers

The sections below describe how to use the General Purpose Register.Monotonic Counter.The sections below describe how to use the General Purpose Register and the Monotonic Counter.

6.4.3.2.1 Using the General-Purpose Register

SNVS implements a 128-bit general-purpose register allows software to store a small amount of data. To maintain backward compatibility with versions of SNVS that implement only a 32-bit general purpose register, the most-significant word of the general purpose register is aliased to the original legacy address, and to maintain backward compatibility with versions of snvs_module_name that implement a 128-bit general purpose register, the most-significant half of the general purpose register is aliased to the previous legacy address address. The data in the GPR will be retained during system power-down mode as long as the SNVS_LP remains powered by an uninterrupted power source.

6.4.4 Reset and Initialization of SNVS

SNVS is implemented in two sections (HP and LP) that both must be initialized by software. If the SNVS_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off. During main SoC power-down SNVS_HP is powered-down, but SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS_LP keeps its registers' values but the LP registers cannot be read or written. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational. The SNVS_HP section is powered from the main SoC power, so it must be initialized after the device is powered on.

6.4.5 SNVS register descriptions

This section contains detailed register descriptions for the SNVS registers. Each description includes a standard register diagram and register table. The register table provides detailed descriptions of the register bit and field functions, in bit order.

SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

Privileged read/write accessible registers can only be accessed for read/write by privileged software. Unauthorized write accesses are ignored, and unauthorized read accesses return zero. Non-privileged software can access privileged access registers when the non-privileged software access enable bit is set in the SNVS_HP Command Register.

- Non-Secure
- Trusted
- Secure

Non-privileged read/write accessible registers are read/write accessible by any software.

The LP register values are set only on LP POR and are unaffected by System (HP) POR. The HP registers are set only on System POR and are unaffected by LP POR.

The following table shows the SNVS main memory map.

NOTE

For more information on security-related bitfields, see the Security Reference Manual.

6.4.5.1 SNVS Memory map

SNVS base address: 3037_0000h

Offset	Register	Width (In bits)	Access	Reset value
4h	SNVS_HP Command Register (HPCOMR)	32	RW	0000_0000h

6 BTN	Button Value of the BTN input. This is the external button used for PMIC control. 0: BTN not pressed 1: BTN pressed
5 —	Reserved
4 LPDIS	Low Power Disable If 1, the low power section has been disabled by means of an input signal to SNVS.
3-2 —	Reserved
1 —	Reserved
0 HPTA	HP Time Alarm Indicates that the HP Time Alarm has occurred since this bit was last cleared. 0b - No time alarm interrupt occurred. 1b - A time alarm interrupt occurred.

6.4.5.5 SNVS_HP Real Time Counter MSB Register (HPRTCMR)

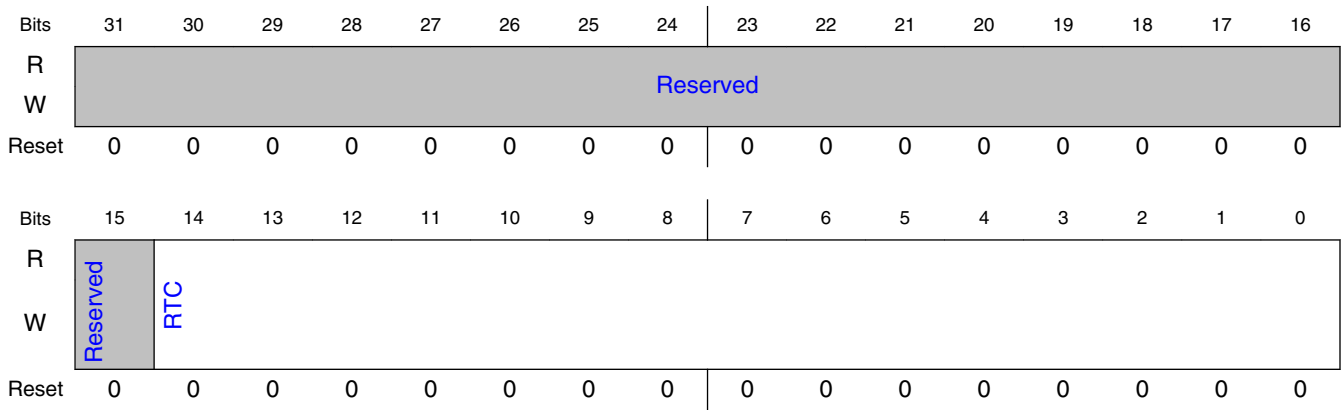
6.4.5.5.1 Offset

Register	Offset
HPRTCMR	24h

6.4.5.5.2 Function

The SNVS_HP Real Time Counter MSB register contains the 15 most-significant bits of the HP Real Time Counter. This is *not* a privileged write register.

6.4.5.5.3 Diagram



6.4.5.5.4 Fields

Field	Function
31-15 —	Reserved
14-0 RTC	HP Real Time Counter The most-significant 15 bits of the RTC. This register can be programmed only when RTC is not active (RTC_EN bit is not set).

6.4.5.6 SNVS_HP Real Time Counter LSB Register (HPRTCLR)

6.4.5.6.1 Offset

Register	Offset
HPRTCLR	28h

6.4.5.6.2 Function

The SNVS_HP Real Time Counter LSB register contains the 32 least-significant bits of the HP real time counter. This is *not* a privileged write register.

6.4.5.6.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RTC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RTC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

6.4.5.6.4 Fields

Field	Function
31-0 RTC	HP Real Time Counter least-significant 32 bits. This register can be programmed only when RTC is not active (RTC_EN bit is not set).

6.4.5.7 SNVS_HP Time Alarm MSB Register (HPTAMR)

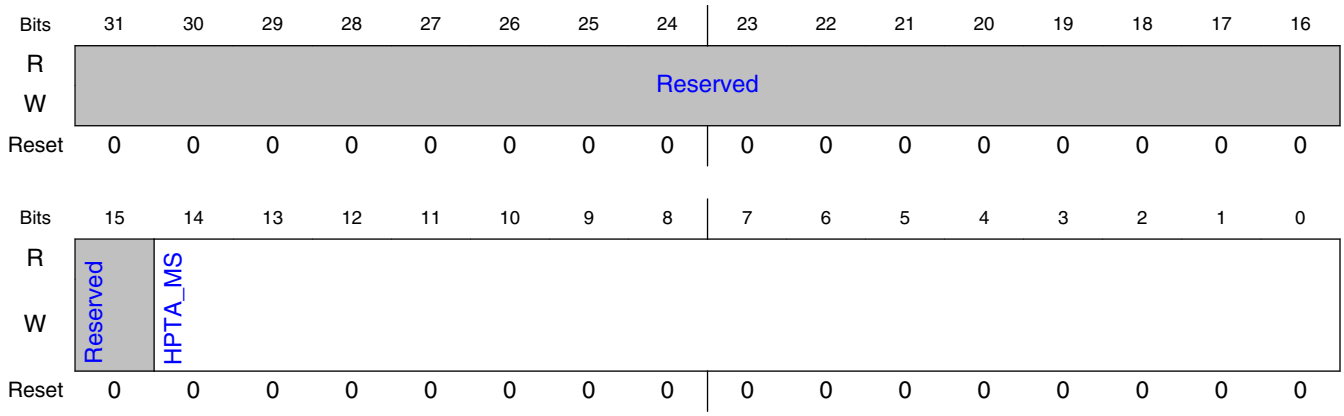
6.4.5.7.1 Offset

Register	Offset
HPTAMR	2Ch

6.4.5.7.2 Function

The SNVS_HP Time Alarm MSB register contains the most-significant bits of the SNVS_HP Time Alarm value. This is *not* a privileged write register.

6.4.5.7.3 Diagram



6.4.5.7.4 Fields

Field	Function
31-15 —	Reserved
14-0 HPTA_MS	HP Time Alarm, most-significant 15 bits. This register can be programmed only when HP time alarm is disabled (HPTA_EN bit is not set).

6.4.5.8 SNVS_HP Time Alarm LSB Register (HPTALR)

6.4.5.8.1 Offset

Register	Offset
HPTALR	30h

6.4.5.8.2 Function

The SNVS_HP Time Alarm LSB register contains the 32 least-significant bits of the SNVS_HP Time Alarm value. This is *not* a privileged write register.

6.4.5.8.3 Diagram

Register	Offset
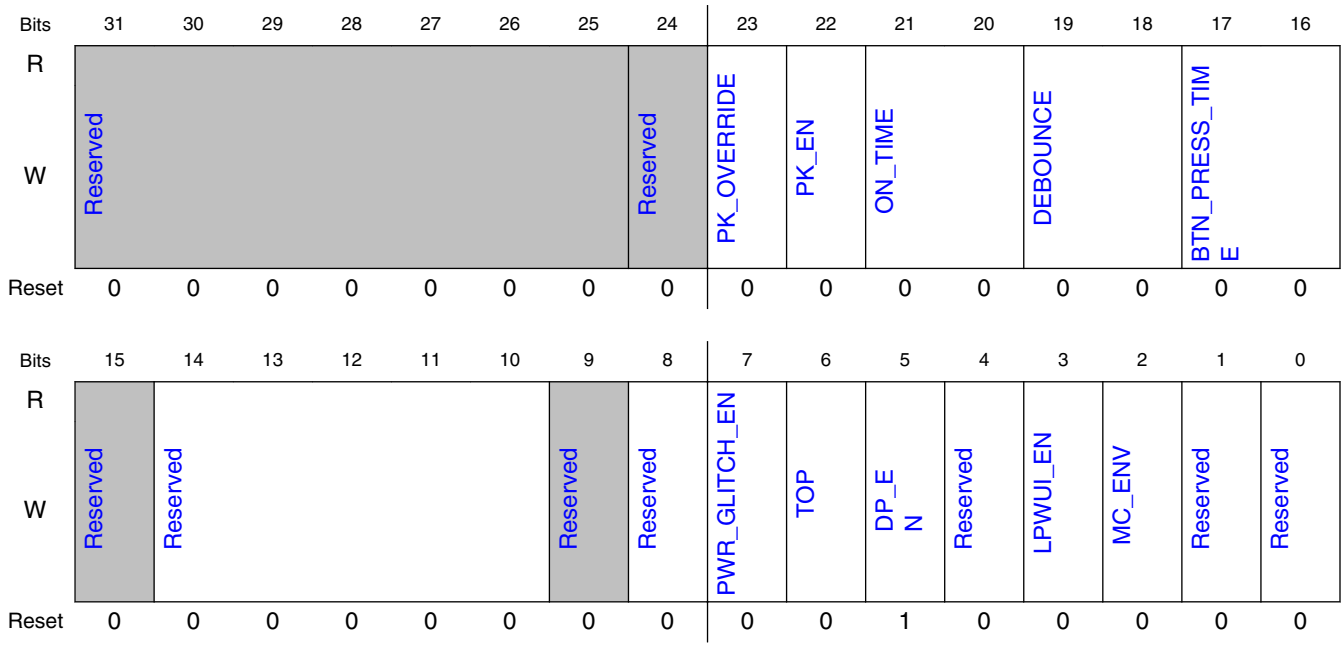
LPCR	38h

6.4.5.10.2 Function

The SNVS_LP Control Register contains various control bits of the LP section of SNVS. This is a privileged write register.

6.4.5.10.3 Diagram



6.4.5.10.4 Fields

Field	Function
31-25 —	Reserved
24 —	Reserved
23 PK_OVERRIDE	PMIC On Request Override The value written to PK_OVERRIDE will be asserted on output signal snvs_lp_pk_override. That signal is used to override the IOMUX control for the PMIC I/O pad.
22 PK_EN	PMIC On Request Enable The value written to PK_EN will be asserted on output signal snvs_lp_pk_en. That signal is used to turn off the pullup/pulldown circuitry in the PMIC I/O pad.
21-20 ON_TIME	The ON_TIME field is used to configure the period of time after BTN is asserted before pmic_en_b is asserted to turn on the SoC power. 00: 500msec off->on transition time 01: 50msec off->on transition time 10: 100msec off->on transition time 11: 0msec off->on transition time
19-18 DEBOUNCE	This field configures the amount of debounce time for the BTN input signal. 00: 50msec debounce 01: 100msec debounce

Table continues on the next page...

Field	Function
	10: 500msec debounce 11: 0msec debounce
17-16 BTN_PRESS_TIME	This field configures the button press time out values for the PMIC Logic. 00 : 5 secs 01 : 10 secs 10 : 15 secs 11 : long press disabled (pmic_en_b will not be asserted regardlessof how long BTN is asserted)
15 —	Reserved
14-10 —	Reserved
9 —	Reserved
8 —	Reserved
7 PWR_GLITCH_EN	Power Glitch Enable By default the detection of a power glitch does not cause the pmic_en_b signal to be asserted. Setting the Power Glitch Enable bit to 1 enables the power glitch event for the PMIC. 0 - disabled 1 - enabled
6 TOP	Turn off System Power Asserting this bit causes a signal to be sent to the Power Management IC to turn off the system power. This bit will clear once power is off. This bit is only valid when the Dumb PMIC is enabled. 0b - Leave system power on. 1b - Turn off system power.
5 DP_EN	Dumb PMIC Enabled When set, software can control the system power. When cleared, the system requires a Smart PMIC to automatically turn power off. 0b - Smart PMIC enabled. 1b - Dumb PMIC enabled.
4 —	Reserved
3 LPWUI_EN	LP Wake-Up Interrupt Enable This interrupt line should be connected to the external pin and is intended to inform the external chip about an SNVS_LP event (MC rollover, SRTC rollover, or time alarm). This wake-up signal can be asserted only when the chip (HP section) is powered down, and the LP section is isolated. 0 LP wake-up interrupt is disabled. 1 LP wake-up interrupt is enabled.
2 MC_ENV	Monotonic Counter Enabled and Valid When set, the MC can be incremented (by write transaction to the LPSMCMR or LPSMCLR). Once MC_SL or MC_HL bit is set this bit can be changed only by LP software reset or LP POR. 0b - MC is disabled or invalid.

Table continues on the next page...

6.4.5.12 SNVS_LP Secure Monotonic Counter MSB Register (LPSMCMR)

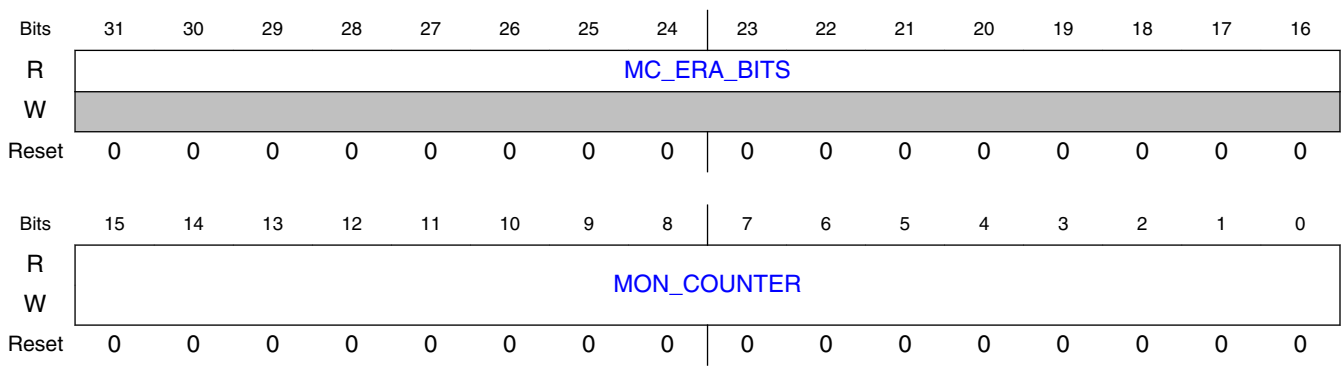
6.4.5.12.1 Offset

Register	Offset
LPSMCMR	5Ch

6.4.5.12.2 Function

The SNVS_LP Secure Monotonic Counter MSB Register contains the monotonic counter era bits and the most-significant 16 bits of the monotonic counter. The monotonic counter is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

6.4.5.12.3 Diagram



6.4.5.12.4 Fields

Field	Function
31-16 MC_ERA_BITS	Monotonic Counter Era Bits These bits are inputs to the module and typically connect to fuses. When the Monotonic Counter is in use (i.e. enabled and valid and powered by an uninterrupted power source), and the boot software detects that the Monotonic Counter most-significant 16 Bits and Monotonic Counter LSB Register have been reset (MC_ENV=0), the boot software can take action to ensure that the value in the monotonic counter remains monotonic (i.e. never decreasing). The action is to blow an additional MC_ERA_BITS fuse. Since the MC_ERA_BITS field forms the most-significant field of the monotonic counter, blowing an additional fuse guarantees that the new monotonic counter value is higher than any previous value. Since the Monotonic Counter is reset on an LP Software Reset, an excessive number of MC_ERA_BITS fusez may be consumed if LP Software Reset is used repeatedly.
15-0	Monotonic Counter most-significant 16 Bits

Field	Function
MON_COUNTER	**Note that writing to this register does *not* change the value of this field to the value that was written.** **The 48-bit monotonic counter value (consisting of LPSMCMR[MON_COUNTER] prepended to LPSMCLR[MON_COUNTER]) is incremented by one when:** • A write transaction to the LPSMCMR or LPSMCLR register is detected. • The MC_ENV bit is set. • MC_SL and MC_HL bits are not set. This value can be reset only by LP software reset or LP POR.

6.4.5.13 SNVS_LP Secure Monotonic Counter LSB Register (LPSMCLR)

6.4.5.13.1 Offset

Register	Offset
LPSMCLR	60h

6.4.5.13.2 Function

The SNVS_LP Secure Monotonic Counter LSB Register contains the 32 least-significant bits of the monotonic counter. The MC is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

6.4.5.13.3 Diagram

6.4.5.17 SNVS_LP General Purpose Registers 0 .. 3 (LPGPR0 - LPGPR3)

6.4.5.17.1 Offset

Register	Offset
LPGPR0	100h
LPGPR1	104h
LPGPR2	108h
LPGPR3	10Ch

6.4.5.17.2 Function

The SNVS_LP General Purpose Register is a 128-bit read/write register located in SNVS_LP, which can be used by any application for retaining data during an SoC power-down mode. This is a privileged read/write register. The full GPR register is accessed as 4 32-bit registers located in successive word addresses starting at offset 100h. For backward compatibility with earlier versions of SNVS, LPGPR0..LPGPR3 are aliased at the earlier offset of 90h and LPGPR0 is also aliased at its original offset of 68h. New software should access the GPR register at the preferred offset of 100h. The GPR will be automatically zeroized when an enabled security event occurs, unless GPR zeroization is disabled via the GPR_Z_DIS bit in the LP Control Register.

6.4.5.17.3 Diagram

6.5 System Reset Controller (SRC)

6.5.1 SRC Overview

The System Reset Controller (SRC) controls the reset and boot operation of the SoC.

It is responsible for the generation of all reset signals and boot decoding.

The reset controller determines the source and the type of reset, such as POR, COLD, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire IC. Whenever the chip is powered on, the reset is issued through SRC_ONOFF signal and the entire chip is reset.

6.5.1.1 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Resets the appropriate domains based upon the resets sources and the nature of the reset
- Latches the SRC_BOOT_MODE pins and common configuration signals from the internal fuse

6.5.2 Top-level resets, power-up sequence and external supply integration

Information found here defines chip resets, power-up sequence, and external supply integration.

6.5.2.1 Reset and Power-up Flow

The chip presumes the following reset and power-up flow:

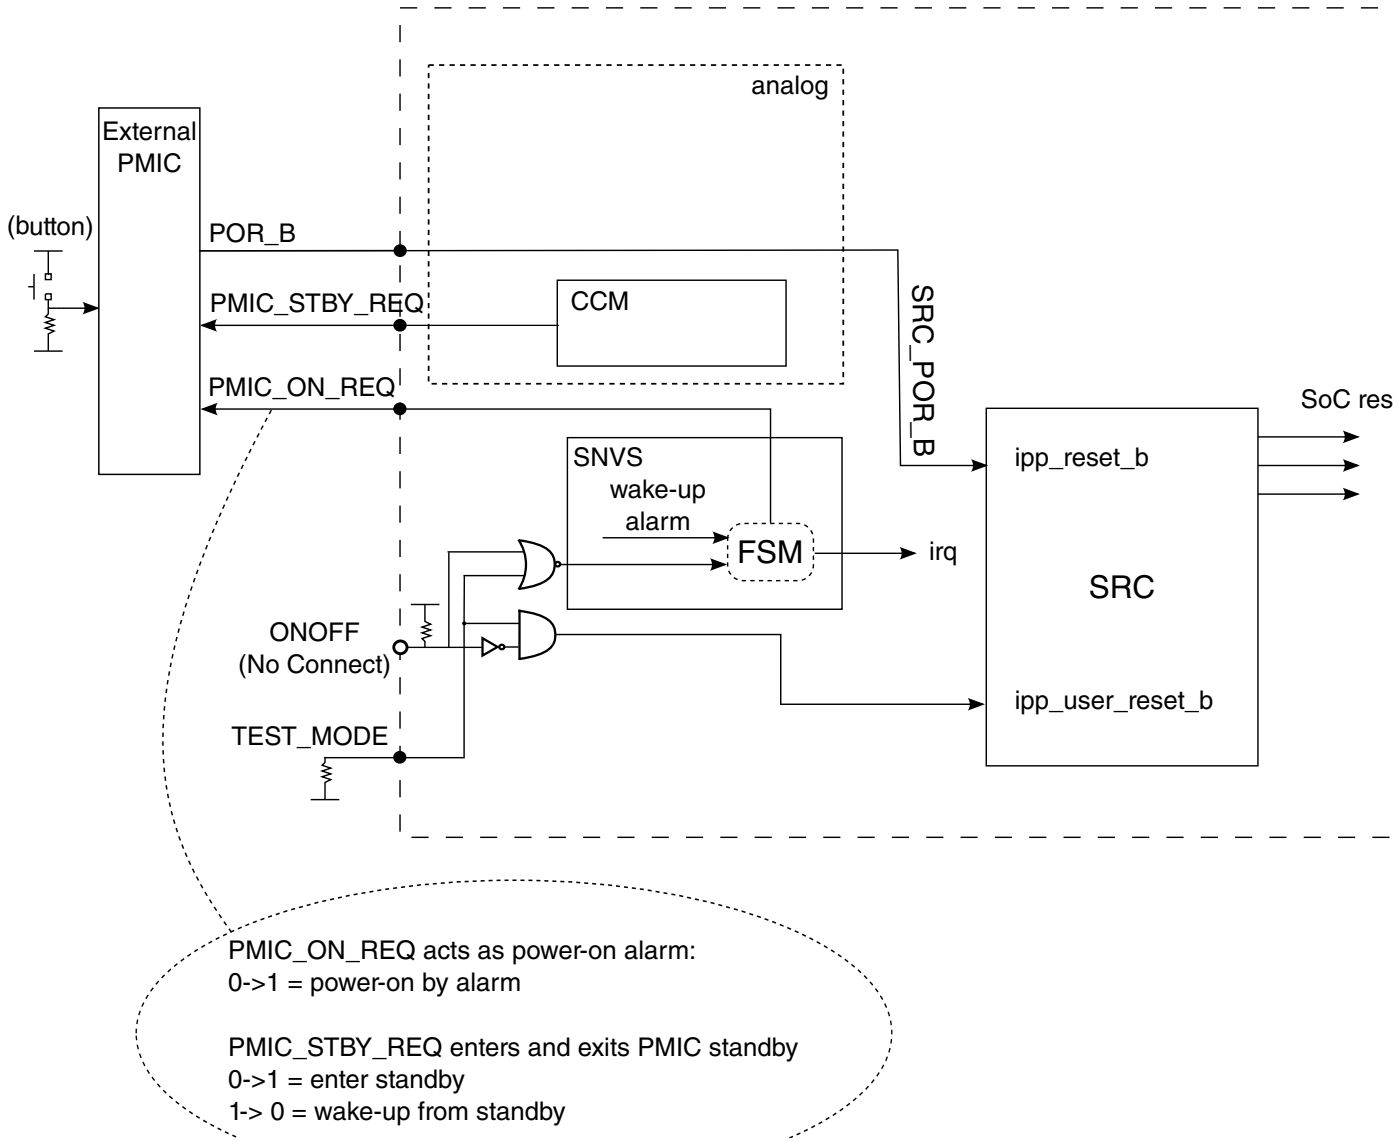

Figure 6-31. Chip reset scheme under external PMIC control

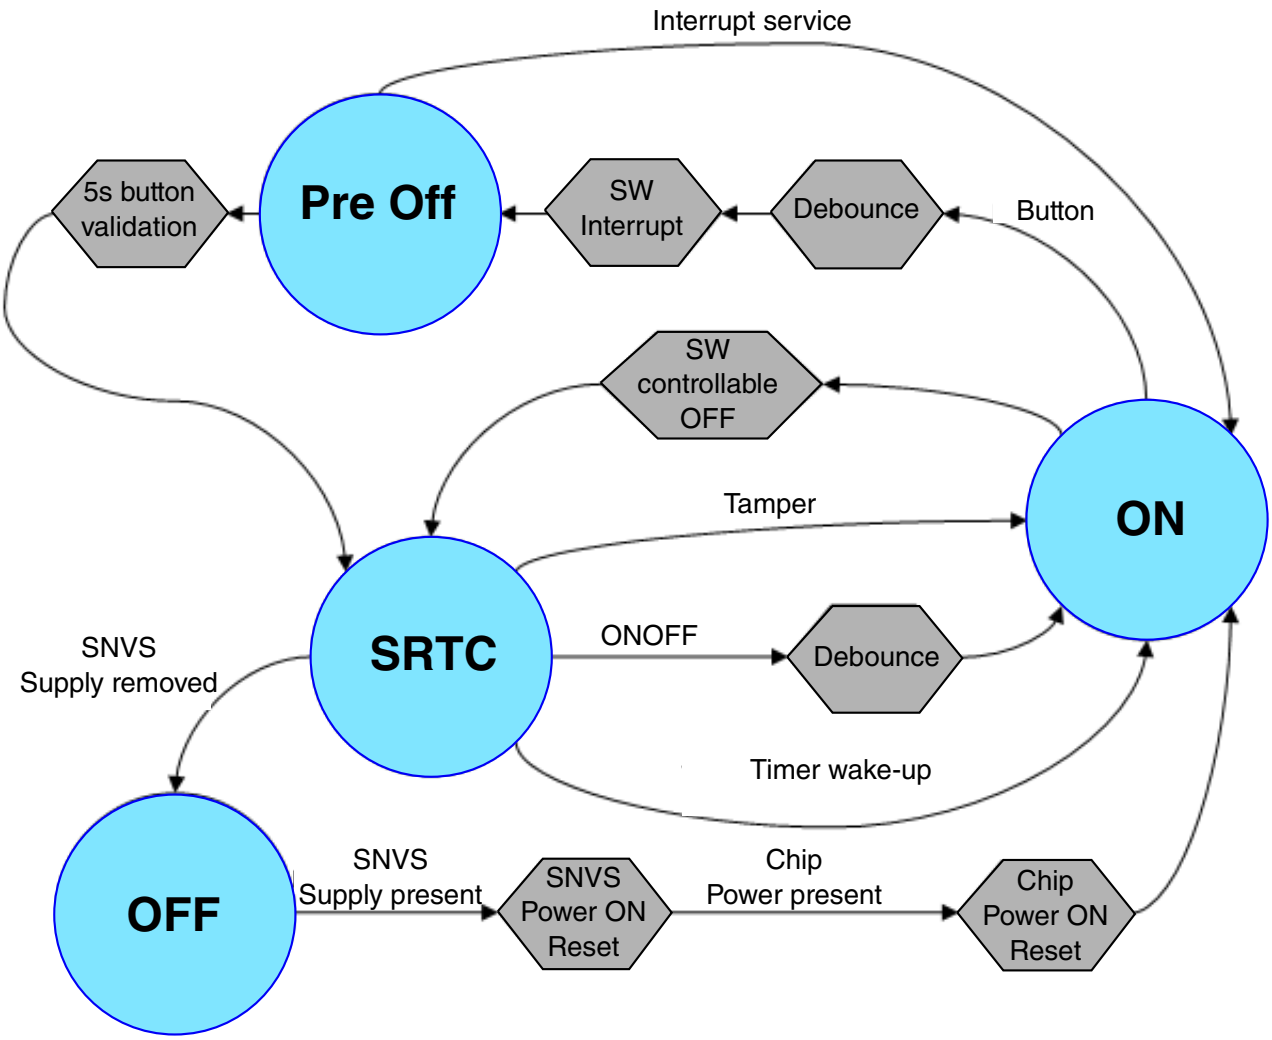

Figure 6-32. Chip on/off state flow diagram

6.5.2.2 Finite-State Machine (FSM)

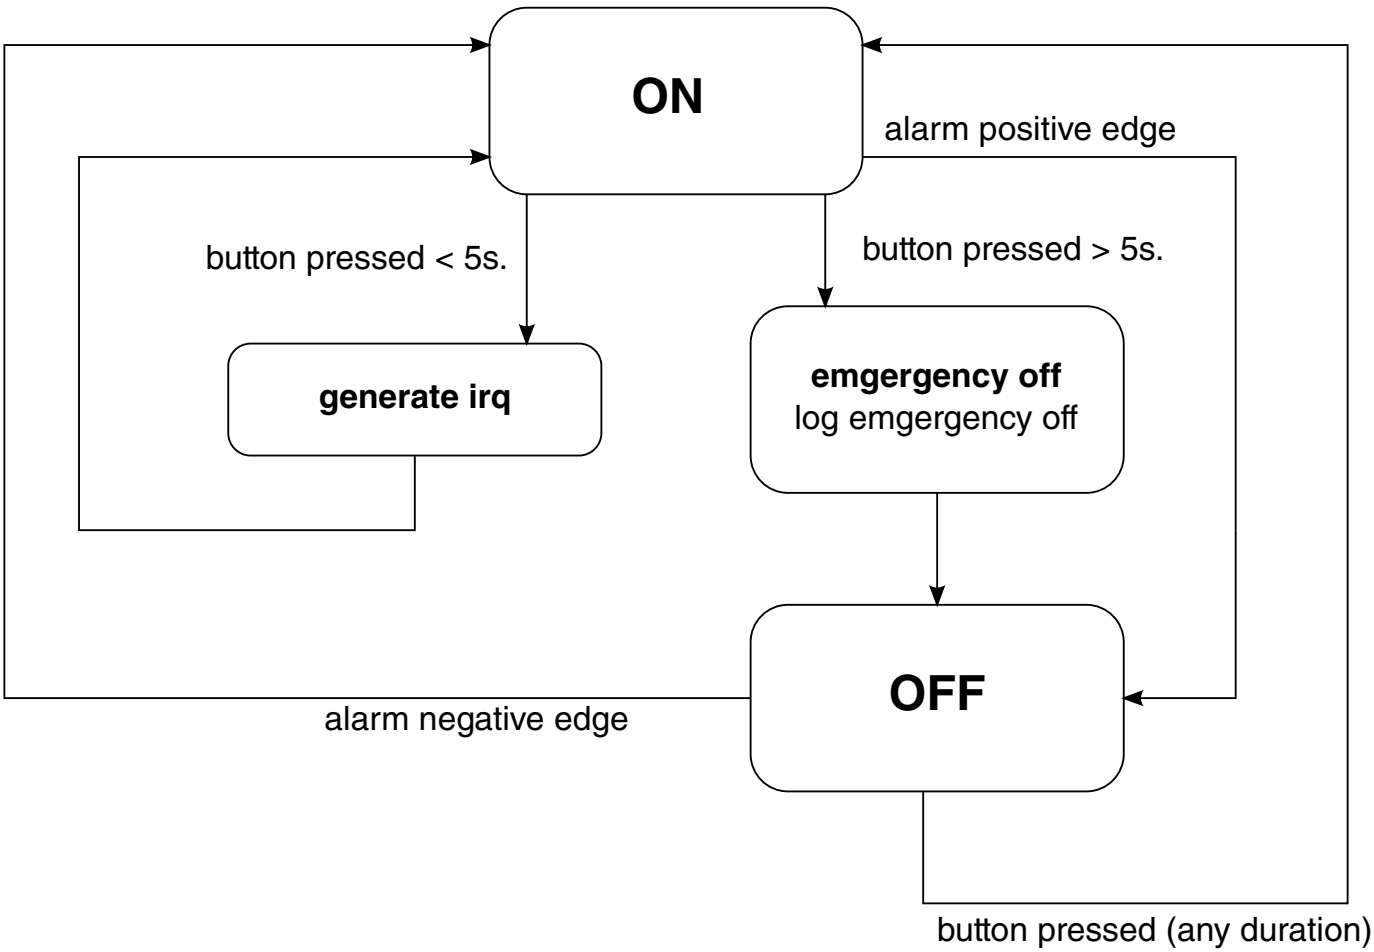

Figure 6-33. FSM

6.5.2.3 Power mode transitions

Table 6-53. Power mode transitions

Power mode	Configuration with external PMIC	Configuration with internal PMIC
ON, first time	1. SoC power supply is connected to SNVS. 2. When button is pressed, PMIC powers on.	1. SoC power supply is connected to SNVS. 2. When button is pressed, 'state' goes ON, PMIC_ON_REQ goes '1'. 3. External regulator is enabled.
Normal ON to OFF, by button	1. Button is pressed for a short duration on the external PMIC. 2. Interrupt request (irq) is sent to SoC from external PMIC. 3. SoC is programming PMIC for power off when standby is asserted.	1. SoC button is pressed for a short duration. 2. Interrupt request (irq) is sent to SoC from FSM. 3. Alarm timer is set up by software routine and started. 4. Upon alarm_in assertion to '1', PMIC_ON_REQ goes '0'. 5. External regulator goes OFF.

Table continues on the next page...

Table 6-53. Power mode transitions (continued)

Power mode	Configuration with external PMIC	Configuration with internal PMIC
	4. In CCM STOP mode, Standby is asserted, PMIC gates SoC supplies.	
Emergency ON to OFF, by button	1. Button is pressed for an extended time on the external PMIC. 2. PMIC is powering off.	1. Button is pressed for longer than 5 seconds on the SoC. 2. FSM validates button pressed for 5 seconds. 3. Emergency power off is logged, PMIC_ON_REQ goes '0', alarm_mask goes '1'. 4. External regulator goes OFF.
OFF to ON, by button	1. Button is pressed on the external PMIC. 2. PMIC powers ON.	1. Button is pressed on the SoC. 2. PMIC_ON_REQ goes '1', alarm_mask goes '0'. 3. External regulator powers ON.
OFF to ON, by timer alarm	1. Timer alarm in SNVS is programmed by software before SoC goes OFF. 2. SoC enters OFF mode. 3. Upon timer limit, wake up alarm goes '0'. PMIC_ON_REQ goes '1'. 4. PMIC receives assertion of PMIC_ON_REQ and wakes up.	1. Timer alarm in SNVS is programmed by software before SoC goes OFF. 2. SoC enters OFF mode. 3. Upon timer limit, wake up alarm goes '0'. PMIC_ON_REQ goes '1'. 4. External regulator is enabled by PMIC_ON_REQ = 1.

6.5.3 Power-On Reset and power sequencing

This module generates an internal POR_B signal that is logically AND'ed with any externally applied SRC_POR_B signal. The internal POR_B signal will be held low until all of the following conditions are met:

- 4ms after the external power supply VDDHIGH_IN is valid
- 1ms after the VDD_SOC_CAP supply is valid

The 4ms and 1ms delays are derived from counting the 32 kHz RTC clock cycles; the accuracy depends on the accuracy of the RTC. When the RTC crystal is either absent or in the process of powering up, an internal ring oscillator will be the source of RTC, which is not as accurate as the crystal.

6.5.3.1 External POR using SRC_POR_B

If the external SRC_POR_B signal is used to control the processor POR, SRC_POR_B must remain low (asserted) until the VDD_ARM_CAP and VDD_SOC_CAP supplies are stable.

6.5.3.2 Internal POR

If the external SRC_POR_B signal is not used (always held high or left unconnected), the processor defaults to the internal POR function (PMU controls generation of the POR based on the power supplies).

If the internal POR function is used, the following power supply requirements must be met:

- VDD_ARM_IN and VDD_SOC_IN may be supplied from the same source, or
- VDD_SOC_IN can be supplied before VDD_ARM_IN with a maximum delay of 1 ms.

6.5.4 Functional Description

6.5.4.1 Reset Control

This section details the reset control of this device.

6.5.4.1.1 Reset inputs and outputs

The reset control logic receives reset requests from all potential reset sources. All the immediate sources of reset are directly passed to the reset stretching block, whereas the resets requiring qualification are passed on to the reset qualification logic before they are sent to the reset stretching block.

All reset inputs and outputs are described in the following figure:

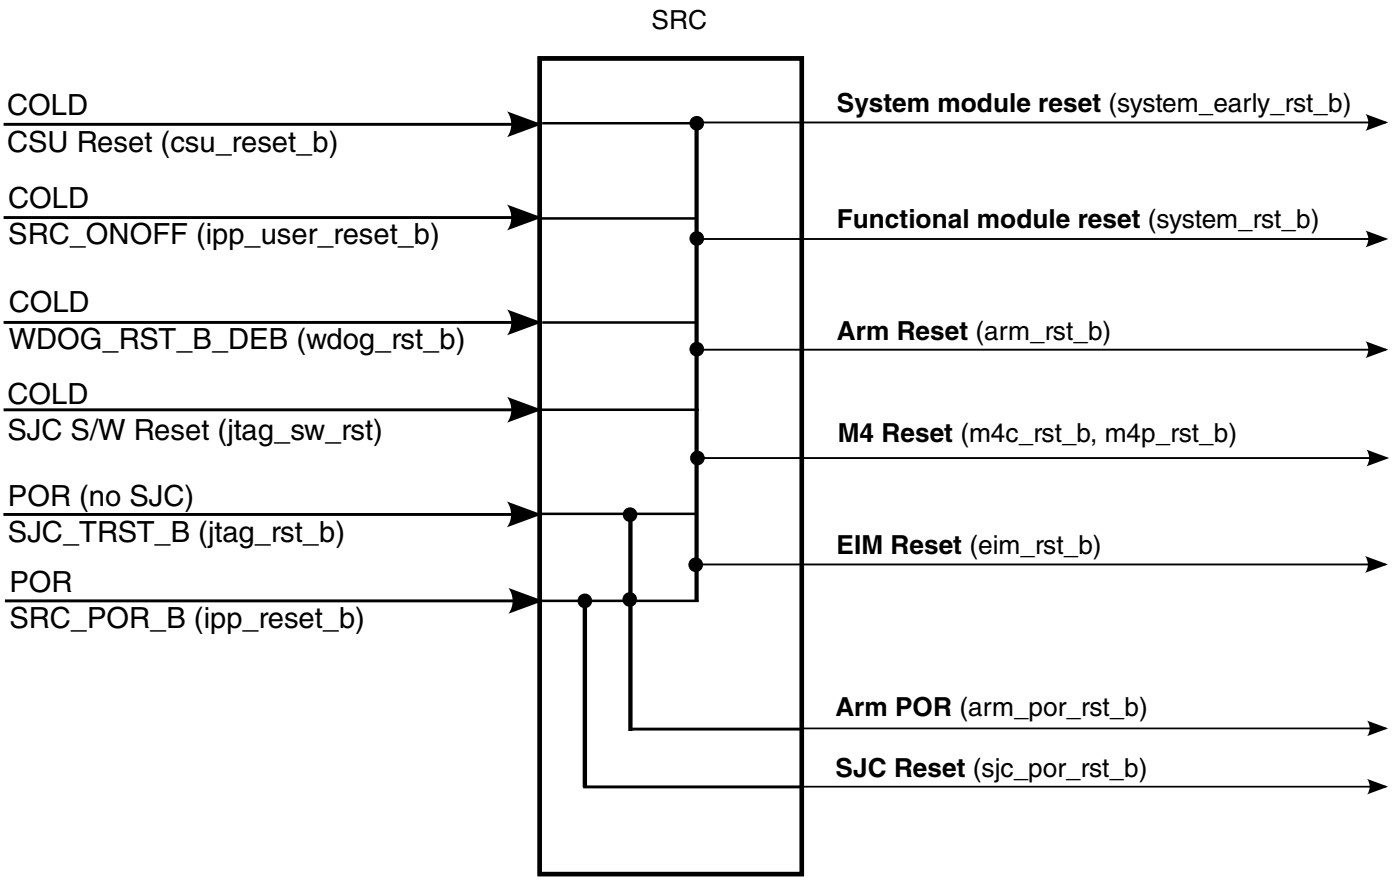

Figure 6-34. SRC inputs and outputs

The reset types and modules they affect are shown in Table 6-54. As there is no chip POR, the POR_B is used to reset the entire chip including test logic and JTAG modules.

NOTE

All resets are expected to be active low except jtag_sw_rst.

Table 6-54. SRC reset functionality

SoC Modules	POR	COLD
System modules (PLLs, fuses, etc)	yes	yes
Functional modules	yes	yes
Arm	yes	yes
Arm SoC	yes	yes
M4 Core	yes	yes
M4 Platform	yes	yes
Arm POR	yes	no
Arm debug	yes	no
SJC	yes	no
SRTC	yes	no

The reset priorities are POR (strongest) and COLD (weakest). If a stronger reset is asserted during the sequence of a weaker reset, then the weaker sequence will be overridden, and the stronger reset sequence will commence. There is no priority within a reset type (POR, etc). If a reset is asserted during the reset sequence of the same type, the reset sequence will be interrupted and restarted.

The following lists the functionality of each of these reset outputs:

- system_early_rst_b - Resets the system modules that need to start first as CCM, OCOTP_CTRL, FUSEBOX, etc.
- system_rst_b - Resets functional modules
- arm_rst_b - Resets Arm module (on regular system reset)
- arm_por_rst_b - Resets Arm POR input
- arm_soc_rst_b - Reset for Arm SOC
- m4c_rst_b - Reset for M4 core
- m4p_rst_b - Reset for M4 platform
- arm_dbg_rst_b - Reset debug logic of Arm
- test_logic_rst_b - Reset test logic (IOMUXC, DAP)
- sjc_por_rst_b - Reset to SJC
- srtc_rst_b - Resets SRTC

NOTE

It is assumed that each reset source will deassert after its assertion, either due to reset generated to the system from SRC, or by negation of the reset source (if it came from an external source to the chip). In the latter case, the reset source is assumed to be held for at least 2 XTALI clocks so it can be sampled by SRC.

6.5.4.1.2 Reset Handling

6.5.4.1.2.1 POR (SRC_POR_B)

SRC_POR_B is an external reset signal. When the chip is powered up, the reset signal is passed through the POR_B pin indicating power-up sequence. The SRC resets the entire chip including the JTAG (SJC) module. All SRC registers will be reset during the POR sequence.

As soon as SRC_POR_B occurs, all resets are asserted and the entire chip is reset by SRC. The SRC_POR_B is stretched for 2 XTALI cycles and the stretching sequence takes place after 2 XTALI clocks of POR_B pin deassertion.

The srtc_rst_b signal is deasserted together with SRC_POR_B signal. The output are also deasserted after the stretching of SRC_POR_B has deasserted.

The sjc_por_rst_b signal is deasserted together with SRC_POR_B signal. The output is also deasserted after the stretching of SRC_POR_B has deasserted.

Once the above resets deassert, system_early_rst_b reset is deasserted after 2 XTALI clocks. The system_early_rst_b is used for the CCM and PLL-IPs to start generating PLL clock ouputs and the system root clocks.

When the system root clocks are ready, the CCM will assert system_clk_ready signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation.

SRC then enables OCOTP_CTRL and fusebox clocks, so that fuses can be loaded to OCOTP_CTRL.

- SRC will prepare the boot information
- After 8 ipg cycles, resets to all modules will be de-asserted
- After 8 ipg cycles, system clocks will be enabled (en_system_clk).

6.5.4.1.2.2 COLD RESET

The sequence is similar to SRC_POR_B except the memory repair operation is not performed.

Once the reset source deasserts, system_early_rst_b reset is deasserted after at least 2 XTALI clocks. The system_early_rst_b is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

Once the system root clocks are ready, the CCM will assert system_clk_ready signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation. See CCM for more information.

Once system_clk_ready arrives at the SRC, it will enable OCOTP_CTRL and fusebox clocks, so that fuses can be loaded to OCOTP_CTRL. OCOTP_CTRL will notify with iim_ready_flag once the fusebox loading finishes.

- SRC will prepare the boot information
- After 8 ipg cycles resets to all modules will be deasserted
- After 8 ipg cycles, system clocks will be enabled (en_system_clk).

6.5.4.2 Parallel Reset Requests

SRC will follow the following rules in the case of parallel reset requests:

1. The order of strength of resets is POR - strongest, COLD - weakest
2. If a stronger reset is asserted during weaker reset sequence, then the stronger reset will take over and the stronger reset process will commence. The following cases fall into this category:
   - POR reset request in the middle of cold reset process - the cold will be stopped and the POR sequence will start.
3. If a weaker reset is asserted during stronger reset sequence, then the stronger reset sequence will continue without interference. If at the end of the stronger reset process the weaker request is still asserted then the weaker sequence will commence. The following cases fall into this category:
   - COLD reset requests in the middle of POR reset process - the POR process will continue without interference.
4. If a similar reset request is asserted during the process of reset handling, then the process of reset handling will start over (with the same process). The following cases fall into this category:
   - POR reset request in the middle of POR reset process - the POR process will start over.
   - COLD reset request in the middle of COLD reset process - the COLD process will start over.

6.5.4.3 Boot Mode Control

6.5.4.3.1 BOOT_MODE Pin Latching

The exact boot sequence is controlled by the values of the BOOT_MODE pins on this device.

The value of the BOOT_MODE pins will be latched after the OCOTP_CTRL asserts the fuse read completion flag. After latching, the values of the BOOT_MODE pins are used to determine the booting options of the core as described in the SRC_SBMRx registers.

The boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals. The gpio_bt_sel e-fuse defines the source to be used to derive the boot information. When gpio_bt_sel is set, e-fuses are used. When cleared, GPIO signals are used.

The boot information is provided in SRC_SBMR1 register. The figure below shows the selection of boot mode information.

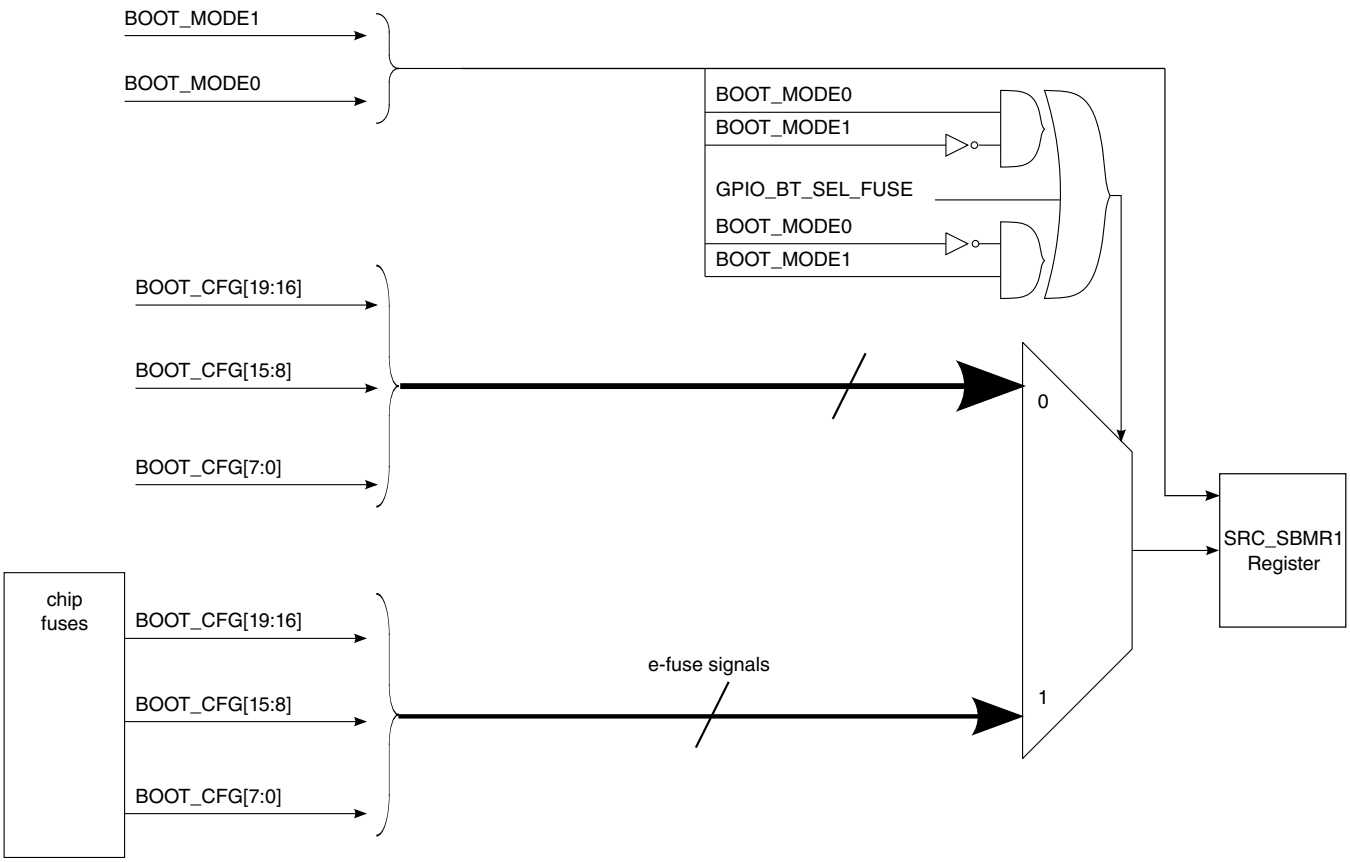

Figure 6-35. Boot mode information

6.5.5 SRC Memory Map/Register Definition

SRC memory map

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SRC_A53RCR0 field descriptions

Field	Description
31 DOM_EN	Domain Control enable for this register. **NOTE:** [31:30] and [27:24] areas are not controlled by this bit. [31:30] and [27:24] area can be modified by any masters from any domains when Lock bit is not set. 0 Disables domain control. All of this register's bits except [31:30] and [27:24] can be modified by any masters 1 Enables domain control. All of this register's bits except [31:30] and [27:24] can only be modified by the masters from the domains specified in [27:24] area.
30 LOCK	Domain control bits lock **NOTE:** Lock bit is a write-once register, once it is set to 1, it can't be write to 0 0 [31] and [27:24] bits can be modified 1 [31] and [27:24] bits cannot be modified
29–28 -	This field is reserved. Reserved
27 DOMAIN3	Domain3 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain3. The master from domain3 cannot write to this register. 1 This register is assigned to domain3. The master from domain3 can write to this register
26 DOMAIN2	Domain2 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain2. The master from domain2 cannot write to this register. 1 This register is assigned to domain2. The master from domain2 can write to this register
25 DOMAIN1	Domain1 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain1. The master from domain1 cannot write to this register. 1 This register is assigned to domain1. The master from domain1 can write to this register
24 DOMAIN0	Domain0 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain0. The master from domain3 cannot write to this register. 1 This register is assigned to domain0. The master from domain3 can write to this register
23–22 -	This field is reserved. Reserved
21 A53_L2RESET	Software reset for A53 Snoop Control Unit (SCU). **NOTE:** This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. 0 do not assert SCU reset 1 assert SCU reset
20 A53_SOC_DBG_RESET	Software reset for system level debug reset. It initializes the shared Debug APB, the CTI, and the CTM. It also causes: • A53_dbgreset[3:0] and A53_etmreset[3:0] to be asserted • debug logic in the processor power domain and in the debug power domain to be reset

Table continues on the next page...

SRC_A53RCR0 field descriptions (continued)

Field	Description
	NOTE: This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. 0 do not assert system level debug reset 1 assert system level debug reset
19–16 MASK_WDOG1_RST	Mask wdog1_rst_b source. If these 4 bits are coded from A to 5 then, the wdog1_rst_b input to SRC will be masked and the wdog1_rst_b will not create a reset to the chip. **NOTE:** During the time the WDOG event is masked using SRC logic, it is likely that the WDOG Reset Status Register (WRSR) bit 1 (which indicates a WDOG timeout event) will get asserted. software / OS developer must prepare for this case. Re-enabling the WDOG is possible, by un-masking it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module. (Hardware reset is the only way to cause the de-assertion of that bit). Any other code will be coded to 1010 i.e. wdog1_rst_b is not masked 0101 wdog1_rst_b is masked 1010 wdog1_rst_b is not masked
15 A53_ETM_RESET3	Software reset for core3 ETM only. **NOTE:** This is a self clearing bit. Once it is set to 1, the rest process will begin, and once it finished, this bit will be self-cleared. 0 do not assert core3 ETM reset 1 assert core3 ETM reset
14 A53_ETM_RESET2	Software reset for core2 ETM only. **NOTE:** This is a self clearing bit. Once it is set to 1, the rest process will begin, and once it finished, this bit will be self-cleared. 0 do not assert core2 ETM reset 1 assert core2 ETM reset
13 A53_ETM_RESET1	Software reset for core1 ETM only. **NOTE:** This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. 0 do not assert core1 ETM reset 1 assert core1 ETM reset
12 A53_ETM_RESET0	Software reset for core0 ETM only. **NOTE:** This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. 0 do not assert core0 ETM reset 1 assert core0 ETM reset
11 A53_DBG_RESET3	Software reset for core3 debug only. It initialize the debug, and breakpoint and watchpoint logic in the core3 processor power domain. It also reset the debug logic for core1 processor, which is in the debug power domain.

Table continues on the next page...

Field	Description
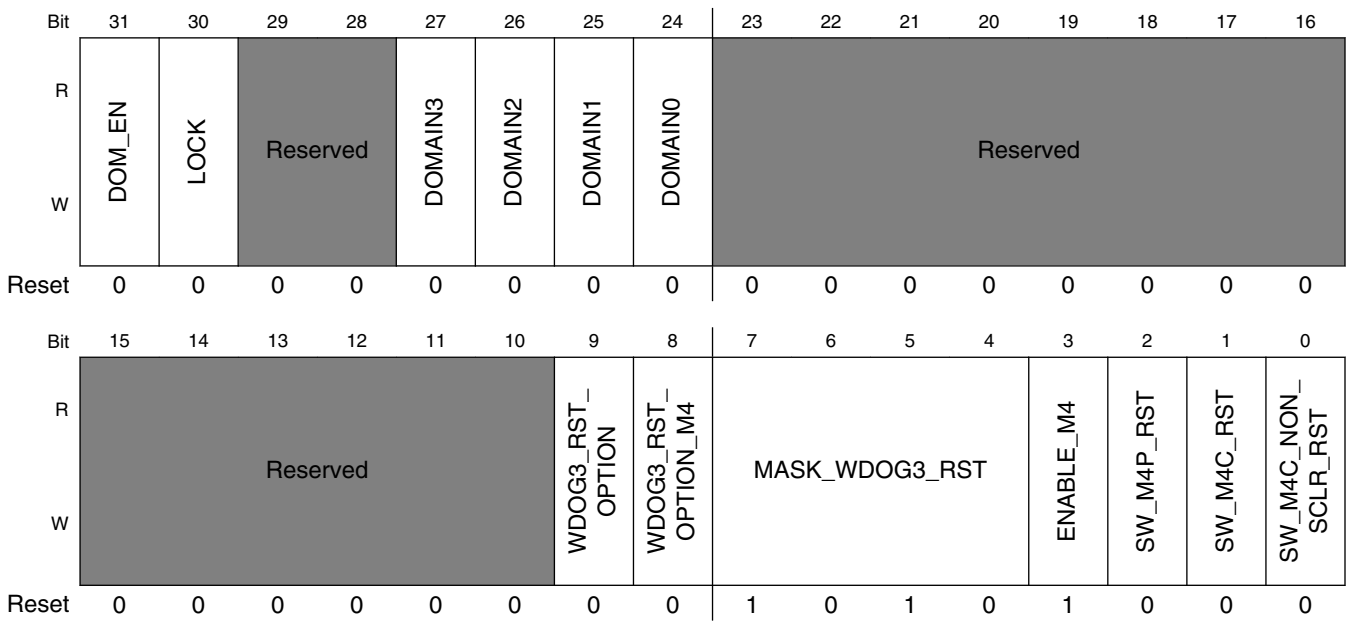
	0 core1 is disabled 1 core1 is enabled
0 A53_CORE0_ENABLE	Always 1, can't be changed.

6.5.5.4 M4 Reset Control Register (SRC_M4RCR)

The M4 Reset Control Register (M4RCR), contains bits that control the M4 reset generation.

Address: 3039_0000h base + Ch offset = 3039_000Ch



SRC_M4RCR field descriptions

Field	Description
31 DOM_EN	Domain Control enable for this register. **NOTE:** [31:30] and [27:24] areas are not controlled by this bit. [31:30] and [27:24] area can be modified by any masters from any domains when Lock bit is not set. 0 Disables domain control. All of this register's bits except [31:30] and [27:24] can be modified by any masters 1 Enables domain control. All of this register's bits except [31:30] and [27:24] can only be modified by the masters from the domains specified in [27:24] area.
30 LOCK	Domain control bits lock

Table continues on the next page...

SRC_M4RCR field descriptions (continued)

Field	Description
	NOTE: Lock bit is a write-once register, once it is set to 1, it can't be write to 0 0 [31] and [27:24] bits can be modified 1 [31] and [27:24] bits cannot be modified
29–28 -	This field is reserved. Reserved
27 DOMAIN3	Domain3 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain3. The master from domain3 cannot write to this register. 1 This register is assigned to domain3. The master from domain3 can write to this register
26 DOMAIN2	Domain2 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain2. The master from domain2 cannot write to this register. 1 This register is assigned to domain2. The master from domain2 can write to this register
25 DOMAIN1	Domain1 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain1. The master from domain1 cannot write to this register. 1 This register is assigned to domain1. The master from domain1 can write to this register
24 DOMAIN0	Domain0 assignment control. Effective when dom_en is set to 1. 0 This register is not assigned to domain0. The master from domain3 cannot write to this register. 1 This register is assigned to domain0. The master from domain3 can write to this register
23–10 -	This field is reserved. Reserved
9 WDOG3_RST_ OPTION	Wdog3_rst_b option 0 Wdog3_rst_b asserts M4 reset 1 Wdog3_rst_b asserts global reset
8 WDOG3_RST_ OPTION_M4	Wdog3_rst_b option for M4. This bit is only effective when wdog3_rst_option is set to 1. 0 wdgo3_rst_b Reset M4 core only 1 Reset both M4 core and platform
7–4 MASK_WDOG3_ RST	Mask wdog3_rst_b source. If these 4 bits are coded from A to 5 then, the wdog3_rst_b input to SRC will be masked and the wdog3_rst_b will not create a reset to the chip. **NOTE:** During the time the WDOG3 event is masked using SRC logic, it is likely that the WDOG3 Reset Status Register (WRSR) bit 1 (which indicates a WDOG3 timeout event) will get asserted. Software / OS developer must prepare for this case. Re-enabling the WDOG3 is possible, by un-masking it in SRC, though it must be preceded by servicing the WDOG3. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG3 module. (Hardware reset is the only way to cause the de-assertion of that bit). Any other code will be coded to 1010 i.e. wdog3_rst_b is not masked 0101 wdog3_rst_b is masked 1010 wdog3_rst_b is not masked
3 ENABLE_M4	Enable M4 0 M4 is disabled 1 M4 is enabled

Table continues on the next page...

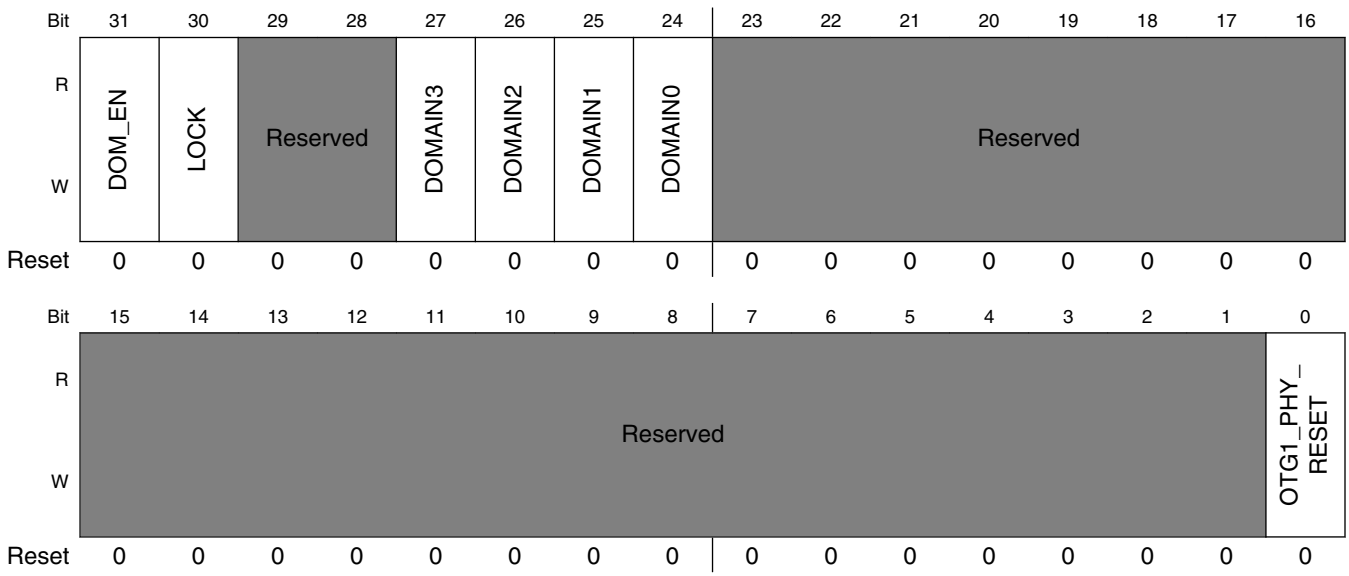
SRC_M4RCR field descriptions (continued)

Field	Description
2 SW_M4P_RST	Self-clearing SW reset for M4 platform **NOTE:** This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SRC_SISR register for details. 0 do not assert M4 platform reset 1 assert M4 platform reset
1 SW_M4C_RST	Self-clearing SW reset for M4 core **NOTE:** This is a self clearing bit. Once it is set to 1, the reset process will begin, and once it finishes, this bit will be self cleared. Software can determine that the reset has finished once this bit is cleared. Software can also configure SRC to generate interrupt once the software has finished. Please refer to SRC_SISR register for details. 0 do not assert M4 core reset 1 assert M4 core reset
0 SW_M4C_NON_SCLR_RST	Non-self-clearing SW reset for M4 core 0 do not assert M4 core reset 1 assert M4 core reset

6.5.5.5 USB OTG PHY1 Reset Control Register (SRC_USBOPHY1_RCR)

The USB OTG PHY1 Reset Control Register (SRC_IP_RCR2), contains bits that control the USB OTG PHY1 reset generation.

Address: 3039_0000h base + 20h offset = 3039_0020h



SRC_USBOPHY1_RCR field descriptions

Field	Description
31 DOM_EN	Domain Control enable for this register. **NOTE:** [31:30] and [27:24] areas are not controlled by this bit. [31:30] and [27:24] area can be modified by any masters from any domains when Lock bit is not set. 0 Disables domain control. All of this register's bits except [31:30] and [27:24] can be modified by any masters 1 Enables domain control. All of this register's bits except [31:30] and [27:24] can only be modified by the masters from the domains specified in [27:24] area.
30 LOCK	Domain control bits lock **NOTE:** Lock bit is a write-once register, once it is set to 1, it can't be write to 0 0 [31] and [27:24] bits can be modified 1 [31] and [27:24] bits cannot be modified

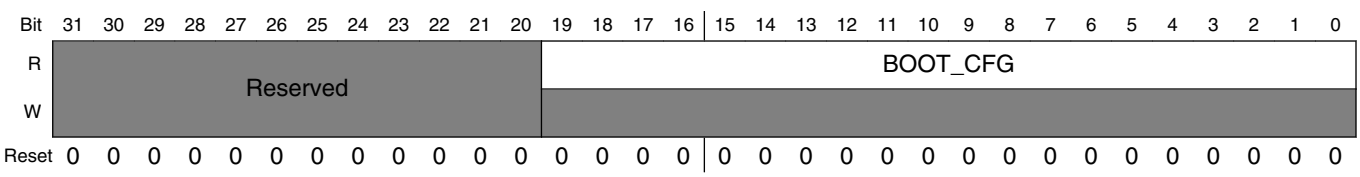
0 VPU_RESET	VPU_RESET

6.5.5.12 SRC Boot Mode Register 1 (SRC_SBMR1)

The Boot Mode register (SBMR) contains bits that reflect the status of Boot Mode Pins of the chip. The reset value is configuration dependent (depending on boot/fuses/IO pads).

Address: 3039_0000h base + 58h offset = 3039_0058h



SRC_SBMR1 field descriptions

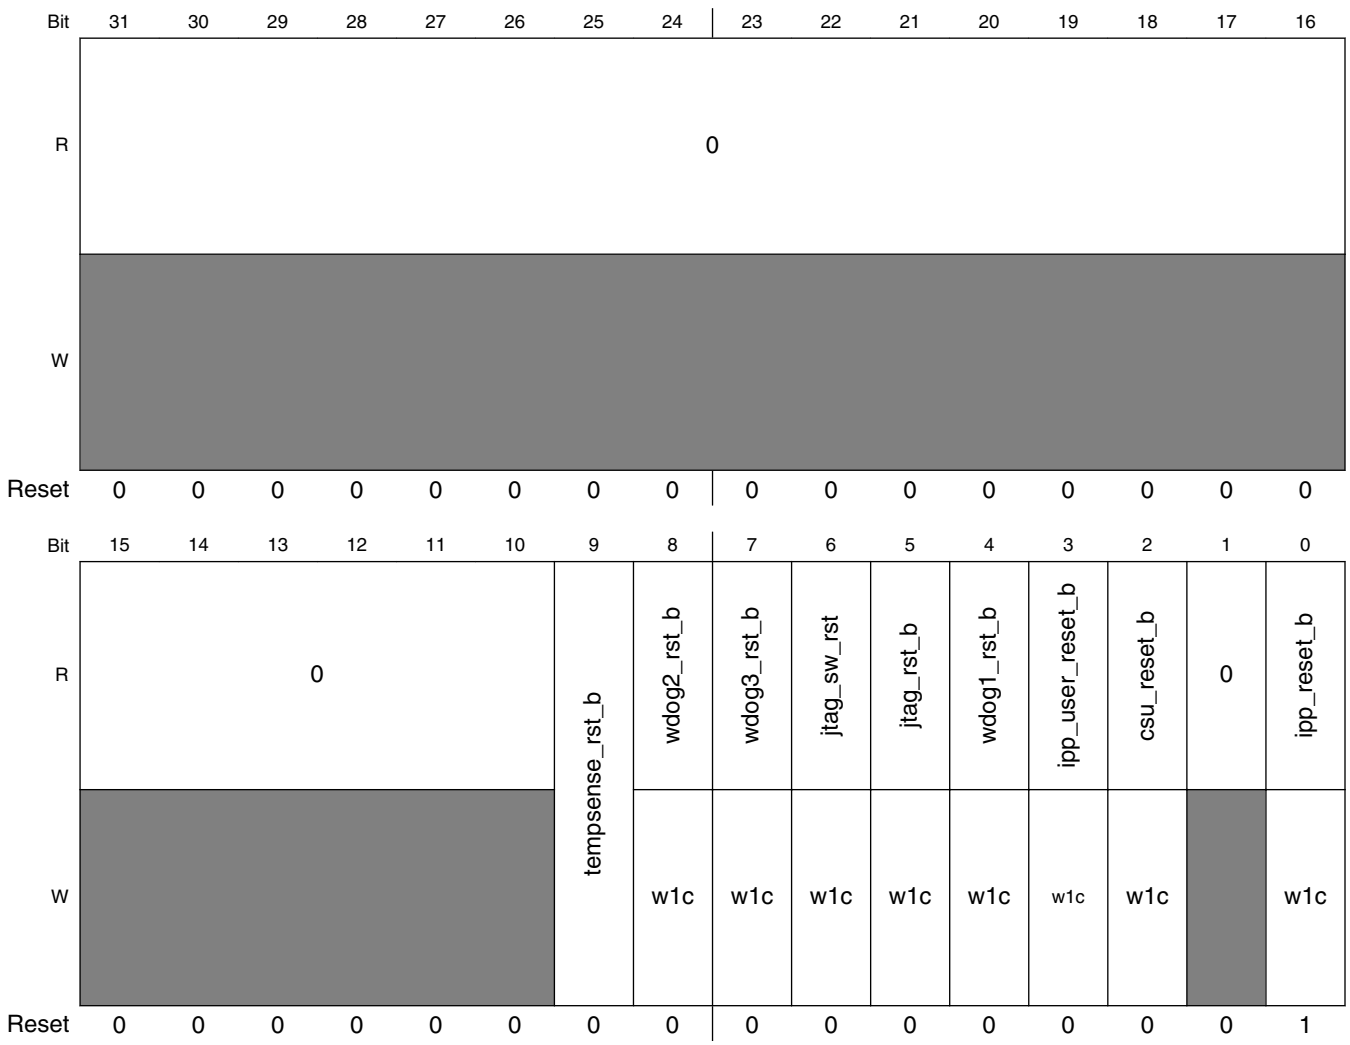
Field	Description
31–20 -	This field is reserved. Reserved
BOOT_CFG	Refer to fusemap.

6.5.5.13 SRC Reset Status Register (SRC_SRSR)

The SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred. This register is reset on ipp_reset_b. This is a read-write register.

For bit[9-0] - writing zero does not have any effect. Writing one will clear the corresponding bit. The individual bits can be cleared by writing one to that bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

Address: 3039_0000h base + 5Ch offset = 3039_005Ch



SRC_SRSR field descriptions

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
9 tempsense_rst_b	Temper Sensor software reset. Indicates whether the reset was the result of software reset from on-chip Temperature Sensor.

Table continues on the next page...

SRC_SRSR field descriptions (continued)

Field	Description
	0 Reset is not a result of software reset from Temperature Sensor. 1 Reset is a result of software reset from Temperature Sensor.
8 wdog2_rst_b	IC Watchdog2 Time-out reset. Indicates whether the reset was the result of the watchdog2 time-out event. 0 Reset is not a result of the watchdog4 time-out event. 1 Reset is a result of the watchdog4 time-out event.
7 wdog3_rst_b	IC Watchdog3 Time-out reset. Indicates whether the reset was the result of the watchdog3 time-out event. 0 Reset is not a result of the watchdog3 time-out event. 1 Reset is a result of the watchdog3 time-out event.
6 jtag_sw_rst	JTAG software reset. Indicates whether the reset was the result of software reset from JTAG. 0 Reset is not a result of software reset from JTAG. 1 Reset is a result of software reset from JTAG.
5 jtag_rst_b	HIGH - Z JTAG reset. Indicates whether the reset was the result of HIGH-Z reset from JTAG. 0 Reset is not a result of HIGH-Z reset from JTAG. 1 Reset is a result of HIGH-Z reset from JTAG.
4 wdog1_rst_b	IC Watchdog1 Time-out reset. Indicates whether the reset was the result of the watchdog time-out event. 0 Reset is not a result of the watchdog1 time-out event. 1 Reset is a result of the watchdog1 time-out event.
3 ipp_user_reset_b	Indicates whether the reset was the result of the ipp_user_reset_b qualified reset. 0 Reset is not a result of the ipp_user_reset_b qualified as COLD reset event. 1 Reset is a result of the ipp_user_reset_b qualified as COLD reset event.
2 csu_reset_b	Indicates whether the reset was the result of the csu_reset_b input. **NOTE:** If case the csu_reset_b occurred during a WARM reset process, during the phase that ipg_clk is not available yet, then the occurrence of CSU reset will not be reflected in this bit. 0 Reset is not a result of the csu_reset_b event. 1 Reset is a result of the csu_reset_b event.
1 Reserved	This read-only field is reserved and always has the value 0.
0 ipp_reset_b	Indicates whether reset was the result of ipp_reset_b pin (Power-up sequence) 0 Reset is not a result of ipp_reset_b pin. 1 Reset is a result of ipp_reset_b pin.

6.5.5.14 SRC Interrupt Status Register (SRC_SISR)

Address: 3039_0000h base + 68h offset = 3039_0068h

6.6 Watchdog Timer (WDOG)

6.6.1 Overview

The Watchdog Timer (WDOG) protects against system failures by providing a method by which to escape from unexpected events or programming errors.

Once the WDOG is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG asserts the internal system reset signal, WDOG_RESET_B_DEB to the System Reset Controller (SRC).

There is also a provision for WDOG signal assertion by timeout counter expiration. There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter timeout is programmable. There is a power down counter which is enabled out of any reset (POR, Warm/Cold). This counter has a fixed timeout period of 16 seconds, upon which it asserts the WDOG signal.

Flow diagrams for the timeout counter, power down counter and interrupt operations are are shown in Flow Diagrams.

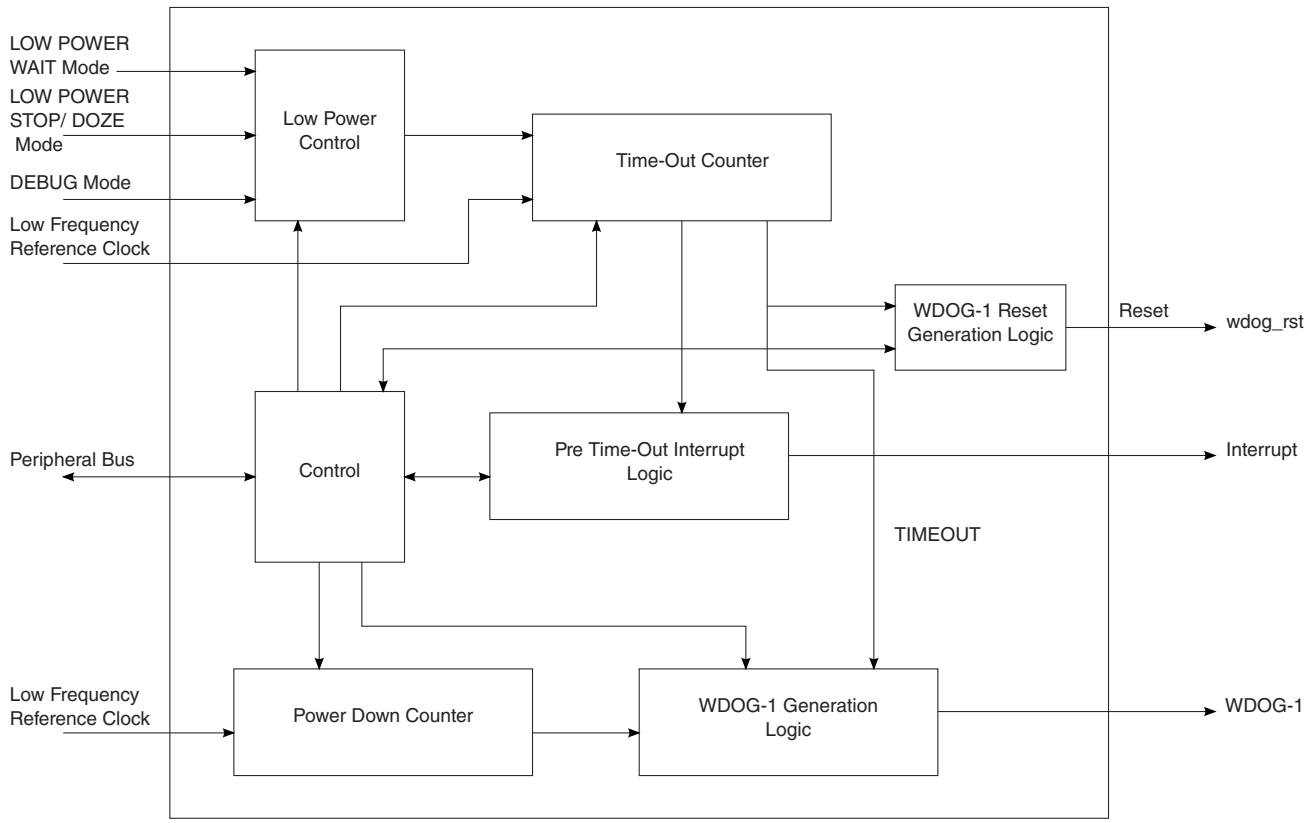

Figure 6-36. WDOG Diagram

6.6.1.1 Features

The WDOG features are listed below:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG_RESET_B_DEB reset signal .
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low-power modes
- Configurable timeout counter that can be programmed to run or stop during DEBUG mode
- Programmable interrupt generation prior to timeout
- The duration between interrupt and timeout events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
- Power down counter with fixed timeout period of 16 seconds, which if not disabled after reset will assert WDOG_B signal low

- Power down counter will be enabled out of any reset (POR, Warm / Cold reset) by default.

6.6.2 Functional description

This section provides a complete functional description of the block.

6.6.2.1 Timeout event

The WDOG provides timeout periods from 0.5 to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the timeout period by writing to the WDOG timeout field (WT[7:0]) in the Watchdog Control Register (WDOG_WCR). The WDOG must be enabled by setting the WDE bit of Watchdog Control Register (WDOG_WCR) for the timeout counter to start running. After the WDOG is enabled, the counter is activated, loads the timeout value and begins to count down from this programmed value. The timer will time out when the counter reaches zero and the WDOG outputs a system reset signal, WDOG_RESET_B_DEB and asserts WDOG_B (WDT bit should be set in Watchdog Control Register (WDOG_WCR)).

However, the timeout condition can be prevented by reloading the counter with the new timeout value (WT[7:0] of WDOG_WCR) if a service routine (see Servicing WDOG to reload the counter) is performed before the counter reaches zero. If any system errors occur which prevent the software from servicing the Watchdog Service Register (WDOG_WSR), the timeout condition occurs. By performing the service routine, the WDOG reloads its counter to the timeout value indicated by bits WT[7:0] of the Watchdog Control Register (WDOG_WCR) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in Flow Diagrams.

NOTE

The timeout value is reloaded to the counter either at the time WDOG is enabled or after the service routine has been performed.

6.6.2.1.1 Servicing WDOG to reload the counter

To reload a timeout value to the counter the proper service sequence begins by writing 0x_5555 followed by 0x_AAAA to the Watchdog Service Register (WDOG_WSR). Any number of instructions can be executed between the two writes. If the WDOG_WSR is

not loaded with 0x_5555 prior to writing 0x_AAAA to the WDOG_WSR, the counter is not reloaded. If any value other than 0x_AAAA is written to the WDOG_WSR after 0x_5555, the counter is not reloaded. This service sequence will reload the counter with the timeout value WT[7:0] of Watchdog Control Register (WDOG_WCR). The timeout value can be changed at any point; it is reloaded when WDOG is serviced by the core.

6.6.2.2 Interrupt event

Prior to timeout, the WDOG can generate an interrupt which can be considered a warning that timeout will occur shortly.

The duration between interrupt event and timeout event can be controlled by writing to the WICT field of Watchdog Interrupt Control Register (WDOG_WICR). It can vary between 0 and 127.5 seconds. If the WDOG is serviced (Servicing WDOG to reload the counter)before the interrupt generation, the counter will be reloaded with the timeout value WT[7:0] of Watchdog Control Register (WDOG_WCR) and the interrupt will not be triggered.

6.6.2.3 Power-down counter event

The power-down counter inside WDOG will be enabled out of reset. This counter has a fixed timeout value of 16 seconds, after which it will drive the WDOG_B signal low.

To prevent this, the software must disable this counter by clearing the PDE bit of Watchdog Miscellaneous Control Register (WDOG_WMCR) within 16 seconds of reset deassertion. Once disabled, this counter can't be enabled again until the next system reset occurs. This feature is intended to prevent the hanging up of cores after reset, as WDOG is not enabled out of reset.

6.6.2.4 Low power modes

6.6.2.4.1 STOP and DOZE mode

If the WDOG timer disable bit for low power STOP and DOZE mode (WDZST) bit in the Watchdog Control Register (WDOG_WCR), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power enable (WDZST) bit is set, the WDOG timer operation will be suspended in low power STOP or DOZE mode. Upon exiting low power STOP or DOZE mode, the WDOG operation returns to what it was prior to entering the STOP or DOZE mode.

6.6.2.4.2 WAIT mode

If the WDOG timer disable bit for low power WAIT mode (WDW) bit in the Watchdog Control Register (WDOG_WCR), is cleared, the WDOG timer continues to operate using the low frequency reference clock . If the low power WAIT enable (WDW) bit is set, the WDOG timer operation will be suspended. Upon exiting low power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

NOTE

The WDOG timer won't be able to detect events that happen for periods shorter than one low frequency reference clock cycle. For example, in repeated WAIT mode entry or exit, if the RUN mode time is less than one low frequency reference clock cycle and if the WDW bit is set, the WDOG timer may never time out, even though the system is in RUN mode for a finite duration; WDOG may not see a low frequency reference clock edge during its wake time.

6.6.2.5 Debug mode

The WDOG timer can be configured for continual operation, or for suspension during debug mode. If the WDOG debug enable (WDBG) bit is set in the Watchdog Control Register (WDOG_WCR), the WDOG timer operation is suspended in debug mode. If the WDBG bit is set and the debug mode is entered, WDOG timer operation is suspended after two low frequency reference clocks. Similarly, WDOG timer operation continues after two low frequency reference clocks of debug mode exit. Register read and write accesses in debug mode continue to function normally. Also, while in debug mode, the WDE bit of Watchdog Control Register (WDOG_WCR) can be enabled/disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG timer operation is not suspended. The power-down counter is not affected by debug mode entry/exit.

NOTE

If the WDE bit of Watchdog Control Register (WDOG_WCR) is set/cleared while in debug mode, it remains set/cleared even after exiting debug mode.

6.6.2.6 Operations

6.6.2.6.1 Watchdog reset generation

The WDOG generated reset signal WDOG_RESET_B_DEB is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the Watchdog Control Register (WDOG_WCR).
- WDOG timeout. See Timeout event.

The $\overline{\text{wdog\_rst}}$ will be asserted for one clock cycle of low frequency reference clock for both a timeout condition and a software write occurrence. It remains asserted for 1 clock cycle of low frequency reference clock even if a system reset is asserted in between. Figure 6-38 shows the timing diagram of this signal due to a timeout condition.

6.6.2.6.2 WDOG_B generation

The WDOG asserts WDOG_B in the following scenarios:

- Software write to WDA bit of Watchdog Control Register (WDOG_WCR). WDOG_B signal remains asserted as long as the WDA bit is "0".
- WDOG timeout condition, WDT bit of Watchdog Control Register (WDOG_WCR) must be set for this scenario. A description of the timeout condition can be found in the Timeout event. WDOG_B signal remains asserted until a power-on reset (POR) occurs. It gets cleared after the POR occurs (not due to any other system reset). Figure 6-39 shows the timing diagram of WDOG_B due to timeout condition.
- WDOG power-down counter timeout, PDE bit of Watchdog Miscellaneous Control Register (WDOG_WMCR) should not be cleared for this scenario. A description of this counter can be found in the Power-down counter event. WDOG_B signal remains asserted for one clock cycle of low frequency reference clock.

Figure 6-37 shows the scenarios under which WDOG_B gets asserted.

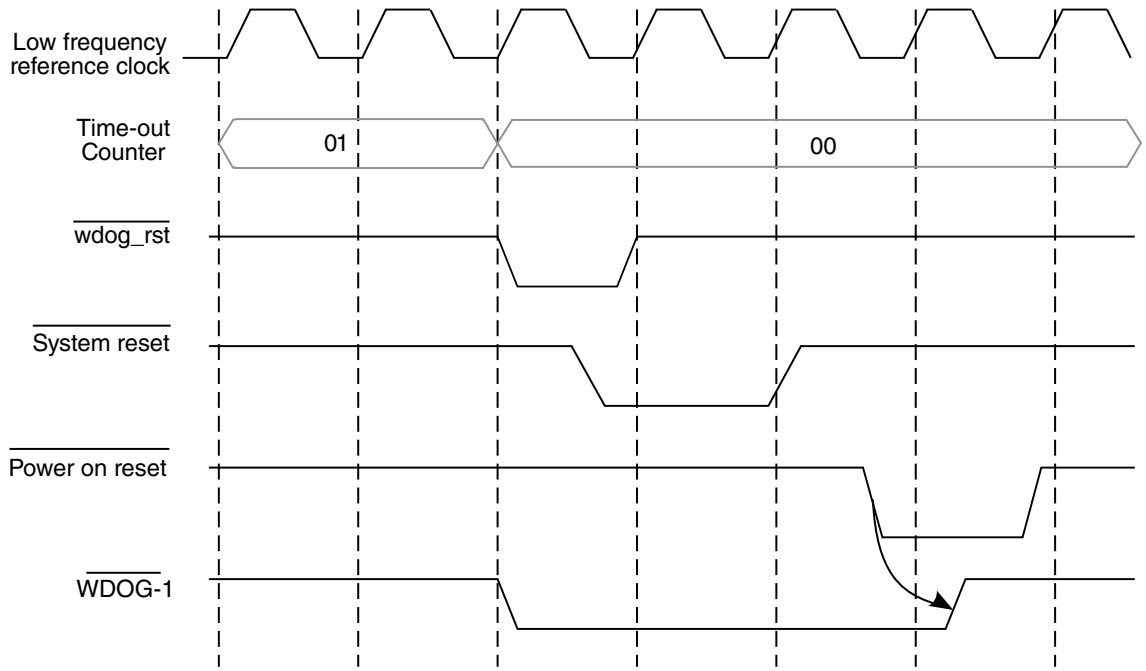

Figure 6-39. WDOG timeout condition/WDT bit is set

6.6.2.7 Reset

The block is reset by a system reset and the WDOG counter will be disabled. The power-down counter is enabled and starts counting.

6.6.2.8 Interrupt

The WDOG has the feature of Interrupt generation before timeout.

The interrupt will be generated only if the WIE bit in Watchdog Interrupt Control Register (WDOG_WICR) is set. The exact time at which the interrupt should occur (prior to timeout) depends on the value of WICT field of Watchdog Interrupt Control Register (WDOG_WICR). For example, if the WICT field has a value 0x04, then the interrupt will be generated two seconds prior to timeout. Once the interrupt is triggered the WTIS bit in Watchdog Interrupt Control Register (WDOG_WICR) will be set. The software needs to clear this bit to deassert the interrupt. If the WDOG is serviced before the interrupt generation then the counter will be reloaded with the timeout value WT[7:0] of Watchdog Control Register (WDOG_WCR) and interrupt would not be triggered.

6.6.2.9 Flow Diagrams

A flow diagram of WDOG operation is shown below.

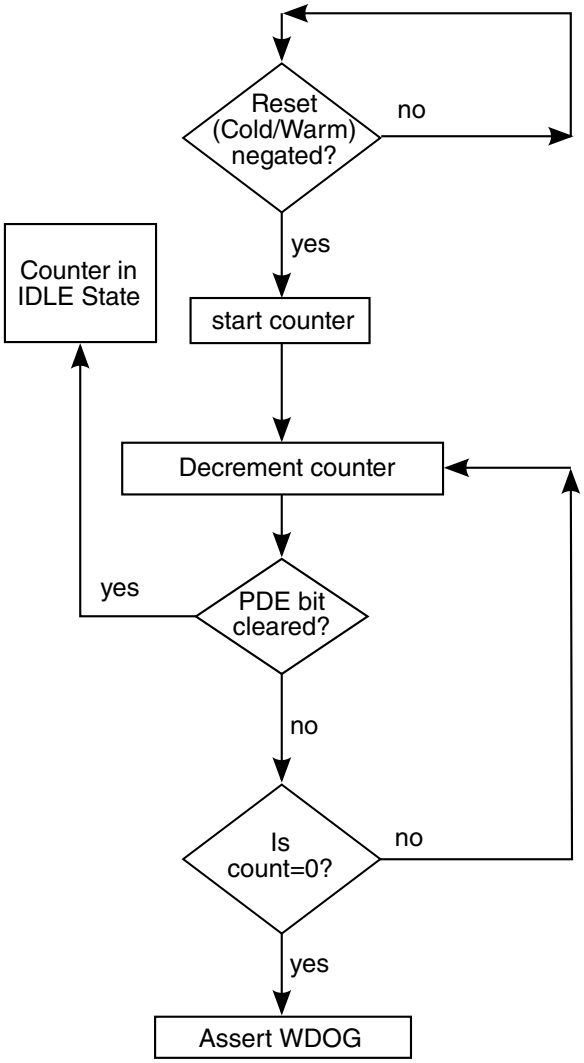

Figure 6-40. Power-Down Counter Flow Diagram

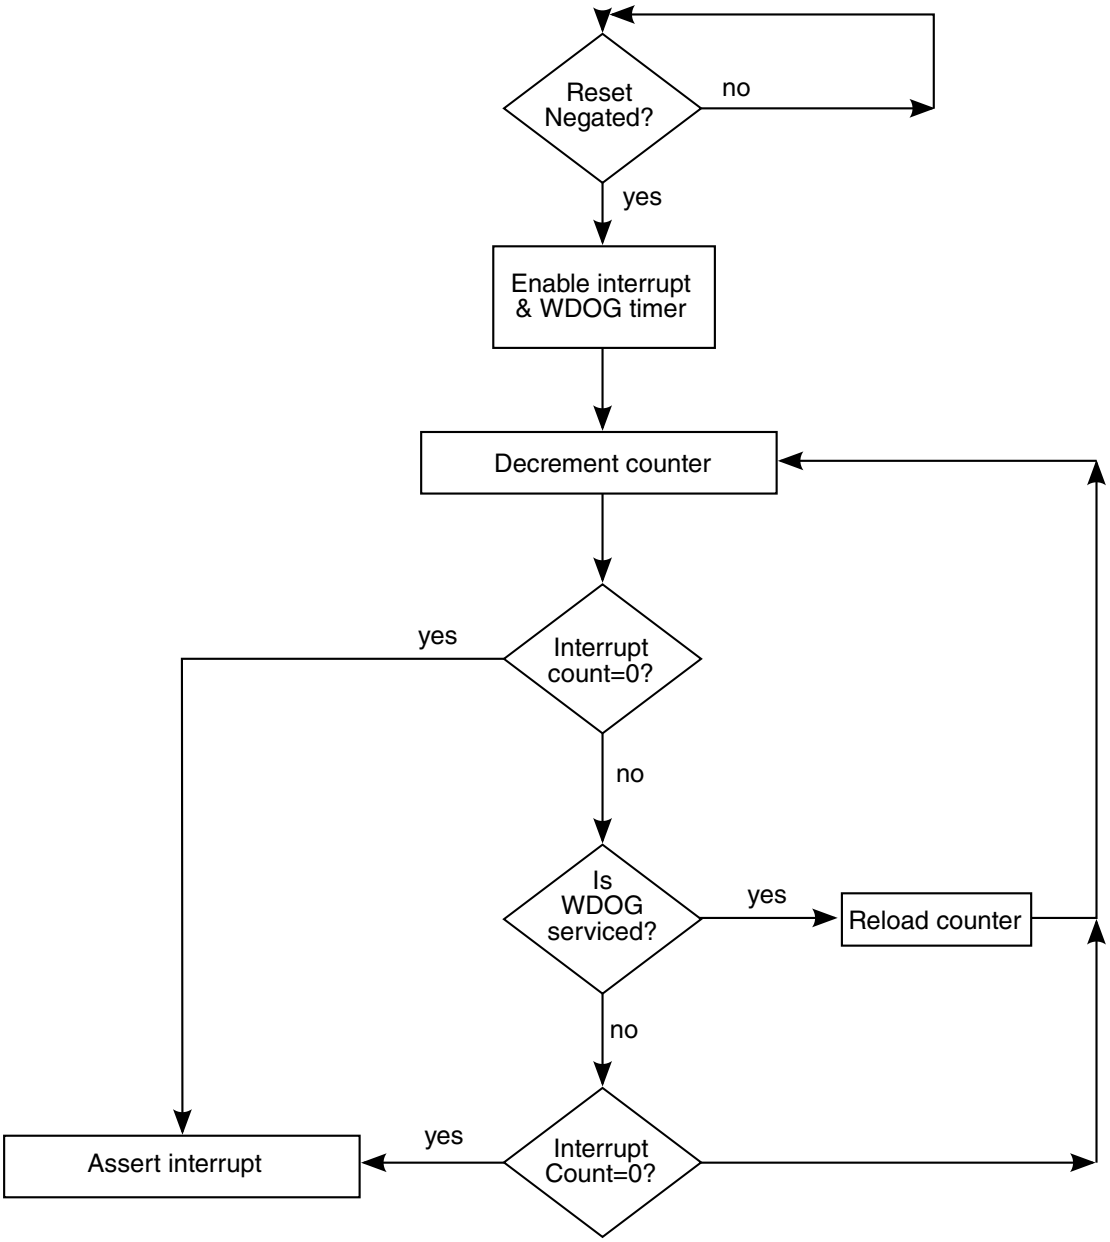

Figure 6-41. Interrupt Generation Flow Diagram

6.6.3 Initialization

The following sequence should be performed for WDOG initialization.

