Chapter 1
Introduction

The MCUXpresso Software Development Kit (MCUXpresso SDK) is a collection of software enablement for NXP Microcontrollers that includes peripheral drivers, multicore support and integrated RTOS support for FreeRTOS™ . In addition to the base enablement, the MCUXpresso SDK is augmented with demo applications, driver example projects, and API documentation to help users quickly leverage the support provided by MCUXpresso SDK. The MCUXpresso SDK Web Builder is available to provide access to all MCUXpresso SDK packages. See the *MCUXpresso Software Development Kit (SDK) Release Notes* (document MCUXSDKRN) in the Supported Devices section at MCUXpresso-SDK: Software Development Kit for MCUXpresso for details.

The MCUXpresso SDK is built with the following runtime software components:

- Arm® and DSP standard libraries, and CMSIS-compliant device header files which provide direct access to the peripheral registers.
- Peripheral drivers that provide stateless, high-performance, ease-of-use APIs. Communication drivers provide higher-level transactional APIs for a higher-performance option.
- RTOS wrapper driver built on top of MCUXpresso SDK peripheral drivers and leverage native RTOS services to better comply to the RTOS cases.
- Real time operation systems (RTOS) for FreeRTOS OS.
- Stacks and middleware in source or object formats including:
  - CMSIS-DSP, a suite of common signal processing functions.
  - The MCUXpresso SDK comes complete with software examples demonstrating the usage of the peripheral drivers, RTOS wrapper drivers, middleware, and RTOSes.

  All demo applications and driver examples are provided with projects for the following toolchains:
  - IAR Embedded Workbench
  - GNU Arm Embedded Toolchain

The peripheral drivers and RTOS driver wrappers can be used across multiple devices within the product family without modification. The configuration items for each driver are encapsulated into C language data structures. Device-specific configuration information is provided as part of the MCUXpresso SDK and need not be modified by the user. If necessary, the user is able to modify the peripheral driver and RTOS wrapper driver configuration during runtime. The driver examples demonstrate how to configure the drivers by passing the proper configuration data to the APIs. The folder structure is organized to reduce the total number of includes required to compile a project.

The rest of this document describes the API references in detail for the peripheral drivers and RTOS wrapper drivers. For the latest version of this and other MCUXpresso SDK documents, see the mcuxpresso.nxp.com/apidoc/.

Chapter 3
Architectural Overview

This chapter provides the architectural overview for the MCUXpresso Software Development Kit (MCUXpresso SDK). It describes each layer within the architecture and its associated components.

Overview

The MCUXpresso SDK architecture consists of five key components listed below.

1. The Arm Cortex Microcontroller Software Interface Standard (CMSIS) CORE compliance device-specific header files, SOC Header, and CMSIS math/DSP libraries.
2. Peripheral Drivers
3. Real-time Operating Systems (RTOS)
4. Stacks and Middleware that integrate with the MCUXpresso SDK
5. Demo Applications based on the MCUXpresso SDK

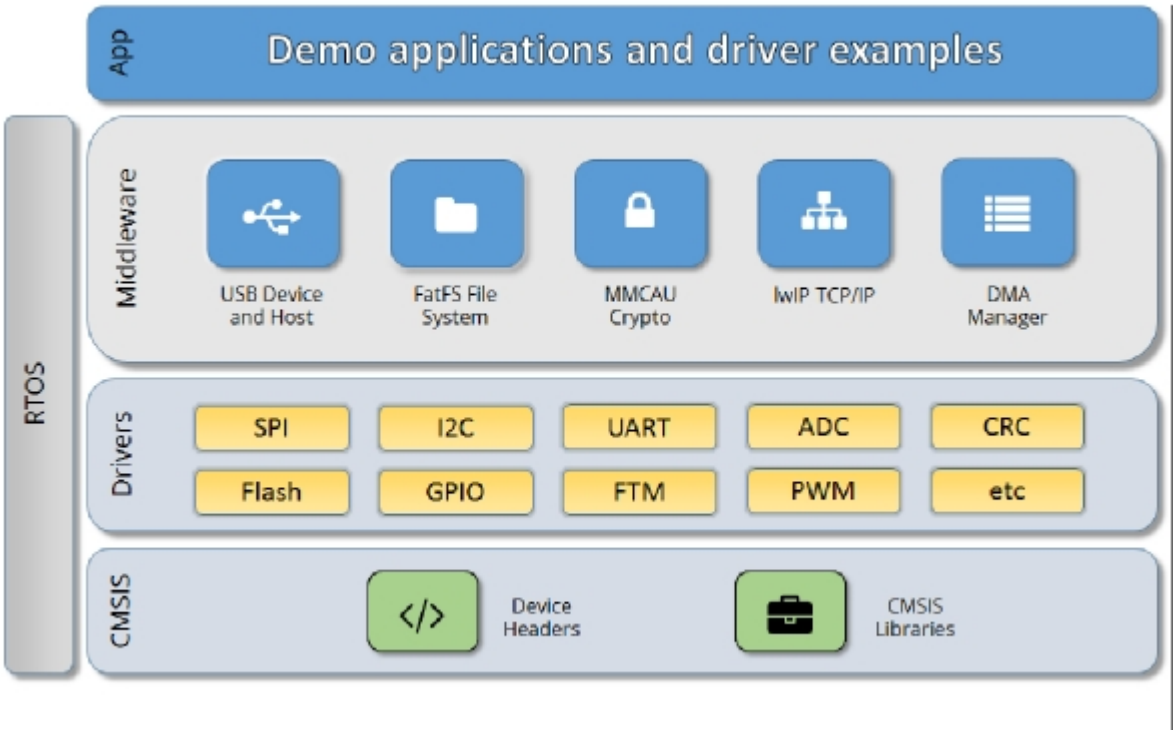

Figure 1: MCUXpresso SDK Block Diagram

MCU header files

Each supported MCU device in the MCUXpresso SDK has an overall System-on Chip (SoC) memory-

mapped header file. This header file contains the memory map and register base address for each peripheral and the IRQ vector table with associated vector numbers. The overall SoC header file provides access to the peripheral registers through pointers and predefined bit masks. In addition to the overall SoC memory-mapped header file, the MCUXpresso SDK includes a feature header file for each device. The feature header file allows NXP to deliver a single software driver for a given peripheral. The feature file ensures that the driver is properly compiled for the target SOC.