- PDE bit of Watchdog Miscellaneous Control Register (WDOG_WMCR) should be cleared to disable the power down counter.

- WT field of Watchdog Control Register (WDOG_WCR) should be programmed for sufficient timeout value.
- WDOG should be enabled by setting WDE bit of Watchdog Control Register (WDOG_WCR) so that the timeout counter loads the WT field value of Watchdog Control Register (WDOG_WCR) and starts counting.

6.6.4 WDOG Memory Map/Register Definition

The WDOG Memory Map/Register Definition can be found here.

The WDOG has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed,the WDOG will not generate a peripheral bus error but will behave normally, like a 16-Bit access, making read/write possible. A 32-Bit access should be avoided, as the system may go to an unknown state.

WDOG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3028_0000	Watchdog Control Register (WDOG1_WCR)	16	R/W	0030h	6.6.4.1/ 956

6.6.4.1 Watchdog Control Register (WDOGx_WCR)

The Watchdog Control Register (WDOG_WCR) controls the WDOG operation.

- WDZST, WDBG and WDW are write-once only bits. Once the software does a write access to these bits, they will be locked and cannot be reprogrammed until the next system reset assertion.
- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next system reset.
- WDT is also a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next POR. This bit does not get reset/ cleared due to any system reset.

Address: Base address + 0h offset

Bit	15	14	13	12	11	10	9	8
Read Write	WT							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	WDW	SRE	WDA	SRS	WDT	WDE	WDBG	WDZST
Reset	0	0	1	1	0	0	0	0

WDOGx_WCR field descriptions

Field	Description
15–8 WT	Watchdog Time-out Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter. **NOTE:** The time-out value can be written at any point of time but it is loaded to the counter at the time when WDOG is enabled or after the service routine has been performed. For more information see Timeout event .

Table continues on the next page...

WDOGx_WCR field descriptions (continued)

Field	Description
	0x00 - 0.5 Seconds (Default). 0x01 - 1.0 Seconds. 0x02 - 1.5 Seconds. 0x03 - 2.0 Seconds. 0xff - 128 Seconds.
7 WDW	Watchdog Disable for Wait. This bit determines the operation of WDOG during Low Power WAIT mode. This is a write once only bit. 0 Continue WDOG timer operation (Default). 1 Suspend WDOG timer operation.
6 SRE	Software Reset Extension. Required to be set to 1 when used in conjunction with the Software Reset Signal (SRS). 0 Reserved 1 This bit must be set to 1.
5 WDA	WDOG_B assertion. Controls the software assertion of the WDOG_B signal. 0 Assert WDOG_B output. 1 No effect on system (Default).
4 SRS	Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal WDOG_RESET_B_DEB. This bit automatically resets to 1 after it has been asserted to 0. For proper operation of this function, the SRE bit in this register must be set to 1. **NOTE:** This bit does not generate the software reset to the block. 0 Assert system reset signal. 1 No effect on the system (Default).
3 WDT	WDOG_B Time-out assertion. Determines if the WDOG_B gets asserted upon a Watchdog Time-out Event. This is a write-one once only bit. **NOTE:** There is no effect on WDOG_RESET_B_DEB (WDOG Reset) upon writing on this bit. WDOG_B gets asserted along with WDOG_RESET_B_DEB if this bit is set. 0 No effect on WDOG_B (Default). 1 Assert WDOG_B upon a Watchdog Time-out event.
2 WDE	Watchdog Enable. Enables or disables the WDOG block. This is a write one once only bit. It is not possible to clear this bit by a software write, once the bit is set. **NOTE:** This bit can be set/reset in debug mode (exception). 0 Disable the Watchdog (Default). 1 Enable the Watchdog.
1 WDBG	Watchdog DEBUG Enable. Determines the operation of the WDOG during DEBUG mode. This bit is write once only. 0 Continue WDOG timer operation (Default). 1 Suspend the watchdog timer.
0 WDZST	Watchdog Low Power. Determines the operation of the WDOG during low-power modes. This bit is write once-only. **NOTE:** The WDOG can continue/suspend the timer operation in the low-power modes (STOP and DOZE mode).

Table continues on the next page...

WDOGx_WCR field descriptions (continued)

Field	Description
	0 Continue timer operation (Default). 1 Suspend the watchdog timer.

6.6.4.2 Watchdog Service Register (WDOGx_WSR)

When enabled, the WDOG requires that a service sequence be written to the Watchdog Service Register (WSR) to prevent the timeout condition.

NOTE

Executing the service sequence will reload the WDOG timeout counter.

Address: Base address + 2h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	WSR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOGx_WSR field descriptions

Field	Description
WSR	Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows: 0x5555 Write to the Watchdog Service Register (WDOG_WSR). 0xAAAA Write to the Watchdog Service Register (WDOG_WSR).

6.6.4.3 Watchdog Reset Status Register (WDOGx_WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Read access to this register is with one wait state. Any write performed on this register will generate a Peripheral Bus Error .

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

Address: Base address + 4h offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	0			POR	0		TOUT	SFTW
Write								
Reset	0	0	0	0	0	0	0	0

WDOGx_WRSR field descriptions

Field	Description
15–5 Reserved	This read-only field is reserved and always has the value 0.
4 POR	Power On Reset. Indicates whether the reset is the result of a power on reset. 0 Reset is not the result of a power on reset. 1 Reset is the result of a power on reset.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1 TOUT	Timeout. Indicates whether the reset is the result of a WDOG timeout. 0 Reset is not the result of a WDOG timeout. 1 Reset is the result of a WDOG timeout.
0 SFTW	Software Reset. Indicates whether the reset is the result of a WDOG software reset by asserting SRS bit 0 Reset is not the result of a software reset. 1 Reset is the result of a software reset.

6.6.4.4 Watchdog Interrupt Control Register (WDOGx_WICR)

The WDOG_WICR controls the WDOG interrupt generation.

Address: Base address + 6h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	WIE	WTIS	0						WICT							
Write		w1c														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

WDOGx_WICR field descriptions

Field	Description
15 WIE	Watchdog Timer Interrupt enable bit. Reset value is 0.

Table continues on the next page...

WDOGx_WICR field descriptions (continued)

Field	Description
	NOTE: This bit is a write once only bit. Once the software does a write access to this bit, it will get locked and cannot be reprogrammed until the next system reset assertion 0 Disable Interrupt (Default). 1 Enable Interrupt.
14 WTIS	Watchdog Timer Interrupt Status bit will reflect the timer interrupt status, whether interrupt has occurred or not. Once the interrupt has been triggered software must clear this bit by writing 1 to it. 0 No interrupt has occurred (Default). 1 Interrupt has occurred
13–8 Reserved	This read-only field is reserved and always has the value 0.
WICT	Watchdog Interrupt Count Time-out (WICT) field determines, how long before the counter time-out must the interrupt occur. The reset value is 0x04 implies interrupt will occur 2 seconds before time-out. The maximum value that can be programmed to WICT field is 127.5 seconds with a resolution of 0.5 seconds. **NOTE:** This field is write once only. Once the software does a write access to this field, it will get locked and cannot be reprogrammed until the next system reset assertion. 0x00 WICT[7:0] = Time duration between interrupt and time-out is 0 seconds. 0x01 WICT[7:0] = Time duration between interrupt and time-out is 0.5 seconds. 0x04 WICT[7:0] = Time duration between interrupt and time-out is 2 seconds (Default). 0xff WICT[7:0] = Time duration between interrupt and time-out is 127.5 seconds.

6.6.4.5 Watchdog Miscellaneous Control Register (WDOGx_WMCR)

WDOG_WMCR Controls the Power Down counter operation.

Address: Base address + 8h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0															PDE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

WDOGx_WMCR field descriptions

Field	Description
15–1 Reserved	This read-only field is reserved and always has the value 0.
0 PDE	Power Down Enable bit. Reset value of this bit is 1, which means the power down counter inside the WDOG is enabled after reset. The software must write 0 to this bit to disable the counter within 16 seconds of reset de-assertion. Once disabled this counter cannot be enabled again. See Power-down counter event for operation of this counter. **NOTE:** This bit is write-one once only bit. Once software sets this bit it cannot be reset until the next system reset.

Table continues on the next page...

WDOGx_WMCR field descriptions (continued)

Field	Description
	0 Power Down Counter of WDOG is disabled. 1 Power Down Counter of WDOG is enabled (Default).

Chapter 7
Interrupts and DMA

7.1 Interrupts and DMA Events

7.1.1 Overview

This chapter provides the interrupt assignments of the ARM domain in A53 Interrupts, CM4 interrupts, and the DMA events in SDMA event mapping

7.1.2 A53 Interrupts

The Global Interrupt Controller (GIC) collects up to 128 interrupt requests from all the chip sources and provides an interface to the Cortex A53 CPU.

Each interrupt can be configured as a normal or a secure interrupt. Software force registers and software priority masking are also supported. The following table describes the A53 interrupt sources.

Table 7-1. ARM Domain Interrupt Summary

IRQ	Module	Logic	Interrupt Description
0	boot	-	Used to notify cores on exception condition while boot
1	dap	-	DAP Interrupt
2	sdma1	-	AND of all 48 SDMA1 interrupts (events) from all the channels
3	gpu3d	-	GPU3D Interrupt
4	snvs_lp_wrapper	OR	ON-OFF button press shorter than 5 secs (pulse event)
4	snvs_hp_wrapper	OR	ON-OFF button press shorter than 5 secs (pulse event)
5	lcdif	-	LCDIF Interrupt
6	spdif1	OR	SPDIF Rx interrupt

7.1.3 CM4 interrupts

The Nested Vectored Interrupt Controller (NVIC) collects up to 128 interrupt requests from all chip sources and provides an interface to the Cortex M4 Core.

The following table describes the M4 interrupt sources.

Table 7-2. CM4 Interrupt Summary

IRQ	Module	Logic	Interrupt Description
0	GPR_IRQ_IRQn	-	Used to notify cores on exception condition while boot.
1	dap	-	DAP Interrupt
2	sdma1	-	AND of all 48 SDMA1 interrupts (events) from all the channels
3	gpu3d	-	GPU3D Interrupt
4	snvs_lp_wrapper	OR	ON-OFF button press shorter than 5 secs (pulse event)

Table continues on the next page...

Table 7-2. CM4 Interrupt Summary (continued)

IRQ	Module	Logic	Interrupt Description
4	snvs_hp_wrapper	OR	ON-OFF button press shorter than 5 secs (pulse event)
5	lcdif	-	LCDIF Interrupt
6	spdif1	OR	SPDIF Rx interrupt
6	spdif1	OR	SPDIF Tx interrupt
7	vpu	-	VPU G1 Decoder Interrupt
8	vpu	-	VPU G2 Decoder Interrupt
9	qos	-	QOS Interrupt
10	wdog3	-	Watchdog Timer reset
11	hs	-	HS Interrupt Request
12	apbhdma	OR4	GPMI operation channel 0 description complete interrupt
12	apbhdma	OR4	GPMI operation channel 1 description complete interrupt

7.2 Smart Direct Memory Access Controller (SDMA)

7.2.1 Overview

The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by off-loading the Arm core in dynamic data routing.

7.2.1.1 Block Diagram

The figure below shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units, and the scheduler.

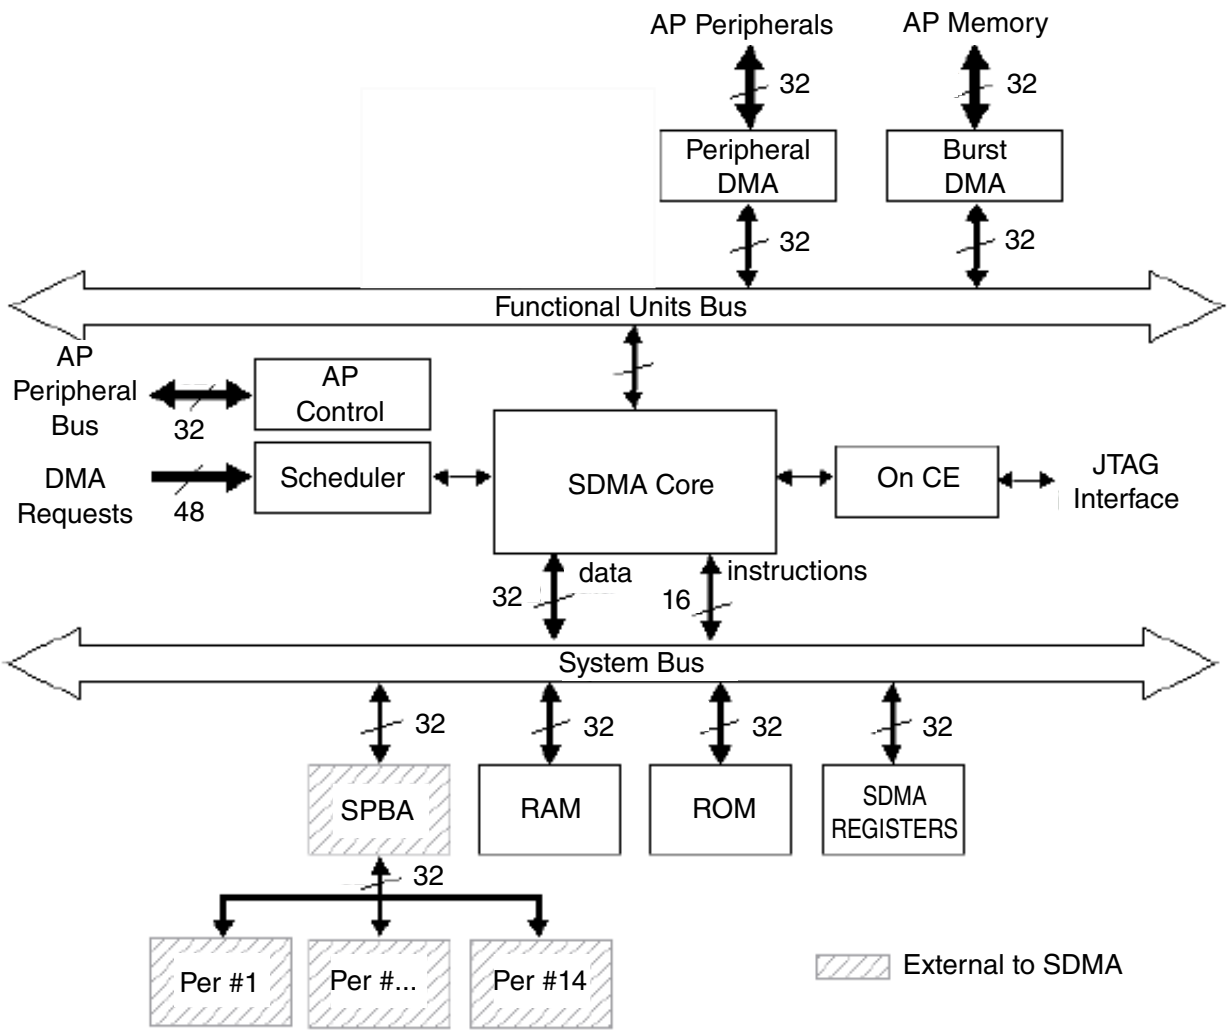

Figure 7-1. SDMA Block Diagram

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in Instruction Memory Map and Data Memory Map).

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the Arm platform. Every channel contains a corresponding channel script located in RAM and/or ROM that can be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to "conditionally yield" the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two yield instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (yieldge), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the "Channel Pending (EP)" register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The Arm platform control block contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This block also contains all other control registers that the Arm platform can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The "receive register full" and "transmit register empty" signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

7.2.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with two-level, priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
  - Auto-flush and prefetch capability
  - Flexible address management (increment, decrement, and no address changes on source and destination address)
  - Misaligned data-transfer support
  - Uni-directional and bi-directional flows (copy mode)
  - Up to eight-word buffers for configurable burst transfers
- Support of byte-swapping
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-Kbyte ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-Kbyte RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
  - Configurable clock options for the SDMA core and the Arm platform DMA units
    - 1:2 ratio with maximum of SDMA core running at Arm platform Peripheral Bus speed and DMA running at max DMA frequency.
    - 1:1 ratio when both SDMA core and Arm platform DMA clocks are set to the Arm platform Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the Arm platform

- The SDMA RISC engine (arithmetic and logic operations), which is referred to as the "SDMA core."
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.
- The peripheral DMA unit that is hooked-up to the Arm platform Crossbar Switch to service Arm peripherals
- The burst DMA unit is able to perform burst accesses to the external memory
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

7.2.2 Functional Description

The figure below shows the SDMA topology, and is composed of the following components:

- SDMA Core (SDMA Core)
- SDMA Scheduler (Scheduler)
- Functional Units:
  - Burst DMA (Burst DMA Unit)
  - Peripheral DMA (Peripheral DMA Unit)
- Arm platform Control for Arm control register access.
- Internal RAM and ROM Memory (SDMA Programming Model)
- OnCE debug Port (The OnCE Controller)

The functional unit bus provides access by the SDMA core to the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

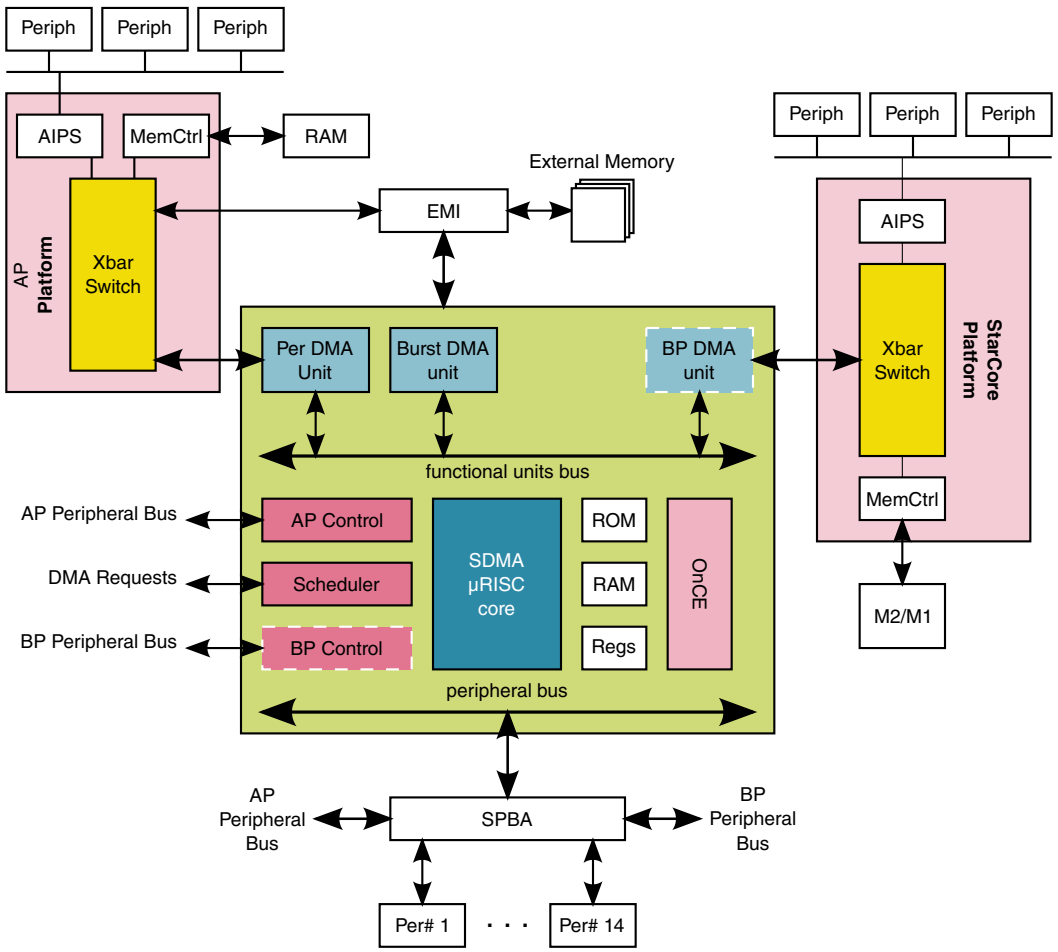

Figure 7-2. SDMA Connections

7.2.2.1 SDMA Core

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing.

The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

7.2.2.1.1 SDMA Core Structure

The figure found here shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

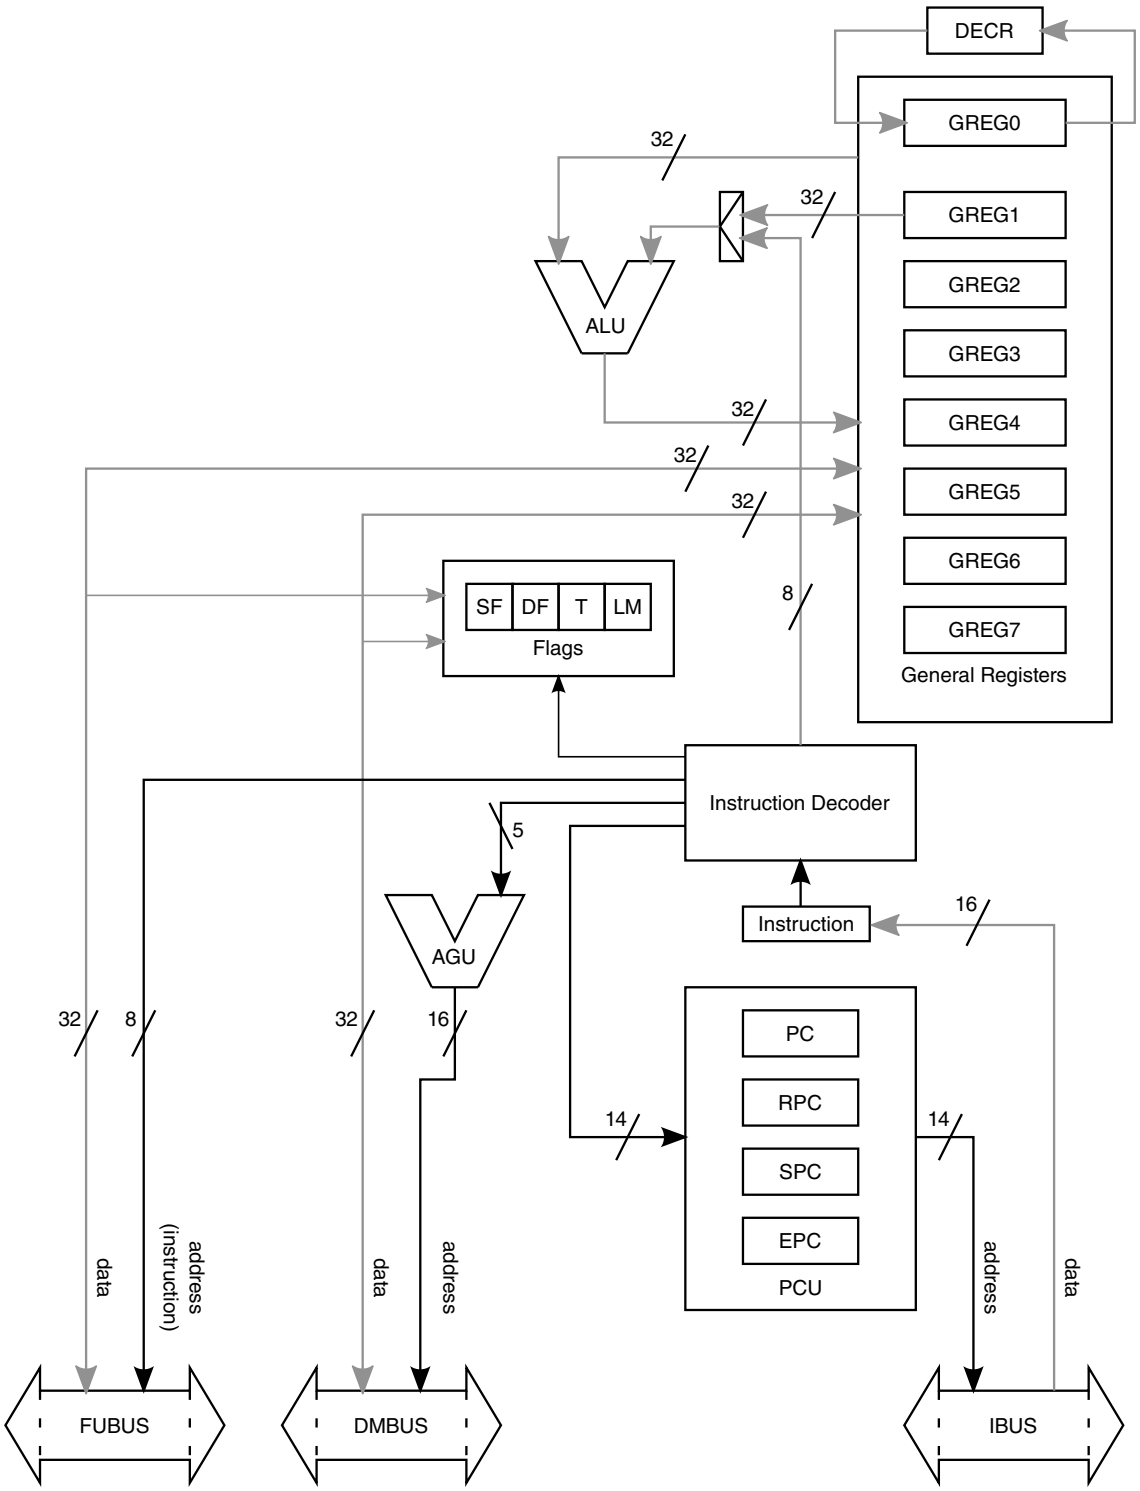

Figure 7-3. SDMA Core

- The Program Control Unit (PCU) is described in Program Control Unit (PCU). It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA

core instruction register prior to their decoding. The PCU contains the following registers:
    - The Program Counter (PC) contains the address of the current instruction.
    - The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
    - The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
    - End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.
- The other core registers are the general purpose registers (GREGn) and the flags.
    - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
    - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in Figure 7-3.
    - The flags reflect the status of operations:
        - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
        - LM is set when the core is executing instructions inside a hardware loop.
        - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register's contents into itself (For example, the instruction: mov R0,R0).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that

are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).
- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

7.2.2.1.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine, as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA.

It contains the PC, RPC, SPC, and EPC registers that are described in SDMA Core Structure.

7.2.2.1.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. Standard: Most of the instructions belong to this category, and always last 1 cycle.
2. ldf/stf: These are respectively the load and store instructions that access the functional units. They last 1+n cycles where n is the number of wait-states of the targeted functional unit.
3. ld/st: These are the load and store instructions that access the memory and peripherals. They last 1+n cycles where n is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. Branch: These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. Loop,Modified Load or Store: The hardware loop instruction modifies the potential behavior of any load or store inside the loop (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the ld/st/ldf/stf original execution delay). Although there is usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.

6. Done: The done, yield, or yieldge instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in Context Switching).

7.2.2.1.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see Real-Time Debug Outputs) or the OnCE status register(see OnCE Status Register (OSTAT)).

The PCU state is a four-bit field that can take the values shown in the following table. Figure 7-4 shows the possible state transitions and the corresponding conditions.

Table 7-5. PCU States

Value	State	Description
0	Program	This is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	The SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in Channel 0 Boot Address (SDMAARM_CHN0ADDR)).
15	Restore	The context switch FSM is restoring the next channel context.

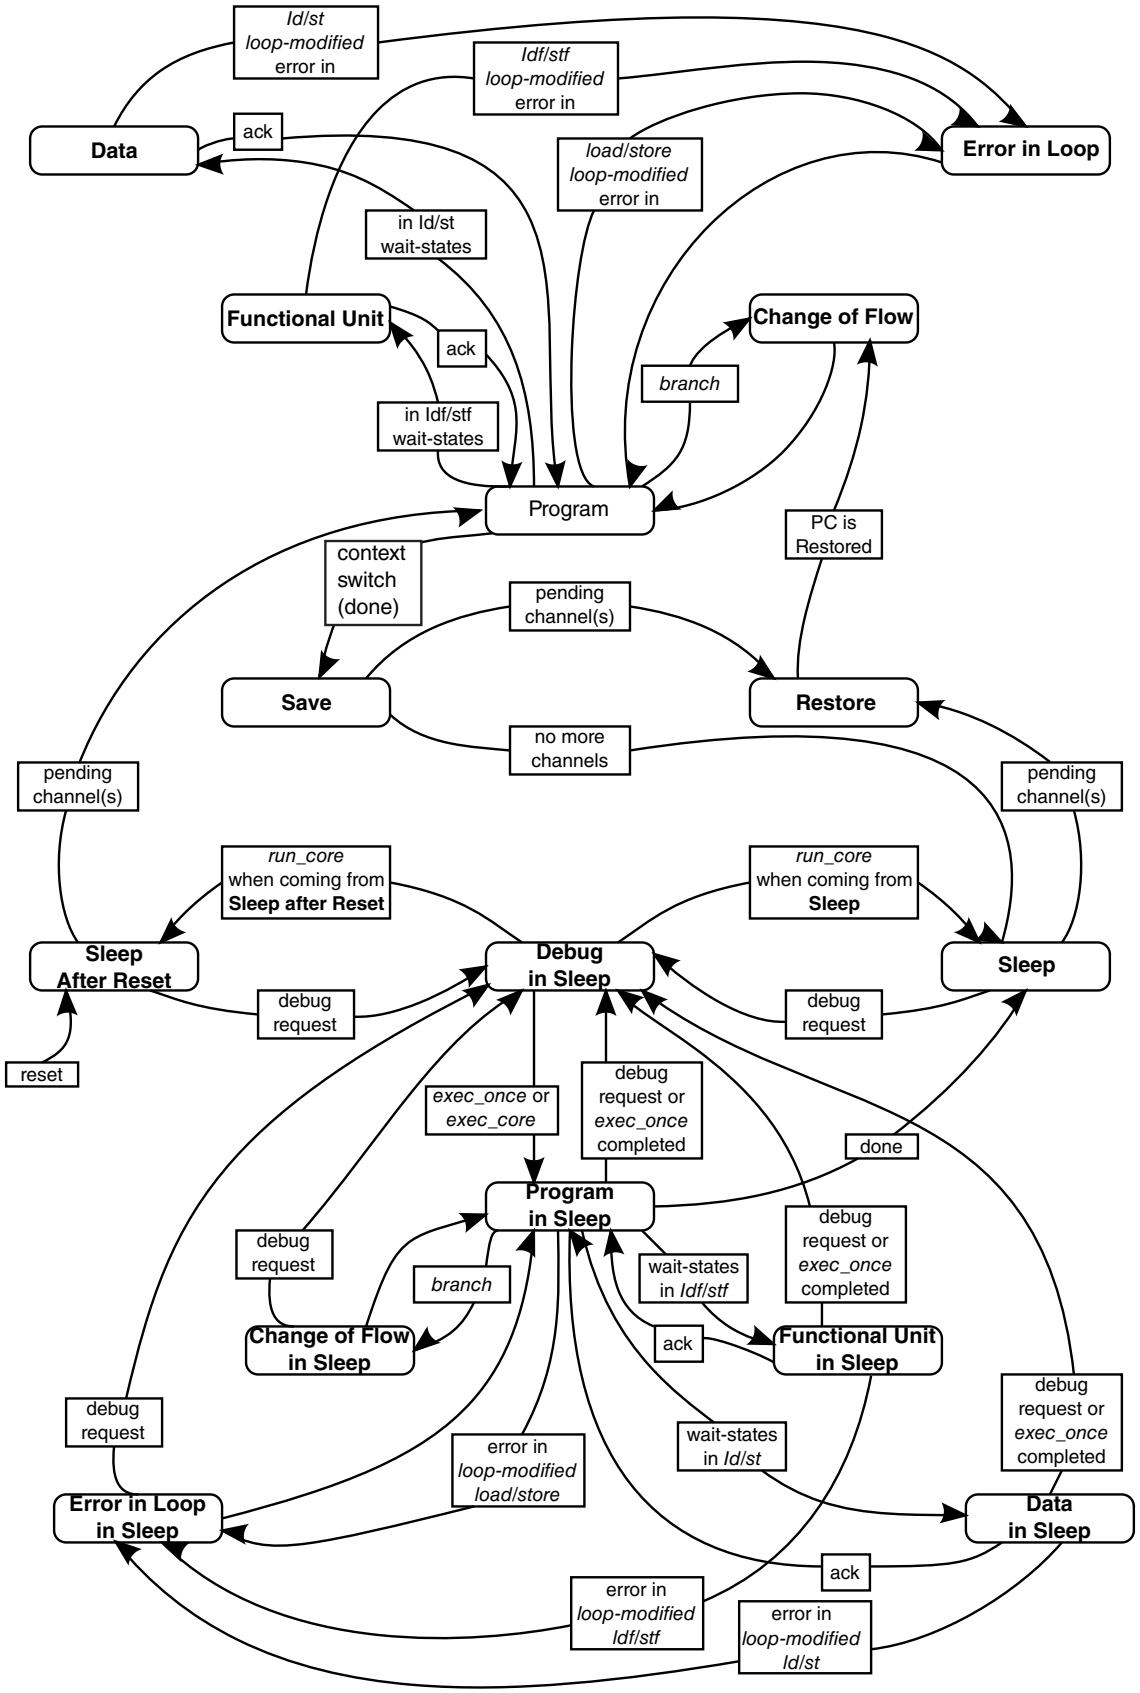

Figure 7-4. PCU State Diagram

7.2.2.1.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write.

Program and data memory is further described in Address Space.

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

7.2.2.2 Scheduler

All channel scheduling hardware is included in the Scheduler.

7.2.2.2.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority.

The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service
- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

7.2.2.2.2 Channels and DMA Requests

7.2.2.2.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional.

The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the Arm platform software.

7.2.2.2.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

7.2.2.2.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels).

The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event.

Every channel also has a three-bit register that indicates its priority.

7.2.2.2.3 Scheduler Functional Description

Scheduler Overview describes the behavior of the SDMA scheduler-from the channel enabling conditions to the highest priority pending channel selection.

7.2.2.2.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the Arm platform to control its behavior.

The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top priority and its associated channel, and selects the next active channel when the current channel yields.

The following figure shows a functional overview.

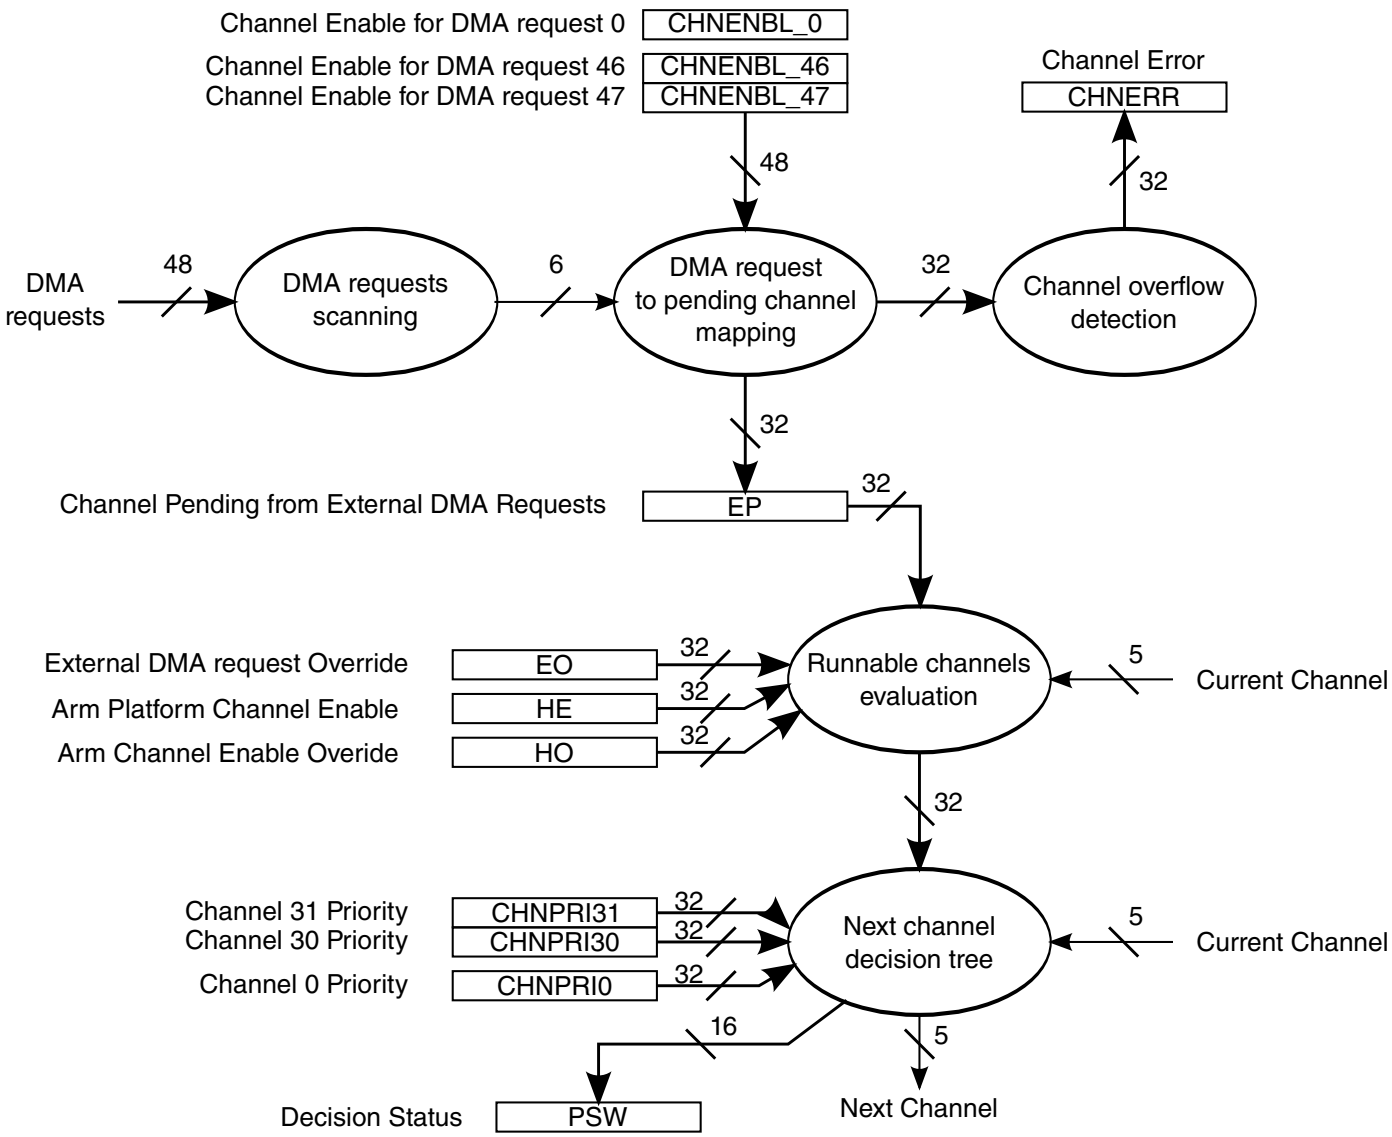

Figure 7-5. SDMA Hardware Scheduler

7.2.2.2.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage.

The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

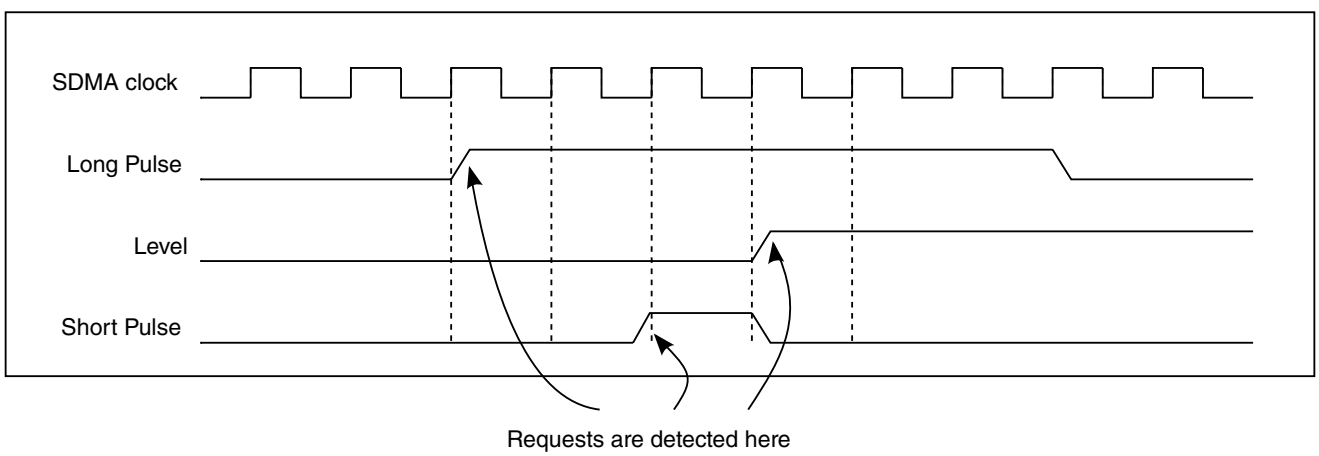

Figure 7-6. Examples of Valid DMA Requests

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

7.2.2.2.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated.

This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by the following equation:

EP = EP or CHNENBLn

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. The following table illustrates an example configuration.

NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

7.2.2.2.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel *n* by setting bit *n* of the register EP, but this bit is already set, meaning channel *n* is already pending. This can come from an overrun/underrun condition.

This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the Arm platform when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

7.2.2.2.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable.

Registers EO, DO, HO and HE, are controlled by the Arm platform. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The i^{th} channel is runnable if (and only if) the condition below is true:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i])

The registers in these equations are controlled as follows:

- Arm platform (host) channel enable flag HE[i] may be set or cleared by the Arm platform with the HSTART and STOP_STAT registers. It can also be cleared by the i^{th} channel script.

  Typical usage is for the Arm platform to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.

- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i^{th} channel script.
- The Arm platform channel override flag HO[i] may be set or cleared by the Arm platform. When set, it enables the i^{th} channel to run without the involvement of the Arm platform.

  Typical usage is for the Arm platform to set this flag for channels that do not need Arm platform supervision such as channels that are controlled by DMA request events (EP).

- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the Arm platform. When set, it prevents the i^{th} channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of a done or notify instruction. The done instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the notify instruction does not. The done and notify instructions can clear either HE[i] or EP[i] (never more than one at a time).

Table 7-7. Runnable Channel Selection Control

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register

Table continues on the next page...

Table 7-7. Runnable Channel Selection Control (continued)

Register	Set by	Cleared By
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the done or notify instructions.
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the done or notify instructions

7.2.2.2.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities.

It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a yield, yieldge, or done instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority.

The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a yield, not a yieldge), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a yield(ge) or a done instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the following table. The grayed cells correspond to unusual cases that should not occur with a typical usage of the SDMA.

Table 7-8. Channel Switching Decision with a yield, yield(ge), or done

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yield (done 0)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next[1]

Table continues on the next page...

Table 7-8. Channel Switching Decision with a yield, yield(ge), or done (continued)

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the Arm platform)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the Arm platform)
yieldge (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next[1]
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the Arm platform)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the Arm platform)
done (done>1)	Not runnable	Not runnable	none	none[2]
	Runnable	Not runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next[1]
	Runnable	Runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)

1. Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes
2. Current channel context is saved and SDMA enters IDLE mode
3. Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in Scheduler Pipeline Timing Diagram.

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since 24 > 13.
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.
- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a yieldge; it is preempted by channel 29. After a period of time, channel 29 runs a yieldge, it is then preempted by channel 23 that is the selected channel since channel 29 is the current channel. Later, channel 23 runs a yieldge and is preempted by channel 29. Channels 23 and 29 will go on switching after every yieldge until one of them terminates. It is only at that point that channel 7 becomes eligible again.
- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a yield instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a yield and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number 11 < 18).

7.2.2.2.3.7 Scheduler State Diagram

The Figure 7-7 summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in Scheduler Pipeline Timing Diagram.