CMSIS Support

Along with the SoC header files and peripheral extension header files, the MCUXpresso SDK also includes common CMSIS header files for the Arm Cortex-M core and the math and DSP libraries from the latest CMSIS release. The CMSIS DSP library source code is also included for reference.

MCUXpresso SDK Peripheral Drivers

The MCUXpresso SDK peripheral drivers mainly consist of low-level functional APIs for the MCU product family on-chip peripherals and also of high-level transactional APIs for some bus drivers/DMA driver/eDMA driver to quickly enable the peripherals and perform transfers.

All MCUXpresso SDK peripheral drivers only depend on the CMSIS headers, device feature files, fsl_common.h, and fsl_clock.h files so that users can easily pull selected drivers and their dependencies into projects. With the exception of the clock/power-relevant peripherals, each peripheral has its own driver. Peripheral drivers handle the peripheral clock gating/ungating inside the drivers during initialization and deinitialization respectively.

Low-level functional APIs provide common peripheral functionality, abstracting the hardware peripheral register accesses into a set of stateless basic functional operations. These APIs primarily focus on the control, configuration, and function of basic peripheral operations. The APIs hide the register access details and various MCU peripheral instantiation differences so that the application can be abstracted from the low-level hardware details. The API prototypes are intentionally similar to help ensure easy portability across supported MCUXpresso SDK devices.

Transactional APIs provide a quick method for customers to utilize higher-level functionality of the peripherals. The transactional APIs utilize interrupts and perform asynchronous operations without user intervention. Transactional APIs operate on high-level logic that requires data storage for internal operation context handling. However, the Peripheral Drivers do not allocate this memory space. Rather, the user passes in the memory to the driver for internal driver operation. Transactional APIs ensure the NVIC is enabled properly inside the drivers. The transactional APIs do not meet all customer needs, but provide a baseline for development of custom user APIs.

Note that the transactional drivers never disable an NVIC after use. This is due to the shared nature of interrupt vectors on devices. It is up to the user to ensure that NVIC interrupts are properly disabled after usage is complete.

Interrupt handling for transactional APIs

A double weak mechanism is introduced for drivers with transactional API. The double weak indicates two levels of weak vector entries. See the examples below:

```
        PUBWEAK SPI0_IRQHandler
        PUBWEAK SPI0_DriverIRQHandler
SPI0_IRQHandler
```

```
LDR     R0, =SPI0_DriverIRQHandler
BX      R0
```

The first level of the weak implementation are the functions defined in the vector table. In the devices/<-DEVICE_NAME>/<TOOLCHAIN>/startup_<DEVICE_NAME>.s/.S file, the implementation of the first layer weak function calls the second layer of weak function. The implementation of the second layer weak function (ex. SPI0_DriverIRQHandler) jumps to itself (B). The MCUXpresso SDK drivers with transactional APIs provide the reimplementation of the second layer function inside of the peripheral driver. If the MCUXpresso SDK drivers with transactional APIs are linked into the image, the SPI0_-DriverIRQHandler is replaced with the function implemented in the MCUXpresso SDK SPI driver.

The reason for implementing the double weak functions is to provide a better user experience when using the transactional APIs. For drivers with a transactional function, call the transactional APIs and the drivers complete the interrupt-driven flow. Users are not required to redefine the vector entries out of the box. At the same time, if users are not satisfied by the second layer weak function implemented in the MCU-Xpresso SDK drivers, users can redefine the first layer weak function and implement their own interrupt handler functions to suit their implementation.

The limitation of the double weak mechanism is that it cannot be used for peripherals that share the same vector entry. For this use case, redefine the first layer weak function to enable the desired peripheral interrupt functionality. For example, if the MCU's UART0 and UART1 share the same vector entry, redefine the UART0_UART1_IRQHandler according to the use case requirements.

Feature Header Files

The peripheral drivers are designed to be reusable regardless of the peripheral functional differences from one MCU device to another. An overall Peripheral Feature Header File is provided for the MCUXpresso SDK-supported MCU device to define the features or configuration differences for each sub-family device.

4.0.1.6.8 void ADC16_SetChannelMuxMode (ADC_Type * *base*, adc16_channel_mux_mode_t *mode*)

4.0.1.6.9 void ADC16_SetHardwareCompareConfig (ADC_Type * *base*, const adc16_hardware_compare_config_t * *config*)

mask	Mask value for the cleared flags. See "_adc16_status_flags".

4.0.1.6.13 void ADC16_SetChannelConfig (ADC_Type * *base,* uint32_t *channelGroup,* const adc16_channel_config_t * *config*)

This operation triggers the conversion when in software trigger mode. When in hardware trigger mode, this API configures the channel while the external trigger source helps to trigger the conversion.

Note that the "Channel Group" has a detailed description. To allow sequential conversions of the ADC to be triggered by internal peripherals, the ADC has more than one group of status and control registers, one for each conversion. The channel group parameter indicates which group of registers are used, for example, channel group 0 is for Group A registers and channel group 1 is for Group B registers. The channel groups are used in a "ping-pong" approach to control the ADC operation. At any point, only one of the channel groups is actively controlling ADC conversions. The channel group 0 is used for both software and hardware trigger modes. Channel group 1 and greater indicates multiple channel group

registers for use only in hardware trigger mode. See the chip configuration information in the appropriate MCU reference manual for the number of SC1n registers (channel groups) specific to this device. Channel group 1 or greater are not used for software trigger operation. Therefore, writing to these channel groups does not initiate a new conversion. Updating the channel group 0 while a different channel group is actively controlling a conversion is allowed and vice versa. Writing any of the channel group registers while that specific channel group is actively controlling a conversion aborts the current conversion.

Parameters

base	ADC16 peripheral base address.
channelGroup	Channel group index.
config	Pointer to the "adc16_channel_config_t" structure for the conversion channel.

4.0.1.6.14 static uint32_t ADC16_GetChannelConversionValue (ADC_Type * *base,* uint32_t *channelGroup*) [inline], [static]

Parameters

base	ADC16 peripheral base address.

4.0.3 CRC: Cyclic Redundancy Check Driver

4.0.3.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Cyclic Redundancy Check (CRC) module of MCUXpresso SDK devices.

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection. The CRC module also provides a programmable polynomial, seed, and other parameters required to implement a 16-bit or 32-bit CRC standard.