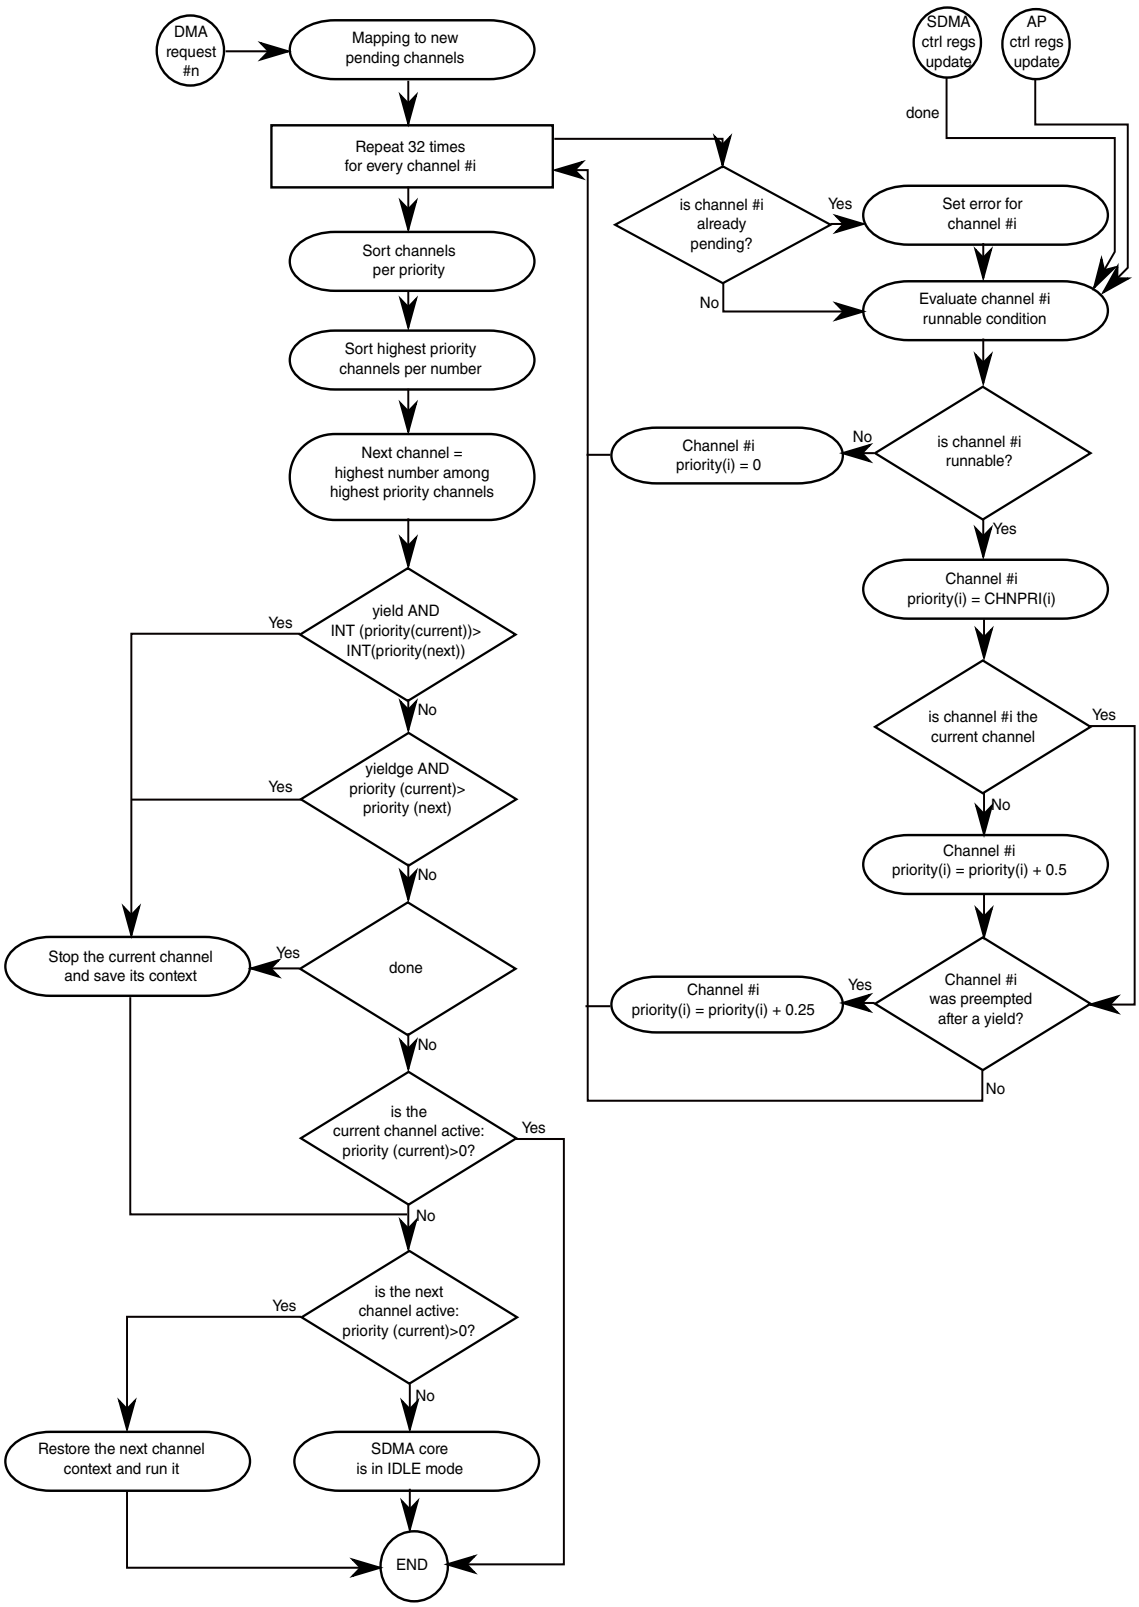

Figure 7-7. Scheduler State Diagram

7.2.2.2.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate.

The figure below shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

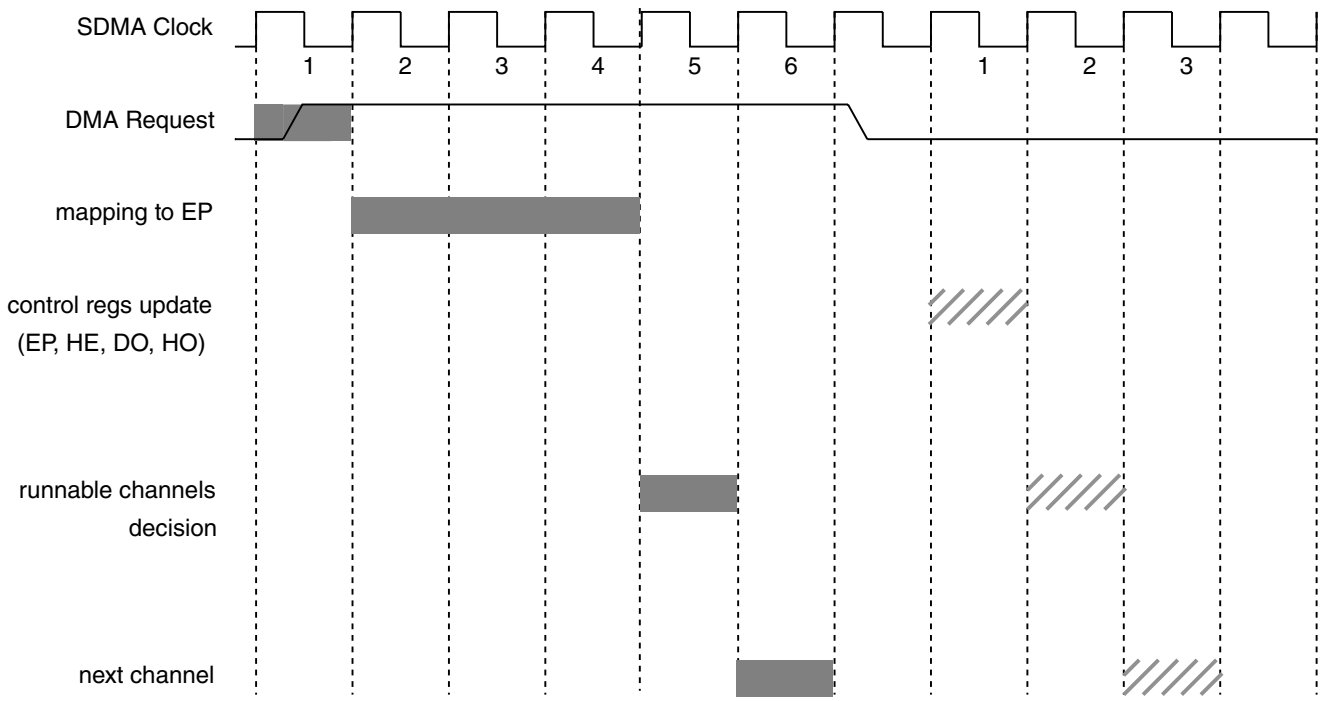

Figure 7-8. Scheduler Timing Diagram

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a done instruction or the Arm platform with a write access through the corresponding control port on their respective peripheral bus).

7.2.2.2.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. Refer to the respective chapters for this information.

7.2.2.2.3.10 Examples: How to Start a Channel

A channel can be started when the following equation is true for channel *i*:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by Arm platform software:
   - Initially, configure HO[i]=0, DO[i]=1, and EO[i]=1 using registers indicated in Table 7-7.
   - Arm platform software triggers the channel by writing to the HSTART register to set HE[i]=1, thereby setting the above equation true.
2. To start a channel triggered by DMA request event.
   - Initially, configure HO[i]=1, DO[i]=1, and EO[i]=0 using registers indicated in Table 7-7.
   - The DMA request is asserted to trigger the channel by setting EP[i]=1, which makes the above equation true.

7.2.2.2.4 Context Switching

On execution of a done or yield(ge) instruction, the current channel may be changed either because it has finished (which necessarily happens when the done instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the yield(ge) is executed).

Upon a channel change the SDMA goes through a context switch procedure.

When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in Context Switching-Programming and Table 7-13. There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total RAM

space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

7.2.2.2.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the Arm platform in the CONFIG control register.

The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)-which leaves very few registers to save when the switch is decided-resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.
- In a "static" context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootload

channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

7.2.2.2.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the Arm platform.

The context switch procedure is as follows:

1. Load the current context's spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

   On a done or yield(ge) that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.

3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

   As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

   Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a done or yield(ge) instruction. That means the current channel cannot be modified by the Arm platform, even if it is no more runnable or if its priority is modified.

   The Arm platform can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a done instruction. That feature should only be used to stop the SDMA in emergency cases.

4. Load the context base-address of the new channel.

   In "static" mode, all the registers are restored. In either "dynamic" modes, only the PCU registers are restored.

   The new channel is running. In "static" mode, no more activity regarding context restoring or saving is performed. In either "dynamic" modes, the registers are restored in the background every time an access to the context RAM is possible, and

priority is given to restoring the registers that are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In "dynamic" and "dynamic with no loop" modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In "dynamic" and "dynamic with no loop" modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In "dynamic power" and "static" modes, the contents of the context RAM remain unchanged until the channel terminates with a done or gets preempted.

7.2.2.2.4.3 Context Map in Memory

Refer to Context Switching-Programming.

7.2.2.3 Functional Units

The functional units are small systems that are used by the SDMA core to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units' registers via the FUBUS. This is done with the ldf and stf instructions.

The following sections provide introductions to the available functional units. Functional Units Programming Model provides descriptions the functional units' behaviors.

7.2.2.3.1 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the Arm platform memory.

It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the Arm platform memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the Arm platform memory at once or twice the SDMA core frequency
- Copy data from one Arm platform memory location to another Arm platform memory location at the Arm platform bus speed, which provides a very high throughput
- Control the method for addressing the Arm platform memory (automatic increment of addresses or frozen addresses-the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the Arm platform memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the Arm platform memory. Or, it forces a flush when a data transfer must terminate.
- In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the Arm platform memory.

  In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the Arm platform memory. This error status is retrieved by a later access to the burst DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the Arm platform memory is caught.

- Handle address alignment issues between the Arm platform memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding Arm platform address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the Arm platform memory space.

This unit structure and registers are described in Burst DMA Structure and Burst DMA Registers.

7.2.2.3.1.1 Burst DMA Structure

The burst DMA is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

The burst DMA is depicted in the figure below.

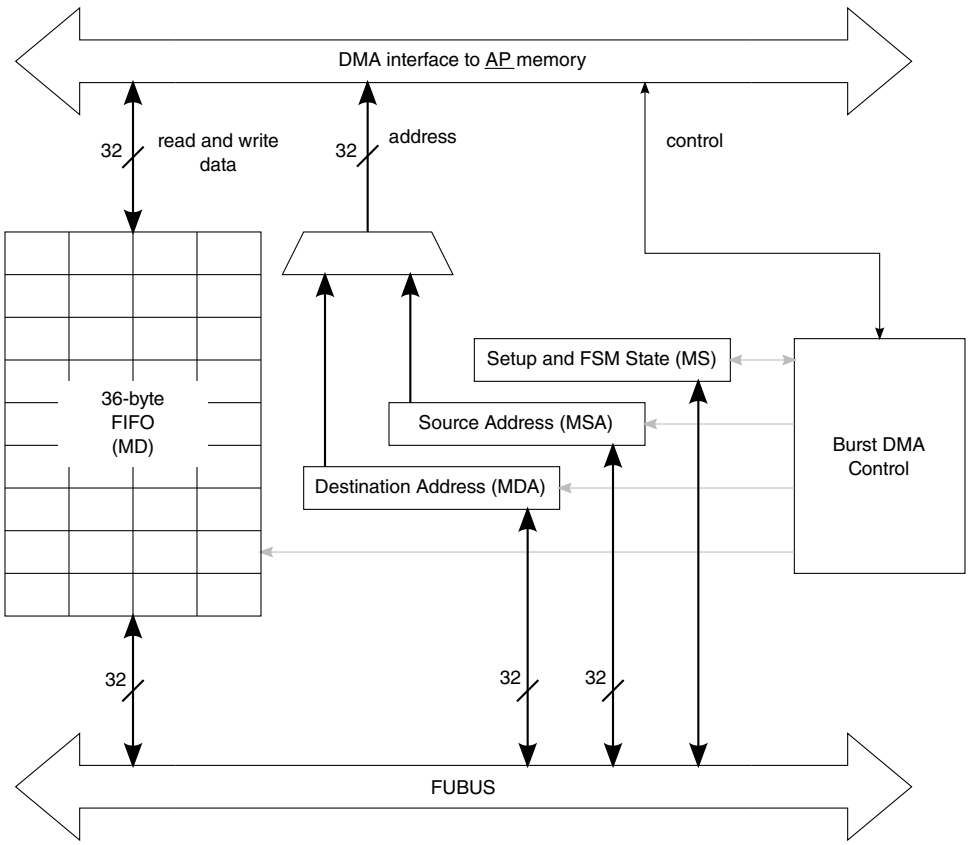

Figure 7-9. Burst DMA Structure

7.2.2.3.1.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- MSA (Memory Source Address) - Holds the source byte address in the Arm platform memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- MDA (Memory Destination Address) - Holds the destination byte address in the Arm platform memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.
- MD (Memory Data) - Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the

FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the Arm platform memory).

- When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the Arm platform memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to Arm platform memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

  Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the Arm platform memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the Arm platform memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to Arm platform memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- MS (Memory Setup) - Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

7.2.2.3.1.3 Burst DMA Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both.

Every case requires a different procedure, as listed in the following sections:

7.2.2.3.1.3.1 Data Retrieval from the Arm platform Memory

The following steps retrieve data from Arm platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from Arm platform memory, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

7.2.2.3.1.3.2 Storing Data Into the Arm platform Memory

The following steps store data from Arm platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).
- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the Arm platform memory and the error status of the transfer is available in the DF flag.

7.2.2.3.1.3.3 Transferring Data Between Two Arm platform Memory Locations-Burst DMA Unit

The following steps copy data between two Arm platform memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

7.2.2.3.2 Peripheral DMA Unit

The peripheral DMA unit is the second functional unit that connects the SDMA to the Arm platform memory.

Unlike the burst DMA, it does not support burst transfers and is optimized for accessing peripherals. It does not provide control to assign a privilege level to the DMA access. Its feature list comprises the following:

- Access to the Arm platform peripherals or memory at once or twice the SDMA core frequency

- Data copy from one Arm platform memory location to another Arm platform memory location at memory bus speed, improving throughput
- Control of the method for addressing the Arm platform memory (automatic increment or decrement of addresses or frozen addresses, the first ones aimed at accessing RAM-like memory and the last one aimed at accessing single-address FIFOs)
- Selectable automatic prefetch when reading data from the Arm platform memory. In prefetch mode, the peripheral DMA automatically fetches another data-without waiting for the SDMA core to request it-when its data register is empty, which improves the throughput
- Selectable automatic flush. In this mode, the SDMA core may only be stalled when it tries writing data and the previous write operation is not finished yet; whereas, in forced flush mode, the core is stalled until the data is effectively written to the Arm platform memory.
- In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the Arm platform memory or the peripheral. This error status is retrieved by a later access to the peripheral DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the Arm platform memory has been caught.

This unit structure and registers are described in Peripheral DMA Structure and Peripheral DMA Registers.

7.2.2.3.2.1 Peripheral DMA Structure

The peripheral DMA is made up of a 32-bit data register, two address registers, and a controlling state-machine. The state-machine manages clock adaptation, when required.

It is shown in the following figure.

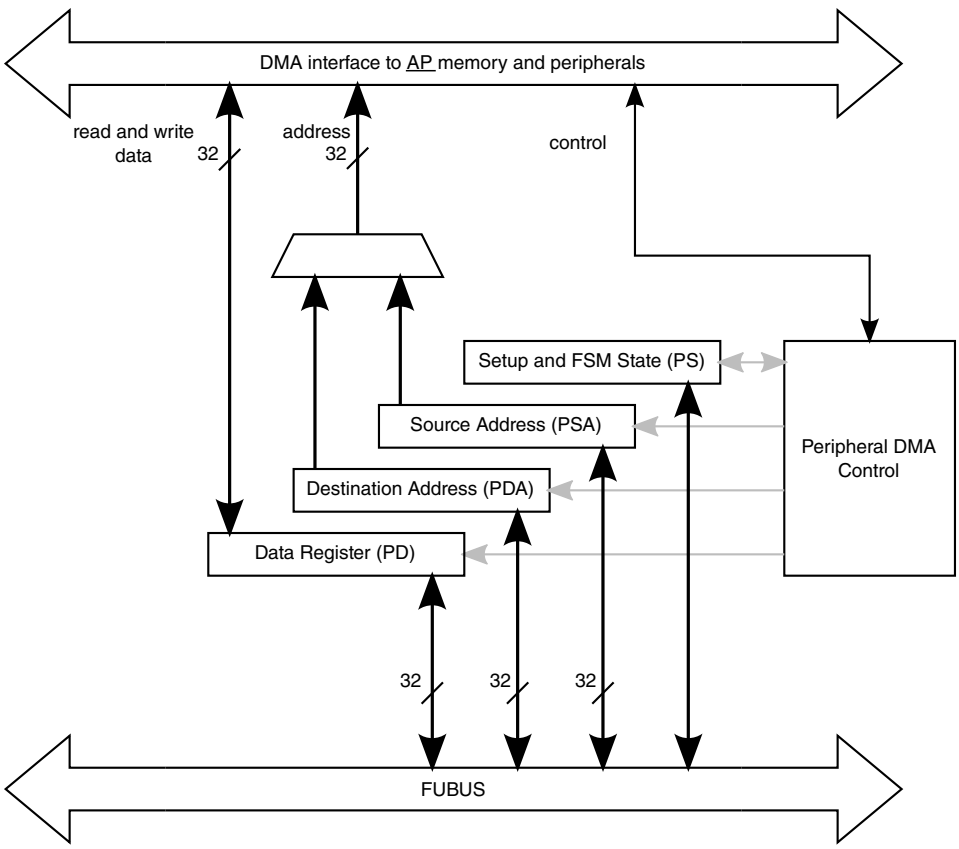

Figure 7-10. Peripheral DMA structure

7.2.2.3.2.2 Peripheral DMA Registers

According to Figure 7-10, the peripheral DMA has four registers that may be read or written by the SDMA core:

- *PD (Peripheral Data)* is the DMA 32-bit data register.
- *PSA (Peripheral Source Address)* holds the source byte address in the Arm platform memory map for reading data from this location. This register is automatically modified every time the core reads a new data from PD.

- *PDA (Peripheral Destination Address)* holds the destination byte address in the Arm platform memory map for writing data to this location. This register is automatically modified every time the core writes a new data into PD.
- *PS (Peripheral Setup)* contains the state of the peripheral DMA control, two configuration fields that define the way address registers are modified after every data access, two additional configuration fields that define the data size to access the source and destination devices, and another field that contains the latest transfer error status.

7.2.2.3.2.3 Peripheral DMA Data Transfers

There are three typical usages that involve the peripheral DMA, whether it is the data transfer start-point, endpoint, or both.

Every case requires a different procedure, as described in Data Retrieval from the Arm platform Memory or Peripheral, Storing Data into the Arm platform Memory or Peripheral, and Transferring Data Between Two Arm platform Memory Locations-Peripheral DMA Unit.

7.2.2.3.2.3.1 Data Retrieval from the Arm platform Memory or Peripheral

The following steps retrieve data from Arm platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the source (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the source address register itself (PSA) with an address that is aligned to the programmed data size.
- Read data from PD using the ldf PD instruction as many times as needed. If an error occurs during the fetch from the Arm platform memory or peripheral, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from PD.

7.2.2.3.2.3.2 Storing Data into the Arm platform Memory or Peripheral

The following steps store data to Arm platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the destination (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the destination address register itself (PDA) with an address that is aligned to the programmed data size.

- Store data into PD using the *stf PD* instruction as many times as needed.
- When the transfer is finished and if the peripheral DMA worked in automatic flush mode, force the flush of PD. This instruction is stalled until PD contents are effectively sent to the Arm platform memory or peripheral, and the error status of the transfer is available in the DF flag.

7.2.2.3.2.3.3 Transferring Data Between Two Arm platform Memory Locations-Peripheral DMA Unit

The following steps copy data between two Arm platform memory locations using the peripheral DMA unit:

- Set up the PS fields to reflect the modes and data size for the source and destination addresses (all the combinations of addressing modes are possible, but both data sizes must be identical), then initialize the source address register (PSA) and the destination address register (PDA). Both addresses must be aligned with the programmed data size.
- Use as many *stf PD* instructions with the *COPY* flag as needed. Every instruction triggers a single read from the source address; a single write of the received data immediately follows. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the peripheral DMA to check the error status.

7.2.2.4 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The Arm platform loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in Locked Mode.

7.2.2.4.1 Locked Mode

The LOCK bit in the SDMA_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM.

After initial RAM contents are uploaded, Arm platform software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a '1', the SDMA is "locked" until reset.

The LOCK bit can be read in the SDMA's internal memory map in the LOCK register (see Section SDMA LOCK (SDMAARM_SDMA_LOCK)). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation (see SDMA Scripts).

While SDMA is locked, attempts to write to the SDMA_LOCK, CHN0ADR, ILLINSTADDR, and ONCE_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET_LOCK_CLR bit in the SDMA_LOCK register is set. Since SDMA_LOCK register cannot be updated if SDMA is locked, the SRESET_LOCK_CLR bit must be configured before setting the LOCK bit. The SREST_LOCK_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE_ENB register cannot be written to prevent the OnCE under Arm platform control from being used to gain access to SDMA internal memory. If Arm platform control of the OnCE is enabled before setting the LOCK bit, the Arm platform can use the ONCE for debug purpose after LOCK is set.

7.2.2.5 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions.

Refer to Figure 7-4 for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a SoftBkpt instruction from the channel script or receive a debug request. When either happens, the SDMA enters its "Classical" *Debug* state, which is described in OnCE and Real-Time Debug.
- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the exec_core instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a SoftBkpt is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. The following table summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in OnCE and Real-Time Debug.

Table 7-9. SDMA in Debug Mode

Instruction	Debug	Debug in Sleep
exec_once	exec_once <instruction> SDMA executes the <instruction> and returns to the *Debug* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.	exec_once <instruction> SDMA executes the <instruction> and returns to the *Debug in Sleep* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.
run_core	run_core <instruction> SDMA executes the <instruction>, leaves the *Debug* state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.	run_core <instruction> SDMA executes the <instruction> and returns to its *Sleep* or *Sleep after Reset* initial state. This command must not be used with an instruction that modifies the PC value.
exec_core	exec_core <instruction> It is similar to run_core except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the *Debug* state and starts executing instructions from this new PC value.	exec_core <instruction> If the previous state was *Sleep after Reset*, the SDMA returns to this state, and Chn0Addr value overrides the PC value. Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.

NOTE

The feature exec_core in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC

value. The SDMA will be ready to boot at the Chn0Addr address.

7.2.2.6 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller block and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA.

Root clock control is available from the SoC clock controller block.

There are numerous clock sources that are used in the SDMA. They belong to one of two possible clock domains listed in the following table, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the Arm platform/SDMA clock domain, all clocks must come from the same DPLL. The Arm platform DMA interfaces (peripheral DMA and burst DMA) receive their clock from the Arm platform DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the Arm platform DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum Arm platform DMA frequency, the SDMA core clock is tied to the Arm platform peripheral clock frequency.

The Arm platform Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

Table 7-10. Clocking Scheme

Clock Domain	Source Clock	Comments
Arm platform	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-blocks.
	Arm platform DMA	DMA interface for the peripheral DMA and the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	Arm platform peripheral	Connection to the Arm platform peripheral bus. It is a sub-frequency of the main clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the JTAG interface works properly when the frequency of TCK is lower than $1/8^{th}$ of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

7.2.2.6.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

7.2.2.6.1.1 Coarse Clock Gating

Every sub-block clock comes from one of the five available sources, and is gated with the sub-block specific enabling condition.

The following table displays the sub-block clocks and their source. It also indicates the relationships that may exist between different sub-blocks clock enables.

Table 7-11. Sub-blocks Clocks

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-block clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-block clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-block clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-block clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the Arm platform modifies the channel running conditions.	None
Arm platform Control	SDMA Main Core & Arm platform peripheral	The Arm platform peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on *SDMA main clock*; it is active when the Arm platform or the SDMA modifies the contents of one of these registers.	None
Burst DMA	SDMA Main Core & Arm platform DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the Arm platform DMA clock and drives registers that are connected to the Arm platform DMA bus outside the SDMA. Both clocks are enabled	Disabled when Core sub-block clock is disabled

Table continues on the next page...

Table 7-11. Sub-blocks Clocks (continued)

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
		during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	
Peripheral DMA	SDMA Main Core & Arm platform DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the Arm platform DMA clock and drives registers that are connected to the Arm platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the Arm platform peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to Synchronization Implementation.	When enabled, all other clocks are systematically on (clock gating is off)

7.2.2.6.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis.

Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

7.2.2.6.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG.

The following table describes these modes, and shows how to switch from one mode to another.

Table 7-12. Power Modes

Power Mode	Sub-blocks							Comments
	Core	Memories	Scheduler	Arm platform Control	Burst DMA	Peripheral DMA	OnCE	
SLEEP	off[1]	off	wait[2]	wait	off	off	off	Set when the PCU state is either *Sleep* or *Sleep after Reset* and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on[3]	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: *Program*, *Data*, *Change of Flow*, *Error in Loop*, *Debug*, *Functional Unit*, *Save,* or *Restore*.
DEBUG	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either *clk_gating_off* pin high or ONCE_ENB[0] set).

1. *off*: no clock
2. *wait*: only clocked when accessed or stimulated
3. *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in SLEEP Mode.

7.2.2.6.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode.

However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in Stop Mode Response.

7.2.2.6.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

7.2.2.6.1.3.3 DEBUG Mode

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA.

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

7.2.2.6.1.4 Stop Mode Response

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode.

If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMAs clocks can be turned off.

7.2.2.6.2 Reset

After reset (either received from the reset block or a software reset required by the Arm platform), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated.

Activating a channel can be done by the Arm platform after programming a positive priority and setting the channel bit in the EVTPEND register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes

7.2.2.7 Software Interface

Appendix A fully describes the SDMA Application Programming Interface (API).

7.2.2.8 Initialization Information

This section discusses the following:

- Hardware Reset
- Channel Script Execution
- Initialization and Script Execution Setup Sequence

7.2.2.8.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents.

The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The Arm platform will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the Arm platform first creates some channel control blocks (CCB) and buffer descriptors (BD) in Arm platform memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (SDMA_MC0PTR) to the address of the first control block. Data Structures for Boot Code and Channel Scripts provides an overview of the data structure for the CCB and BD's. The SDMA_HSTART, SDMA_HOSTOVR and SDMA_EVTOVR registers are then configured according to Runnable Channels Evaluation to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (SDMA_CHN0ADDR) in the program memory. The reset value of SDMA_CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (SDMA_MC0PTR) to determine the location of the Channel Control Block (SDMA_CCB) in Arm platform memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its Arm platform Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the SDMA_CHN0ADDR register in the Arm platform programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

7.2.2.8.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters allowed to the buffer. All these items must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the Arm platform by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The Arm platform selects which trigger conditions that must occur for the channel to start by configuring the SDMA_CHNENBL, SDMA_HOSTOVR and SDMA_EVTOVR registers. The trigger events include Arm platform setting HE (SDMA_HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can become active according to its priority compared with other runnable channels when the selected trigger(s) cause the condition described in Runnable Channels Evaluation to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to SDMA Scripts for complete script documentation. Buffer Descriptor Format provides an overview of the buffer descriptor format.

7.2.2.8.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and SDMA_CHNENBLn registers have unpredictable contents after this reset.
- Initialize SDMA_CHNENBLn registers to map DMA request events to desired channels.

- Configure SDMA_CHNPRIn registers to select priority for runnable channels. A non-zero priority is required for the channel to run.
- Configure the SDMA_CONFIG register to select DMA to SDMA core clock ratio .
- Set up channel control blocks and buffer descriptors in Arm platform to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference Data Structures for Boot Code and Channel Scripts.
- Configure SDMA_MC0PTR register with base address of Arm platform Channel Control Block base address.
- Initialize SDMA_CHNENBLn registers to map DMA request events to associated channel. Reference Mapping DMA Requests to Pending Channels.
- Configure SDMA_CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure SDMA_HOSTOVR (HO) and SDMA_EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference Runnable Channels Evaluation.
- Set bit 0 of the SDMA_HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] andDO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_SDMA_INTR register, or by optional interrupt to the Arm platform.
- Set the LOCK bit in the SDMA_SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scripts can now be run by enabling the selected software or hardware trigger event according to Runnable Channels Evaluation.

7.2.2.9 SDMA Programming Model

This section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the Arm platform memory maps. The Arm platform processor has no access to any hardware resource described, except when those resources are described in Arm Platform Memory Map and Control Register Summary. .

7.2.2.9.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time.

This chapter lists the components of every channel state.

7.2.2.9.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the loop instruction, but otherwise can be used for any purpose.

7.2.2.9.3 Functional Unit State

Each channel context has some state that is part of the functional units.

The specific allocation of this state is part of the functional unit definition that is described in Burst DMA Unit Programming, Peripheral DMA Unit Programming .

This state must be saved/restored on context switches.

7.2.2.9.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction.

A low order bit of zero selects the most significant half of the word.[1]

7.2.2.9.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.
- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (CLRF and loop). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.

1. For example, big-Endian.

- Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

  The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the loop instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.

- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the loop instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch Greg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

7.2.2.9.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions.

Instructions are available to transfer its contents to and from a general register.

7.2.2.9.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the loop instruction to the location immediately following it.

7.2.2.9.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the loop instruction to the location of the next instruction after the loop.

7.2.2.9.4 Context Switching-Programming

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units.

The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode (Context Switching), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a done or yield(ge) instruction, SDMA goes into "real" context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel *i* is *CONTEXT_BASE* + 24**i* or *CONTEXT_BASE* + *32*i w*here CONTEXT_BASE equals 0x0800. The table below presents the layout of a channel context in memory:

Table 7-13. Layout of a Channel Context in Memory for SDMA

7.2.2.9.5 Address Space

The SDMA has four internal buses which are listed here.

- The Instruction bus reads instructions from the memory. Its address map is described in Instruction Memory Map.
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in Data Memory Map.
- The Functional Units bus (FUBUS) accesses the , Burst DMA, Peripheral DMA . The addressing mechanism is further detailed in Functional Units Programming Model.
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and

otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

7.2.2.9.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus.

Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a jmp to handle routines.

Table 7-14. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Block Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	-	0	4 Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	-	0	8 Kbyte internal RAM with channels context and user data/routines.

7.2.2.9.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA.

This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)
- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the Arm platform)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GReg*n*). The mapping between the general purpose register contents and the address bus is given in the following table:

Table 7-15. GReg*n* to DMBUS Address Mapping

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 7-16. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbyte	4 Kbyte internal ROM with boot code and standard routines
Reserved	0x0400 → 0x07FF	4 Kbyte	4 Kbyte Reserved

Registers	0x7000 → 0x7FFF	16 Kbyte	Memory mapped registers
per7	0x8000 → 0x8FFF	16 Kbyte	*peripheral 7* memory space (4 Kbyte peripheral's address space)
per8	0x9000 → 0x9FFF	16 Kbyte	*peripheral 8* memory space (4 Kbyte peripheral's address space)
per9	0xA000 → 0xAFFF	16 Kbyte	*peripheral 9* memory space (4 Kbyte peripheral's address space)
per10	0xB000 → 0xBFFF	16 Kbyte	*peripheral 10* memory space (4 Kbyte peripheral's address space)
per11	0xC000 → 0xCFFF	16 Kbyte	*peripheral 11* memory space (4 Kbyte peripheral's address space)
per12	0xD000 → 0xDFFF	16 Kbyte	*peripheral 12* memory space (4 Kbyte peripheral's address space)
per13	0xE000 → 0xEFFF	16 Kbyte	*peripheral 13* memory space (4 Kbyte peripheral's address space)
per14	0xF000 → 0xFFFF	16 Kbyte	*peripheral 14* memory space (4 Kbyte peripheral's address space)

7.2.2.10 SDMA Initialization

Appendix A describes the setup of the SDMA . This section provides a quick description of several initialization procedures.

NOTE

There may be differences with the actual implementation in the API.

7.2.2.10.1 Hardware Reset-SDMA

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content.

The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

7.2.2.10.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register-detailed in Configuration Register (SDMAARM_CONFIG)-to determine the Arm platform DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (seeChannel Enable RAM (SDMAARM_CHNENBL*n*)).
3. Program the channel control registers-Channel Event Override (SDMAARM_EVTOVR), Channel BP Override (SDMAARM_DSPOVR), Channel BP Override (SDMA_HOSTOVR), and Channel Event Pending (SDMAARM_EVTPEND)-according to the channel allocation.
4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A).
5. Trigger channel 0 with the Channel Start (SDMAARM_HSTART) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

7.2.2.10.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the Configuration Register (SDMAARM_CONFIG)Channel Enable RAM (SDMAARM_CHNENBL*n*), Channel Event Override (SDMAARM_EVTOVR), Channel BP Override (SDMAARM_DSPOVR), Channel Arm platform Override (SDMAARM_HOSTOVR), and Channel Event Pending (SDMAARM_EVTPEND).

2. Use the OnCE (either via its JTAG interface or its Arm platform control registers) to download any code in the SDMA RAM. Accessing the Memory describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in Channel 0 Boot Address (SDMAARM_CHN0ADDR). (This register default address points to the standard boot script.)

7.2.2.10.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The Arm platform manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the Arm platform via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the Arm platform can enable any channel that becomes active and begins fetching and executing instructions from its script.

7.2.2.11 Instruction Description

The following sections introduce the instruction of the SDMA.

Instruction set details are available in Instruction Set.

7.2.2.11.1 Scheduling Instructions

The following are scheduling instructions:

- done-The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The done 5 has a special usage reserved for debug, as explained in Debug Instructions.

- yield-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.
- yieldge-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- notify-The notify instruction affects the scheduling bits, but does not cause rescheduling.

7.2.2.11.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied.

Otherwise, control passes to the next sequential instruction.

- BF-Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- BT-Branch if True. The branch is taken if the T bit in the processor status is one (true).
- BSF-Branch if Source Fault. The branch is taken if the SF bit in the processor status is one.
- BDF-Branch if Destination Fault. The branch is taken if the DF bit in the processor status is one.

7.2.2.11.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer.

Absolute transfers have a 14-bit address field that replaces the current PC.

- JMP-Jump. Causes the processor to jump to an absolute address encoded in the instruction itself.
- JSR-Jump to Subroutine. Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.

- JMPR-Jump through Register. Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- JSRR-Jump to Subroutine through Register. Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

7.2.2.11.4 Subroutine Return Instructions

The following are subroutine return instructions:

- RET-Return from Subroutine. The RET restores the contents of RPC to PC.
- LDRPC-Load from RPC to Register. THe LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

7.2.2.11.5 Loop Instruction

The following is a loop instruction:

LOOP-Enters Loop Mode. Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

7.2.2.11.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- CLRF-Clear Fault Flags. This instruction clears any combination of SF and DF.
- MOV r,s-This moves data from GReg[s] to GReg[r].
- LDI r,immediate-This loads GReg[r] with a zero-extended immediate value.

7.2.2.11.7 Logic Instructions

The following are logic instructions:

- XORr,s-This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- XORIr,immediate-This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- ORr,s-This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].

- ORIr,immediate-This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- ANDNr,s-This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- ANDNIr,immediate-This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- ANDr,s-This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- ANDIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

7.2.2.11.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- ADD r,s-This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- ADDI r,immediate-This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- SUB r,s-This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- SUBIr,immediate-This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

7.2.2.11.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- CMPEQ r,s-This sets T when registers GReg[r] and GReg[s] are equal.
- CMPEQIr,immediate-This sets T when register GReg[r] and the zero-extended immediate value are equal.
- CMPLTr,s-This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- CMPHS r,s-This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

7.2.2.11.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- TSTr,s-This performs an and between GReg[r] and GReg[s], and sets T if the result is not zero.
- TSTIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and sets T if the result is not zero.

7.2.2.11.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3, b_2, b_1, b_0.

- RORBr-The rotate right byte. The result is b_0, b_3, b_2, b_1.
- REVBr-The reverse bytes in word. The result is b_0, b_1, b_2, b_3.
- REVBLOr-The reverse, two low-order bytes. The result is b_3, b_2, b_0, b_1.

7.2.2.11.12 Bit Shift Instructions

The following are bit shift instructions:

- ROR1r-The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- LSR1r-The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- ASR1r-The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- LSL1r-The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

7.2.2.11.13 Bit Manipulation Instructions

- BCLRIr,n-The bit clear is immediate; clears bit number *i* in register *r*.
- BSETIr,n-The bit set is immediate; sets bit number *i* in register *r*.
- BTSTIr,n-The bit test is immediate; tests bit number *i* in register *r* (T becomes equal to the selected register bit).

7.2.2.11.14 SDMA Memory Access Instructions

All memory accesses are 32 bits.

Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s.

All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault.

What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- LDr,(b,d)-The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- STr,(b,d)-The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

7.2.2.11.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus.

Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See Functional Units Programming Model.

There are two functional unit instructions, as follows:

- LDFr,fub-The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- STFr,fub-The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

7.2.2.11.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR) register (the default value is 0x0001).

ILLEGAL-Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

7.2.2.11.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT-The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug block only.
- done 5-This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in Saving the Context.
- CpShReg-This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in Restoring the Context.

7.2.2.12 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus.

Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in the following table. In order to establish a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 7-17. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit Programming	SDMSA	Memory Source Address Register	Memory Source Address Register (MSA)
	MDA	Memory Destination Address Register	Memory Destination Address Register (MDA)
	MD	Memory Data Buffer Register	Memory Data Buffer Register (MD)

Table continues on the next page...

Table 7-17. Functional Unit Registers (continued)

Functional Unit	Register	Register Name	Section/Page
			(Write) Burst DMA Write (stf) (Read) Burst DMA Read (ldf)
	MS	Memory State Register	State Register (MS)
Peripheral DMA Unit Programming	PSA	Peripheral Source Address Register	Peripheral Source Address Register (PSA)
	PDA	Peripheral Destination Address Register	Peripheral Destination Address Register (PDA)
	PD	Peripheral Data Buffer Register	Peripheral Data Register (PD) (Write) Peripheral DMA Write (stf)-Write Mode (Read) Peripheral DMA Read (ldf)-Read Mode
	PS	Peripheral State Register	Peripheral State Register (PS)

More information regarding the functional units can be found in Peripheral DMA Unit, and Burst DMA Unit.

7.2.2.12.1 Burst DMA Unit Programming

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus.

There are four registers associated with the burst DMA unit: a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS). The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

7.2.2.12.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EXTMC memory associated with the next read data transfer. It has byte granularity.

Reading the register with the ldf instruction has no side effects, and gives the address value in the EXTMC memory of the next data that is read by the SDMA during an ldf MD instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen-In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)-In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

7.2.2.12.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EXTMC memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the ldf instruction has no side effects. It gives the address value in the EXTMC memory where the next SDMA data (stf r,MD instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen-In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)-The MDA register is incremented by the number of bytes transferred during write cycles.

7.2.2.12.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO.

This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode).

The MD register is in write mode after a writing in MDA or after an stf MD instruction.

In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EXTMC controller are based on burst accesses.

An ldf r,MD|SIZE instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An stf r,MD|SIZE instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EXTMC (reading or writing), no immediate error is possible because the block manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EXTMC memory mapping. The only potential error, in this mode, would be the error sent back by the EXTMC controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in Burst DMA Unit Error Management.

7.2.2.12.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

Table 7-18. SDMA_MS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																

Table 7-19. SDMA_MS Field Descriptions

Field	Description
31-22	Reserved

Table continues on the next page...

Table 7-19. SDMA_MS Field Descriptions (continued)

Field	Description
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen-MSA is not modified. 1 Incremented-MSA is incremented by the number of transferred bytes during read access.
19-18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16 dtype	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses. 0 Frozen-MDA is not modified. 1 Incremented-MDA is incremented by the number of transferred bytes during write access.
15-12	Reserved
11 y	Conditional Yielding selector. When selected, theyield/yieldge instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by stf MD instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an ldf MD instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 error read burst
7-6	Reserved
5-0 n	Number of bytes in the MD FIFO.

7.2.2.12.1.5 Burst DMA Write (stf)

When received from a stf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 7-20. STF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy			sz	
MS								

Table 7-21. STF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value

Table continues on the next page...

Table 7-21. STF Code Bit Field Descriptions (continued)

Field	Description
	1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in the table below (unused bits should always be cleared).

Table 7-22. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.
00_0_1_00_00	stf r,MSA|FR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSA|PF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.
00_1_1_00_00	stf r,MSA|PF|FR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDA|FR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MD|SZ0|FL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MD|SZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MD|SZ8|FL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MD|SZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MD|SZ16|FL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MD|SZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MD|SZ32|FL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MD|CPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of *r* register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MS|SZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as clref MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the stf r,MD instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an ldf from MS before terminating a channel in order to check the final error status. (The ldf from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every stf MD instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

7.2.2.12.1.6 Burst DMA Read (ldf)

When received from an ldf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 7-23. LDF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD			p				sz	
MS								

Table 7-24. LDF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MD)	Prefetch Flag 0 no prefetch 1 automatic prefetch

Table continues on the next page...

Table 7-24. LDF Code Bit Field Descriptions (continued)

Field	Description
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The table below lists the possible write instructions (unused bits should always be cleared).

Table 7-25. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an ldf MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MD|SZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MD|SZ8|PF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MD|SZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MD|SZ16|PF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MD|SZ32	32-bit (word) read
00_1_0_10_11	ldf r,MD|SZ32|PF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

7.2.2.12.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed.

When the RISC core requires a prefetch (p = 1) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32'nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an stf MD|SZ8 is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an stf MD|SZ16 is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an stf MD|SZ32 is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.

- Therefore, if an stf MD|SZ32 is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (stf) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

  For example, consider the case where data is written using a byte access, stf MD| SZ8. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.
- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EXTMC controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush (which occurs only at the beginning of a misaligned write transfer) no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

7.2.2.12.1.8 Data Alignment and Endianness-Burst DMA Unit

7.2.2.12.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). The following table shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 7-26. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

7.2.2.12.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. The following table shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 7-27. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww x0 x1 x2 x3 ?? ?? ?? ??
01	tt uu vv ww xx ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	10	tt uu vv ww xx x0 ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	11	tt uu vv ww xx x0 x1 ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	01	tt uu vv ww xx x0 x1 x2 x3 ?? ?? ??
10	tt uu vv ww xx yy ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	11	tt uu vv ww xx yy x0 ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	00	tt uu vv ww xx yy x0 x1 ?? ?? ?? ??
		sz32	x0 x1 x2 x3	10	tt uu vv ww xx yy x0 x1 x2 x3 ?? ??
11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0

Table continues on the next page...

Table 7-27. FIFO Write Configuration (continued)

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
					x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an ldf MD is executed after stf MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a stfMD|SZ0|FL instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

7.2.2.12.1.8.3 Endianness-Burst DMA Unit

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian.

Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

7.2.2.12.1.9 Burst DMA Unit Copy Mode

A mechanism is available to perform fast Arm-to-Arm transfers.

Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag).

It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an stf MD|CPY is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)-given by the SDMA general register (4 LSB)-is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Burst DMA copy mode example

```
          ldi r0,@src
          stf r0,MSA                          // Source address setup
          ldi r1,@dst
          stf r1,MSA                          // Destination address setup
          ldi r0,0x64                         // data transfer counter
          ldi r1,0x8
MAIN_XFER:
          cmphs r0,r1                         // Is r0 >= 0x8
          bf LAST_XFER                      // If not, jump to last transfer label
          stf r1,MD|CPY                        // Copy 8 words from MSA to MDA address.
          subi r0,0x8                         // Decrement counter
          jmp MAIN_XFER                     // return to main transfer loop
LAST_XFER:
          stf r0,MD|CPY
```

The main transfer loop is executed 12 times; then r0 equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

7.2.2.12.1.10 Burst DMA Unit Error Management

Another point to consider is the management of errors.

Because the DMA immediately sends an acknowledge to the RISC core (except for the stf MS|SZ0|FLS instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access.

This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the ldf copy or stf copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after ldf instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a stf MD|COPY instruction will cancel the error mode. The following table shows when an immediate error is sent back according to the executed instruction.

Table 7-28. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (|U |PF) stf rn, MDA stf rn,MD|COPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the stf MD|COPY, a copy loop is executed.
stf rn, MS	NO	MS is updated.
ldf rn, MS ldf rn, MSA ldf rn, MDA	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 7-29. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an stf MS|SZ0 instruction.
ldf rn, MS ldf rn, MSA ldf rn, MDA	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	Yes	Whatever the DMA direction (read or write), an ldf rn triggers an immediate error.

7.2.2.12.1.11 Conditional Yielding-Burst DMA Unit

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Hardware Loop

```
loop
load Rn,source            // can be ldf or ld
<computation>            // can be done through functional units
store Rn,dest              // can be st or stf
done 0               // yield
```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes-conditional or always-true-for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

7.2.2.12.2 Peripheral DMA Unit Programming

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the Arm platform.

Its goal is to perform data transfers between any blocks connected to the DMA bus of this platform. These blocks are either peripherals or memories. The peripheral DMA could be seen as the Arm platform DMA controller.

The DMA performs data transfers in three modes:

- Read mode, where data is read from peripherals or from memory connected to the Arm platform and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode-When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.
- Incremented mode-When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.
- Decremented mode-In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

7.2.2.12.2.1 Peripheral Source Address Register (PSA)

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an ldf MD instruction. Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all ldf MD instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (ssize). If source is a memory in incremented mode, first programmed in word mode (stf PSA|SZ32|I), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the stf PSA instruction as described in the write section. The ssize and stype registers are part of the DMA status register (PS).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

7.2.2.12.2.2 Peripheral Destination Address Register (PDA)

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PDA) to store the address value
- A 2-bit register (dtype) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (dsize) to store the destination target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an stfMD instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the stf PDA instruction and may also generate an error in case of incorrect programming.

7.2.2.12.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to PD will automatically flush the new input data.

The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an ldf instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag-part of PS-is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

7.2.2.12.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer.

Although all PS fields can be written by an stf instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

Table 7-30. PS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ssize		stype		dsize		dtype

R	0	0	0	0	0	d	e		0	0	0	0	0	n		
W																

Table 7-31. PS Field Descriptions

Field	Description
31-24	Reserved
23-22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
21-20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
19-18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
17-16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
15-11	Reserved
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by stf PD instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an ldf PD instruction. Reading PDA or PSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 Error read
7-3	Reserved

Table continues on the next page...

Table 7-31. PS Field Descriptions (continued)

Field	Description
2-0 n	number of bytes in PD

NOTE

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

7.2.2.12.2.5 Peripheral DMA Write (stf)-Write Mode

When written by an stf instruction, the function code bits are interpreted as follows:

Table 7-32. STF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s		p	ar	am		sz	
PDA								
PD			pdsel					
PS			pssel					

Table 7-33. STF Code Bits Field Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3-2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen-Address registers are not modified after the transfer. 01 Incremented-Address registers are incremented by the number of transferred bytes. 10 Decremented-Address registers are decremented by the number of transferred bytes. 11 Updated-PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1-0 sz	Transfer Size 00 *reserved*

Table continues on the next page...

Table 7-33. STF Code Bits Field Descriptions (continued)

Field	Description
	01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5-0 pdsel	PD access selector 001000 is the only valid option
5-0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible stf instructions, the following table provides only a short list of all the possible write instructions:

Table 7-34. Peripheral DMA STF Instruction List

Binary	Assembly	Comments
11_00_00_01 11_00_00_10 11_00_00_11	stf Rn, PSA|SZ8 |F stf Rn, PSA|SZ16|F stf Rn, PSA|SZ32|F	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is frozen.
11_10_00_01 11_10_00_10 11_10_00_11	stf Rn,PSA|SZ8 |F|PF stf Rn,PSA |SZ16|F|PF stf Rn,PSA |SZ32|F|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • 1, 2, or 4 bytes are *fetched* from the peripheral source. • Source address is frozen.
11_00_01_01 11_00_01_10 11_00_01_11	stf Rn, PSA|SZ8 |I stf Rn, PSA|SZ16|I stf Rn, PSA| SZ32|I	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1,2 or 4 after read PD.
11_10_01_01 11_10_01_10 11_10_01_11	stf Rn, PSA|SZ8 |I|PF stf Rn, PSA|SZ16|I|PF stf Rn, PSA|SZ32|I|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1, 2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.
11_00_10_01 11_00_10_10 11_00_10_11	stf Rn, PSA|SZ8 |D stf Rn, PSA|SZ16|D stf Rn, PSA|SZ32|D	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA-1,2, or 4 after read PD.
11_10_10_01 11_10_10_10 11_10_10_11	stf Rn, PSA|SZ8 |D|PF stf Rn, PSA|SZ16|D|PF stf Rn, PSA|SZ32|D|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA-1,2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.

Table continues on the next page...

11_10_11_01 11_10_11_10 11_10_11_11	stf Rn, PSA|SZ8 |PF|U stf Rn, PSA|SZ16 |PF|U stf Rn, PSA|SZ32 |PF|U	• *Update* source pointer, which becomes a pointer to a target accessed in byte, half-word, or word. • PSA value is not modified by Rn. • Bytes present in PD are lost. • 1, 2, or 4 bytes are *fetched* from the memory source.
11_01_00_01 11_01_00_10 11_01_00_11	stf Rn, PDA|SZ8 |F stf Rn, PDA|SZ16|F stf Rn, PDA|SZ32|F	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is frozen.
11_01_01_01 11_01_01_10 11_01_01_11	stf Rn, PDA|SZ8 |I stf Rn, PDA|SZ16|I stf Rn, PDA|SZ32|I	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA + 1, 2, or 4 after write PD.
11_01_10_01 11_01_10_10 11_01_10_11	stf Rn, PDA|SZ8 |D stf Rn, PDA|SZ16|D stf Rn, PDA|SZ32|D	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA-1, 2, or 4 after write PD.
11_01_11_01 11_01_11_10 11_01_11_11	stf Rn, PDA|SZ8 |U stf Rn, PDA|SZ16 |U stf Rn, PDA|SZ32 |U	• *Update* destination pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PDA value is not modified by Rn • bytes present in PD are lost
11_00_10_00	stf Rn, PD	• Write "dsize" bytes of Rn in PD and automatically flush to destination target
11_11_11_11	stf Rn, PS	• Write status register
11_00_11_00	stf Rn,clrefPS	• Clear error flag if set

NOTE

When writing PD, size information is not important: It is embedded in the dsize field of PDA register. If dsize is 1, 2, or 4, then one, two, or four bytes from Rn is written to the PD register, and automatically flushed out to the destination target.

7.2.2.12.2.6 Peripheral DMA Read (ldf)-Read Mode

When received from an ldf instruction, the function code bits are interpreted as follows.

Table 7-35. LDF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s			ar	a			
PDA								
PD			p	cpy				
PS			pssel					

Table 7-36. LDF Code Bits Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
4 cpy (PD)	Copy Mode 0 standard access 1 copy mode access
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5-0 pssel	PS access selector 111111 is the only valid option to read PS

Table 7-37. Peripheral DMA LDF Instruction List

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PD|PF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PD|COPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are *not* the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

NOTE

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

7.2.2.12.2.7 Peripheral DMA Unit Copy Mode

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers.

Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for transfers that involve two targets of the same data path width.

Since copy mode is invoked with an ldf instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

7.2.2.12.2.8 Error Management

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

7.2.2.12.2.8.1 Immediate Errors

The following table lists all incorrect DMA register setups.

Table 7-38. Immediate Errors with Peripheral DMA

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSA|SZ16|F stf Rn, PSA|SZ16|I stf Rn, PDA|SZ16|F stf Rn, PDA|SZ16|I	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSA|SZ32|F stf Rn, PSA|SZ32|I stf Rn, PDA|SZ32|F stf Rn, PDA|SZ32|I	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]-PDA[1:0]	DMA instruction	Comments

Table continues on the next page...

Table 7-38. Immediate Errors with Peripheral DMA (continued)

Rn[1:0] values	DMA instruction	Comments
0x01 0x10 0x11	stf Rn, PSA|SZ32|U stf Rn, PDA|SZ32|U	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSA|SZ16|U stf Rn, PDA|SZ16|U	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	Comments	
stf Rn,PD ldf Rn,PD	If PDA size (dsize) has never been set up before an stf PD instruction (dsize=0) If PSA size (ssize) has never been set up before an ldf PD instruction (ssize=0)	
ldf Rn,PD|CPY	Copy mode is possible only between two targets whose data path width is identical. It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.	

7.2.2.12.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an ldf PD or stf PD instruction would be the error of the previous DMA cycle.

Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral).

When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: Read Error (First Phase), Write Error and Read Error (Second Phase), and Copy Mode Errors handling.

7.2.2.12.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next ldf PD instruction and writing PSA, PDA, or PD will cancel the error flag.

The block returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. The following table details which instructions can be executed in this mode.

Table 7-39. Possibilities in ERROR READ Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn,PD|COPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the ldf PD|COPY, a copy loop is executed.
stf rn, PS	NO	PS is updated.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

7.2.2.12.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in Read Error (First Phase), when an ldf PD is executed while the block is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, stf instructions may raise an immediate error, and ldf instructions will not (as detailed in the table below).

Table 7-40. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an stf PS instruction.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Whatever the DMA direction (read or write), an ldf rn, PD instruction will show an immediate error.

7.2.2.12.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in Read Error (First Phase) and Write Error and Read Error (Second Phase) : It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an ldf instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another ldf instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual stf PD instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual stf PD instruction.

7.2.2.12.2.8.6 Error Check Example

The following code illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first bdf instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the ldf PS instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an ldf command sets the SF flag and any error returned on an stf instruction sets the DF flag. This can create a situation as shown in the example where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an ldf instruction.

Peripheral DMA Error Check

```
    clrf    0            // Clear SF and DF flags
 stf    R4, PD        // Write data to memory
bdf    error_routine    // Check for immediate error from write to PD.
ldf    r3, PS        // Read PS (PS value in R3 can be ignored)
    bsf    error_routine    // Check for bus error from "stf R4,PD"
           // SF is set because it is a ldf instruction, even though
           // the original error was a destination fault
```

7.2.2.12.2.9 Peripheral DMA Unit Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a stf PD instruction-assuming PDA is correctly programmed-it is automatically flushed to the destination.

An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

7.2.2.12.3 OnCE and Real-Time Debug

The On-Chip Emulation block (OnCE) is the debug interface to the SDMA.

It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core. The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

7.2.2.12.3.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the Arm platform Control interface when the OnCE is controlled by the Arm platform, as described in the "Using BP" section.

7.2.2.12.3.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core.

A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see Arm platform Channel 0 Pointer (SDMAARM_MC0PTR)): You can modify them through a regular memory access or the Arm platform control interface.

7.2.2.12.3.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

7.2.2.12.3.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode.

No hardware step execution mode is implemented in the OnCE, but this feature may be implemented at the software level with this instruction.

7.2.2.12.3.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status.

Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

7.2.2.13 The OnCE Controller

The OnCE controller receives commands from the Arm platform or from the JTAG controller. Each command is interpreted before being sent to the core.

7.2.2.13.1 OnCE Commands

A small set of commands supports the communication between the OnCE and the external world.

This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE. Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: The following table presents their formats.

Table 7-41. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TARM platform controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE. The nature of the associated data field is clearly identified. The dmov command is followed by a 32-bit data value (which is a data value for the SDMA); the exec_once and the exec_core commands are followed by a 16-bit data value (which is an instruction for the SDMA); the rstatus command is followed by a 16-bit control value (which is the content of the OnCE status register); the rbuffer command is followed by a 32-bit data value. The debug_rqst and the run_core commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

7.2.2.13.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one Arm platform access to the OnCE is provided.

7.2.2.13.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal.

It produces shift-enable signals (shift_ir and shift_dr), and updates enable signals (update_ir and update_dr). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the shift_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp_en), instruction enable signal (inst_en), data enable (data_en), and status enable signal (stat_en).

During the shift_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the Arm platform access is enabled.

7.2.2.13.2.2 Using the Arm platform

The Arm platform access to the OnCE is not the standard access, but it is required if the JTAG is not available.

For example, if the SDMA ROM is out of use on a chip in production, and the Arm platform needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an Arm platform access to the OnCE.

To drive the OnCE, the Arm platform uses some registers contained in the Arm platform Control block of the SDMA. These registers are accessed through the Arm platform peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the Arm platform Control block is listed below:

- ONCE_ENB register (1 bit, read/write)-This 1-bit register enables the Arm platform access to the OnCE. When this bit is set, the signals from the JTAG are ignored. When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.
- ONCE_CMD register (4 bits, read/write)-This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing "0001" in this register, a dmov command is executed.

NOTE

On the Arm platform side, the rstatus and bypass commands are not supported. This register is reset on a JTAG reset.

- ONCE_DATA register (32 bits, read/write)-This 32-bit register is connected to the SDMA data register. This register is used when executing a dmov or rbuffer command.

NOTE

Before requesting a dmov command, the 32-bit data to transfer must be written in the ONCE_DATA register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- ONCE_INSTR register (16 bits, read/write)-This 16-bit register is connected to the SDMA instruction register. This register is used when executing an exec_core or an exec_once command.

NOTE

Before requesting an exec_core or an exec_once command, the appropriate instruction must be written in the ONCE_INSTR register. This register is reset on a JTAG reset.

- ONCE_STAT register (16 bits, read only)-A read access to the ONCE_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the Arm platform controls the OnCE, therefore no register is defined in the Arm platform Control block to access the bypass register.

7.2.2.13.2.3 Conflicts Between the JTAG and the Arm platform Accesses

When Arm platform access to the SDMA OnCE is enabled (that is, when the bit in the ONCE_ENB register is set), the JTAG access is disabled. This guarantees that the block is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a dmov command from debug mode (with neither 0xffffffff nor 0x0 as dmov value: 0x5a5a5a5a is good).

- Execute another dmov command (the value here is not important).
- The returned value from the latter dmov command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

7.2.2.13.3 Executing a Command from the OnCE

All the commands defined in OnCE Commands can be accessed through the JTAG. The Arm platform can access all these commands except the rstatus command.

On the Arm platform side, the OnCE status is directly accessed by reading the ONCE_STAT register.

7.2.2.13.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: rstatus and rbuffer. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: dmov, run_core, exec_core, exec_once, and debug_rqst. These commands are core status dependent, as follows:

- During user mode only the debug_rqst is taken into account.
- During debug mode, all these commands are taken into account except the debug_rqst. For example, an exec_once command requested while not in debug mode has no effect.

7.2.2.13.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is send after decoding the update_dr state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the Arm platform side, the request is sent after detecting a write access to the ONCE_CMD register. All the registers involved in this operation must be loaded first.

The following is an example of an exec_core command execution from the Arm platform side: After writing '010' in the ONCE_CMD register, the OnCE controller asks the SDMA to execute the instruction contained in the ONCE_INSTR register. The instruction involved should be available in the ONCE_INSTR register before the beginning of the execution.

7.2.2.13.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- rstatus command execution-The rstatus command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the capture_dr state, and shifted out after 16 TCK clock cycles in the shift_dr state. The rstatus command is not supported on the Arm platform side, but a status register is provided instead. The rstatus may be performed in both debug and user modes.
- dmov command execution-The dmov command accesses SDMA internal registers. Executing a dmov instruction exchanges the 32-bit data values between the SDMA data register and the general register GReg[1].
- If the JTAG is used, the content of GReg1 is captured in the SDMA data register during the capture_dr state, then it is shifted out after 32 TCK clock cycles in the shift_dr state. During the update_dr state, GReg1 is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the Arm platform side, the data values contained in GReg1 and the SDMA data register are exchanged after detecting a write access to the ONCE_CMD register. The ONCE_DATA register must therefore be loaded first.

- exec_once command execution-The exec_once command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.
- Change of flow instructions as well as instructions that may cause a context switch are not supported: The comprehensive list comprises done/yield/yiedge (except done 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions.

  No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the rstatus OnCE command, monitoring the debug_mode pin, or checking the OnCE Status Register (SDMAARM_ONCE_STAT) register via the Arm platform control interface.

NOTE

Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. A request is sent to the core when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- run_core command execution-The run_core command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in Restoring the Context.
- If the JTAG is used, a 1-bit bypass value is shifted in the bypass register in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the core is rerun when detecting a write access to the ONCE_CMD register.

- exec_core command execution-The exec_core command resumes program execution from any address. The 16-bit instruction provided with the exec_core overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted from any address. After executing an exec_core command, the SDMA leaves debug mode. The exec_core command is usually used with a jmp instruction.
- If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the SDMA reruns when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a jump to address 0x100 instruction.

- debug_rqst command execution-The debug_rqst command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the shift_dr state. A debug request is sent to the SDMA when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the Arm platform side, the debug request is sent when detecting a write access to the ONCE_CMD register. When the SDMA is already in debug mode, this command is simply ignored.
- rbuffer command execution-The rbuffer command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is

captured in the SDMA data register during the capture_dr state. The register is completely shifted out after maintaining the shift_dr state during 32 TCK clock cycles. If the OnCE is driven from the Arm platform side, the content of the RTB is captured in the ONCE_DATA register after detecting a write access to the ONCE_CMD register.

- bypass command execution-This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

7.2.2.13.4 Registers Descriptions

See SDMACORE, and SDMAARM, for detailed information on each register.

7.2.2.13.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request.

This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

7.2.2.13.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers-the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: addra_cond or addrb_cond. Every address register is cleared on a JTAG reset.

7.2.2.13.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit *i* of this register is set, then bit *i* of the

address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

7.2.2.13.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the data_cond condition.

The event cell data register is cleared on a JTAG reset.

7.2.2.13.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data.

Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

7.2.2.13.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode.

Refer to Real Time Buffer for more details.

7.2.2.13.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions.

The event cell control register is cleared on a JTAG reset. See also OnCE Event Detection Unit for more details.

7.2.2.13.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer.

See Trace Buffer for more details.

7.2.2.13.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register.

Refer to OnCE Status Register (SDMAARM_ONCE_STAT) for detailed description of the individual fields in the OSTAT register.

The following figure shows the OSTAT structure.

Table 7-42. OnCE Status Register (OnCE)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PST[3:0]				RCV	EDR	ODR	SWB	MST					ECDR[2:0]		

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the Arm platform control interface, and when ECDR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an rstatus command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the Arm platform access. Executing the rstatus command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the exec_once command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

7.2.2.13.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

7.2.2.13.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see Figure 7-11) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, TCK < CLK/8, limitation guarantees that all operations are performed as expected.

7.2.2.13.5.2 Synchronization Implementation

The figure found here shows the synchronization mechanism.

Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge_detected and negedge_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to yield the TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

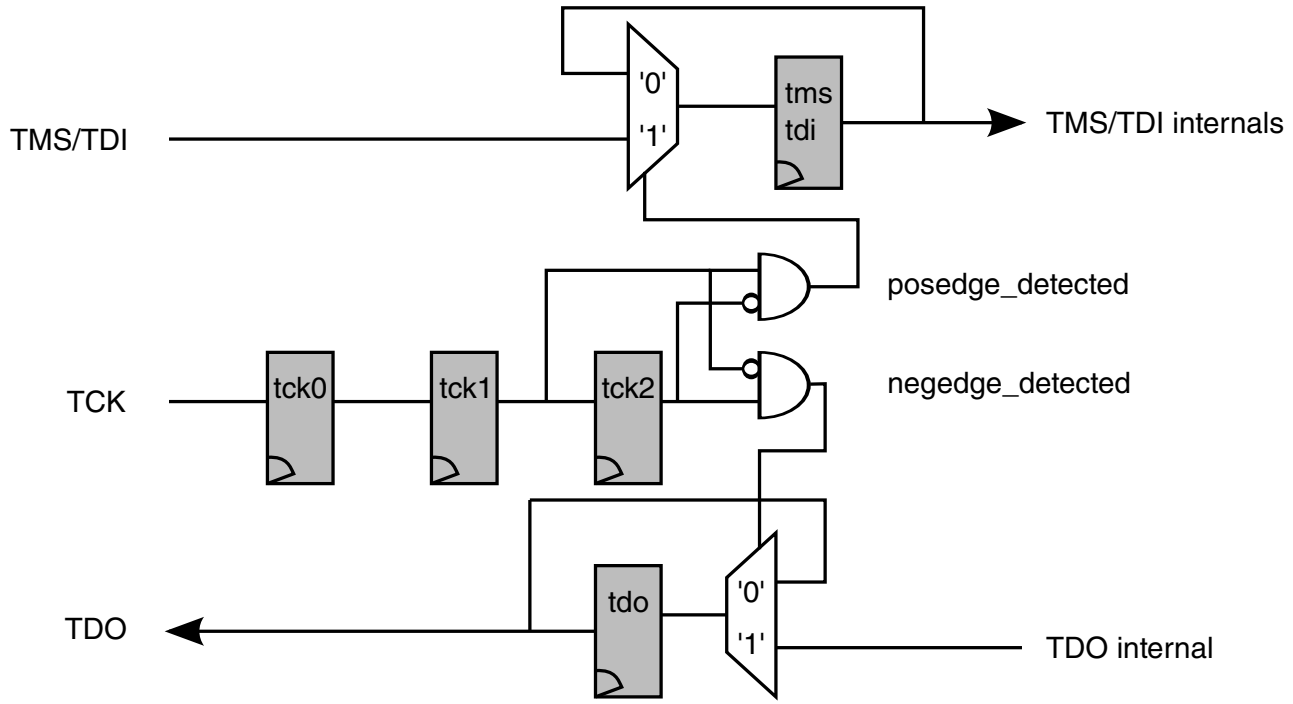

Figure 7-11. OnCE Synchronization Layer

The following figure shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

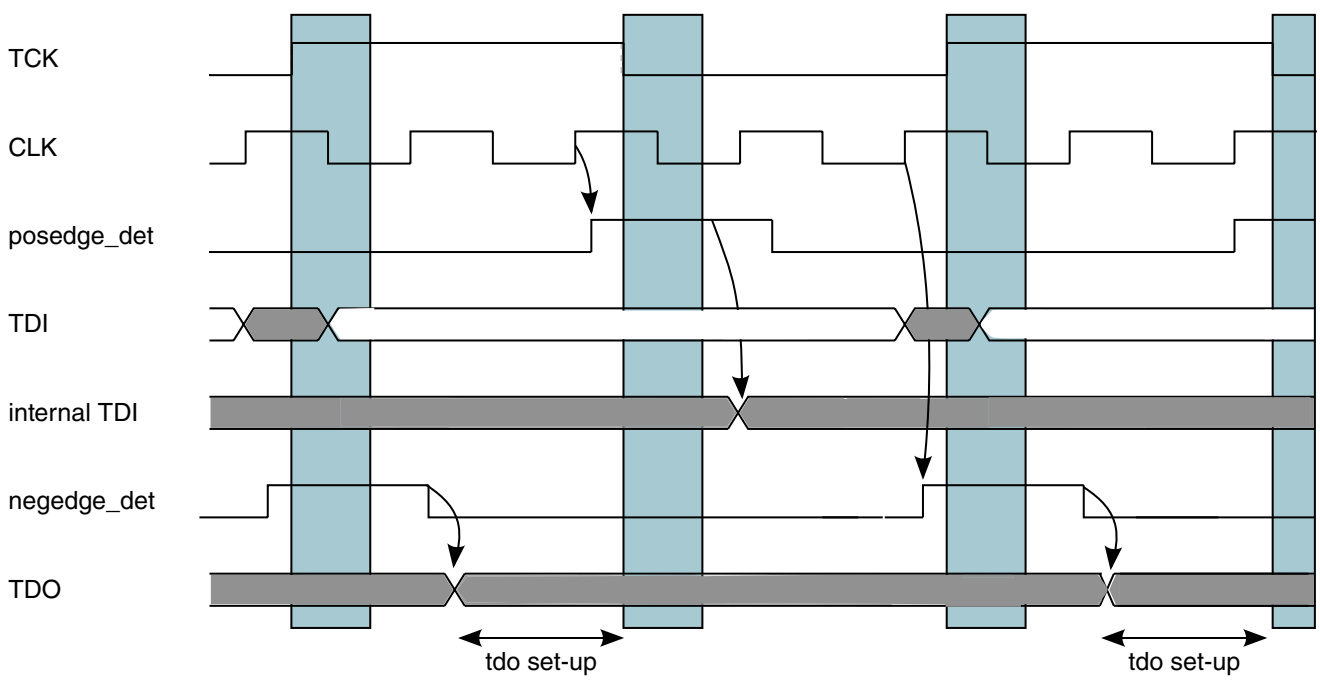

Figure 7-12. Synchronization Timings

7.2.2.13.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

7.2.2.14 Using the OnCE

This section provides the elements necessary to run the OnCE during a debug process.

In addition to the basic set of commandsdescribed in OnCE Commands, more complex commands can be built to meet users' requirements.

7.2.2.14.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed.

This is the case for instances when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the clk_gating_off input.
- For the Arm platform access, the SDMA clock gating is automatically turned off when the Arm platform access is enabled (see OnCE Enable (SDMAARM_ONCE_ENB)).

7.2.2.14.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA.

It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA.

Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

7.2.2.14.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch.

The request is ignored when the core is already in debug mode. Refer to Figure 7-4, which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

7.2.2.14.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see Activating Clocks in Debug Mode). The debug request line should be not be maintained high when the SDMA is in debug mode.

NOTE

The debug_rqst command (from the OnCE command set) is not supported during system reset.

7.2.2.14.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a debug_rqst command.

   The debug_rqst command can be sent by the JTAG access or by an access on the Arm platform side (if the Arm platform access is enabled).

7.2.2.14.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

7.2.2.14.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus.

See OnCE Event Detection Unit for more details.

7.2.2.14.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the exec_once command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution.

Some instructions are not supported by the exec_once command: done/yield/yiedge (except done 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

7.2.2.14.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the Arm platform and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);                 // executing my_command with a data field
my_command(-);                        // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an Arm platform access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in); // returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

7.2.2.14.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like dmov or exec_once), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus();        // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-);   // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

7.2.2.14.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags.

Use the general register GReg[1] as an intermediate register to export the entire context of the SDMA.

The following example shows how to save GReg[0], GReg[1], GReg[2] and GReg[3]. The sequence of commands used to export additional general registers is very similar to this.

Save GReg[0], GReg[1], GReg[2], and GReg[3]

```
GReg1_data = dmov(-);                          // the value exported is the content of
GReg[1]
exec_once("mov GReg1,GReg0");                      // puts the content of GReg[0] into
GReg[1]
GReg0_data = dmov(-);                          // the value exported is the content of
GReg[0]
exec_once("mov GReg1, GReg2");                     // puts the content of GReg[2] into
GReg[1]
GReg2_data = dmov(-);                          // the value exported is the content of
GReg[2]
exec_once("mov GReg1, GReg3");                     // puts the content of GReg[3] into
GReg[1]
GReg3_data = dmov(-);                          // the value exported is the content of
GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a done 5, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the

values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5");                    // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Exporting the Context

```
dmov(ctx_base_addr);                                  // loading GReg[1] with the channel
context base address
exec_once("ld GReg0,(GReg1,0)");                          // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)");                         // get SPC-EPC into GReg1
Loop_data = dmov(-);                                // read back the value of Loop registers
exec_once("mov GReg1, GReg0");                          // puts the PC info into GReg1
PC_data = dmov(-);                                  // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

7.2.2.14.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE.

The example found hereshows how it is possible to modify the current channel context.

Modifying the Current Channel Context

```
dmov(Loop_data);                                    // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1");                          // copy to GReg[0]
dmov(PC_data);                                      // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1");                          // copy to GReg[2]
dmov(ctx_base_addr);                                  // put channel context base address into
GReg[1]
exec_once("st GReg0, (GReg1,1)");                         // restore Loop context
exec_once("st GReg2, (GReg1,0)");                         // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once("cpShReg");                    // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

The following example shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Restoring the General Register Context

```
dmov(GReg3_data);                    // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1"); // restore GReg[3]
dmov(GReg2_data);                    // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1"); // restore GReg[2]
dmov(GReg0_data);                    // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1"); // restore GReg[0]
dmov(GReg1_data);                    // restore GReg[1]
```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a mov instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a mov to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The cpShReg instruction is meant to provide a means for changing these register contents via the context memory.

7.2.2.14.5.4 Accessing the Memory

In the example shown here, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```
macro READ:            dmov(target_addr);                                  // put the target
address in GReg[1]
                    exec_once("ld GReg1,(GReg1,0)");                        // execute the
load instruction
                    res_data = dmov(-);                                 // exports the result
data value
```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```
macro WRITE:             dmov(target_addr);                                  // puts the
target address in GReg[1]
                    exec_once("mov GReg0,GReg1");                          // puts the target
address in GReg[0]
                    dmov(target_data);                                  // puts the target
data in GReg[1]
                    exec_once("st GReg1,(GReg0,0)");                            // performs the
store operation
```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

7.2.2.14.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA.

Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-);                          // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the exec_core command. The data field provided with this command must be the encoding of a jump instruction.

```
exec_core("jmp start_addr"); // rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

7.2.2.14.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

The following example shows the macro functions READ and WRITE, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2);                        // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the "bkpt_addr"
```

```
instr_save = READ(bkpt_addr/2);                          // save the instruction before
overwriting
STORE("bkpt instruction",bkpt_addr/2);                        // store the bkpt instruction
in memory
exec_core("jmp run_addr");                              // rerun the SDMA
rstatus(-);                                          // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);                           // restore the instruction
overwritten
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

7.2.2.14.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

7.2.2.14.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers.

A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true.

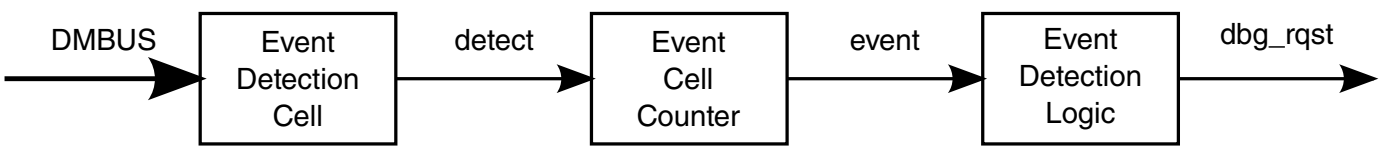

Figure 7-13. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic block that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

The following figure shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference

values located in memory mapped registers-the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

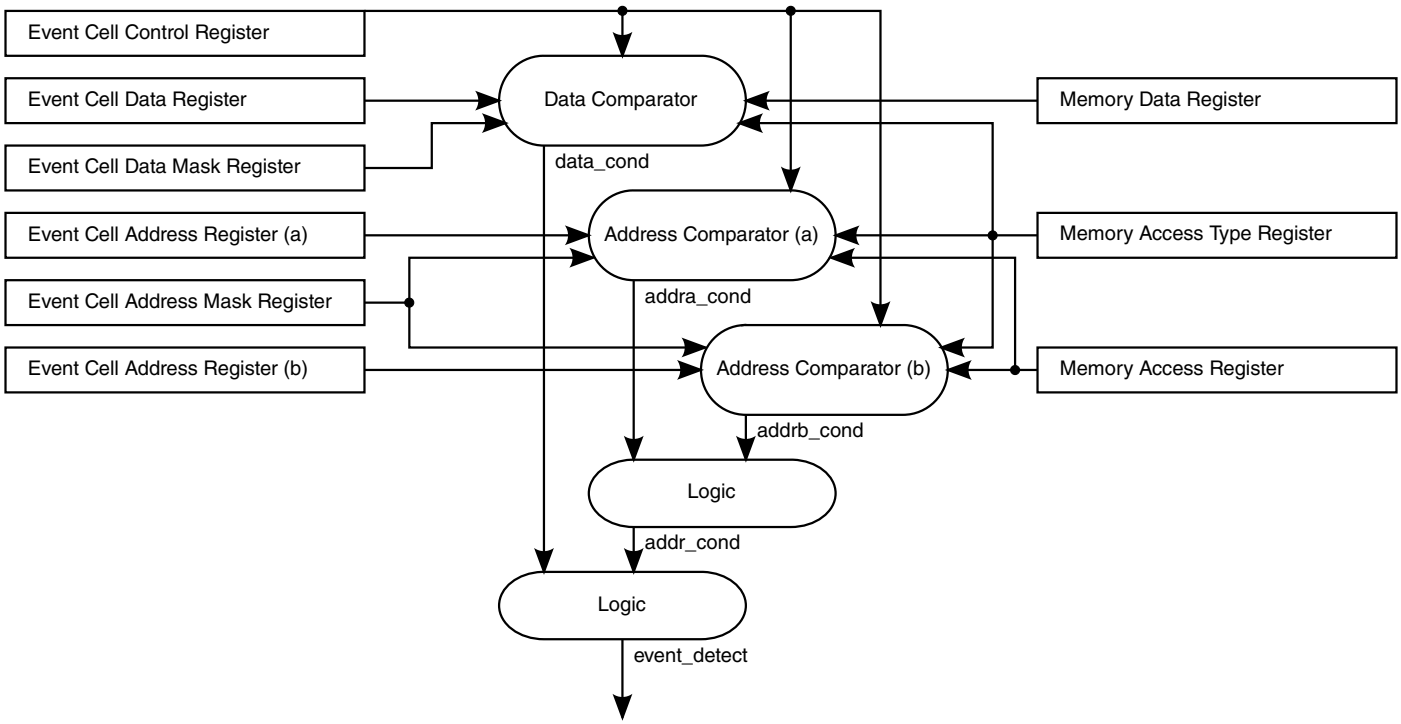

Figure 7-14. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

7.2.2.14.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

7.2.2.14.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE.

When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port clk_gating_off. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

When the OnCE is accessed through the Arm platform Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE_ENB register (see OnCE Enable (SDMAARM_ONCE_ENB)) is set. A write access to this register is possible even when the OnCE clock is not running. If the Arm platform access is used, the bit in the ONCE_ENB register must be set before any attempt to access any other OnCE register.

7.2.2.14.7.2 Resets

The OnCE reset is different from the SDMA main reset.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

7.2.2.14.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution.

The content of this register may be exported through JTAG ports without stopping the core.

7.2.2.14.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution.

The following figure shows an overview of the Trace Buffer.

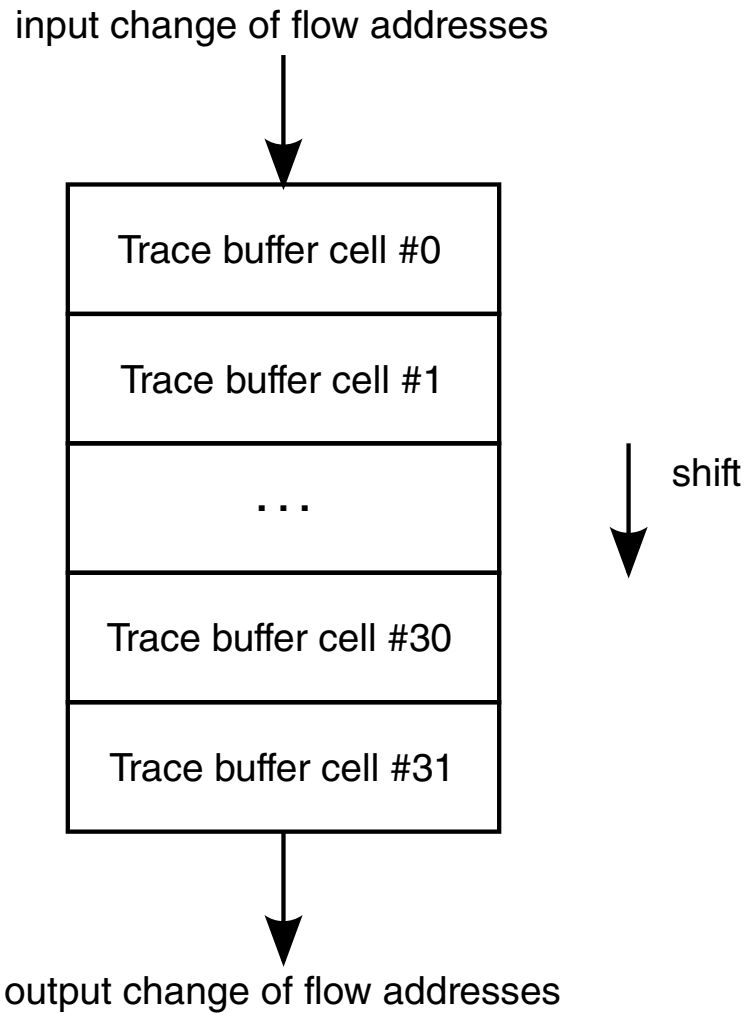

Figure 7-15. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is a follows:

```
exec_once("mov r1, TB");                              // stores the oldest change-of-flow in
GReg1
dmov(-);                                          // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

7.2.2.14.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE.

Executing ar rbuffer command (see The OnCE Controller for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a rbuffer command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

7.2.2.14.8.3 Emulation Pin

The debug_matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit.

Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

7.2.2.14.8.4 Real-Time Debug Outputs

The table found here shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 7-43. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	The core_state bits reflect the state of the SDMA core. • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the core idle state); the "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel
debug_yield	Pulse that is active when a yield (done 0) or a yieldge (done 1) instruction is executed. 0 - 1 yield/yieldge executed
debug_core_run	Active when the SDMA core is executing instructions. 0 Debug or sleep mode

Table continues on the next page...

Table 7-43. Real-Time Debug Output Pins (continued)

Pin	Description
	1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (ld, st, ldf, or stf instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, "no access" is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 PSA 6 PDA 7 PD 8 PS 9 RESERVED 10 RESERVED 11 RESERVED 12 RESERVED 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register

Table continues on the next page...

Table 7-43. Real-Time Debug Output Pins (continued)

Pin	Description
	18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1) (as described in SDMAARM). The following two parameters are available for every line: • CNF-Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]-Gives the number of the DMA request or channel to monitor

The matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the Configuration Register (SDMAARM_CONFIG) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

7.2.3 Instruction Set

7.2.3.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

```
x...x - don't care

rrr - destination/source general register

sss - additional source general register

bbb - general register used as address base register

ddddd - address displacement

nnnnn - bit number
uuuuuuuu - function unit command bits

pppppppp - branch displacement (signed)

iiiiiiii - 8-bit immediate

jjj - control bit to clear

ff - flag to clear
00000jjj00000000        - done (done,yield,wait)

7.2.3.2 SDMA Instruction Set

This section describes all the useful instructions from the SDMA set.

Table 7-44. SDMA Instruction List

Instruction	Description	Page
ADD	Addition	ADD (Addition)
ADDI	Add with Immediate Value	ADDI (Add with Immediate Value)
AND	Logical AND	AND (Logical AND)
ANDI	Logical AND with Immediate Value	ANDI (Logical AND with Immediate Value)
ANDN	Logical AND NOT	ANDN (Logical AND NOT)
ANDNI	Logical AND with Negated Immediate Value	ANDNI (Logical AND with Negated Immediate Value)
ASR1	Arithmetic Shift Right by 1 Bit	ASR1 (Arithmetic Shift Right by 1 Bit)
BCLRI	Bit Clear Immediate	BCLRI1 (Bit Clear Immediate)
BDF	Conditional Branch if Destination Fault	BDF (Conditional Branch if Destination Fault)
BF	Conditional Branch if False	Functional Units Programming Model
BSETI	Bit Set Immediate	BSETI (Bit Set Immediate)
BSF	Conditional Branch if Source Fault	BSF (Conditional Branch if Source Fault)
BT	Conditional Branch if True	BT (Conditional Branch if True)
BTSTI	Bit Test immediate	BTSTI (Bit Test immediate)
CLRF	Clear Arm platform flags	CLRF (Clear Arm platform flags)
CMPEQ	Compare for Equal	CMPEQ (Compare for Equal)
CMPEQI	Compare with Immediate for Equal	CMPEQI (Compare with Immediate for Equal)
CMPHS	Compare for Higher or Same	CMPHS (Compare for Higher or Same)
CMPLT	Compare for Less Than	CMPLT (Compare for Less Than)
cpShReg	Update Context of PCU Registers and Flags	cpShReg (Update Context of PCU Registers and Flag)
DONE	DONE, Yield	DONE (DONE, Yield)
ILLEGAL	ILLEGAL Instruction	ILLEGAL (ILLEGAL Instruction)
JMP	Unconditional Jump Immediate	JMP (Unconditional Jump Immediate)
JMPR	Unconditional Jump	JMPR (Unconditional Jump)
JSR	Unconditional Jump to Subroutine Immediate	JSR (Unconditional Jump to Subroutine Immediate)
JSRR	Unconditional Jump to Subroutine	JSRR (Unconditional Jump to Subroutine)
LD	Load Register	LD (Load Register)
LDF	Load Register from Functional Unit	LDF (Load Register from Functional Unit)
LDI	Load Register with Immediate Value	LDI (Load Register with Immediate Value)
LDRPC	Load from RPC to Register	LDRPC (Load from RPC to Register)

Table continues on the next page...

Table 7-44. SDMA Instruction List (continued)

Instruction	Description	Page
LOOP	Hardware Loop	LOOP (Hardware Loop)
LSL1	Logical Shift Left by 1 Bit	LSL1 (Logical Shift Left by 1 Bit)
LSR1	Logical Shift Right by 1 Bit	LSR1 (Logical Shift Right by 1 Bit)
MOV	Logical Move	MOV (Logical Move)
NOTIFY	Notify to Arm platform	NOTIFY (Notify to Arm platform)
OR	Logical OR	OR (Logical OR)
ORI	Logical OR with Immediate Value	ORI (Logical OR with Immediate Value)
RET	Return from Subroutine	RET (Return from Subroutine)
REVB	Reverse Byte Order	REVB (Reverse Byte Order)
REVBLO	Reverse Low Order Bytes	Reverse Low Order Bytes(REVBLO)
ROR1	Rotate Right by 1 Bit	ROR1 (Rotate Right by 1 Bit)
RORB	Rotate Right by 1 Byte	RORB (Rotate Right by 1 Byte)
SOFTBKPT	Software Breakpoint	SOFTBKPT (Software Breakpoint)
ST	Store Register	ST (Store Register)
STF	Store Register in Functional Unit	STF (Store Register in Functional Unit)
SUB	Subtract	SUB (Subtract)
SUBI	Subtract with Immediate	SUBI (Subtract with Immediate)
TST	Test with Zero	TST (Test with Zero)
TSTI	Test Immediate	TSTI (Test Immediate)
XOR	Logical Exclusive OR	XOR (Logical Exclusive OR)
XORI	Exclusive OR with Immediate	XORI (Exclusive OR with Immediate)

7.2.3.2.1 ADD (Addition)

Operation:

```
GReg[r] ← GReg[s] + GReg[r]

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: add r,s

Example: add 0,3
```

ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Cycles: 1

Description: Performs the ADDition of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*. The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.2 ADDI (Add with Immediate Value)

Operation:

```
GReg[r] ← GReg[r] + immediate

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: addi r,immediate

Example: add 6,112
```

ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Adds a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

 ...

11111110 - 254

11111111 - 255
```

7.2.3.2.3 AND (Logical AND)

Operation:

```
GReg[r] ← GReg[s] & GReg[r]
```

Assembler:

```
Syntax: and r,s

Example: and 1,2
```

AND GReg[1] and GReg[2] and store the result in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.4 ANDI (Logical AND with Immediate Value)

Operation:

```
GReg[r] ← GReg[r] & immediate
```

Assembler:

```
Syntax: andi r,immediate

Example: andi 7,45
```

AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

7.2.3.2.5 ANDN (Logical AND NOT)

Operation:

```
GReg[r] ← ~GReg[s] & GReg[r]
```

Assembler:

```
Syntax:andn r,s

Example: andn 3,4
```

AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

Table 7-45. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	0	s	s	s

Instruction Fields:

rrr /sss - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.6 ANDNI (Logical AND with Negated Immediate Value)

Operation:

```
GReg[r] ← GReg[r] & ~immediate
```

Assembler:

```
Syntax: andni r,immediate

Example: andni 0,2
```

AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

7.2.3.2.7 ASR1 (Arithmetic Shift Right by 1 Bit)

Operation:

```
GReg[r]:{b31,b30,...,b1,b0} ← GReg[r]:{b31,b31,b30,...,b1}
```

Assembler:

```
Syntax: asr1 r

Example: asr1 3
```

divide by 2 the signed value of GReg[3] and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

Table 7-46. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.8 BCLRI1 (Bit Clear Immediate)

Operation:

```
GReg[r]:{b31,...,b(i+1),0,b(i-1),...,b0} ← GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

```
Syntax: bclri r,i

Example: bclri 1,12
```

clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	1	i	i	i	i	i

rrr - register field:

```
000 - GReg[0]
```

```
001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - immediate value:

```
00000 - 0

00001 - 1

...