4.0.3.2 CRC Driver Initialization and Configuration

CRC_Init() function enables the clock gate for the CRC module in the SIM module and fully (re-)configures the CRC module according to the configuration structure. The seed member of the configuration structure is the initial checksum for which new data can be added to. When starting a new checksum computation, the seed is set to the initial checksum per the CRC protocol specification. For continued checksum operation, the seed is set to the intermediate checksum value as obtained from previous calls to CRC_Get16bitResult() or CRC_Get32bitResult() function. After calling the CRC_Init(), one or multiple CRC_WriteData() calls follow to update the checksum with data and CRC_Get16bitResult() or CRC_Get32bitResult() follow to read the result. The crcResult member of the configuration structure determines whether the CRC_Get16bitResult() or CRC_Get32bitResult() return value is a final checksum or an intermediate checksum. The CRC_Init() function can be called as many times as required allowing for runtime changes of the CRC protocol.

CRC_GetDefaultConfig() function can be used to set the module configuration structure with parameters for CRC-16/CCIT-FALSE protocol.

4.0.3.3 CRC Write Data

The CRC_WriteData() function adds data to the CRC. Internally, it tries to use 32-bit reads and writes for all aligned data in the user buffer and 8-bit reads and writes for all unaligned data in the user buffer. This function can update the CRC with user-supplied data chunks of an arbitrary size, so one can update the CRC byte by byte or with all bytes at once. Prior to calling the CRC configuration function CRC_Init() fully specifies the CRC module configuration for the CRC_WriteData() call.

4.0.3.4 CRC Get Checksum

The CRC_Get16bitResult() or CRC_Get32bitResult() function reads the CRC module data register. Depending on the prior CRC module usage, the return value is either an intermediate checksum or the final checksum. For example, for 16-bit CRCs the following call sequences can be used.

CRC_Init() / CRC_WriteData() / CRC_Get16bitResult() to get the final checksum.

CRC_Init() / CRC_WriteData() / ... / CRC_WriteData() / CRC_Get16bitResult() to get the final checksum.

CRC_Init() / CRC_WriteData() / CRC_Get16bitResult() to get an intermediate checksum.

CRC_Init() / CRC_WriteData() / ... / CRC_WriteData() / CRC_Get16bitResult() to get an intermediate checksum.

4.0.3.5 Comments about API usage in RTOS

If multiple RTOS tasks share the CRC module to compute checksums with different data and/or protocols, the following needs to be implemented by the user.

The triplets

CRC_Init() / CRC_WriteData() / CRC_Get16bitResult() or CRC_Get32bitResult()

The triplets are protected by the RTOS mutex to protect the CRC module against concurrent accesses from different tasks. This is an example. 4.0.4 DAC: Digital-to-Analog Converter Driver

4.0.4.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Digital-to-Analog Converter (DAC) module of MCUXpresso SDK devices.

The DAC driver includes a basic DAC module (converter) and a DAC buffer.

The basic DAC module supports operations unique to the DAC converter in each DAC instance. The APIs in this section are used in the initialization phase, which enables the DAC module in the application. The APIs enable/disable the clock, enable/disable the module, and configure the converter. Call the initial APIs to prepare the DAC module for the application.

The DAC buffer operates the DAC hardware buffer. The DAC module supports a hardware buffer to keep a group of DAC values to be converted. This feature supports updating the DAC output value automatically by triggering the buffer read pointer to move in the buffer. Use the APIs to configure the hardware buffer's trigger mode, watermark, work mode, and use size. Additionally, the APIs operate the DMA, interrupts, flags, the pointer (the index of the buffer), item values, and so on.

Note that the most functional features are designed for the DAC hardware buffer.

baudRate_Bps	The desired baud rate in bits per second

4.0.7.7.25 void DSPI_MasterSetDelayScaler (SPI_Type * *base*, dspi_ctar_selection_t *whichCtar*, uint32_t *prescaler*, uint32_t *scaler*, dspi_delay_type_t *whichDelay*)

These delay names are available in the type dspi_delay_type_t.

The user passes the delay to the configuration along with the prescaler and scaler value. This allows the user to directly set the prescaler/scaler values if pre-calculated or to manually increment either value.

Parameters

base	DSPI peripheral address.

whichCtar	The desired Clock and Transfer Attributes Register (CTAR) of type dspi_ctar_selection_t.
prescaler	The prescaler delay value (can be an integer 0, 1, 2, or 3).

These delay names are available in the type dspi_delay_type_t.

The user passes which delay to configure along with the desired delay value in nanoseconds. The function calculates the values needed for the prescaler and scaler. Note that returning the calculated delay as an exact delay match may not be possible. In this case, the closest match is calculated without going below the desired delay value input. It is possible to input a very large delay value that exceeds the capability of the part, in which case the maximum supported delay is returned. The higher-level peripheral driver alerts the user of an out of range delay input.

Parameters

whichCtar	The desired Clock and Transfer Attributes Register (CTAR) of type dspi_ctar_selection_t.
whichDelay	The desired delay to configure, must be of type dspi_delay_type_t

In master mode, the 16-bit data is appended to the 16-bit command info. The command portion provides characteristics of the data, such as the optional continuous chip select operation between transfers, the

desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). This is an example.

```
*  dspi_command_data_config_t commandConfig;
*  commandConfig.isPcsContinuous = true;
*  commandConfig.whichCtar = kDSPICtar0;
*  commandConfig.whichPcs = kDSPIPcs0;

```
*  dspi_command_data_config_t  command;
*  DSPI_GetDefaultDataCommandConfig(&command);
*
```

Parameters

4.0.7.7.29 void DSPI_MasterWriteDataBlocking (SPI_Type * *base,* dspi_command_data_config_t * *command,* uint16_t *data*)

In master mode, the 16-bit data is appended to the 16-bit command info. The command portion provides characteristics of the data, such as the optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). This is an example.