11110 - 30

11111 - 31
```

7.2.3.2.9 BDF (Conditional Branch if Destination Fault)

Operation:

```
if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1
```

Assembler:

```
Syntax:bdf label

Example: bdf LLL
```

Jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

7.2.3.2.10 BF (Conditional Branch if False)

Operation:

```
if (T == 0)

PC ← PC + 1 + displacement

else

PC ← PC + 1
```

Assembler:

```
Syntax: bf label

Example: bf LLL
```

Jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

ppppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

7.2.3.2.11 BSETI (Bit Set Immediate)

Operation:

```
GReg[r]:{b31,...,b(i+1),1,b(i-1),...,b0} ← GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

```
Syntax: bseti r,i

Example: bseti 6,5
```

Set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number i in the selected General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]
```

```
010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - bit number field:

```
00000 - 0

00001 - 1

...

11110 - 30

11111 - 31
```

7.2.3.2.12 BSF (Conditional Branch if Source Fault)

Operation:

```
if (SF == 1) PC ← PC + 1 + displacement else PC ← PC + 1
```

Assembler:

```
Syntax: bsf label

Example: bsf LLL
```

Jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

7.2.3.2.13 BT (Conditional Branch if True)

Operation

```
if (T == 1)

PC ← PC + 1 + displacement

else

PC ← PC + 1
```

Assembler

```
Syntax: bt label

bt LLL
```

Jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110- 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 -  (-2)

11111111 - (-1)
```

7.2.3.2.14 BTSTI (Bit Test immediate)

Operation:

```
T ← GReg[r]:b(i)
```

Assembler:

```
Syntax: btsti r,i

Example: btsti 2,29
```

Test bit 29 in GReg[2] and copy its value in flag T

CPU flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

Instruction Format:

Table 7-47. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]
```

```
010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - bit number field:

```
0000 - 0

0001 - 1

...

11110 - 30

11111 - 31
```

7.2.3.2.15 CLRF (Clear Arm platform flags)

Operation:

```
 if (ff%2 == 0)

SF ← 0

if (ff/2 == 0)

DF ← 0
```

Assembler:

```
Syntax: clrf ff

Example: clrf 2
```

Clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the Arm platform fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

ff - flags field:

```
00 - clear SF and clear DF

01 - clear DF

10 - clear

SF 11 - no clear
```

7.2.3.2.16 CMPEQ (Compare for Equal)

Operation:

```
T ← (GReg[s] == GReg[r])
```

Assembler:

```
Syntax: cmpeq r,s

Example: cmpeq 7,5
```

Compare GReg[7] and GReg[5] and set flag T if they are equal

CPU flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.17 CMPEQI (Compare with Immediate for Equal)

Operation:

```
T ← (GReg[r] == immediate)
```

Assembler:

```
Syntax: cmpeqi r,immediate

Example: cmpeqi 2,13
```

Compare GReg[2] and decimal value 13 and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254
```

```
11111111 - 255
```

7.2.3.2.18 CMPHS (Compare for Higher or Same)

Operation:

```
T ← (GReg[r] ≥ GReg[s])
```

Assembler:

```
Syntax: cmphs r,s

Example: cmphs 0,1
```

Compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.19 CMPLT (Compare for Less Than)

Operation:

```
T ← (GReg[r] < GReg[s])
```

Assembler:

```
Syntax: cmplt r,s

Example: cmplt 7,4
```

Compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.20 cpShReg (Update Context of PCU Registers and Flag)

Assembler:

```
Syntax: cpShReg
```

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC,LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done *5* operation.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

7.2.3.2.21 DONE (DONE, Yield)

Operation:

```
if (jjj&6 == 2) HE[CCR] ← 0

if (jjj == 3) HI[CCR] ← 1

if (jjj == 4) EP[CCR] ← 0

if ((jjj == 0) && (NCP > CCP)) CCR ← NCR

else if ((jjj == 1) && (NCP >= CCP))

CCR ← NCR

else

CCR ← NCR
```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

Assembler:

```
Syntax: done jjj

Example: done 3
```

Clear HE bit for the current channel, send an interrupt to the Arm platform for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding Arm platform by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched. If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending). If no flag is modified, the reschedule can allow the replacement of the current

channel by another channel with a priority strictly greater than the current channel priority (yield). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (yieldge). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

jjj - Channel Flags field:

000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)

001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)

010 - Clear HE for the current channel and reschedule 011 - Clear HE, set HI for the current channel and reschedule 100 - Clear EP for the current channel and reschedule

101 - Reserved for debug to copy relevant registers into context memory

110 - RESERVED

111 - RESERVED

For the scheduling rules, refer to Scheduler Functional Description. Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a Arm platform start via the Channel Start (SDMAARM_HSTART) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a Arm platform start via the Channel Start (SDMAARM_HSTART) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the Arm platform upon closure;

- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

7.2.3.2.22 ILLEGAL (ILLEGAL Instruction)

Operation:

```
PC ← 0001
```

Assembler:

```
Syntax: illegal
```

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format

Table 7-48. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

7.2.3.2.23 JMP (Unconditional Jump Immediate)

Operation:

```
PC ← absolute_address
```

Assembler:

```
Syntax: jmp label

Example: jmp LLL
```

The assembler translates the label to the exact address

CPU Flags:Unaffected

Cycles: 2

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaa - address field:

```
00000000000000 - 0

00000000000001 - 1

...

11111111111110 - 16382

11111111111111 - 16383
```

7.2.3.2.24 JMPR (Unconditional Jump)

Operation:

```
PC ← GReg[r]
```

Assembler:

```
Syntax: jmpr r

Example: jmpr 0
```

Jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]
```

```
010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.25 JSR (Unconditional Jump to Subroutine Immediate)

Operation:

```
RPC ← PC + 1

PC ← absolute_address
```

Assembler:

```
Syntax: jsr r

Example:jsr LLL
```

Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaa - address field:

```
00000000000000 - 0

00000000000001 - 1

...

11111111111110 - 16382

11111111111111 - 16383
```

7.2.3.2.26 JSRR (Unconditional Jump to Subroutine)

Operation:

```
RPC ← PC + 1

PC ← GReg[r]
```

Assembler:

```
Syntax: jsrr r

Example:jsrr 5
```

Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.27 LD (Load Register)

Operation:

```
GReg[r] ← [GReg[b] + displacement]

if (transfer_error)

SF ← 1

else

SF ← 0
```

Assembler:

```
Syntax: ld r,(b,displacement)

Example: ld 1,(2,23)
```

Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

rrr / bbb - register field:

```
 000 - GReg[0]

 001 - GReg[1]

 ...

 111 - GReg[7]
```

ddddd - displacement value:

```
00000 - 0

00001 - 1

...

11111 - 31
```

7.2.3.2.28 LDF (Load Register from Functional Unit)

Operation:

```
GReg[r] ← [fu_address]

if (transfer_error)

SF ← 1
```

```
else

SF ←0
```

fu_address is an 8-bit field and depends on addressed functional unit

Assembler:

```
Syntax: ldf r,fu_address

Example: ldf 0,13
```

Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- Burst DMA Read (ldf) for Burst DMA
- Peripheral DMA Read (ldf)-Read Mode for Peripheral DMA

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

ffffffff - functional unit source register and action (unspecified values are reserved):

```
00000000 - MSA

00000100 - MDA

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - MS

00101001 - MD byte - prefetch

00101010 - MD halfword - prefetch

00101011 - MD word - prefetch

01000000 - DSA

11000000 - PSA

11001000 - PD

11010000 - PDA

11011000 - PD in copy mode (rrr contents are lost)

11101000 - PD - prefetch next data

11111111 - PS
```

7.2.3.2.29 LDI (Load Register with Immediate Value)

Operation:

```
GReg[r] ← immediate
```

Assembler:

```
Syntax: ldi r,immediate

Example: ldi 6,1
```

loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

7.2.3.2.30 LDRPC (Load from RPC to Register)

Operation:

```
GReg[r] ← RPC
```

Assembler:

```
Syntax: ldrpc r

Example: ldrpc 3
```

copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.31 LOOP (Hardware Loop)

Operation:

```
if (ff%2 == 0)
   SF ← 0
if (ff/2 == 0)
  DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
   PC ← PC + loop_size + 1
else
   {
      SPC ← PC + 1
      EPC ← PC + loop_size + 1
      LM ← 1
      PC ← PC + 1
   }
```

during every instruction execution in the loop:

```
if ((SF == 1) || (DF == 1))
 {
```

```
    LM ← 0
    PC ← EPC
  }
else if ((PC + 1) == EPC)
 {
    GReg[0] ← GReg[0] - 1
    if (GReg[0] == 0)
      {
         LM ← 0
         PC ← EPC
       }
     else
         PC ← SPC
   }
else
  PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)
   T ← 1
else
   T ← 0
```

Assembler:

```
Syntax: loop n{,ff}
Example: loop 3,1
```

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the ff field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The loop instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times. The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body). The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

Limitations:

1. 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. 2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. 3. The empty loop (0 instruction in the body) is forbidden.
4. 4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

Instruction Fields:

```
ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear SF
```

```
11 - no clear
```

nnnnnnnn - loop size

```
00000000 - empty loop: forbidden value

00000001 - 1 instruction in the loop

00000010 - 2 instructions in the loop

...

11111111 - 255 instructions in the loop
```

7.2.3.2.32 LSL1 (Logical Shift Left by 1 Bit)

Operation:

```
GReg[r]:{b30,...,b1,b0,0} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: lsl1 r

Example: lsl1 2
```

multiplies by 2 the value in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]
```

```
111 - GReg[7]
```

7.2.3.2.33 LSR1 (Logical Shift Right by 1 Bit)

Operation:

```
GReg[r]:{0,b31,b30,...,b1} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: lsr1 r

Example: lsr1 4
```

divides by 2 the unsigned value contained in GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.34 MOV (Logical Move)

Operation:

```
GReg[r] ← GReg[s]
```

Assembler:

```
Syntax: mov r,s

Example: mov 4,0
```

copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register s to the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.35 NOTIFY (Notify to Arm platform)

Operation:

```
 if (jjj & 4 == 0)

 {

   if (jjj&2 == 2)

      HE[CCR] ← 0

   if (jjj&1== 1)

       HI[CCR] ← 1

  }

else if (jjj == 4)
```

```
   EP[CCR] ← 0
else
```

(CCR stands for Current Channel Register)

Assembler:

```
Syntax: notify jjj
Example: notify 3
```

clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding Arm platform by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

jjj - Channel Flags field:

```
000 - unused
001 - set HI for the current channel
010 - clear HE for the current channel
011 - clear HE, set HI for the current channel
100 - clear EP for the current channel
101 - RESERVED
110 - RESERVED
111 - RESERVED
```

7.2.3.2.36 OR (Logical OR)

Operation:

```
GReg[r] ← GReg[s] | GReg[r]
```

Assembler:

```
Syntax: or r,s
```

```
Example: or 3,6
```

ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.37 ORI (Logical OR with Immediate Value)

Operation:

```
GReg[r] ← GReg[r] | immediate
```

Assembler:

```
Syntax: ori r,immediate

Example: ori 1,56
```

ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

Description: Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

7.2.3.2.38 RET (Return from Subroutine)

Operation:

```
PC ← RPC
```

Assembler:

```
Syntax: ret
```

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

7.2.3.2.39 REVB (Reverse Byte Order)

Operation:

```
GReg[r]:{B3,B2,B1,B0} ← GReg[r]:{B0,B1,B2,B3}
```

Assembler:

```
Syntax: revb r

Example:  revb 5
```

reverses bytes order in GReg[5]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.40 Reverse Low Order Bytes(REVBLO)

Operation:

```
GReg[r]:{B3,B2,B0,B1} ← GReg[r]:{B3,B2,B1,B0}
```

Assembler:

```
Syntax: revblo r

Example: revblo 0
```

reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.41 ROR1 (Rotate Right by 1 Bit)

Operation:

```
GReg[r]:{b0,b31,b30,...,b1} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: ror1 r

Example: ror1 3
```

rotates bits to the right in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.42 RORB (Rotate Right by 1 Byte)

Operation:

```
GReg[r]:{B0,B3,B2,B1} ← GReg[r]:{B3,B2,B1,B0}
```

Assembler:

```
Syntax: rorb r

Example: rorb 2
```

rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.43 SOFTBKPT (Software Breakpoint)

Operation:

Stops the current script and enters debug mode

Assembler:

```
softbkpt
```

CPU Flags: Unaffected

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in OnCE and Real-Time Debug.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

7.2.3.2.44 ST (Store Register)

Operation:

```
[GReg[b] + displacement] ← GReg[r]
```

```
if (transfer_error)

 DF ← 1

 else

DF ← 0
```

Assembler:

```
Syntax: st r,(b,displacement)

Example: st 7,(0,9)
```

stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

rrr / bbb - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

ddddd - displacement value:

```
00000 - 0
```

```
00001 - 1

...

11111 - 31
```

7.2.3.2.45 STF (Store Register in Functional Unit)

Operation:

```
[fu_address] ← GReg[r] 0

if (transfer_error) 0

DF ← 1 0

else 0

DF ← 0
```

fu_address is an 8-bit field

Assembler:

```
Syntax: stf r,fu_address

Example: stf 3,0x2B
```

stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Table 7-49. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	1	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the STF instruction usage with each functional unit:

- Burst DMA Write (stf) for Burst DMA
- Peripheral DMA Write (stf)-Write Mode for Peripheral DMA

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

ffffffff - functional unit destination register and action (unspecified values are reserved):

00000000 - MSA in incremented mode

00000100 - MDA in incremented mode

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - clear MS error flag

00001111 - MS

00010000 - MSA in frozen mode

00010100 - MDA in frozen mode

00011000 - MD in copy mode - number of words in rrr

00100000 - MSA in incremented mode - start prefetch

00101000 - MD no data - flush

00101001 - MD byte - flush

00101010 - MD halfword - flush

00101011 - MD word - flush

00110000 - MSA in frozen mode - start prefetch

11000001 - PSA in frozen mode - 8-bit data width

11000010 - PSA in frozen mode - 16-bit data width

11000011 - PSA in frozen mode - 32-bit data width

11000101 - PSA in incremented mode - 8-bit data width

11000110 - PSA in incremented mode - 16-bit data width

11000111 - PSA in incremented mode - 32-bit data width

11001000 - PD

11001001 - PSA in decremented mode - 8-bit data width

11001010 - PSA in decremented mode - 16-bit data width

11001011 - PSA in decremented mode - 32-bit data width

11001100 - clear PS error flag

11001101 - PSA data width becomes 8-bit

11001110 - PSA data width becomes 16-bit

11001111 - PSA data width becomes 32-bit

11010001 - PDA in frozen mode - 8-bit data width

11010010 - PDA in frozen mode - 16-bit data width

11010011 - PDA in frozen mode - 32-bit data width

11010101 - PDA in incremented mode - 8-bit data width

11010110 - PDA in incremented mode - 16-bit data width

11111111- PS

7.2.3.2.46 SUB (Subtract)

Operation:

```
GReg[r] ← GReg[r] - GReg[s]

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: sub r,s

Example: sub 4,7
```

SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register s from the destination General Register r, and stores the result in the destination General Register r. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

Instruction Fields:

rrr / sss - register fields:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.47 SUBI (Subtract with Immediate)

Operation:

```
GReg[r] ← GReg[r] - immediate

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: sub r,immediate

Example: sub 1,255
```

SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

7.2.3.2.48 TST (Test with Zero)

Operation:

```
T ← ((GReg[s] & GReg[r]) != 0)
```

Assembler:

```
Syntax: tst r,s

Example: tst 2,3
```

ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.49 TSTI (Test Immediate)

Operation:

```
T ← ((GReg[r] & immediate) != 0)
```

Assembler:

```
Syntax: tsti r,immediate

Example: tsti 5,13
```

ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]
```

```
010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

7.2.3.2.50 XOR (Logical Exclusive OR)

Operation:

```
GReg[r] ← GReg[s] ^ GReg[r]
```

Assembler:

```
Syntax: xor r,s

Example: xor 0,3
```

XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]
```

```
010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

7.2.3.2.51 XORI (Exclusive OR with Immediate)

Operation:

```
GReg[r] ← GReg[r] ^ immediate
```

Assembler:

```
Syntax: xori r,immediate

Example: xor 7,5
```

XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]
```

```
111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

7.2.3.2.52 YIELD, YIELDGE (DONE, Yield)

By default, unsupported assembler syntax. Can be aliased to the corresponding done instructions (yield = done 0; yieldge = done 1). Refer to the done instruction description DONE (DONE, Yield) .

7.2.4 Software Restrictions

7.2.4.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior.

An example of the sequence which could result in undefined results is shown in the following example:

Instruction sequence not supported

```
stf r1, MSA|PF          ; Update source address, triggers data pre-fetch in the
                        ; background
mov R0,R0               ; Execute multiple assembly instructions, none of which
                        ; read
mov R0,R0               ; or write data to/from MD
stf MD|SZ0|FL           ; Flush FIFO without writing data. If the pre-fetch is still
                        ; in progress when this instruction is executed, there
                        ; could be undefined operation
```

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Work-Around to previous example

```
stf r1, MSA|PF          ; Update source address, triggers data pre-fetch.
```

```
mov R0,R0              ; Execute multiple assembly instructions, none of which
                       ; read
mov R0,R0              ; or write data to/from MD
ldf r2, MD             ; dummy read of MD to ensure pre-fetch is complete
                       ; before the next instruction
stf MD|SZ0|FL          ; Flush FIFO without writing data
```

7.2.5 Application Notes

7.2.5.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application.

The boot code is run after reset when channel 0 is started by the Arm platform. The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the Arm platform memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation (see SDMA Scripts).

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

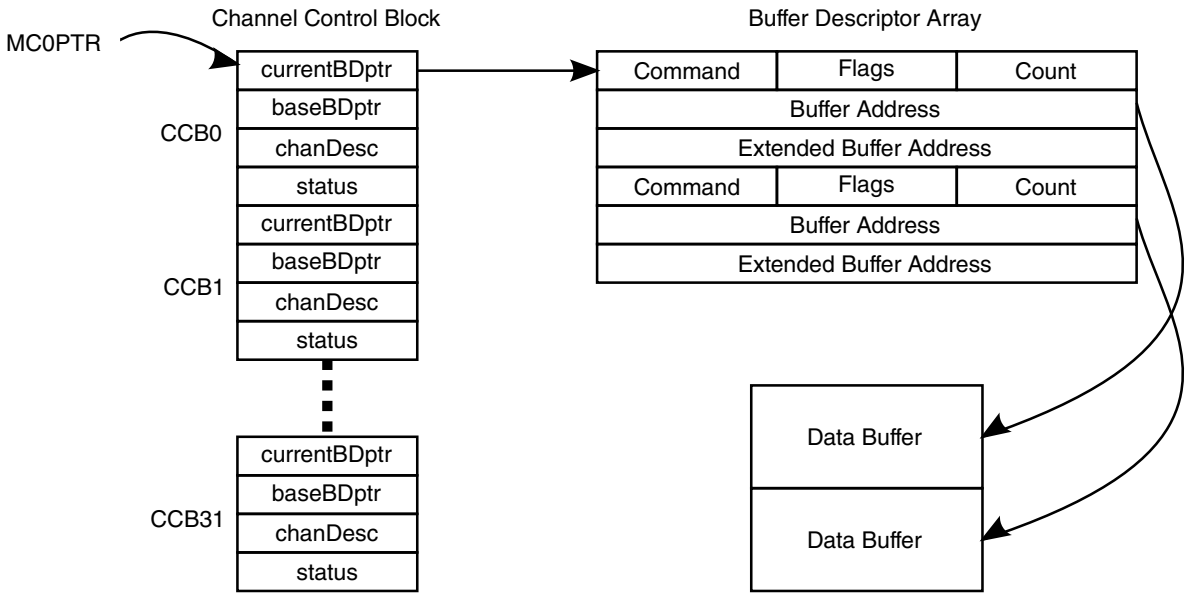

Figure 7-16. Data Structures Layout

The previous figure shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MC0PTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described Buffer Descriptor Format.

7.2.5.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as, shown in the figure found here.

A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the Arm platform processor memory. The CCB contains a pointer to the base BD as well as the current BD.

Table 7-50. Buffer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Command								-	-	L	R	I	C	W	D	Count															
Buffer Address																															
Extended Buffer Address																															

Table 7-51. Buffer Descriptor Field Descriptions

Field	Description
31-24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootload script are defined in Buffer Descriptor Commands for Bootload scripts. Refer to the individual script definition in script library documents in SDMA Scripts for command field definitions for other scripts.
23	Reserved
22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over.This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set.For example, when the DSP prepares a single buffer descriptor with count equals to 25 and Arm platform prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to Arm platform, the DSP buffer descriptor is normally closed while the Arm platform buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the Arm platform. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	Continuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers.The Continuous bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the Arm platform wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONtinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 Arm platform owns the buffer. 1 SDMA owns the buffer
15-0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31-0	Buffer address. Address pointer to the data buffer.
31-0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit W=1, the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the Arm platform with D=0, and the remainder owned by the SDMA with D=1. The count field of the buffer descriptor indicates how much data has been transmitted.

If Arm platform has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONT*inous bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3rd BD. The SDMA script opens and processes BD#1. Since *CONT*inous bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3rd BD, if *CONT*inous is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONT*inous bit and *Wrap* bits are both set in the 3rd BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONT*inous bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desires the SDMA to fill them again. Basically, if the Arm platform expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the Arm platform to set the *Done* bit of a buffer descriptor at an appropriate time.

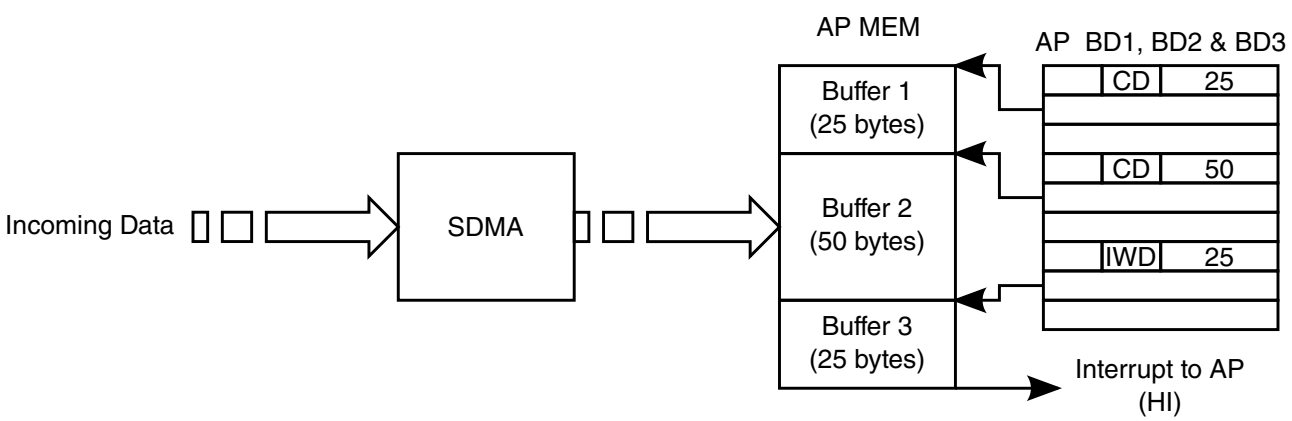

Figure 7-17. Buffer Descriptor Flow

The previous figure shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the CONTinuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The Done bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the Arm platform because the Interrupt flag is set in the 3rd BD. The CONTinuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the Wrap flag was set in the 3rd BD. It is the Arm platform responsibility to set the Done bit of all the BD if it wants to use the same buffers.

7.2.5.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script.

The following table lists the buffer descriptor commands defined for the channel 0 bootload script.

Table 7-52. Channel Zero Buffer Descriptor Commands

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from Arm platform memory buffer	Arm platform memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to Arm platform memory buffer	Arm platform memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from Arm platform memory buffer	Arm platform memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to Arm platform memory buffer	Arm platform memory destination address	SDMA memory source address
cccc_c111 (0x07 | CHN)	C0_SETCTX	Load Context for channel cccc into SDMA RAM from Arm platform memory buffer	Arm Platform memory source address	-
cccc_c011 (0x03 | CHN)	C0_GETCTXT	Copy Context for channel ccccc from SDMA RAM to Arm platform memory buffer	Arm platform memory destination address	-

The Channel 0 bootload commands are summarized as follows:

- C0_SET_[PM-DM]: load the buffer descriptor data in the SDMA local memory at the address pointed to by the "extended buffer address" field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0_SET_PM is used, the count field is expressed in "shorts" (16-bit half words), this command can be used to download scripts. When C0_SET_DM is

used, the count field is expressed in "long" (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.

- C0_GET_[PM-DM]: write to the buffer descriptor's data buffer the content of the SDMA local memory from the address pointed to by the "extended buffer address" field for the length defined by the count in the buffer descriptor. C0_GET_PM is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in "shorts"; while C0_GET_DM is used to dump to the buffer descriptor's data buffer, so the count field is in "longs."
- C0_SETCTX: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination address in SDMA memory. Then the C0_SET_DM command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.
- Command value: (in binary) cccc c111, where ccccc is the channel number (5 bits). For instance, 0x0F means set context for channel 1, 0xFF means set context for channel 31.

- C0_GETCTX: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the C0_GET_DM command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.
- Command value: (in binary): cccc c011, where ccccc is the channel number (5 bits). For instance, 0x03 means get context of channel 1, 0xFB means get context of channel 31.

NOTE

To download channel context, C0_SETDM and C0_SETCTXT command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the C0_SETDM, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

7.2.5.1.3 Example of Buffer Descriptors for Channel 0.

Figure 7-19 illustrates the buffer descriptors that must be set in Arm platform memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in the following figure.

7.2.5.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed.

The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure below shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

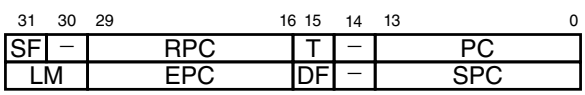
A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

The structure is divided in 4 areas:

- Channel status registers
- General purpose registers
- Functional units state registers reflecting the state of the Arm platform DMAs (Burst and Peripheral DMA).
- Scratch RAM

The details of the channel context status registers are described in the following figure.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0_SETPM command.



SF: Source fault while loading data
RPC: Return program counter
T: Test bit: status of arithmetic and test instructions
PC: Program counter
LM: Loop mode
EPC: Loop end program counter
DF: Destination fault while storing data
SPC: Loop Start program counter

Figure 7-20. SDMA State Registers (ShPC, ShLoop)

7.2.5.2 Typical Data Transfer Supported by SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units.

The Arm platform memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See the following table for the summary.

Table 7-53. Typical Data Transfers Summary

Data Transfer	Peripheral DMA	Burst DMA	Comments
Arm platform External Memory ↔ Arm platform External Memory		3	Copy mode Script example, see Burst DMA Unit Copy Mode and External Memory to External Memory.
Arm platform Peripheral ↔ Arm platform Peripheral	3		Copy mode if same data path width Script example, see Peripheral to Peripheral Transfer.
Arm platform External Memory ↔ Arm platform Peripheral	3	3	Data transit through SDMA Script example, see Transfer Between Peripheral and External Memory.
Arm platform External Memory ↔ Arm platform Internal Memory		3	Copy mode Script example, see Transfer Between External Memory and Internal Memory.
Arm platform Internal Memory ↔ Arm platform Internal Memory		3	Copy mode Script example, see Internal Memory to Internal Memory.
Arm platform Internal memory ↔ Arm platform Peripheral	3		Data transit through SDMA Script example, see Transfer Between Peripheral and Internal Memory.

NOTE

These scripts are provided as examples of how to use DMA blocks to perform required data transfers: They are not "official" programs.

7.2.5.2.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory.

For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register.

The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

Data Moves in External Memory

```
1         stf r1,MSA                          // Source address setup

2         stf r2,MDA                          // Destination address setup

3         ldi r0,0x64                         // 64 words must be transferred from MSA to
MDA

4         ldi r1,0x8

MAIN_XFER:

5         cmphs r0,r1                         // Is r0 >= 0x8

6         bf LAST_XFER                      // If not, jump to last transfer label

7         stf r1,MD|CPY                        // Copy 8 words from MSA to MDA address.

8         subi r0,0x8                         // Decrement counter

9         jmp MAIN_XFER                     // return to main transfer loop

LAST_XFER:

10        stf r0,MD|CPY                        // perform last transfer
```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN_XFER), r1 always equals 8, so burst lengths are 8 words. On the last ldf |CPY instruction (10), r1 equals the reminder of r0 divided by 8; therefore, the length of bursts triggered in copy mode equal r1 value, which is between 1 and 7.

7.2.5.2.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used.

It is programmed in copy mode, so no data will transmit through the SDMA general register used in the ldf instruction, but the contents of the general register are lost. The SDMA core only monitors the transfer.

7.2.5.2.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

Same Data Path Width for Source and Destination

```
//SETUP SECTION
1         stf r1, PSA|SZ16|F                    //r1=0x1002 Source address register setup
2         stf r2, PDA|SZ16|F                    //r2=0x2006 Destination address register
setup
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0xa                           //loop counter is 10
//MAIN LOOP TRANFER
copy_loop:

5         loop 2,0
6           ldf r7,PD|CPY                      //Reads 1 half-word from src and writes to
dest.
7           yield
8         bdf ERROR_DURING_XFER
ERROR_ADDR_SETUP:
                    //correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
//flag error is set,
//PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware loop instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute he next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction ldf is a multi-cycle instruction.

7.2.5.2.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag.

The following example shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

Different Data Path Width for Source and Destination

```
//SETUP SECTION
1         stf r1, PSA|SZ32|F|PF                    //r1=0x1000 and prefetch data
2         stf r2, PDA|SZ16|F                      //r2=0x2006
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0xa                             //loop counter is 10
//MAIN LOOP TRANFER
main_loop_xfer_16_16:
5         loop 6,0
6           ldf r7,PD                           //copy 32-bit of PD in r7
7           stf r7,PD                            //store 16 LSB of r7 in PD and a flush is
executed
8           rorb r7
9           rorb r7                            //16 MSB --> 16 LSB
10          stf r7,PD                            //store 16 LSB of r6 in PD and a flush.
11          yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the ldf will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

7.2.5.2.3 Transfer Between Peripheral and External Memory

7.2.5.2.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from word peripheral to the external memory would be as follows:

Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1         stf r1, PSA|SZ16|F|PF                    //r1=0x1000 and prefetch 32-bit data
2         stf r2, MDA                            //r2=0x2000, setup burst DMA destination
address
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0x64                            //loop counter is 100
5
          //MAIN LOOP TRANFER
6         loop 3,0
7           ldf r1,PD|PF                         // read 32 bits of PD and initiate a new read
```

```
access.
8           stf r1,MD|32                    // store 32 bits of r1 in the MD fifo.
9           yield
10        ldf r1,PD                       // last word data is read
11        stf r1,MD|32|FL                   // to flush all remaining bytes of MD
```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. The following figures show how the peripheral DMA and burst DMA work in parallel.

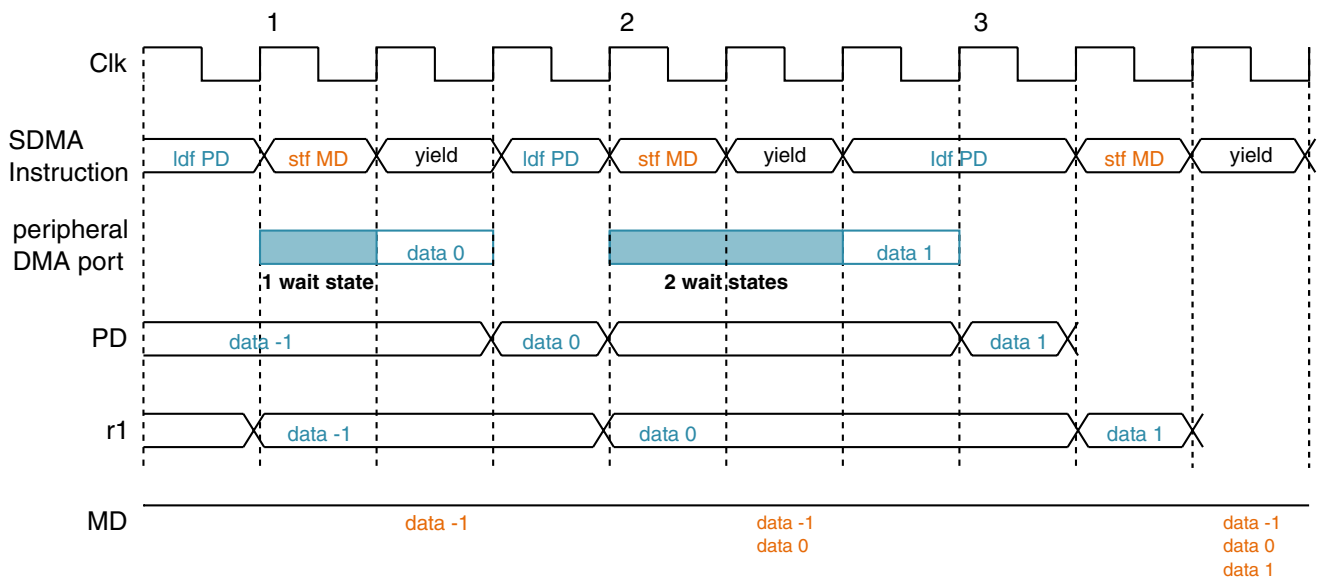


Figure 7-21. Peripheral to External Memory Example (1)

As seen in the figure above, the read access triggered by the ldf PD instruction is symbolized by the blue bar when in progress. After wait states, the read data (data 0, data 1) is stored in PD on the clk rising edge. On edge 2, data 0 is available in PD so it can be transferred to the SDMA general register r1, and then stored in MD FIFO. On edge 3, data 1 is not in PD; therefore, SDMA is stalled on the ldf instruction, which lasts two cycles. The figure below shows an example of when MD FIFO is full with data.

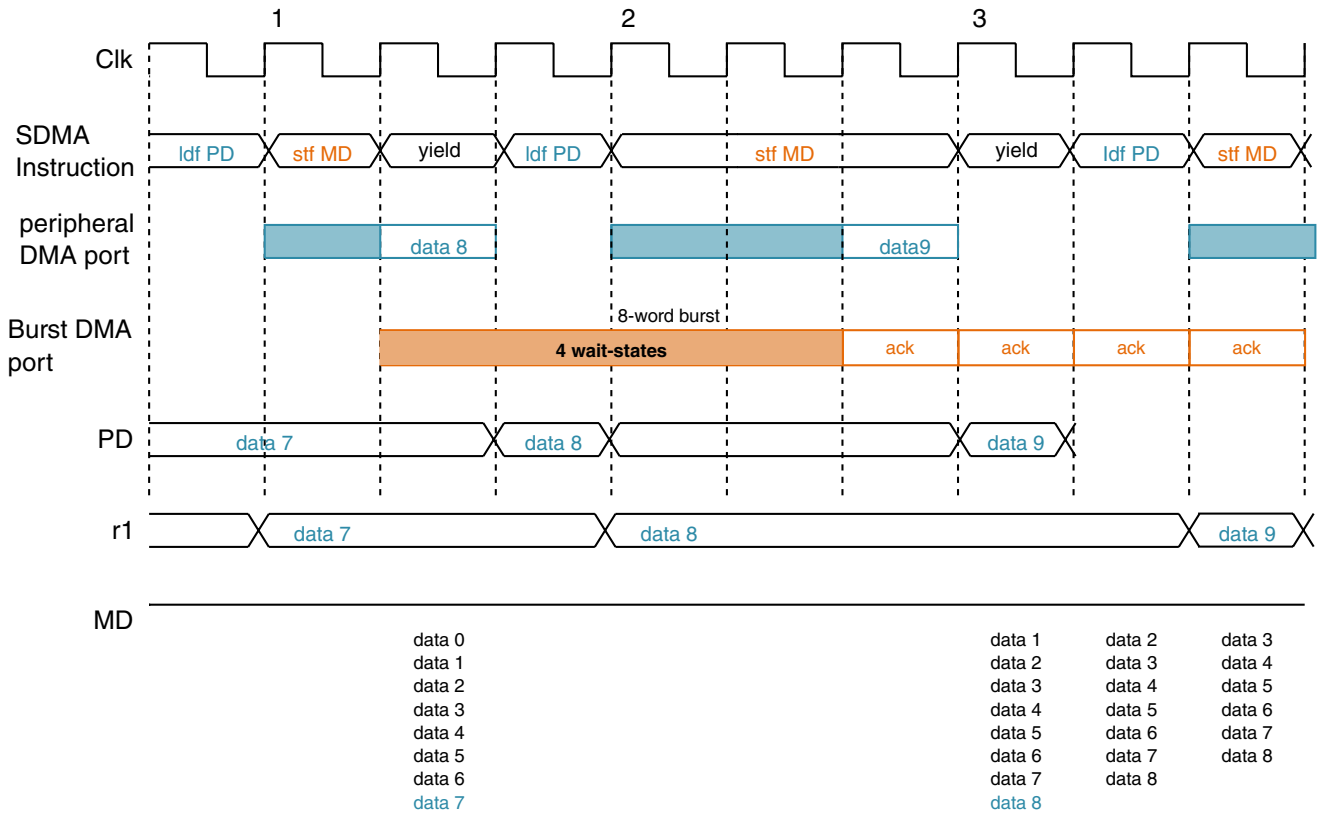

Figure 7-22. Peripheral to External Memory Example (2)

In the previous figure, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction stf because no acknowledge was received, MD FIFO is full, and there is no empty slot to store data 9. When an acknowledge is sampled by the burst DMA, FIFO is shifted and data 8 is written. As long as there is at least one empty slot in MD FIFO, the stf MD instruction lasts one cycle.

7.2.5.2.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from external memory to a word peripheral would be as follows:

External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1         stf r1, MSA|PF             //r1=0x1000 and starts a 8-word read burst
2         stf r2, PDA|SZ32|P          //r2=0x2010, setup peripheral DMA destination address
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0x64               //loop counter is 100
//MAIN LOOP TRANFER
```