```
*  dspi_command_config_t commandConfig;
*  commandConfig.isPcsContinuous = true;
*  commandConfig.whichCtar = kDSPICtar0;
```

```
*  commandConfig.whichPcs = kDSPIPcs1;
*  commandConfig.clearTransferCount = false;
*  commandConfig.isEndOfQueue = false;
*  DSPI_MasterWriteDataBlocking(base, &commandConfig, dataWord);
*
```

Note that this function does not return until after the transmit is complete. Also note that the DSPI must be enabled and running to transmit data (MCR[MDIS] & [HALT] = 0). Because the SPI is a synchronous protocol, the received data is available when the transmit completes.

Parameters

base	DSPI peripheral address.
command	Pointer to the command structure.
data	The data word to be sent.

4.0.7.7.30 static uint32_t DSPI_MasterGetFormattedCommand (dspi_command_data_config_t * *command*) [inline], [static]

This function allows the caller to pass in the data command structure and returns the command word formatted according to the DSPI PUSHR register bit field placement. The user can then "OR" the returned command word with the desired data to send and use the function DSPI_HAL_WriteCommandDataMastermode or DSPI_HAL_WriteCommandDataMastermodeBlocking to write the entire 32-bit command data word to the PUSHR. This helps improve performance in cases where the command structure is constant. For example, the user calls this function before starting a transfer to generate the command word. When they are ready to transmit the data, they OR this formatted command word with the desired data to transmit. This process increases transmit performance when compared to calling send functions, such as DSPI_HAL_WriteDataMastermode, which format the command word each time a data word is to be sent.

Parameters

command	Pointer to the command structure.

Returns

The command word formatted to the PUSHR data register bit field.

4.0.7.7.31 void DSPI_MasterWriteCommandDataBlocking (SPI_Type * *base,* uint32_t *data*)

In this function, the user must append the 16-bit data to the 16-bit command information and then provide the total 32-bit word as the data to send. The command portion provides characteristics of the data, such as the optional continuous chip select operation between transfers, the desired Clock and Transfer Attributes register to use for the associated SPI frame, the desired PCS signal to use for the data transfer, whether

the current transfer is the last in the queue, and whether to clear the transfer count (normally needed when sending the first frame of a data packet). The user is responsible for appending this command with the data to send. This is an example:

```
*  dataWord = <16-bit command> | <16-bit data>;
*  DSPI_MasterWriteCommandDataBlocking(base, dataWord);
*
```

Note that this function does not return until after the transmit is complete. Also note that the DSPI must be enabled and running to transmit data (MCR[MDIS] & [HALT] = 0). Because the SPI is a synchronous protocol, the received data is available when the transmit completes.

For a blocking polling transfer, see methods below. Option 1: uint32_t command_to_send = DSPI_-MasterGetFormattedCommand(&command); uint32_t data0 = command_to_send | data_need_to_send-_0; uint32_t data1 = command_to_send | data_need_to_send_1; uint32_t data2 = command_to_send | data_need_to_send_2;

DSPI_MasterWriteCommandDataBlocking(base,data0); DSPI_MasterWriteCommandDataBlocking(base,data1); DSPI_MasterWriteCommandDataBlocking(base,data2);

4.0.8.5 Function Documentation

4.0.8.5.1 void DSPI_MasterTransferCreateHandleDMA (SPI_Type ∗ *base,* dspi_master_dma_handle_t ∗ *handle,* dspi_master_dma_transfer_callback_t *callback,* void ∗ *userData,* dma_handle_t ∗ *dmaRxRegToRxDataHandle,* dma_handle_t ∗ *dmaTxDataToIntermediaryHandle,* dma_handle_t ∗ *dmaIntermediaryToTxRegHandle*)

This function initializes the DSPI DMA handle which can be used for other DSPI transactional APIs. Usually, for a specified DSPI instance, call this API once to get the initialized handle.

Note that DSPI DMA has a separated (Rx and Tx as two sources) or shared (Rx and Tx is the same source) DMA request source. (1) For a separated DMA request source, enable and set the Rx DMAMUX source for dmaRxRegToRxDataHandle and Tx DMAMUX source for dmaIntermediaryToTxRegHandle. (2) For a shared DMA request source, enable and set the Rx/Rx DMAMUX source for dmaRxRegToRxDataHandle.

Parameters

base	DSPI peripheral base address.

handle	DSPI handle pointer to dspi_master_dma_handle_t.
callback	DSPI callback.
userData	A callback function parameter.
dmaRxRegToRxDataHandle	dmaRxRegToRxDataHandle pointer to dma_handle_t.
dmaTxDataToIntermediaryHandle	dmaTxDataToIntermediaryHandle pointer to dma_handle_t.

4.0.8.5.4 status_t DSPI_MasterTransferGetCountDMA (SPI_Type * *base*, dspi_master_dma_handle_t * *handle*, size_t * *count*)

This function gets the master DMA transfer remaining bytes.

Parameters

base	DSPI peripheral base address.
handle	A pointer to the dspi_master_dma_handle_t structure which stores the transfer state.
count	A number of bytes transferred by the non-blocking transaction.

Returns

This function initializes the DSPI DMA handle which can be used for other DSPI transactional APIs. Usually, for a specified DSPI instance, call this API once to get the initialized handle.

Note that DSPI DMA has a separated (Rx and Tx as two sources) or shared (Rx and Tx is the same source) DMA request source. (1) For a separated DMA request source, enable and set the Rx DMAMUX source for dmaRxRegToRxDataHandle and Tx DMAMUX source for dmaTxDataToTxRegHandle. (2) For a shared DMA request source, enable and set the Rx/Rx DMAMUX source for dmaRxRegToRxDataHandle.

Parameters

base	DSPI peripheral base address.

handle	DSPI handle pointer to dspi_slave_dma_handle_t.
callback	DSPI callback.
userData	A callback function parameter.

4.0.11.5 Typedef Documentation

4.0.11.5.1 typedef void(* edma_callback)(struct _edma_handle *handle, void *userData, bool transferDone, uint32_t tcds)

This callback function is called in the EDMA interrupt handle. In normal mode, run into callback function means the transfer users need is done. In scatter gather mode, run into callback function means a transfer control block (tcd) is finished. Not all transfer finished, users can get the finished tcd numbers using interface EDMA_GetUnusedTCDNumber.

Parameters

handle	EDMA handle pointer, users shall not touch the values inside.
userData	The callback user parameter pointer. Users can use this parameter to involve things users need to change in EDMA callback function.
transferDone	If the current loaded transfer done. In normal mode it means if all transfer done. In scatter gather mode, this parameter shows is the current transfer block in EDMA register is done. As the load of core is different, it will be different if the new tcd loaded into EDMA registers while this callback called. If true, it always means new tcd still not loaded into registers, while false means new tcd already loaded into registers.
tcds	How many tcds are done from the last callback. This parameter only used in scatter gather mode. It tells user how many tcds are finished between the last callback and this.

Returns

Major loop count which has not been transferred yet for the current TCD.

Note

1. This function can only be used to get unfinished major loop count of transfer without the next TCD, or it might be inaccuracy.
   1. The unfinished/remaining transfer bytes cannot be obtained directly from registers while the channel is running. Because to calculate the remaining bytes, the initial NBYTES configured in DMA_TCDn_NBYTES_MLNO register is needed while the eDMA IP does not support getting it while a channel is active. In another word, the NBYTES value reading is always the actual (decrementing) NBYTES value the dma_engine is working with while a channel is running. Consequently, to get the remaining transfer bytes, a software-saved initial value of NBYTES (for example copied before enabling the channel) is needed. The formula to calculate it is shown below: RemainingBytes = RemainingMajorLoopCount * NBYTES(initially configured)

Note

The data address and the data width must be consistent. For example, if the SRC is 4 bytes, the source address must be 4 bytes aligned, or it results in source address error (SAE).

4.0.11.7.37 status_t EDMA_SubmitTransfer (edma_handle_t * *handle*, const edma_transfer_config_t * *config*)

Parameters

handle	DMA handle pointer.

Returns

The next TCD address.

4.0.11.7.43 void EDMA_HandleIRQ (edma_handle_t * *handle*)

This function clears the channel major interrupt flag and calls the callback function if it is not NULL.

Note: For the case using TCD queue, when the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled).

For instance, when the time interrupt of TCD[0] happens, the TCD[1] has already been loaded into the eDMA engine. As sga and sga_index are calculated based on the DLAST_SGA bitfield lies in the TCD_CSR register, the sga_index in this case should be 2 (DLAST_SGA of TCD[1] stores the address of TCD[2]). Thus, the "tcdUsed" updated should be (tcdUsed - 2U) which indicates the number of TCDs can be loaded in the memory pool (because TCD[0] and TCD[1] have been loaded into the eDMA engine at this point already.).

For the last two continuous ISRs in a scatter/gather process, they both load the last TCD (The last ISR does not load a new TCD) from the memory pool to the eDMA engine when major loop completes. Therefore, ensure that the header and tcdUsed updated are identical for them. tcdUsed are both 0 in this case as no TCD to be loaded.

See the "eDMA basic data flow" in the eDMA Functional description section of the Reference Manual for further details.

Parameters

handle	eDMA handle pointer.

4.0.12.6 Function Documentation

4.0.12.6.1 void EWM_Init (EWM_Type * *base,* const ewm_config_t * *config*)

This function is used to initialize the EWM. After calling, the EWM runs immediately according to the configuration. Note that, except for the interrupt enable control bit, other control bits and registers are write once after a CPU reset. Modifying them more than once generates a bus transfer error.

This is an example.