```
6          loop 3,0
7            ldf r1,MD|32|PF          // read 32 bits of MD and initiate a new read access
                                   // if MD is empty after this reading.
8            stf r1,PD              // store 32 bits of r1 in the PD.
9            yield
           10 ldf r1,MD|32            // last word data is read
11         stf r1,PD                 // last write access
```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

7.2.5.2.4 Transfer Between External Memory and Internal Memory

Since the internal memory (Arm platform RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in Transfer Between Peripheral and External Memory can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

7.2.5.2.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in Peripheral to Peripheral Transfer can be reused with a different programming of the peripheral DMA address registers.

7.2.5.2.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode.

The SDMA script is very similar to the one described in Peripheral to Peripheral Transfer, except for the peripheral DMA address registers programming.

7.2.6 Arm Platform Memory Map and Control Register Definitions

The Arm platform controls the SDMA by means of several interface registers. Those registers are described in the current section.

All registers are clocked with the SDMA clock (which means the Arm platform must ensure that the SDMA clock is running when it wants to access any register).

SDMAARM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

7.2.6.1 Arm platform Channel 0 Pointer (SDMAARMx_MC0PTR)

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MC0PTR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARMx_MC0PTR field descriptions

Field	Description
MC0PTR	**Channel 0 Pointer** contains the 32-bit address, in Arm platform memory, of channel 0 control block (the boot channel). Appendix A fully describes the SDMA Application Programming Interface (API). The Arm platform has a read/write access and the SDMA has a read-only access.

7.2.6.2 Channel Interrupts (SDMAARMx_INTR)

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARMx_INTR field descriptions

Field	Description
HI[31:0]	The Arm platform Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the Arm platform. This register is a "write-ones" register to the Arm platform. When the Arm platform sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding `done` instruction is executed.

7.2.6.3 Channel Stop/Channel Status (SDMAARMx_STOP_STAT)

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARMx_STOP_STAT field descriptions

Field	Description
HE	This 32-bit register gives access to the Arm platform Enable bits. There is one bit for every channel. This register is a "write-ones" register to the Arm platform. When the Arm platform writes 1 in bit i of this register, it clears the HE[i] and HSTART[i] bits. Reading this register yields the current state of the HE[i] bits.

7.2.6.4 Channel Start (SDMAARMx_HSTART)

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HSTART_HE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARMx_HSTART field descriptions

Field	Description
HSTART_HE	The HSTART_HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the Arm platform to trigger a channel a second time before the first trigger is processed. • This register is a "write-ones" register to the Arm platform. Neither HSTART[i] bit can be set while the corresponding HE[i] bit is cleared. • When the Arm platform tries to set the HSTART[i] bit by writing a one (if the corresponding HE[i] bit is clear), the bit in the HSTART[i] register will remain cleared and the HE[i] bit will be set. • If the corresponding HE[i] bit was already set, the HSTART[i] bit will be set. The next time the SDMA channel *i* attempts to clear the HE[i] bit by means of a `done` instruction, the bit in the HSTART[i] register will be cleared and the HE[i] bit will take the old value of the HSTART[i] bit. • Reading this register yields the current state of the HSTART[i] bits. This mechanism enables the Arm platform to pipeline two HSTART commands per channel.

7.2.6.5 Channel Event Override (SDMAARMx_EVTOVR)

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	EO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARMx_EVTOVR field descriptions

Field	Description
EO	The Channel Event Override register contains the 32 EO[i] bits. A bit set in this register causes the SDMA to ignore DMA requests when scheduling the corresponding channel.

7.2.6.6 Channel BP Override (SDMAARMx_DSPOVR)

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARMx_HOSTOVR field descriptions

Field	Description
HO	The Channel Arm platform Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the Arm platform enable bit (HE) when scheduling the corresponding channel.

7.2.6.8 Channel Event Pending (SDMAARMx_EVTPEND)

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EP																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARMx_EVTPEND field descriptions

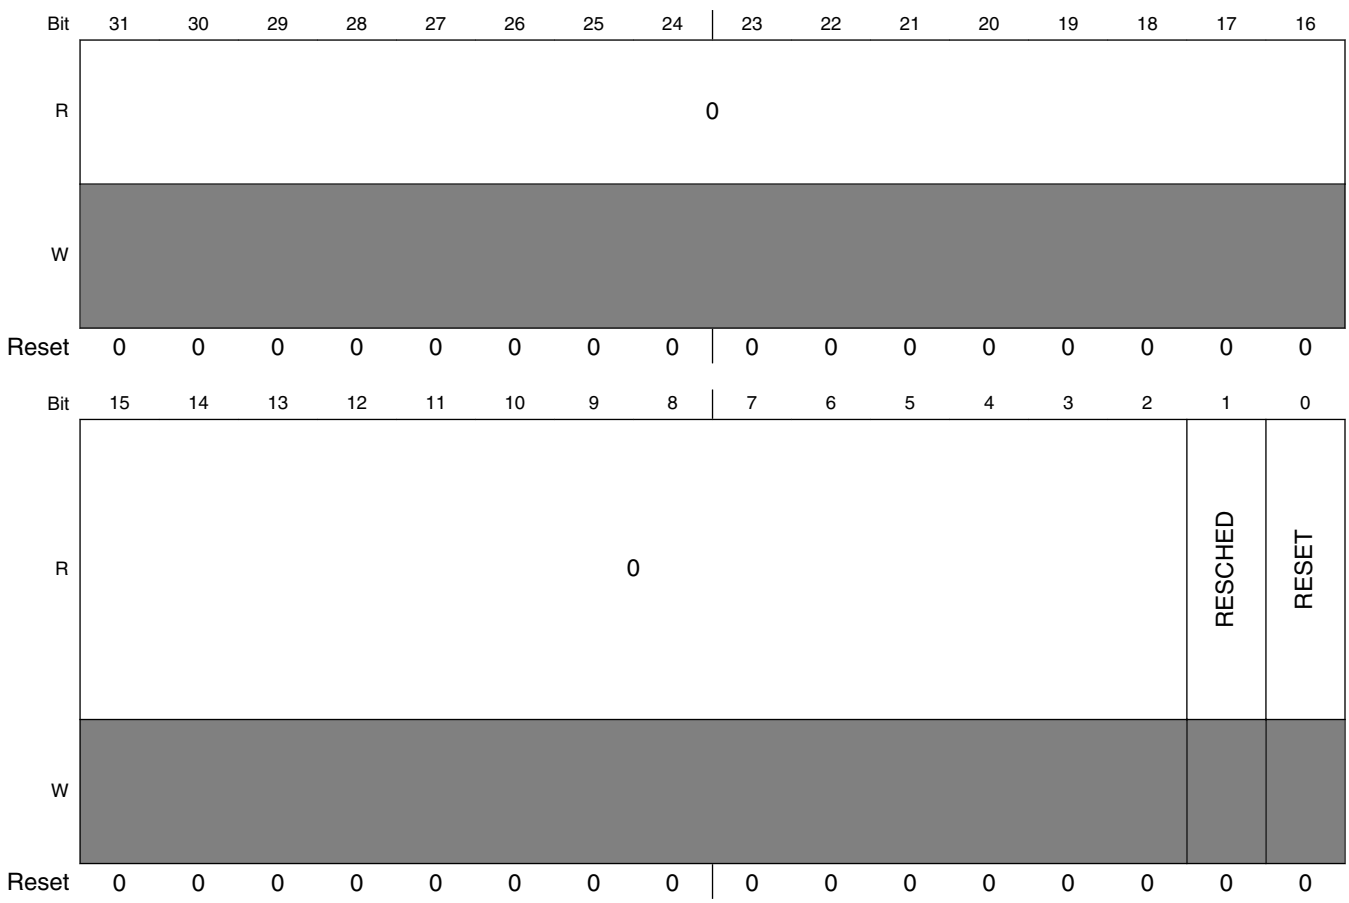
Field	Description
EP	The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the Arm platform to determine what channels are pending after the reception of a DMA request.

SDMAARMx_EVTPEND field descriptions (continued)

Field	Description
	• Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests. • The EP[i] bit may be cleared by the `done` instruction when running the channel *i* script. This a "write-ones" mechanism: Writing a '0' does not clear the corresponding bit.

7.2.6.9 Reset Register (SDMAARMx_RESET)

Address: Base address + 24h offset



SDMAARMx_RESET field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a `done` instruction. This enables the Arm platform to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.

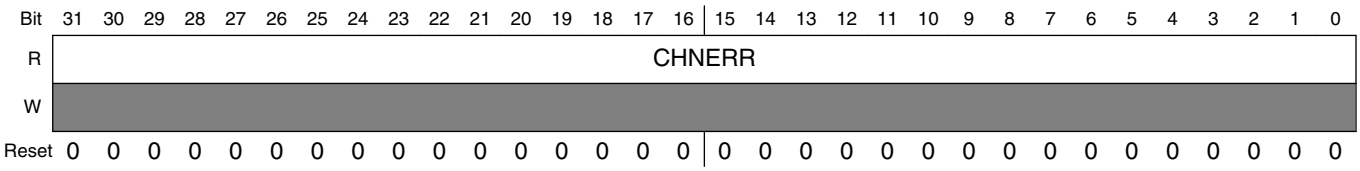
Table continues on the next page...

SDMAARMx_RESET field descriptions (continued)

Field	Description
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

7.2.6.10 DMA Request Error Register (SDMAARMx_EVTERR)

Address: Base address + 28h offset

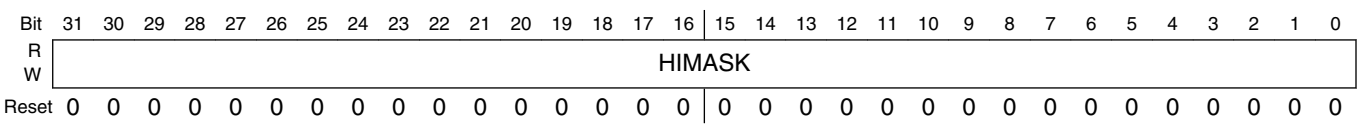


SDMAARMx_EVTERR field descriptions

Field	Description
CHNERR	This register is used by the SDMA to warn the Arm platform when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel. • An interrupt is sent to the Arm platform if the corresponding channel bit is set in the INTRMASK register. • This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the Arm platform or during SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel *i* is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the Arm platform tries to set the EP[i] bit, whereas, that EP[i] bit is already set.

7.2.6.11 Channel Arm platform Interrupt Mask (SDMAARMx_INTRMASK)

Address: Base address + 2Ch offset



SDMAARMx_INTRMASK field descriptions

Field	Description
HIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit HIMASK[i] is set, the HI[i] bit is set and an interrupt is sent to the Arm platform when a DMA request error is detected on channel *i* (for example, EVTERR[i] is set).

7.2.6.12 Schedule Status (SDMAARMx_PSW)

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARMx_PSW field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning. 0 No running channel 1 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel. 0 No running channel 1 Active channel priority
CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA. SDMA. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

7.2.6.13 DMA Request Error Register (SDMAARMx_EVTERRDBG)

Address: Base address + 34h offset

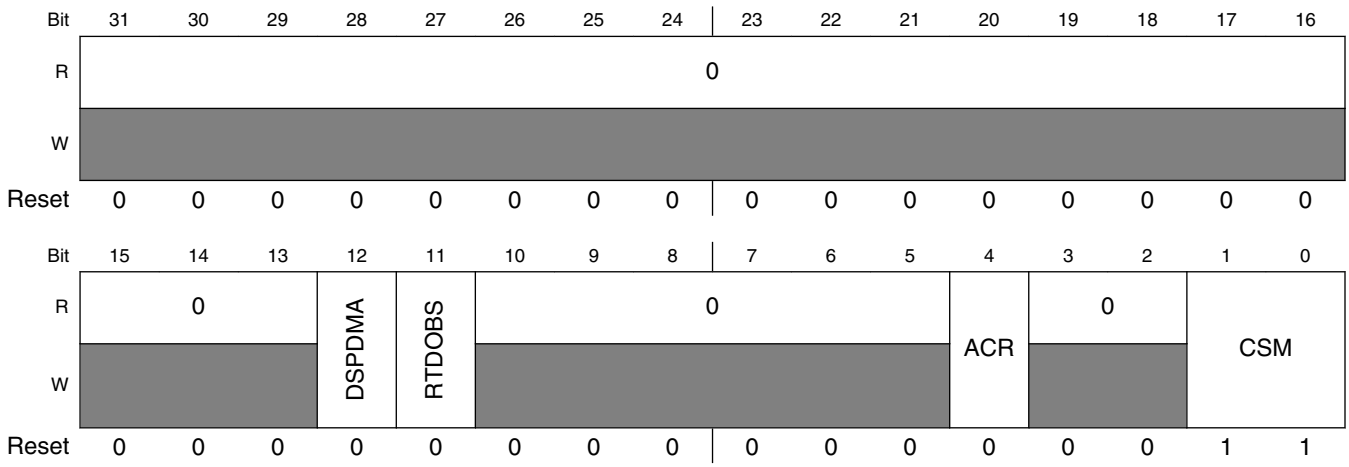
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CHNERR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARMx_EVTERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVTERR, except reading it does not clear its contents. This address is meant to be used in debug mode. The Arm platform OnCE may check this register value without modifying it.

7.2.6.14 Configuration Register (SDMAARMx_CONFIG)

Address: Base address + 38h offset



SDMAARMx_CONFIG field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 DSPDMA	This bit's function is reserved and should be configured as zero. 0 - Reset Value 1 - Reserved
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–5 Reserved	This read-only field is reserved and always has the value 0.
4 ACR	Arm platform DMA / SDMA Core Clock Ratio. Selects the clock ratio between Arm platform DMA interfaces (burst DMA and peripheral DMA) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 Arm platform DMA interface frequency equals twice core frequency 1 Arm platform DMA interface frequency equals core frequency
3–2 Reserved	This read-only field is reserved and always has the value 0.
CSM	Selects the Context Switch Mode. The Arm platform has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase. NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used.

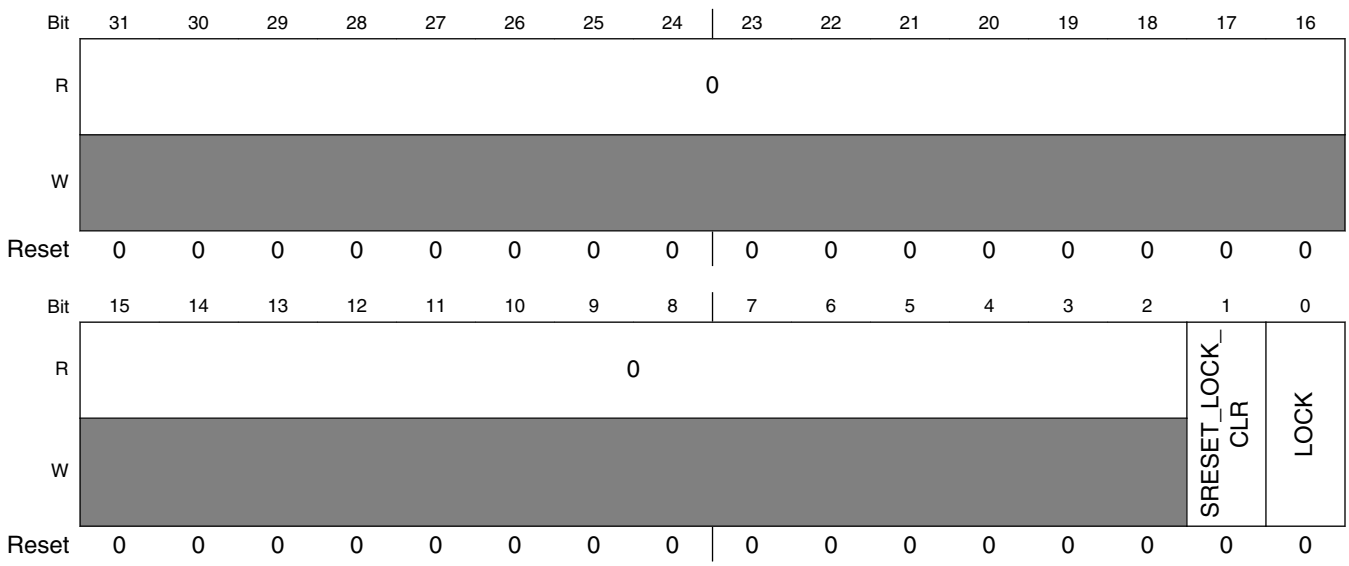
Table continues on the next page...

SDMAARMx_CONFIG field descriptions (continued)

Field	Description
	0 static 1 dynamic low power 2 dynamic with no loop 3 dynamic

7.2.6.15 SDMA LOCK (SDMAARMx_SDMA_LOCK)

Address: Base address + 3Ch offset



SDMAARMx_SDMA_LOCK field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.
1 SRESET_LOCK_CLR	The SRESET_LOCK_CLR bit determine if the LOCK bit is cleared on a software reset triggered by writing to the RESET register. This bit cannot be changed if LOCK=1. SREST_LOCK_CLR is cleared by conditions that clear the LOCK bit. 0 Software Reset does not clear the LOCK bit. 1 Software Reset clears the LOCK bit.
0 LOCK	The LOCK bit is used to restrict access to update SDMA script memory through ROM channel zero scripts and through the OnCE interface under Arm platform control. The LOCK bit is set: • The SDMA_LOCK, ONCE_ENB,CH0ADDR, and ILLINSTADDR registers cannot be written. These registers can be read, but writes are ignored. • SDMA software executing out of ROM or RAM may check the LOCK bit in the LOCK register Lock Status Register (SDMACORE_SDMA_LOCK) to determine if certain operations are allowed, such as up-loading new scripts.

Table continues on the next page...

SDMAARMx_SDMA_LOCK field descriptions (continued)

Field	Description
	Once the LOCK bit is set to 1, only a reset can clear it. The LOCK bit is cleared by a hardware reset. LOCK is cleared by a software reset only if SRESET_LOCK_CLR is set. 0 LOCK disengaged. 1 LOCK enabled.

7.2.6.16 OnCE Enable (SDMAARMx_ONCE_ENB)

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

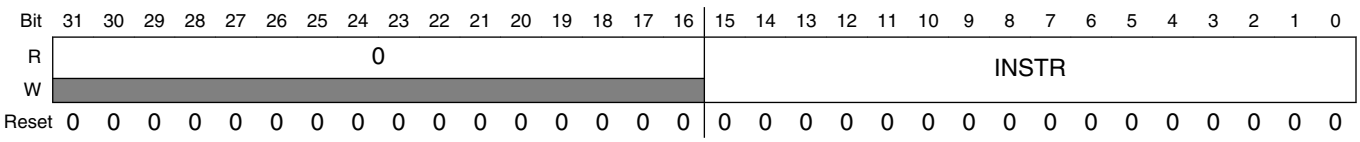
SDMAARMx_ONCE_DATA field descriptions

Field	Description
DATA	Data register of the OnCE JTAG controller. Refer to OnCE and Real-Time Debug for information on this register.

7.2.6.18 OnCE Instruction Register (SDMAARMx_ONCE_INSTR)

Address: Base address + 48h offset

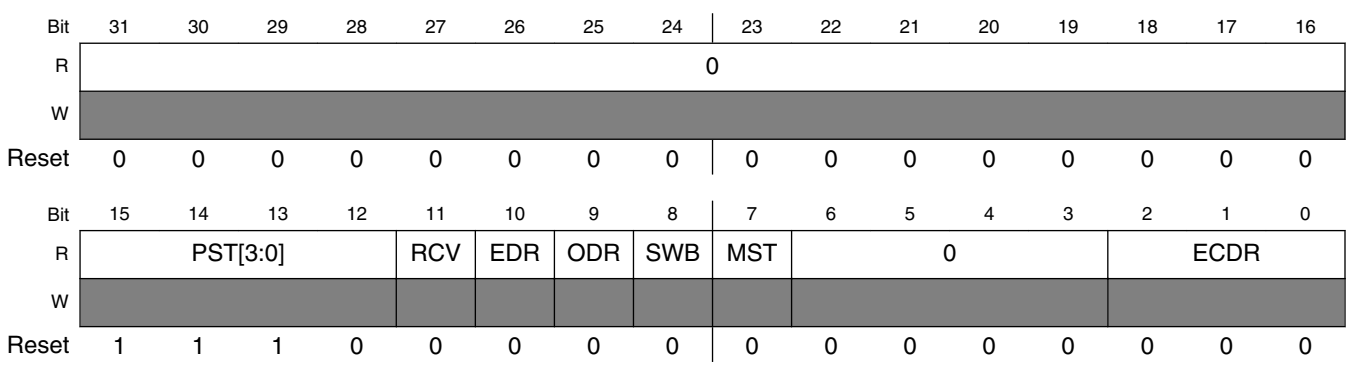


SDMAARMx_ONCE_INSTR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
INSTR	Instruction register of the OnCE JTAG controller. Refer to OnCE and Real-Time Debug for information on this register.

7.2.6.19 OnCE Status Register (SDMAARMx_ONCE_STAT)

Address: Base address + 4Ch offset



SDMAARMx_ONCE_STAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows: • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st).

Table continues on the next page...

SDMAARMx_ONCE_STAT field descriptions (continued)

Field	Description
	• The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the Arm platform peripheral interface. 0 The JTAG interface controls the OnCE. 1 The Arm platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value 0.
ECDR	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addra_cond, addrb_cond, and data_cond conditions. The value of those fields is given by the EDR bits.

Table continues on the next page...

SDMAARMx_ONCE_STAT field descriptions (continued)

Field	Description
	0 1 matched addra_cond 1 1 matched addrb_cond 2 1 matched data_cond

7.2.6.20 OnCE Command Register (SDMAARMx_ONCE_CMD)

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

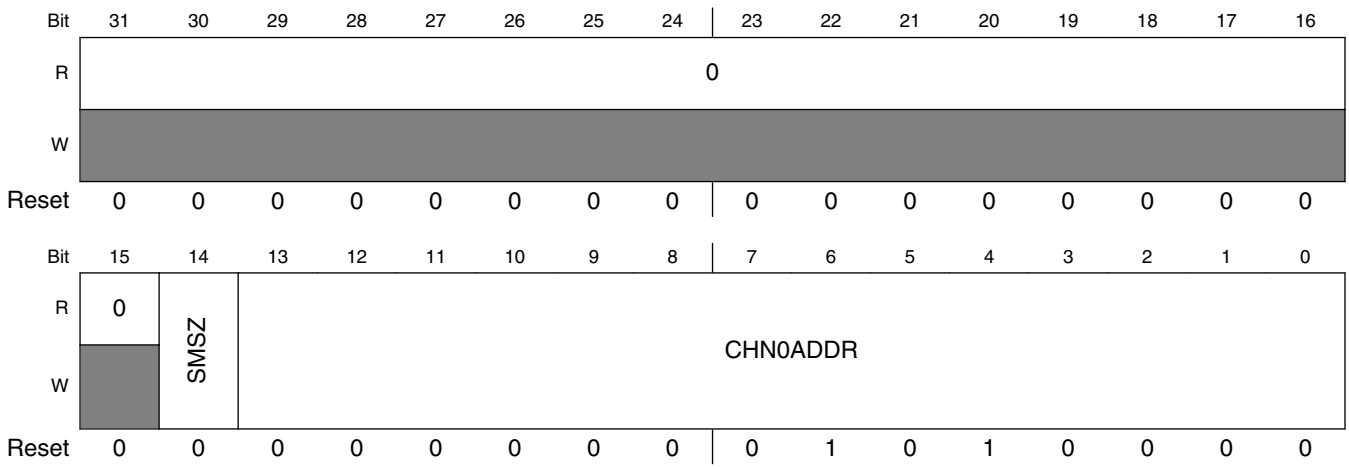
SDMAARMx_ILLINSTADDR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
ILLINSTADDR	The Illegal Instruction Trap Address is the address where the SDMA jumps when an illegal instruction is executed. It is 0x0001 after reset. The value of ILLINSTADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

7.2.6.22 Channel 0 Boot Address (SDMAARMx_CHN0ADDR)

Address: Base address + 5Ch offset



SDMAARMx_CHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set. 0 24 words per context 1 32 words per context
CHN0ADDR	This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80). The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

7.2.6.23 DMA Requests (SDMAARMx_EVT_MIRROR)

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARMx_EVT_MIRROR field descriptions

Field	Description
EVENTS	This register reflects the DMA requests received by the SDMA for events 31-0. The Arm platform and the SDMA have a read-only access. There is one bit associated with each of 32 DMA request events. This information may be useful during debug of the blocks that generate the DMA requests. The EVT_MIRROR register is cleared following read access. 0 DMA request event not pending 1 DMA request event pending

7.2.6.24 DMA Requests 2 (SDMAARMx_EVT_MIRROR2)

Address: Base address + 64h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

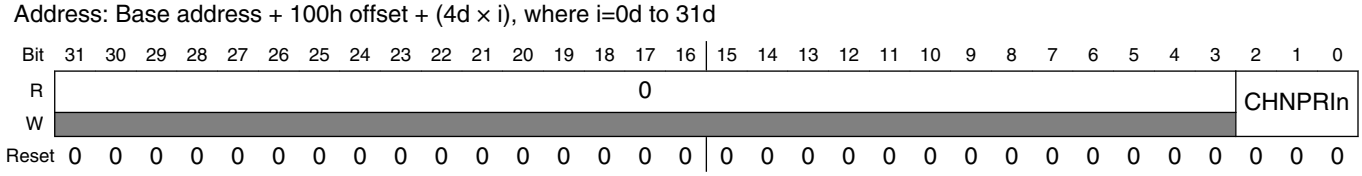
6 CNF4	Configuration of the SDMA event line number *i* that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution. 0 channel 1 DMA request
NUM4[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number *i*.

7.2.6.27 Channel Priority Registers (SDMAARMx_SDMA_CHNPRI*n*)

Address: Base address + 100h offset + (4d × i), where i=0d to 31d



SDMAARMx_SDMA_CHNPRI*n* field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
CHNPRIn	This contains the priority of channel number *n*. Useful values are between 1 and 7; 0 is reserved by the SDMA hardware to determine when there is no pending channel. Reset value is 0, which prevents the channels from starting.

7.2.6.28 Channel Enable RAM (SDMAARMx_CHNENBL*n*)

Address: Base address + 200h offset + (4d × i), where i=0d to 47d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ENBLn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARMx_CHNENBL*n* field descriptions

Field	Description
ENBLn	This 32-bit value selects the channels that are triggered by the DMA request number *n*. If ENBLn[i] is set to 1, bit EP[i] will be set when the DMA request *n* is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the Arm platform to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

7.2.6.29 SDMA DONE0 Configuration (SDMAARMx_DONE0_CONFIG)

7.2.7 BP Memory Map and Control Register Definitions

The following section describes SDMA control registers available to the BP.

NOTE

These registers are physically implemented in all platforms, but are not accessible when the SDMA BP control port is not connected. Reset values are calculated to allow the system to work when those registers cannot be accessed.

All registers are clocked with the SDMA clock (which means the SDMA clock must be running when the BP wants to access any register).

SDMABP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

SDMABPx_DC0PTR field descriptions

Field	Description
DC0PTR	**Channel 0 Pointer** contains the 32-bit address, in BP memory, of the array of channel control blocks starting with the one for channel 0 (the control channel). This register should be initialized by the BP before it enables a channel (for example, channel 0). See the API document SDMA Scripts User Manual for the use of this register. The BP has a read/write access and the SDMA has a read-only access.

7.2.7.2 Channel Interrupts (SDMABPx_INTR)

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMABPx_INTR field descriptions

Field	Description
DI	The BP Interrupts register contains the 32 DI[i] bits. If any bit is set, it will cause an interrupt to the BP. • This register is a "write-ones" register to the BP. When the BP sets a bit in this register, the corresponding DI[i] bit is cleared. • The interrupt service routine should clear individual channel bits when their interrupts are serviced; failure to do so will cause continuous interrupts. • The SDMA is responsible for setting the DI[i] bit corresponding to the current channel when the corresponding `done` instruction is executed.

7.2.7.3 Channel Stop/Channel Status (SDMABPx_STOP_STAT)

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABPx_STOP_STAT field descriptions

Field	Description
DE	This 32-bit register gives access to the BP (DSP) Enable bits, DE. There is one bit for every channel. • This register is a "write-ones" register to the BP. • When the BP writes 1 in bit *i* of this register, it clears the DE[i] and DSTART[i] bits. • Reading this register yields the current state of the DE[i] bits.

7.2.7.4 Channel Start (SDMABPx_DSTART)

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABPx_DSTART field descriptions

Field	Description
DSTART_DE	The DSTART_DE registers are 32 bits wide with one bit for every channel. • When a bit is written to 1, it enables the corresponding channel. • Two physical registers are accessed with that address (DSTART and DE), which enables the BP to trigger a channel a second time before the first trigger was processed. • This register is a "write-ones" register to the BP. Neither DSTART[i] bit can be set while the corresponding DE[i] bit is cleared. • When the BP tries to set the DSTART[i] bit by writing a one (if the corresponding DE[i] bit is clear), the bit in the DSTART[i] register will remain cleared and the DE[i] bit will be set. If the corresponding DE[i] bit was already set, the DSTART[i] bit will be set. • The next time the SDMA channel *i* attempts to clear the DE[i] bit by means of a `done` instruction, the bit in the DSTART[i] register will be cleared and the DE[i] bit will take the old value of the DSTART[i] bit. • Reading this register yields the current state of the DSTART[i] bits. This mechanism enables the BP to pipeline two DSTART commands per channel.

7.2.7.5 DMA Request Error Register (SDMABPx_EVTERR)

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMABPx_EVTERR field descriptions

Field	Description
CHNERR	This register is used by the SDMA to warn the BP when an incoming DMA request was detected; it then triggers a channel that is already pending or being serviced, which may mean there is an overflow of data

SDMABPx_EVTERR field descriptions (continued)

Field	Description
	for that channel. An interrupt is sent to the BP if the corresponding channel bit is set in the INTRMASK register. • This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the BP or during an SDMA reset. • The CHNERR[i] bit is set when a DMA request that triggers channel *i* is received through the corresponding input pins and the EP[i] bit is already set. The EVTERR[i] bit is unaffected if the BP tries to set the EP[i] bit when that EP[i] bit is already set.

7.2.7.6 Channel DSP Interrupt Mask (SDMABPx_INTRMASK)

Address: Base address + 2Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DIMASK																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABPx_INTRMASK field descriptions

Field	Description
DIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit DIMASK[i] is set, the DI[i] bit is set and an interrupt is sent to the BP when a DMA request error is detected on channel *i* (for example, EVTERR[i] is set).

7.2.7.7 DMA Request Error Register (SDMABPx_EVTERRDBG)

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CHNERR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMABPx_EVTERRDBG field descriptions

Field	Description
CHNERR	This register is the same as EVTERR except reading it does not clear its contents. This address is meant to be used in debug mode. The BP OnCE may check this register value without modifying it.

7.2.8 SDMA Internal (Core) Memory Map and Internal Register Definitions

The actual SDMA memory mapped registers are summarized in the following sections; for peripherals' memory maps, refer to the respective chapters.

The following definitions serve as a key for the SDMA internal register summary.

SDMACORE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
302B_0000	Arm platform Channel 0 Pointer (SDMACORE3_MC0PTR)	32	R	0000_0000h	7.2.8.1/ 1211
302B_0008	Current Channel Pointer (SDMACORE3_CCPTR)	32	R	0000_0000h	7.2.8.2/ 1211
302B_000C	Current Channel Register (SDMACORE3_CCR)	32	R	0000_0000h	7.2.8.3/ 1212
302B_0010	Highest Pending Channel Register (SDMACORE3_NCR)	32	R	0000_0000h	7.2.8.4/ 1212
302B_0014	External DMA Requests Mirror (SDMACORE3_EVENTS)	32	R	0000_0000h	7.2.8.5/ 1213
302B_0018	Current Channel Priority (SDMACORE3_CCPRI)	32	R	0000_0000h	7.2.8.6/ 1214
302B_001C	Next Channel Priority (SDMACORE3_NCPRI)	32	R	0000_0000h	7.2.8.7/ 1214
302B_0020	OnCE Event Cell Counter (SDMACORE3_ECOUNT)	32	R/W	0000_0000h	7.2.8.8/ 1215
302B_0024	OnCE Event Cell Control Register (SDMACORE3_ECTL)	32	R/W	0000_0000h	7.2.8.9/ 1215
302B_0028	OnCE Event Address Register A (SDMACORE3_EAA)	32	R/W	0000_0000h	7.2.8.10/ 1217
302B_002C	OnCE Event Cell Address Register B (SDMACORE3_EAB)	32	R/W	0000_0000h	7.2.8.11/ 1217
302B_0030	OnCE Event Cell Address Mask (SDMACORE3_EAM)	32	R/W	0000_0000h	7.2.8.12/ 1217
302B_0034	OnCE Event Cell Data Register (SDMACORE3_ED)	32	R/W	0000_0000h	7.2.8.13/ 1218
302B_0038	OnCE Event Cell Data Mask (SDMACORE3_EDM)	32	R/W	0000_0000h	7.2.8.14/ 1218