```
*   ewm_config_t config;
*   EWM_GetDefaultConfig(&config);
*   config.compareHighValue = 0xAAU;
*   EWM_Init(ewm_base,&config);
*
```

Parameters

base	EWM peripheral base address
config	The configuration of the EWM

4.0.12.6.2 void EWM_Deinit (EWM_Type * *base*)

This function is used to shut down the EWM.

Parameters

base	EWM peripheral base address

4.0.12.6.3 void EWM_GetDefaultConfig (ewm_config_t * *config*)

This function initializes the EWM configuration structure to default values. The default values are as follows.

```
*   ewmConfig->enableEwm = true;
*   ewmConfig->enableEwmInput = false;
*   ewmConfig->setInputAssertLogic = false;
*   ewmConfig->enableInterrupt = false;
*   ewmConfig->ewm_lpo_clock_source_t = kEWM_LpoClockSource0;
*   ewmConfig->prescaler = 0;
*   ewmConfig->compareLowValue = 0;
*   ewmConfig->compareHighValue = 0xFEU;
*
```

Parameters

config	Pointer to the EWM configuration structure.

This is an example for getting the running flag.

```
*   uint32_t status;
*   status = EWM_GetStatusFlags(ewm_base) & kEWM_RunningFlag;
*
```

Parameters

4.0.13 C90TFS Flash Driver

4.0.13.1 Overview

The flash provides the C90TFS Flash driver of Kinetis devices with the C90TFS Flash module inside. The flash driver provides general APIs to handle specific operations on C90TFS/FTFx Flash module. The user can use those APIs directly in the application. In addition, it provides internal functions called by the driver. Although these functions are not meant to be called from the user's application directly, the APIs can still be used.

4.0.21 FlexBus: External Bus Interface Driver

4.0.21.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Crossbar External Bus Interface (FlexBus) block of MCUXpresso SDK devices.

A multifunction external bus interface is provided on the device with a basic functionality to interface to slave-only devices. It can be directly connected to the following asynchronous or synchronous devices with little or no additional circuitry.

- External ROMs
- Flash memories
- Programmable logic devices
- Other simple target (slave) devices

For asynchronous devices, a simple chip-select based interface can be used. The FlexBus interface has up to six general purpose chip-selects, FB_CS[5:0]. The number of chip selects available depends on the device and its pin configuration.

4.0.21.2 FlexBus functional operation

To configure the FlexBus driver, use on of the two ways to configure the flexbus_config_t structure.

1. Using the FLEXBUS_GetDefaultConfig() function.
2. Set parameters in the flexbus_config_t structure.

To initialize and configure the FlexBus driver, call the FLEXBUS_Init() function and pass a pointer to the flexbus_config_t structure.

To de-initialize the FlexBus driver, call the FLEXBUS_Deinit() function.

4.0.21.3 Typical use case and example

This example shows how to write/read to external memory (MRAM) by using the FlexBus module.

Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/flexbus

4.0.22 FTM: FlexTimer Driver

4.0.22.1 Overview

The MCUXpresso SDK provides a driver for the FlexTimer Module (FTM) of MCUXpresso SDK devices.

4.0.22.2 Function groups

The FTM driver supports the generation of PWM signals, input capture, dual edge capture, output compare, and quadrature decoder modes. The driver also supports configuring each of the FTM fault inputs.

4.0.22.2.1 Initialization and deinitialization

The function FTM_Init() initializes the FTM with specified configurations. The function FTM_GetDefaultConfig() gets the default configurations. The initialization function configures the FTM for the requested register update mode for registers with buffers. It also sets up the FTM's fault operation mode and FTM behavior in the BDM mode.

The function FTM_Deinit() disables the FTM counter and turns off the module clock.

4.0.22.2.2 PWM Operations

The function FTM_SetupPwm() sets up FTM channels for the PWM output. The function sets up the PWM signal properties for multiple channels. Each channel has its own duty cycle and level-mode specified. However, the same PWM period and PWM mode is applied to all channels requesting the PWM output. The signal duty cycle is provided as a percentage of the PWM period. Its value should be between 0 and 100 0=inactive signal (0% duty cycle) and 100=always active signal (100% duty cycle).

The function FTM_UpdatePwmDutycycle() updates the PWM signal duty cycle of a particular FTM channel.

The function FTM_UpdateChnlEdgeLevelSelect() updates the level select bits of a particular FTM channel. This can be used to disable the PWM output when making changes to the PWM signal.

4.0.22.2.3 Input capture operations

The function FTM_SetupInputCapture() sets up an FTM channel for the input capture. The user can specify the capture edge and a filter value to be used when processing the input signal.

The function FTM_SetupDualEdgeCapture() can be used to measure the pulse width of a signal. A channel pair is used during capture with the input signal coming through a channel n. The user can specify whether to use one-shot or continuous capture, the capture edge for each channel, and any filter value to be used when processing the input signal.

4.0.22.2.4 Output compare operations

The function FTM_SetupOutputCompare() sets up an FTM channel for the output comparison. The user can specify the channel output on a successful comparison and a comparison value.

4.0.22.2.5 Quad decode

The function FTM_SetupQuadDecode() sets up FTM channels 0 and 1 for quad decoding. The user can specify the quad decoding mode, polarity, and filter properties for each input signal.

4.0.22.2.6 Fault operation

The function FTM_SetupFault() sets up the properties for each fault. The user can specify the fault polarity and whether to use a filter on a fault input. The overall fault filter value and fault control mode are set up during initialization.

4.0.22.3 Register Update

Some of the FTM registers have buffers. The driver supports various methods to update these registers with the content of the register buffer. The registers can be updated using the PWM synchronized loading or an intermediate point loading. The update mechanism for register with buffers can be specified through the following fields available in the configuration structure. Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/ftmMultiple PWM synchronization update modes can be used by providing an OR'ed list of options available in the enumeration ftm_pwm_sync_method_t to the pwmSyncMode field.

When using an intermediate reload points, the PWM synchnronization is not required. Multiple reload points can be used by providing an OR'ed list of options available in the enumeration ftm_reload_point_t to the reloadPoints field.

The driver initialization function sets up the appropriate bits in the FTM module based on the register update options selected.

If software PWM synchronization is used, the below function can be used to initiate a software trigger. Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/ftm

4.0.22.4 Typical use case

4.0.22.4.1 PWM output

Output a PWM signal on two FTM channels with different duty cycles. Periodically update the PWM signal duty cycle. Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/ftm

4.0.25 FGPIO Driver

This section describes the programming interface of the FGPIO driver. The FGPIO driver configures the FGPIO module and provides a functional interface to build the GPIO application.

Note

Modules

4.0.27 I2C Driver

4.0.27.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Inter-Integrated Circuit (I2C) module of MCUXpresso SDK devices.

The I2C driver includes functional APIs and transactional APIs.

Functional APIs target the low-level APIs. Functional APIs can be used for the I2C master/slave initialization/configuration/operation for optimization/customization purpose. Using the functional APIs requires knowing the I2C master peripheral and how to organize functional APIs to meet the application requirements. The I2C functional operation groups provide the functional APIs set.

Transactional APIs target the high-level APIs. The transactional APIs can be used to enable the peripheral quickly and also in the application if the code size and performance of transactional APIs satisfy the requirements. If the code size and performance are critical requirements, see the transactional API implementation and write custom code using the functional APIs or accessing the hardware registers.

Transactional APIs support asynchronous transfer. This means that the functions I2C_MasterTransferNonBlocking() set up the interrupt non-blocking transfer. When the transfer completes, the upper layer is notified through a callback function with the status.

4.0.27.7.1 void I2C_MasterInit (I2C_Type * *base*, const i2c_master_config_t * *masterConfig*, uint32_t *srcClock_Hz*)

Call this API to ungate the I2C clock and configure the I2C with master configuration.

Note

This is an example.

```
* i2c_master_config_t config = {

* .enableStopHold = false,
* .highDrive = false,
* .baudRate_Bps = 100000,

4.0.27.7.32 status_t I2C_SlaveTransferNonBlocking (I2C_Type * *base*, i2c_slave_handle_t * *handle*, uint32_t *eventMask*)

Call this API after calling the I2C_SlaveInit() and I2C_SlaveTransferCreateHandle() to start processing transactions driven by an I2C master. The slave monitors the I2C bus and passes events to the callback that was passed into the call to I2C_SlaveTransferCreateHandle(). The callback is always invoked from the interrupt context.

The set of events received by the callback is customizable. To do so, set the *eventMask* parameter to the OR'd combination of i2c_slave_transfer_event_t enumerators for the events you wish to receive. The kI2C_SlaveTransmitEvent and #kLPI2C_SlaveReceiveEvent events are always enabled and do not need to be included in the mask. Alternatively, pass 0 to get a default set of only the transmit and receive events that are always enabled. In addition, the kI2C_SlaveAllEvents constant is provided as a convenient way to enable all events.

Parameters

base	The I2C peripheral base address.
handle	Pointer to #i2c_slave_handle_t structure which stores the transfer state.
eventMask	Bit mask formed by OR'ing together i2c_slave_transfer_event_t enumerators to specify which events to send to the callback. Other accepted values are 0 to get a default set of only the transmit and receive events, and kI2C_SlaveAllEvents to enable all events.

Return values

#kStatus_Success	Slave transfers were successfully started.
kStatus_I2C_Busy	Slave transfers have already been started on this handle.

4.0.27.7.33 void I2C_SlaveTransferAbort (I2C_Type * *base*, i2c_slave_handle_t * *handle*)

4.0.32.2.1 Initialization and deinitialization

The function LPTMR_Init() initializes the LPTMR with specified configurations. The function LPTMR_GetDefaultConfig() gets the default configurations. The initialization function configures the LPTMR for a timer or a pulse counter mode mode. It also sets up the LPTMR's free running mode operation and a clock source.

The function LPTMR_DeInit() disables the LPTMR module and gates the module clock.

4.0.32.2.2 Timer period Operations

The function LPTMR_SetTimerPeriod() sets the timer period in units of count. Timers counts from 0 to the count value set here.

The function LPTMR_GetCurrentTimerCount() reads the current timer counting value. This function returns the real-time timer counting value ranging from 0 to a timer period.

The timer period operation function takes the count value in ticks. Call the utility macros provided in the fsl_common.h file to convert to microseconds or milliseconds.