302B_003C	OnCE Real-Time Buffer (SDMACORE3_RTB)	32	R/W	0000_0000h	7.2.8.15/ 1219
302B_0040	OnCE Trace Buffer (SDMACORE3_TB)	32	R	0000_0000h	7.2.8.16/ 1219

Table continues on the next page...

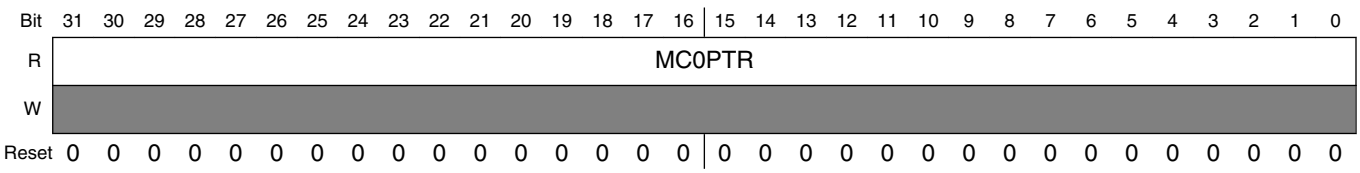
7.2.8.1 Arm platform Channel 0 Pointer (SDMACOREx_MC0PTR)

Address: Base address + 0h offset

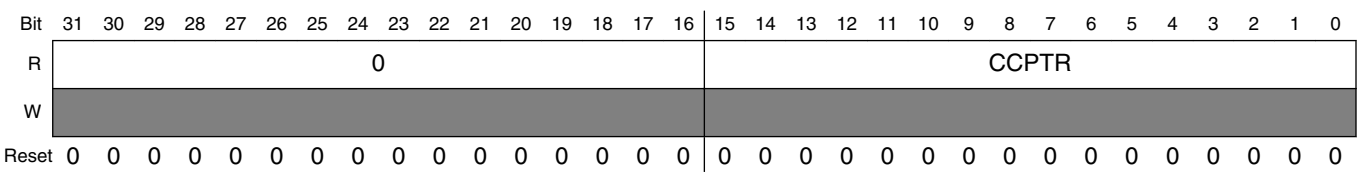


SDMACOREx_MC0PTR field descriptions

Field	Description
MC0PTR	Contains the address-in the Arm platform memory space-of the initial SDMA context and scripts that are loaded by the SDMA boot script running on channel 0.

7.2.8.2 Current Channel Pointer (SDMACOREx_CCPTR)

Address: Base address + 8h offset



SDMACOREx_CCPTR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
CCPTR	Contains the start address of the context data for the current channel: Its value is *CONTEXT_BASE* + 24* *CCR* or *CONTEXT_BASE* + 32* *CCR* where CONTEXT_BASE = 0x0800. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in Channel 0 Boot Address (SDMAARM_CHN0ADDR) .

7.2.8.3 Current Channel Register (SDMACOREx_CCR)

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																											CCR				
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACOREx_CCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
CCR	Contains the number of the current running channel whose context is installed. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel. The PST bits in the OSTAT register indicate when the SDMA is in sleep state.

7.2.8.4 Highest Pending Channel Register (SDMACOREx_NCR)

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																											NCR				
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACOREx_NCR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
NCR	Contains the number of the pending channel that the scheduler has selected to run next.

7.2.8.5 External DMA Requests Mirror (SDMACOREx_EVENTS)

NOTE

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words).

If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.

The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the Arm platform programmed.

Address: Base address + 14h offset

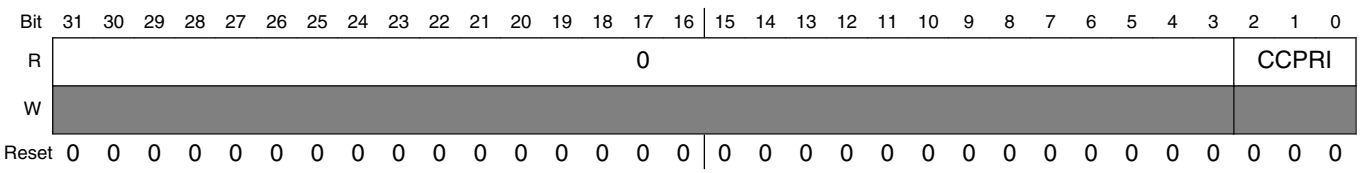
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EVENTS																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACOREx_EVENTS field descriptions

Field	Description
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 0-31. The EVENTS2 register displays events 32-47.

7.2.8.6 Current Channel Priority (SDMACOREx_CCPRI)

Address: Base address + 18h offset

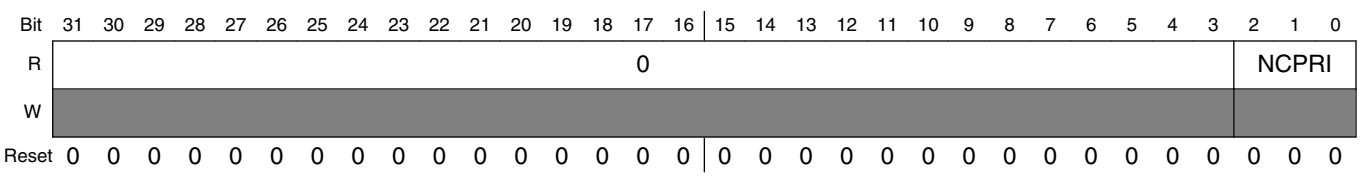


SDMACOREx_CCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
CCPRI	Contains the 3-bit priority of the channel whose context is installed. It is 0 when no channel is running. **NOTE:** 1-7 current channel priority 0 no running channel

7.2.8.7 Next Channel Priority (SDMACOREx_NCPRI)

Address: Base address + 1Ch offset

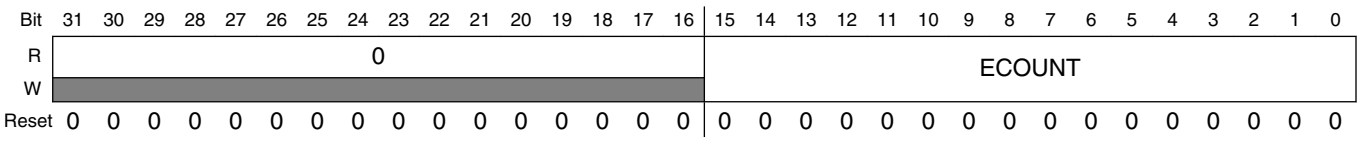


SDMACOREx_NCPRI field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
NCPRI	Contains the 3-bit priority of the channel the scheduler has selected to run next. It is 0 when no other channel is pending.

7.2.8.8 OnCE Event Cell Counter (SDMACOREx_ECOUNT)

Address: Base address + 20h offset

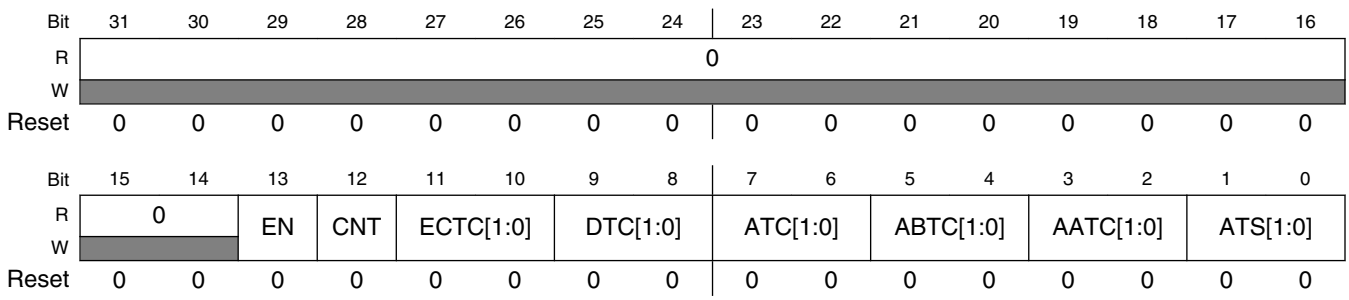


SDMACOREx_ECOUNT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
ECOUNT	The event cell counter contains the number of times minus one that an event detection must occur before generating a debug request. • This register should be written before any attempt to use the event detection counter during an event detection process. • The counter is cleared on a JTAG reset.

7.2.8.9 OnCE Event Cell Control Register (SDMACOREx_ECTL)

Address: Base address + 24h offset



SDMACOREx_ECTL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 EN	Event Cell Enable. If the EN bit is set, the event cell is allowed to generate debug requests (the cell is awakened). If it is cleared, the event detection unit is disabled and no hardware breakpoint is generated, but matching conditions are still reflected on the emulation pin. 0 Cell is disabled. 1 Cell is enabled.
12 CNT	Event Counter Enable. The event counter enable bit determines if the cell counter is used during the event detection. In order to use the event counter during an event detection process, the event cell counter register should be loaded with a value equal to the number of times minus one that an event occurs before a debug request is sent. After every event detection, the counter is decreased. When the counter reaches

Table continues on the next page...

SDMACOREx_ECTL field descriptions (continued)

Field	Description
	the value 0, the event detection cell sends a debug request to the core. The event counter register should be written and the EN bit should be set before each new event detection process uses the event counter. 0 Counter is disabled. 1 Counter is enabled.
11–10 ECTC[1:0]	The event cell trigger condition bits select the combination of address and data matching conditions that generate the final address/data condition. During program execution, if this event cell trigger condition goes to 1, a debug request is sent to the SDMA. The EN bit must be set to enable the debug request generation. 00 address ONLY 01 data ONLY 10 address AND data 11 address OR data
9–8 DTC[1:0]	The data trigger condition bits define when data is considered matching after comparison with the data register of the event detection unit. The operations are performed on unsigned values. 00 equal 01 not equal 10 greater than 11 less than
7–6 ATC[1:0]	The address trigger condition bits select how the two address conditions (addressA and addressB) are combined to define the global address matching condition. The supported combinations are described, as follows. 00 addressA ONLY 01 addrA AND addrB 10 addrA OR addrB 11 reserved
5–4 ABTC[1:0]	The Address B Trigger Condition (ABTC) controls the operations performed by address comparator B. All operations are performed on unsigned values. This comparator B outputs the addressB condition. 00 equal 01 not equal 10 greater than 11 less than
3–2 AATC[1:0]	The Address A Trigger Condition (AATC) controls the operations performed by address comparator A. All operations are performed on unsigned values. This comparator A outputs the addressA condition. 00 equal 01 not equal 10 greater than 11 less than
ATS[1:0]	The access type select bits define the memory access type required on the SDMA memory bus. 00 read ONLY 01 write ONLY 10 read or write 11 -

7.2.8.10 OnCE Event Address Register A (SDMACORE*x*_EAA)

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE*x*_EAM field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

SDMACORE*x*_EAM field descriptions (continued)

Field	Description
EAM	The Event Cell Address Mask contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before performing the address comparison. **NOTE:** There is a common address mask value for both address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The register is cleared on a JTAG reset.

7.2.8.13 OnCE Event Cell Data Register (SDMACORE*x*_ED)

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMACORE*x*_ED field descriptions

Field	Description
ED	The event cell data register contains a user defined data value. This data value is an input for the data comparator which generates the data condition. It is cleared on a JTAG reset.

7.2.8.14 OnCE Event Cell Data Mask (SDMACORE*x*_EDM)

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	EDM

SDMACORE*x*_EDM field descriptions

Field	Description
EDM	The event cell data mask register contains the user-defined data mask value. • This mask is applied to the data value latched from the memory bus before performing the data comparison. • Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. • The data mask is cleared on a JTAG reset.

7.2.8.15 OnCE Real-Time Buffer (SDMACOREx_RTB)

Address: Base address + 3Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RTB																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACOREx_RTB field descriptions

Field	Description
RTB	The Real Time Buffer register stores and retrieves run time information without putting the SDMA in debug mode. Writing to that register triggers a pulse on a specific real-time debug pin whose connection depends on the chip implementation. The RTB value can be accessed by the OnCE under Arm platform or JTAG control using the rbuffer command.

7.2.8.16 OnCE Trace Buffer (SDMACOREx_TB)

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	TADDR		CHFADDR													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACOREx_TB field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 TBF	The Trace Buffer Flag is set when the buffer contains the addresses of a valid change of flow. The contents of the buffer should be ignored otherwise. 0 Invalid information 1 Valid information
27–14 TADDR	The target address is the address taken after the execution of the change of flow instruction.
CHFADDR	The change of flow address is the address where the change of flow is taken when executing a change of flow instruction.

7.2.8.17 OnCE Status (SDMACOREx_OSTAT)

Address: Base address + 44h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACOREx_OSTAT field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	The Processor Status bits reflect the state of the SDMA RISC engine. • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel-switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel. They are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow Loop Sleep 12 Debug in Sleep 13 Functional Unit in Sleep

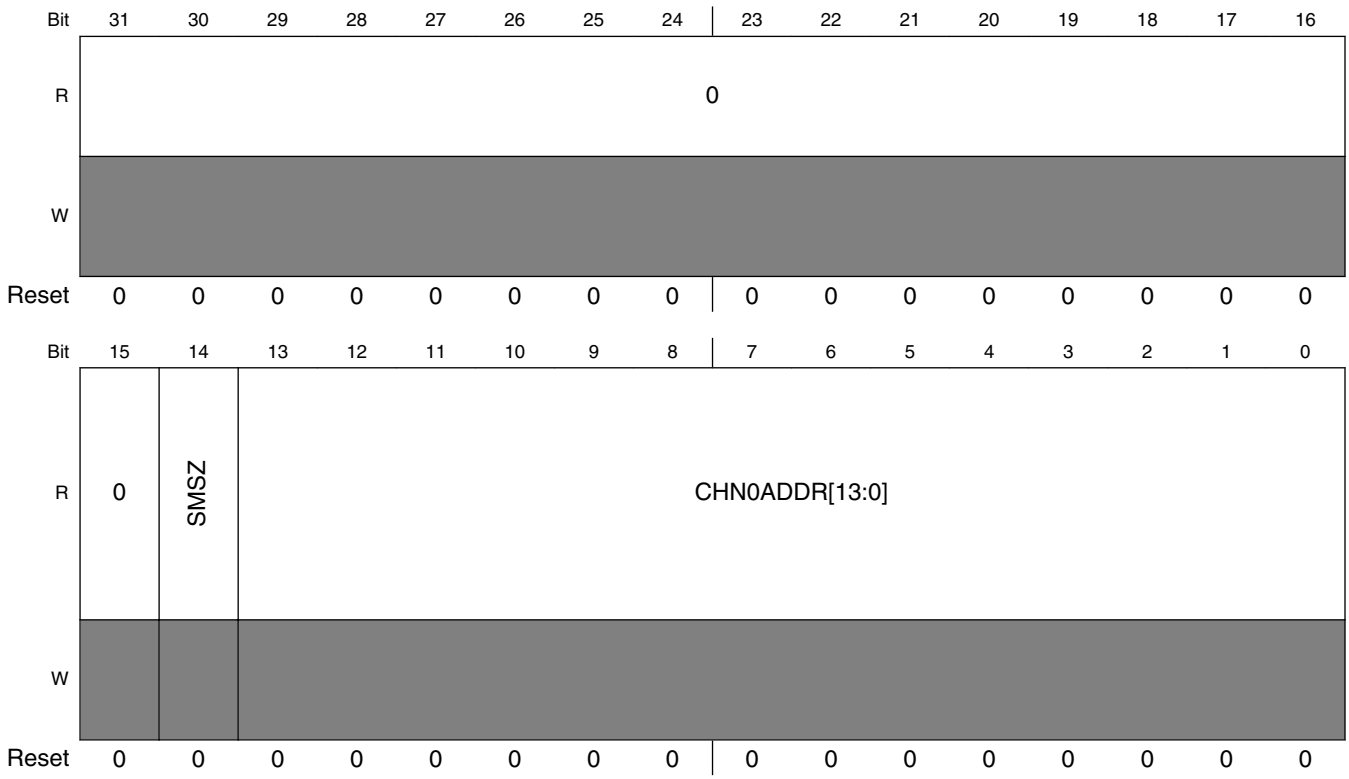
Table continues on the next page...

SDMACOREx_OSTAT field descriptions (continued)

Field	Description
	14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an `rbuffer` command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the Arm platform peripheral interface. 0 JTAG interface controls the OnCE. 1 Arm platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value 0.
ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows: 0 1 matched addressA condition 1 1 matched addressB condition 2 1 matched data condition

7.2.8.18 Channel 0 Boot Address (SDMACOREx_MCHN0ADDR)

Address: Base address + 48h offset

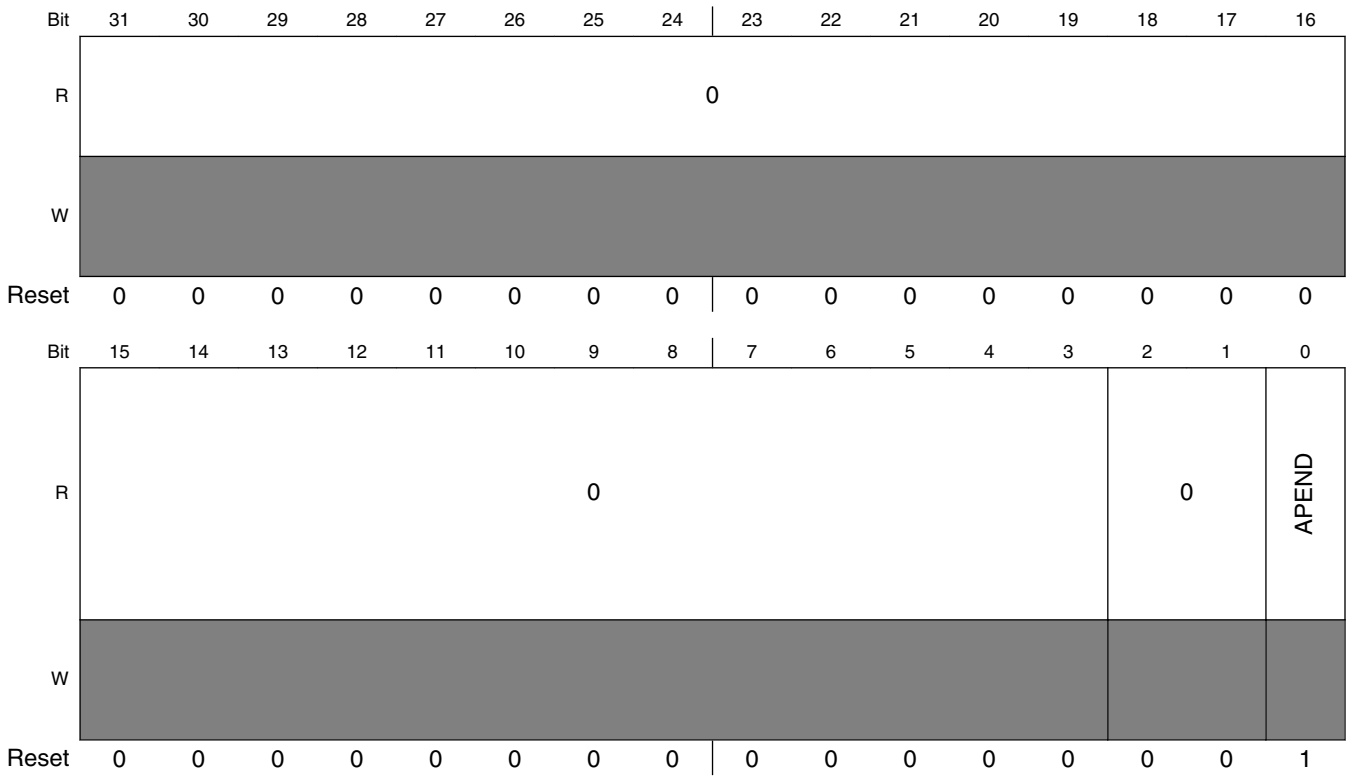


SDMACOREx_MCHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism. 0 24 words per context 1 32 words per context
CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the Arm platform; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

7.2.8.19 ENDIAN Status Register (SDMACOREx_ENDIANNESS)

Address: Base address + 4Ch offset

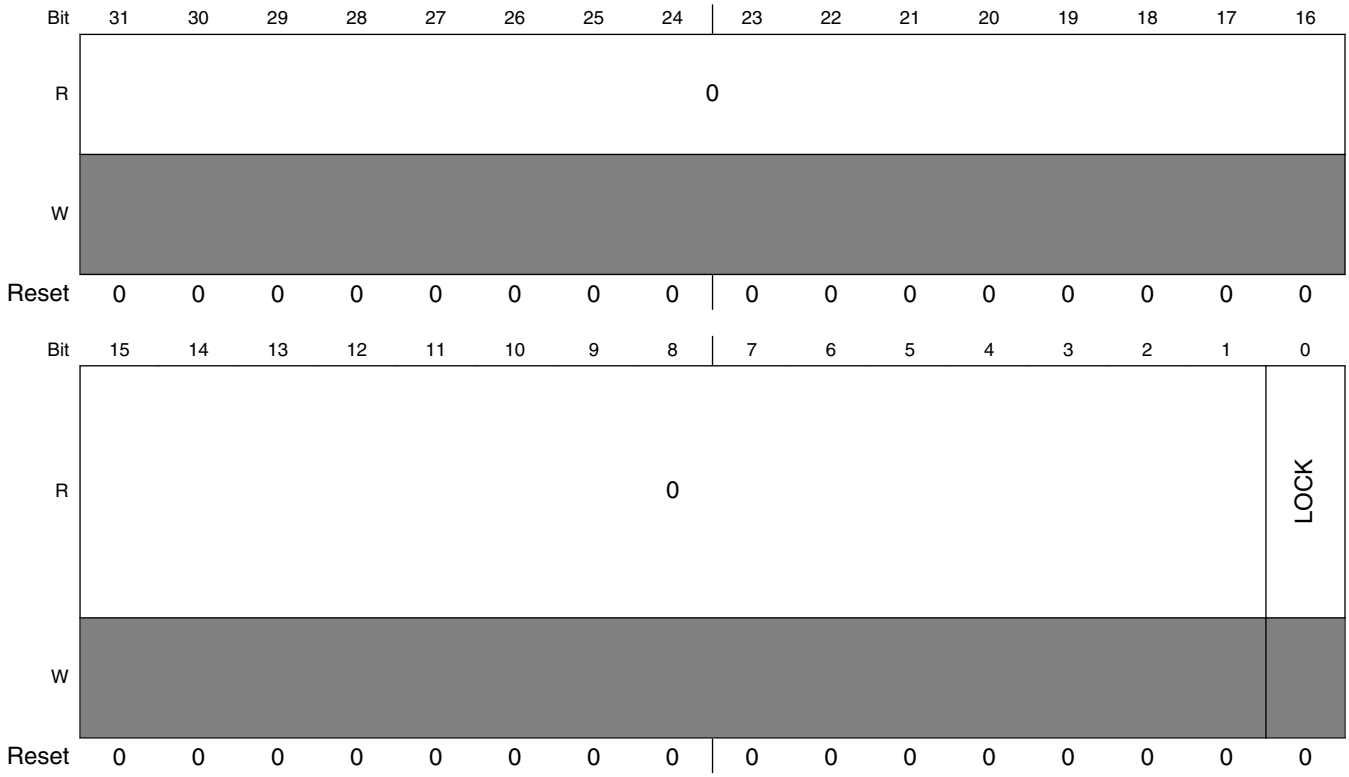


SDMACOREx_ENDIANNESS field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 APEND	APEND indicates the endian mode of the Peripheral and Burst DMA interfaces. This bit is tied to logic '1' indicating little-endian mode. 0 - Arm platform is in big-endian mode 1 - Arm platform is in little-endian mode

7.2.8.20 Lock Status Register (SDMACOREx_SDMA_LOCK)

Address: Base address + 54h offset

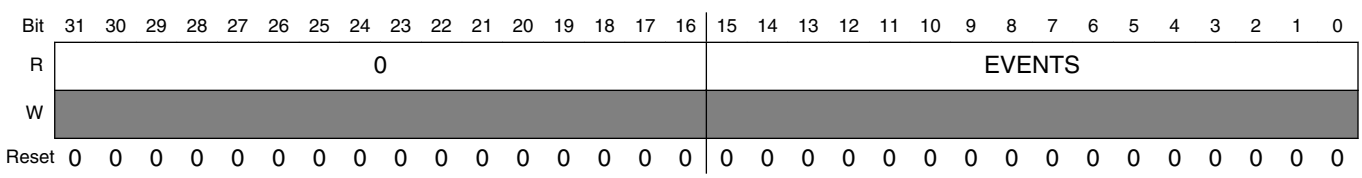


SDMACOREx_SDMA_LOCK field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 LOCK	The LOCK bit reports the value of the LOCK bit in the SDMA_LOCK status register. SDMA software may use this value to determine if certain operations such as loading of new scripts is allowed. 0 - LOCK bit clear 1 - LOCK bit set

7.2.8.21 External DMA Requests Mirror #2 (SDMACOREx_EVENTS2)

Address: Base address + 58h offset



SDMACOREx_EVENTS2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs. This register displays EVENTS 32-47. The separate EVENTS register displays events 0-31.

7.2.9 SDMA Peripheral Registers

Refer to the respective peripherals' chapters for more information.

Chapter 8
Chip IO and Pinmux

8.1 External Signals and Pin Multiplexing

8.1.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength, and hysteresis.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

8.1.1.1 Muxing Options

Table 8-1. Muxing Options

8.2 IOMUX Controller (IOMUXC)

8.2.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

Figure 8-1 illustrates the IOMUX/IOMUXC connectivity in the system.

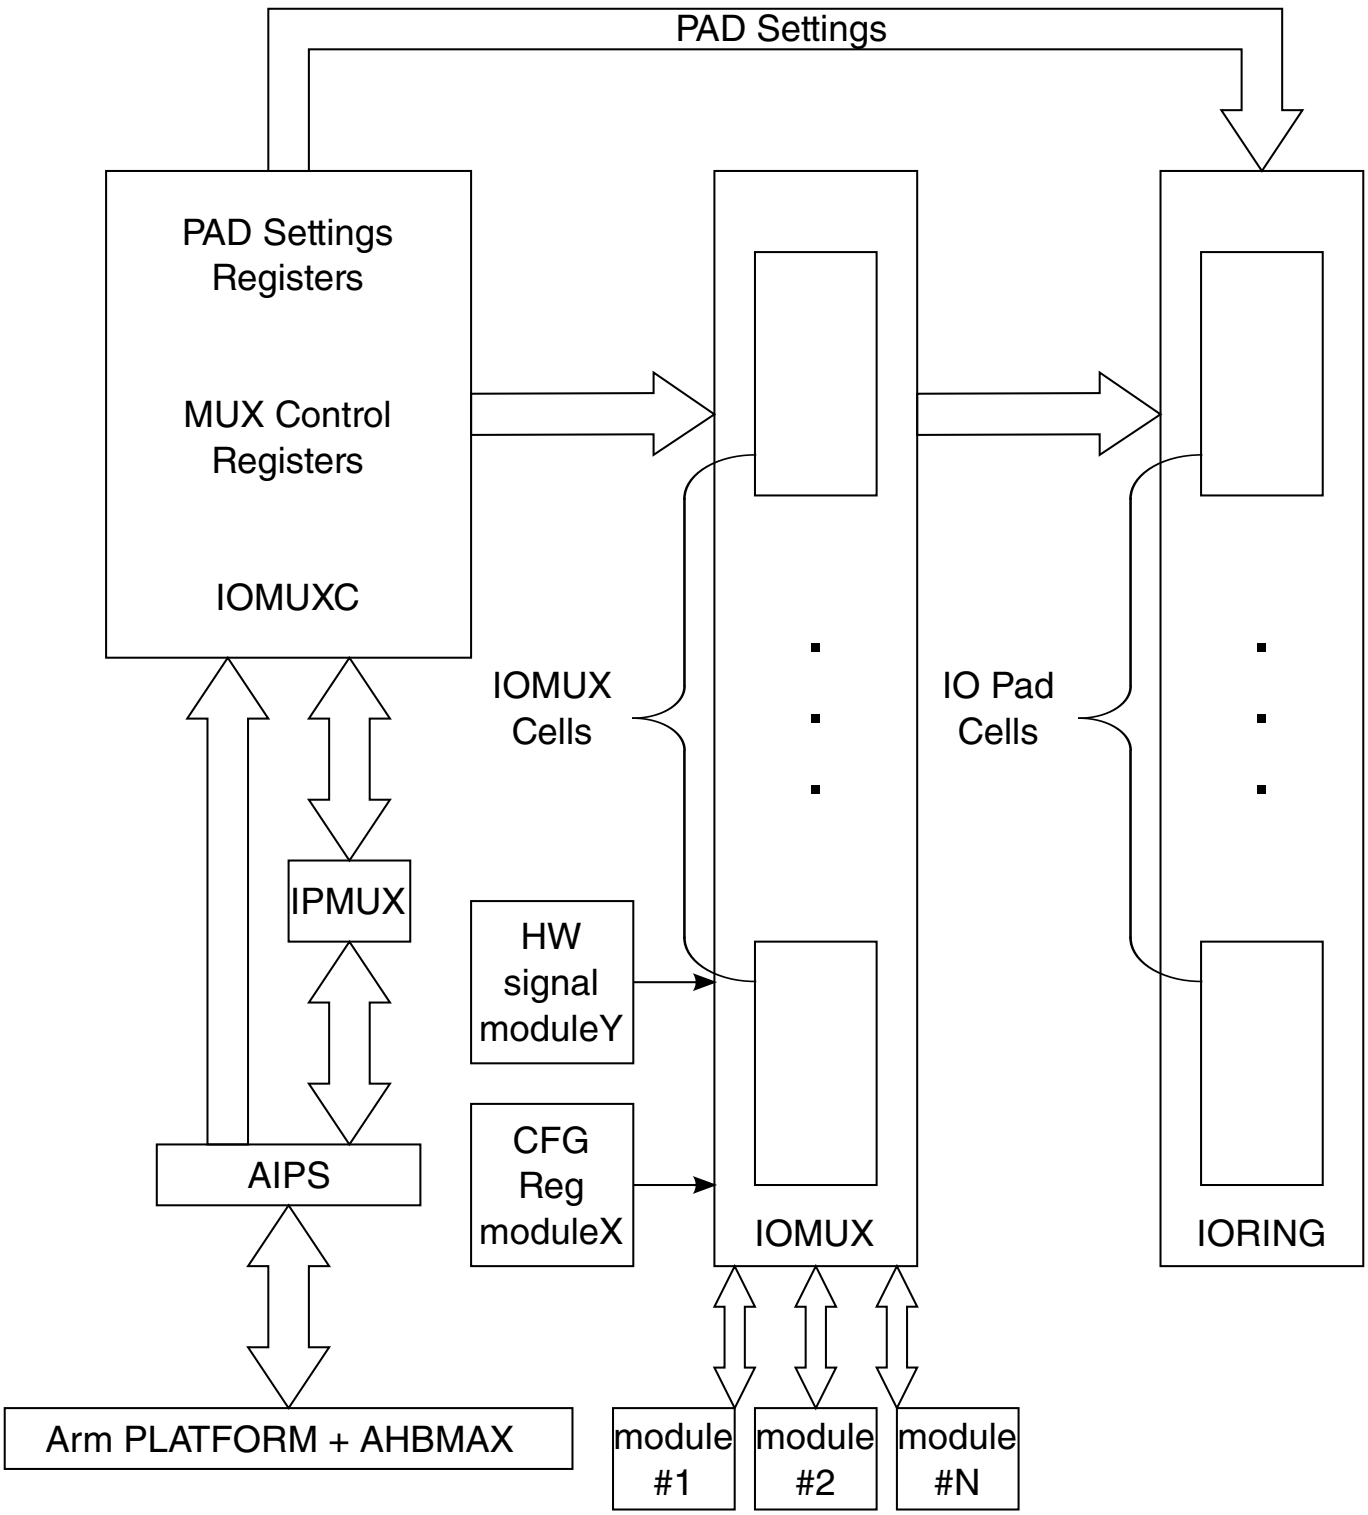

Figure 8-1. IOMUX SoC Level Block Diagram

8.2.1.1 Features

The IOMUXC features are:

- 32-bit software mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure 1 of 8 alternate (ALT) MUX_MODE feilds of each pad or a predefined group of pads and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific pad settings of each pad, or a predefined group of pads.
- 32-bit general purpose registers - 32-bit registers according to SoC requirements for any usage.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pad's group.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

8.2.2 Clocks

The table found here describes the clock sources for IOMUXC.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 8-2. IOMUXC Clocks

Clock name	Clock Root	Description
ipg_clk_s	ipg_clk_root	Peripheral access clock

8.2.3 Functional description

This section provides a complete functional description of the block.

The IOMUXC consists of two sub-blocks:

- IOMUXC_REGISTERS includes all of the IOMUXC registers (see Features).
- IOMUXC_LOGIC includes all of the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUX consists of a number (about the number of pads in the SoC) of basic iomux_cell units. If only one functional mode is required for a specific pad, there is no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

The basic iomux_cell design, which allows two levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in Figure 8-2.

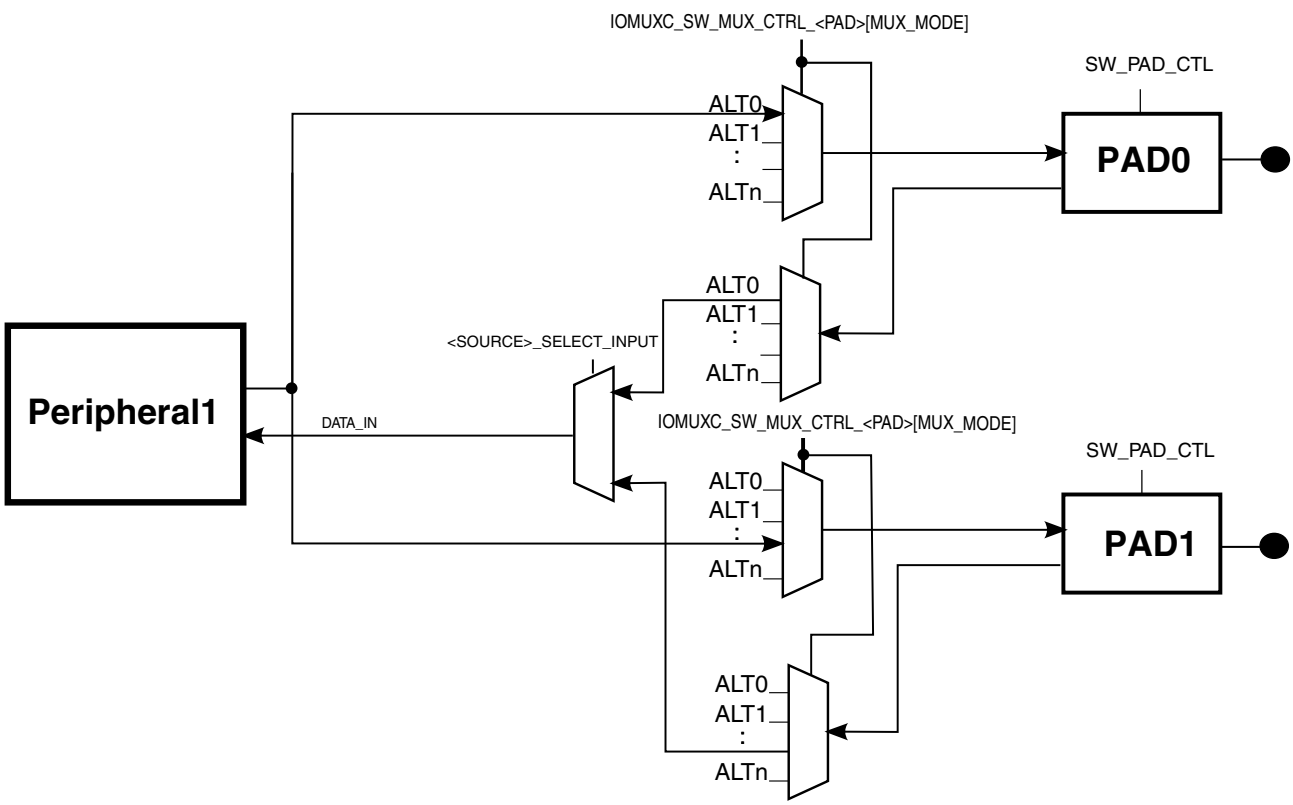

Figure 8-2. IOMUX Cell Block Diagram

8.2.3.1 GPIO pad features

The GPIO pad includes the following features:

- Wide-range voltage interface
  - 1.8V ~ 3.3V I/O interface
- CMOS input / Schmitt trigger Input
- 3-state and open-drain output
- Two slew rate control levels
- Programmable feature support
  - Controllable input enable
  - Controllable CMOS/Schmitt trigger input
  - Controllable pull-up/pull-down resistor
  - Controllable output drive strength (x1 / x2 / x4 / x6)
  - Controllable slew rate control (slow slew / fast slew)

8.2.3.1.1 Pull up/Pull down control

Pull up/Pull down function is controlled by the PE and PS pin.

Table 8-3. Pull up / Pull down control truth table

Mode	State	
	PE	PS
Disable	0	X
Pull-down enable	1	0
Pull-up enable	1	1

8.2.3.1.2 Input control

The IS pin selects CMOS and Schmitt trigger.

Table 8-4. Input control truth table

Mode	State	
	IE	IS
Disable	0	X
CMOS input	1	0
Schmitt trigger input	1	1

8.2.3.1.3 Output driver control

Output drive strength is controlled by the DS0, DS1 pin.

Table 8-5. Drive strength control truth table

State		Driver Strength
DS0	DS1	
0	0	X1
0	1	X2
1	0	X4
1	1	X6

The SR pin controls slew-rate of output driver.

Table 8-6. Slew-rate of output driver

State	Driver Slew
SR	
0	Fast Slew
1	Slow Slew

8.2.3.2 ALT6 and ALT7 extended muxing modes

The ALT7 and ALT6 extended muxing modes allow any signal in the system (such as fuse, pad input, JTAG, or software register) to override any software configuration and to force the ALT6/ALT7 muxing mode.

It also allows an IOMUX software register to control a group of pads.

8.2.3.3 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active (ipp_ibe==1'b1) regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.

8.2.3.4 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers). The daisy chain is illustrated in the figure below.

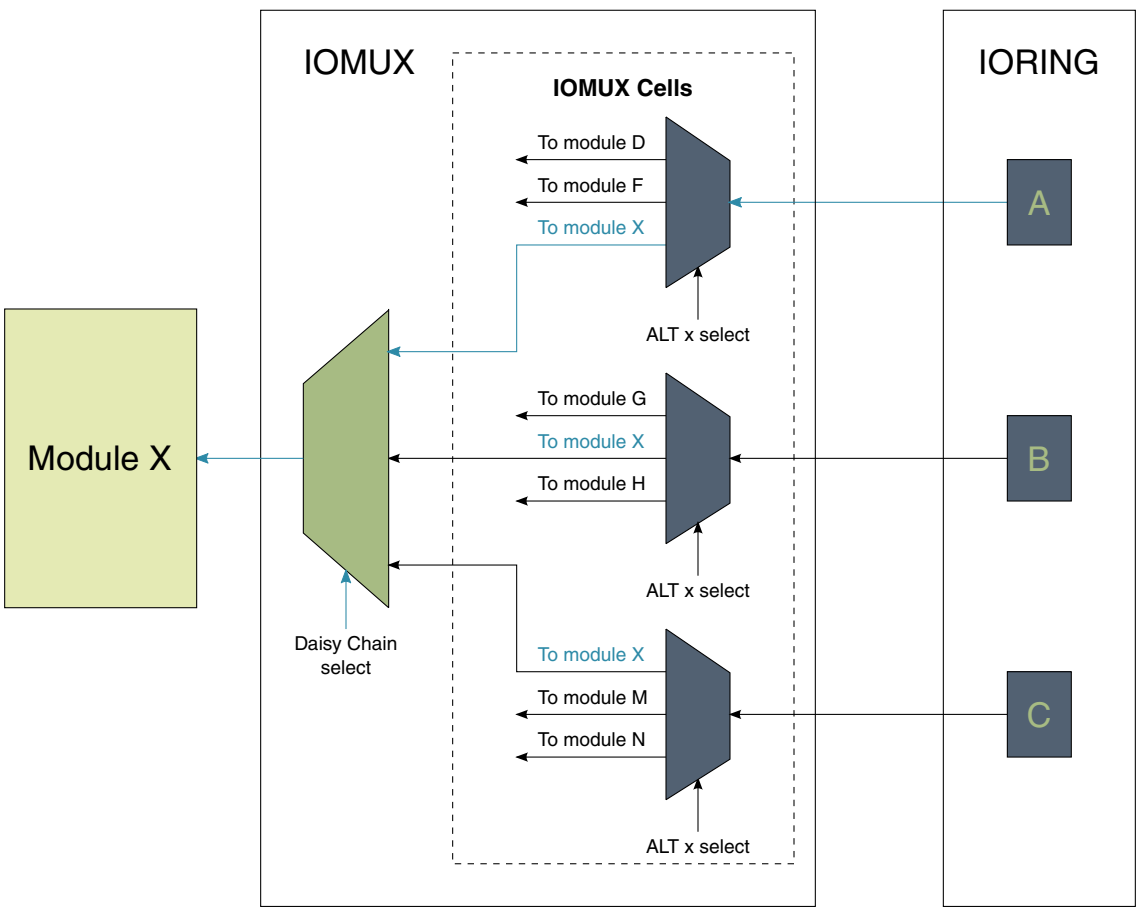

Figure 8-3. Daisy chain illustration

8.2.4 IOMUXC GPR Memory Map/Register Definition

IOMUXC_GPR memory map

IOMUXC_GPR_GPR9 field descriptions

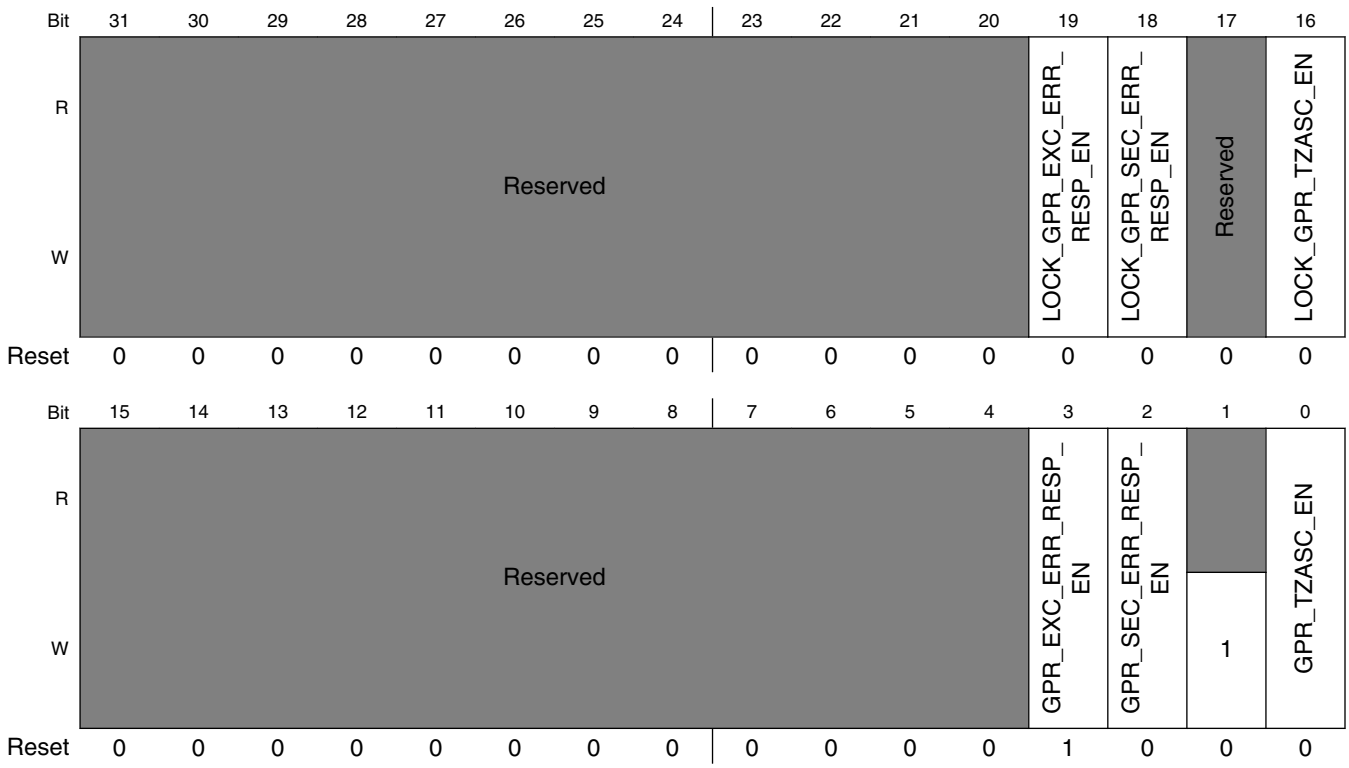
Field	Description
-	This field is reserved.

8.2.4.11 General Purpose Register 10 (IOMUXC_GPR_GPR10)

NOTE

Set GPR10[1] to 1 when TZASC_EN is enabled.

Address: 3034_0000h base + 28h offset = 3034_0028h



IOMUXC_GPR_GPR10 field descriptions

Field	Description
31–20 -	This field is reserved.
19 LOCK_GPR_EXC_ERR_RESP_EN	This is a "sticky" type bit. Lock bit for GPR_EXC_ERR_RESP_EN.
18 LOCK_GPR_SEC_ERR_RESP_EN	This is a "sticky" type bit. Lock bit for GPR_SEC_ERR_RESP_EN.
17 -	This field is reserved. Reserved

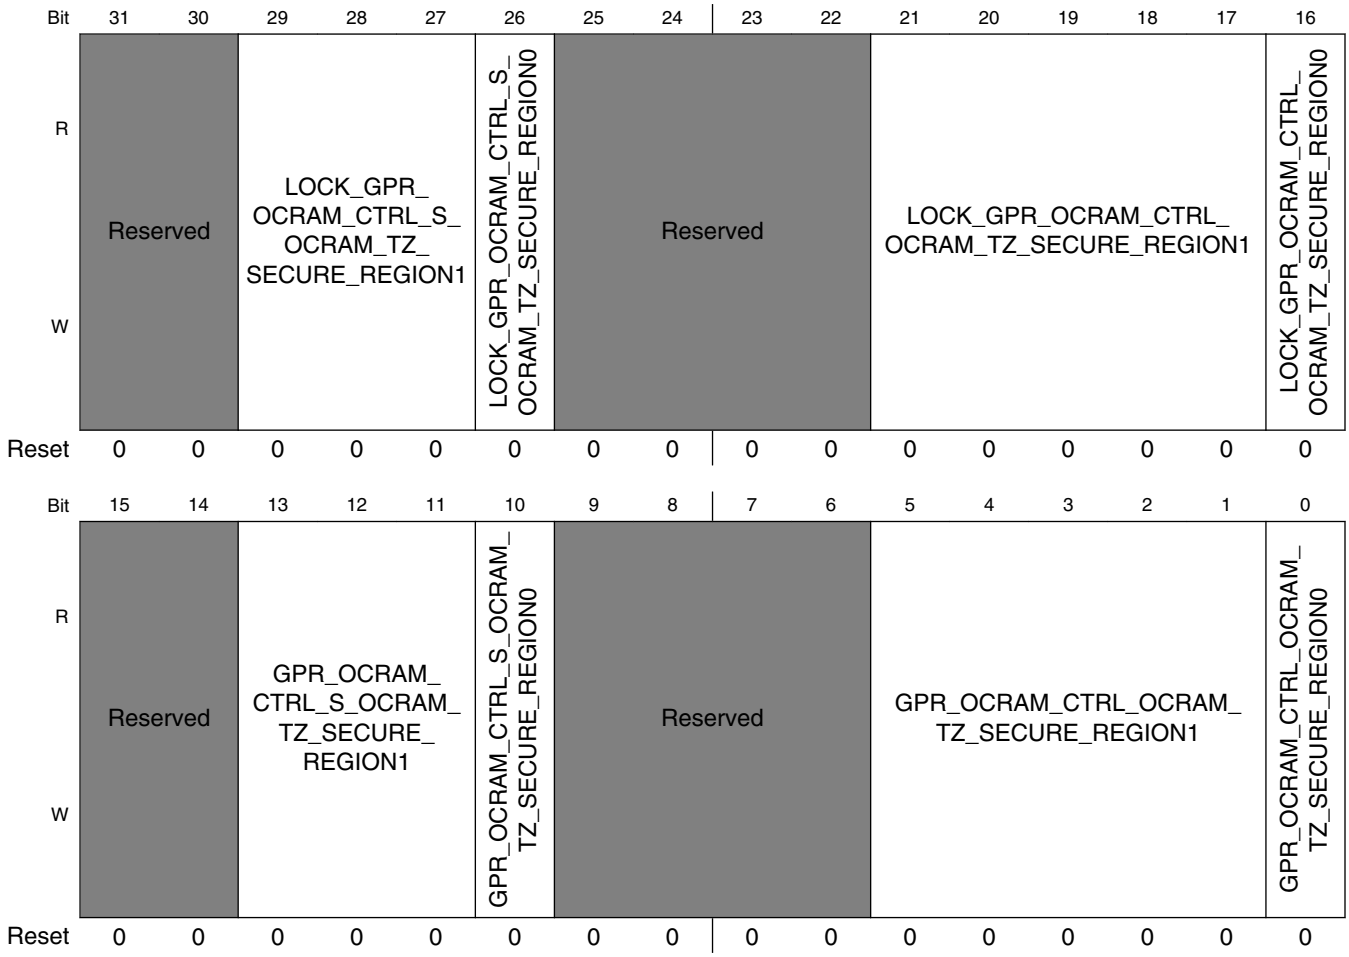
Table continues on the next page...

IOMUXC_GPR_GPR10 field descriptions (continued)

Field	Description
16 LOCK_GPR_ TZASC_EN	This is a "sticky" type bit. Lock bit for GPR_TZASC_EN.
15–4 -	This field is reserved.
3 GPR_EXC_ ERR_RESP_EN	This is a "lock" type bit.
2 GPR_SEC_ ERR_RESP_EN	This is a "lock" type bit.
1 -	Reserved. Set this bit to 1.
0 GPR_TZASC_EN	This is a "lock" type bit. Connect to TZASC_EN input on TZASC_ID_WRAP. **NOTE:** Ensure GPR10[1] is set to 1 when TZASC_EN is enabled. 0 Do not use the TZASC module. All transactions are routed around the TZASC block. 1 Enable the TZASC module. All transactions are processed by this block as per the TZASC TRM describes.

8.2.4.12 General Purpose Register 11 (IOMUXC_GPR_GPR11)

Address: 3034_0000h base + 2Ch offset = 3034_002Ch



IOMUXC_GPR_GPR11 field descriptions

Field	Description
31–30 -	This field is reserved.
29–27 LOCK_GPR_OCRAM_CTRL_S_OCRAM_TZ_SECURE_REGION1	This is a "sticky" type bit. Lock bit for GPR_OCRAM_CTRL_S_OCRAM_TZ_SECURE_REGION1[13:11].
26 LOCK_GPR_OCRAM_CTRL_S_OCRAM_TZ_SECURE_REGION0	This is a "sticky" type bit. Lock bit for GPR_OCRAM_CTRL_S_OCRAM_TZ_SECURE_REGION0[10].

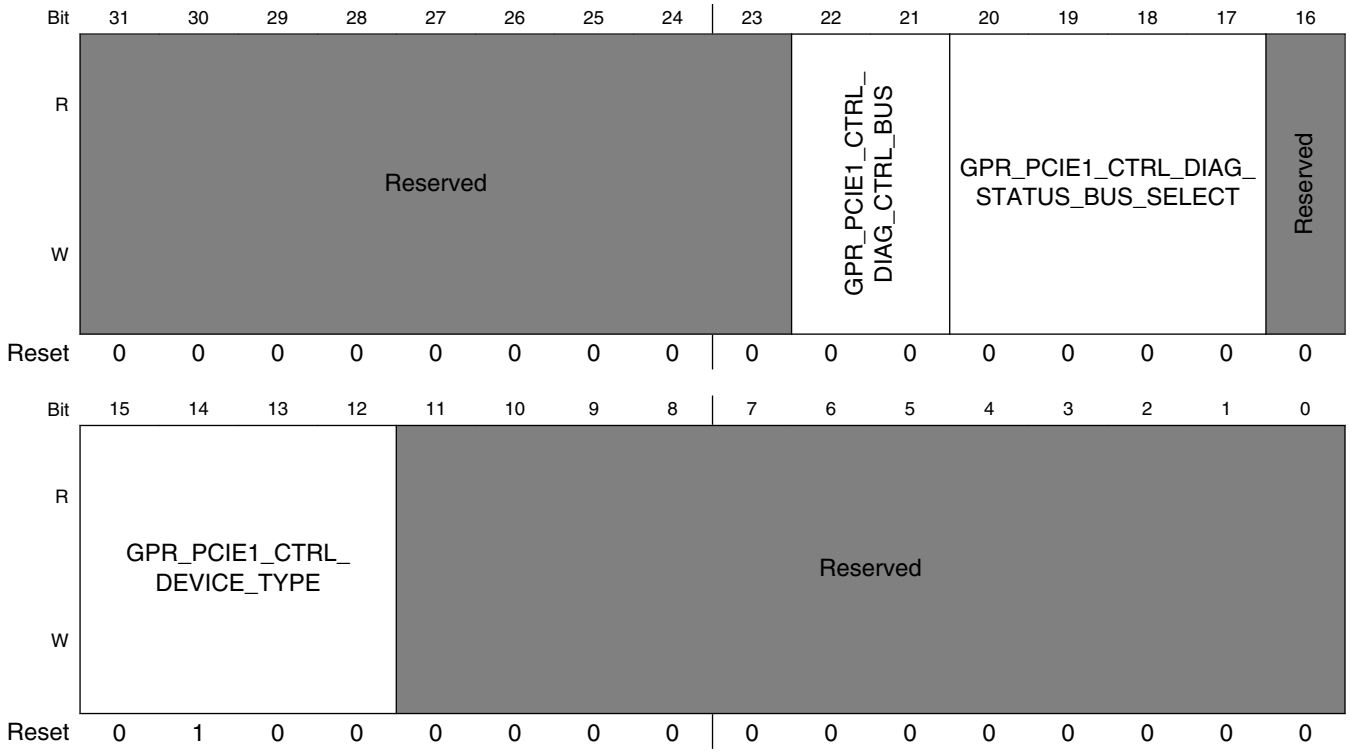
Table continues on the next page...

IOMUXC_GPR_GPR11 field descriptions (continued)

Field	Description
25–22 -	This field is reserved.
21–17 LOCK_GPR_OCRAM_CTRL_OCRAM_TZ_SECURE_REGION1	This is a "sticky" type bit. Lock bit for GPR_OCRAM_CTRL_OCRAM_TZ_SECURE_REGION1[5:1].
16 LOCK_GPR_OCRAM_CTRL_OCRAM_TZ_SECURE_REGION0	This is a "sticky" type bit. Lock bit for GPR_OCRAM_CTRL_OCRAM_TZ_SECURE_REGION0[0].
15–14 -	This field is reserved.
13–11 GPR_OCRAM_CTRL_S_OCRAM_TZ_SECURE_REGION1	This is a "lock" type bit.
10 GPR_OCRAM_CTRL_S_OCRAM_TZ_SECURE_REGION0	This is a "lock" type bit.
9–6 -	This field is reserved.
5–1 GPR_OCRAM_CTRL_OCRAM_TZ_SECURE_REGION1	This is a "lock" type bit.
0 GPR_OCRAM_CTRL_OCRAM_TZ_SECURE_REGION0	This is a "lock" type bit.

8.2.4.13 General Purpose Register 12 (IOMUXC_GPR_GPR12)

Address: 3034_0000h base + 30h offset = 3034_0030h

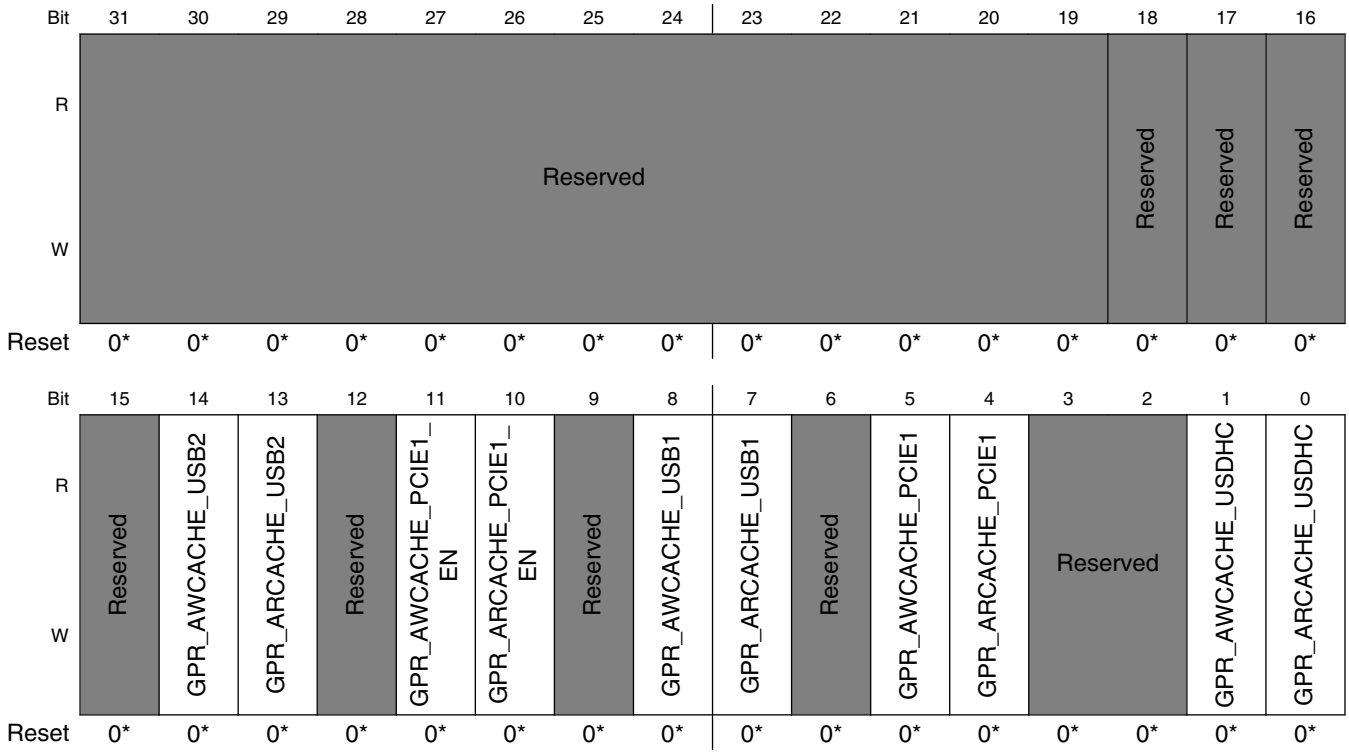


IOMUXC_GPR_GPR12 field descriptions

Field	Description
31–23 -	This field is reserved.
22–21 GPR_PCIE1_CTRL_DIAG_CTRL_BUS	PCIe Diagnostic Control Bus.
20–17 GPR_PCIE1_CTRL_DIAG_STATUS_BUS_SELECT	PCIe Diagnostic Status Bus Select.
16 -	This field is reserved.
15–12 GPR_PCIE1_CTRL_DEVICE_TYPE	PCIe device/port type.
-	This field is reserved.

8.2.4.14 General Purpose Register 13 (IOMUXC_GPR_GPR13)

Address: 3034_0000h base + 34h offset = 3034_0034h



* Notes:
- For reset:

  [31:19] - N/A

  [18:0] - 19'b0

Field	Description
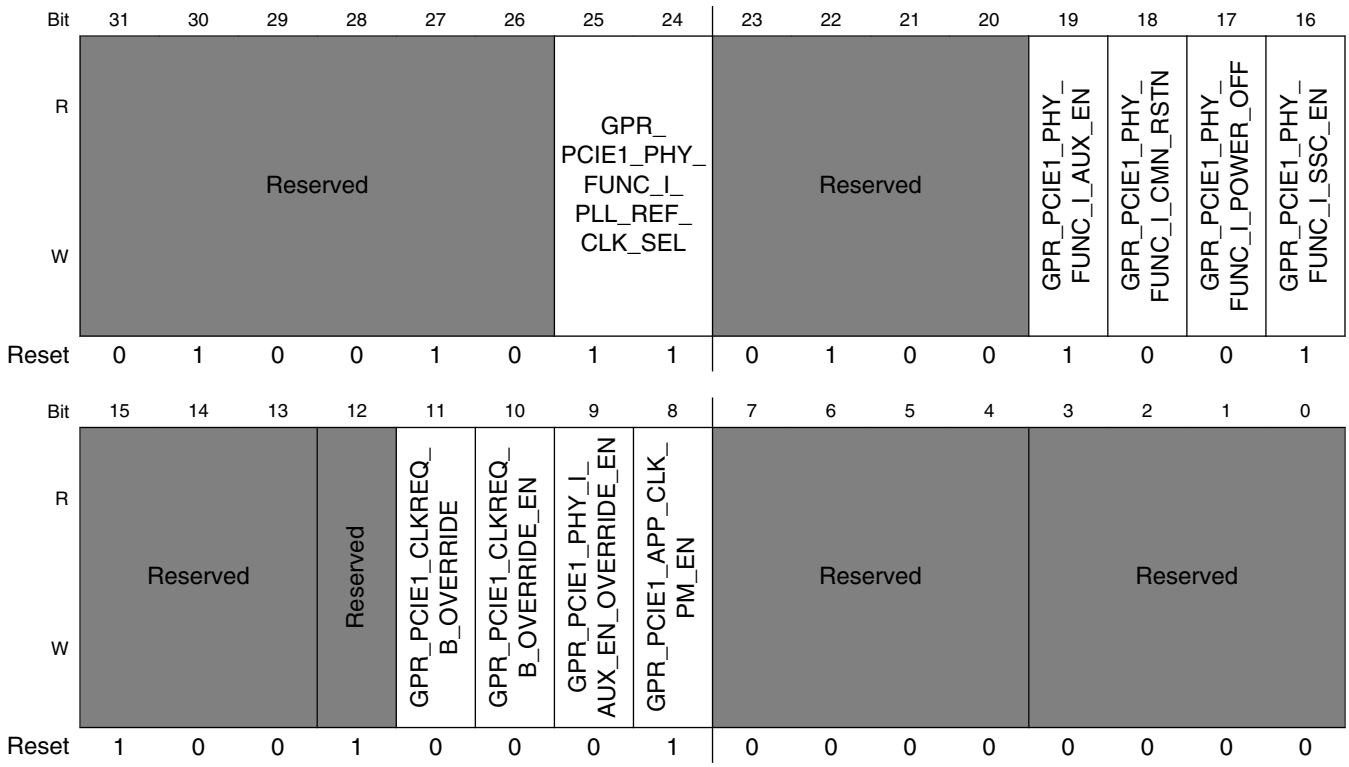
14 GPR_ AWCACHE_ USB2	Control the AWCACHE[1] of USB2 master transaction.
13 GPR_ ARCACHE_ USB2	Control the ARCACHE[1] of USB2 master transaction.
12 -	This field is reserved.
11 GPR_ AWCACHE_ PCIE1_EN	Enable the GPR control of AWCACHE[1] of PCIE1 master transaction.
10 GPR_ ARCACHE_ PCIE1_EN	Enable the GPR control of ARCACHE[1] of PCIE1 master transaction.
9 -	This field is reserved.
8 GPR_ AWCACHE_ USB1	Control the AWCACHE[1] of USB1 master transaction.
7 GPR_ ARCACHE_ USB1	Control the ARCACHE[1] of USB1 master transaction.
6 -	This field is reserved.
5 GPR_ AWCACHE_ PCIE1	Control the AWCACHE[1] of PCIE1 master transaction.
4 GPR_ ARCACHE_ PCIE1	Control the ARCACHE[1] of PCIE1 master transaction.
3–2 -	This field is reserved.
1 GPR_ AWCACHE_ USDHC	Control the AWCACHE[1] of USDHC master transaction.
0 GPR_ ARCACHE_ USDHC	Control the ARCACHE[1] of USDHC master transaction.

8.2.4.15 General Purpose Register 14 (IOMUXC_GPR_GPR14)

Address: 3034_0000h base + 38h offset = 3034_0038h



IOMUXC_GPR_GPR14 field descriptions

Field	Description
31–26 -	This field is reserved.
25–24 GPR_PCIE1_ PHY_FUNC_I_ PLL_REF_CLK_ SEL	00 N/A 01 Selects reference clock from XO (pll_refclk_from_xo) 10 Selects reference clock from IO (ext_ref_clkp/n) 11 Selects reference clock from SOC PLL (pll_refclk_from_syspll)
23–20 -	This field is reserved.
19 GPR_PCIE1_ PHY_FUNC_I_ AUX_EN	External Reference Clock I/O (for PLL) Enable Signal. **NOTE:** Please see bit field 9 for more details. 1 Enable 0 Disable
18 GPR_PCIE1_ PHY_FUNC_I_ CMN_RSTN	Resets the PCIe PHY Common Block Reset. This is an Active low reset for PCIe PHY Common Block.

Table continues on the next page...

IOMUXC_GPR_GPR14 field descriptions (continued)

Field	Description
17 GPR_PCIE1_PHY_FUNC_I_POWER_OFF	PMA power down signal. 1 Power Down 0 Power Up
16 GPR_PCIE1_PHY_FUNC_I_SSC_EN	SSC enable signal. 1 Enable 0 Disable
15–13 -	This field is reserved.
12 -	This field is reserved.
11 GPR_PCIE1_CLKREQ_B_OVERRIDE	Control PCIE_CLKREQ_B to the pad together with CLKREQ_B from controller.
10 GPR_PCIE1_CLKREQ_B_OVERRIDE_EN	Control PCIE_CLKREQ_B to the pad together with CLKREQ_B from controller.
9 GPR_PCIE1_PHY_I_AUX_EN_OVERRIDE_EN	{GPR_PCIE1_PHY_I_AUX_EN_OVERRIDE_EN, GPR_PCIE1_PHY_FUNC_I_AUX_EN} 2'b00 External Reference Clock I/O (for PLL) Disable 2'b01 External Reference Clock I/O (for PLL) Enable 2'b10 External Reference Clock I/O (for PLL) Disable 2'b11 External Reference Clock I/O (for PLL) output is controlled by CLKREQ#
8 GPR_PCIE1_APP_CLK_PM_EN	To PCIe CTRL.
7–4 -	This field is reserved.
-	This field is reserved.