4.0.32.2.3 Start and Stop timer operations

The function LPTMR_StartTimer() starts the timer counting. After calling this function, the timer counts up to the counter value set earlier by using the LPTMR_SetPeriod() function. Each time the timer reaches the count value and increments, it generates a trigger pulse and sets the timeout interrupt flag. An interrupt is also triggered if the timer interrupt is enabled.

The function LPTMR_StopTimer() stops the timer counting and resets the timer's counter register.

4.0.32.2.4 Status

Provides functions to get and clear the LPTMR status.

4.0.32.2.5 Interrupt

Provides functions to enable/disable LPTMR interrupts and get the currently enabled interrupts.

4.0.32.3 Typical use case

4.0.32.3.1 LPTMR tick example

Updates the LPTMR period and toggles an LED periodically. Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/lptmr

4.0.34.7.20 void LPUART_TransferCreateHandle (LPUART_Type * *base*, lpuart_handle_t * *handle*, lpuart_transfer_callback_t *callback*, void * *userData*)

This function initializes the LPUART handle, which can be used for other LPUART transactional APIs. Usually, for a specified LPUART instance, call this API once to get the initialized handle.

The LPUART driver supports the "background" receiving, which means that user can set up an RX ring buffer optionally. Data received is stored into the ring buffer even when the user doesn't call the LPUART_TransferReceiveNonBlocking() API. If there is already data received in the ring buffer, the user can get the received data from the ring buffer directly. The ring buffer is disabled if passing NULL as `ringBuffer`.

Parameters

base	LPUART peripheral base address.
handle	LPUART handle pointer.
callback	Callback function.
userData	User data.

4.0.34.7.21 status_t LPUART_TransferSendNonBlocking (LPUART_Type * *base*, lpuart_handle_t * *handle*, lpuart_transfer_t * *xfer*)

This function send data using an interrupt method. This is a non-blocking function, which returns directly without waiting for all data written to the transmitter register. When all data is written to the TX register in the ISR, the LPUART driver calls the callback function and passes the kStatus_LPUART_TxIdle as status parameter.

Note

The kStatus_LPUART_TxIdle is passed to the upper layer when all data are written to the TX register. However, there is no check to ensure that all the data sent out. Before disabling the TX, check the kLPUART_TransmissionCompleteFlag to ensure that the transmit is finished.

Parameters

base	LPUART peripheral base address.
handle	LPUART handle pointer.
xfer	LPUART transfer structure, see lpuart_transfer_t.

Return values

kStatus_Success	Successfully start the data transmission.
kStatus_LPUART_TxBusy	Previous transmission still not finished, data not all written to the TX register.
kStatus_InvalidArgument	Invalid argument.

4.0.34.7.22 void LPUART_TransferStartRingBuffer (LPUART_Type * *base*, lpuart_handle_t * *handle*, uint8_t * *ringBuffer*, size_t *ringBufferSize*)

This function sets up the RX ring buffer to a specific UART handle.

When the RX ring buffer is used, data received is stored into the ring buffer even when the user doesn't call the UART_TransferReceiveNonBlocking() API. If there is already data received in the ring buffer, the user can get the received data from the ring buffer directly.

Note

When using RX ring buffer, one byte is reserved for internal use. In other words, if `ringBufferSize` is 32, then only 31 bytes are used for saving data.

Parameters

base	LPUART peripheral base address.
handle	LPUART handle pointer.
ringBuffer	Start address of ring buffer for background receiving. Pass NULL to disable the ring buffer.
ringBufferSize	size of the ring buffer.

4.0.34.7.23 void LPUART_TransferStopRingBuffer (LPUART_Type * *base,* lpuart_handle_t * *handle*)

Parameters

base	LPUART peripheral base address.
handle	LPUART handle pointer.

Returns

Length of received data in RX ring buffer.

4.0.34.7.25 void LPUART_TransferAbortSend (LPUART_Type * *base,* lpuart_handle_t * *handle*)

4.0.34.7.26 status_t LPUART_TransferGetSendCount (LPUART_Type * *base*, lpuart_handle_t * *handle*, uint32_t * *count*)

This function gets the number of bytes that have been written to LPUART TX register by an interrupt method.

Parameters

base	LPUART peripheral base address.
handle	LPUART handle pointer.
count	Send bytes count.

Return values

kStatus_NoTransferInProgress	No send in progress.
kStatus_InvalidArgument	Parameter is invalid.

4.0.34.7.27 status_t LPUART_TransferReceiveNonBlocking (LPUART_Type * *base*, lpuart_handle_t * *handle*, lpuart_transfer_t * *xfer*, size_t * *receivedBytes*)

This function receives data using an interrupt method. This is a non-blocking function which returns without waiting to ensure that all data are received. If the RX ring buffer is used and not empty, the data in the ring buffer is copied and the parameter `receivedBytes` shows how many bytes are copied from the ring buffer. After copying, if the data in the ring buffer is not enough for read, the receive request is saved by the LPUART driver. When the new data arrives, the receive request is serviced first. When all data is received, the LPUART driver notifies the upper layer through a callback function and passes a status parameter kStatus_UART_RxIdle. For example, the upper layer needs 10 bytes but there are only 5 bytes in ring buffer. The 5 bytes are copied to xfer->data, which returns with the parameter `receivedBytes` set to 5. For the remaining 5 bytes, the newly arrived data is saved from xfer->data[5]. When 5 bytes are received, the LPUART driver notifies the upper layer. If the RX ring buffer is not enabled, this function enables the RX and RX interrupt to receive data to xfer->data. When all data is received, the upper layer is notified.

Parameters

base	LPUART peripheral base address.
handle	LPUART handle pointer.
xfer	LPUART transfer structure, see uart_transfer_t.
receivedBytes	Bytes received from the ring buffer directly.

Return values

kStatus_Success	Successfully queue the transfer into the transmit queue.
kStatus_LPUART_RxBusy	Previous receive request is not finished.
kStatus_InvalidArgument	Invalid argument.

4.0.34.7.28 void LPUART_TransferAbortReceive (LPUART_Type * *base*, lpuart_handle_t * *handle*)

This function aborts the interrupt-driven data receiving. The user can get the remainBytes to find out how many bytes not received yet.

This function handles the LPUART transmit and receive IRQ request.

Parameters

4.0.38 PDB: Programmable Delay Block

4.0.38.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Programmable Delay Block (PDB) module of MCUXpresso SDK devices.

The PDB driver includes a basic PDB counter, trigger generators for ADC, DAC, and pulse-out.

The basic PDB counter can be used as a general programmable timer with an interrupt. The counter increases automatically with the divided clock signal after it is triggered to start by an external trigger input or the software trigger. There are "milestones" for the output trigger event. When the counter is equal to any of these "milestones", the corresponding trigger is generated and sent out to other modules. These "milestones" are for the following events.

- Counter delay interrupt, which is the interrupt for the PDB module
- ADC pre-trigger to trigger the ADC conversion
- DAC interval trigger to trigger the DAC buffer and move the buffer read pointer
- Pulse-out triggers to generate a single of rising and falling edges, which can be assembled to a window.

The "milestone" values have a flexible load mode. To call the APIs to set these value is equivalent to writing data to their buffer. The loading event occurs as the load mode describes. This design ensures that all "milestones" can be updated at the same time.

4.0.38.2 Typical use case

4.0.38.2.1 Working as basic PDB counter with a PDB interrupt.

Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/pdb

4.0.38.2.2 Working with an additional trigger. The ADC trigger is used as an example.

Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/pdb

4.0.39 PIT: Periodic Interrupt Timer

4.0.39.1 Overview

The MCUXpresso SDK provides a driver for the Periodic Interrupt Timer (PIT) of MCUXpresso SDK devices.

4.0.39.2 Function groups

The PIT driver supports operating the module as a time counter.

4.0.39.2.1 Initialization and deinitialization

The function PIT_Init() initializes the PIT with specified configurations. The function PIT_GetDefaultConfig() gets the default configurations. The initialization function configures the PIT operation in debug mode.

The function PIT_SetTimerChainMode() configures the chain mode operation of each PIT channel.

The function PIT_Deinit() disables the PIT timers and disables the module clock.

4.0.39.2.2 Timer period Operations

The function PITR_SetTimerPeriod() sets the timer period in units of count. Timers begin counting down from the value set by this function until it reaches 0.

The function PIT_GetCurrentTimerCount() reads the current timer counting value. This function returns the real-time timer counting value, in a range from 0 to a timer period.

The timer period operation functions takes the count value in ticks. Users can call the utility macros provided in fsl_common.h to convert to microseconds or milliseconds.

4.0.39.2.3 Start and Stop timer operations

The function PIT_StartTimer() starts the timer counting. After calling this function, the timer loads the period value set earlier via the PIT_SetPeriod() function and starts counting down to 0. When the timer reaches 0, it generates a trigger pulse and sets the timeout interrupt flag.

The function PIT_StopTimer() stops the timer counting.

4.0.39.2.4 Status

Provides functions to get and clear the PIT status.

4.0.39.2.5 Interrupt

Provides functions to enable/disable PIT interrupts and get current enabled interrupts.

4.0.39.3 Typical use case

4.0.39.3.1 PIT tick example

Updates the PIT period and toggles an LED periodically. Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/pit

4.0.39.6.4 static void PIT_SetTimerChainMode (PIT_Type * *base,* pit_chnl_t *channel,* bool *enable*) [inline], [static]

When a timer has a chain mode enabled, it only counts after the previous timer has expired. If the timer n-1 has counted down to 0, counter n decrements the value by one. Each timer is 32-bits, which allows the developers to chain timers together and form a longer timer (64-bits and larger). The first timer (timer 0) can't be chained to any other timer.

Parameters

base	PIT peripheral base address

4.0.39.6.10 static void PIT_SetTimerPeriod (PIT_Type * *base*, pit_chnl_t *channel*, uint32_t *count*) [inline], [static]

Timers begin counting from the value set by this function until it reaches 0, then it generates an interrupt and load this register value again. Writing a new value to this register does not restart the timer. Instead, the value is loaded after the timer expires.

Note

Parameters

base	PIT peripheral base address

Parameters

base	PIT peripheral base address

channel	Timer channel number

Returns

Current timer counting value in ticks

4.0.39.6.12 static void PIT_StartTimer (PIT_Type * *base,* pit_chnl_t *channel*) [inline], [static]

After calling this function, timers load period value, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it generates a trigger pulse and sets the timeout interrupt flag.

Parameters

base	PIT peripheral base address
channel	Timer channel number.

4.0.39.6.13 static void PIT_StopTimer (PIT_Type * *base,* pit_chnl_t *channel*) [inline], [static]

Parameters

base	PIT peripheral base address
channel	Timer channel number.

4.0.43 RNGA: Random Number Generator Accelerator Driver

4.0.43.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Random Number Generator Accelerator (RNGA) block of MCUXpresso SDK devices.

4.0.43.2 RNGA Initialization

1. To initialize the RNGA module, call the RNGA_Init() function. This function automatically enables the RNGA module and its clock.
2. After calling the RNGA_Init() function, the RNGA is enabled and the counter starts working.
3. To disable the RNGA module, call the RNGA_Deinit() function.

4.0.43.3 Get random data from RNGA

1. RNGA_GetRandomData() function gets random data from the RNGA module.

4.0.43.4 RNGA Set/Get Working Mode

The RNGA works either in sleep mode or normal mode

1. RNGA_SetMode() function sets the RNGA mode.
2. RNGA_GetMode() function gets the RNGA working mode.

4.0.43.5 Seed RNGA

1. RNGA_Seed() function inputs an entropy value that the RNGA can use to seed the pseudo random algorithm.

This example code shows how to initialize and get random data from the RNGA driver:

Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/rnga

Note

It is important to note that there is no known cryptographic proof showing this is a secure method for generating random data. In fact, there may be an attack against this random number generator if its output is used directly in a cryptographic application. The attack is based on the linearity of the internal shift registers. Therefore, it is highly recommended that the random data produced by this module be used as an entropy source to provide an input seed to a NIST-approved pseudo-random-number generator based on DES or SHA-1 and defined in NIST FIPS PUB 186-2 Appendix 3 and NIST FIPS PUB SP 800-90. The requirement is needed to maximize the entropy of this input seed. To do this, when data is extracted from RNGA as quickly as the hardware allows, there are one

to two bits of added entropy per 32-bit word. Any single bit of that word contains that entropy. Therefore, when used as an entropy source, a random number should be generated for each bit of entropy required and the least significant bit (any bit would be equivalent) of each word retained. The remainder of each random number should then be discarded. Used this way, even with full knowledge of the internal state of RNGA and all prior random numbers, an attacker is not able to predict the values of the extracted bits. Other sources of entropy can be used along with RNGA to generate the seed to the pseudorandom algorithm. The more random sources combined to create the seed, the better. The following is a list of sources that can be easily combined with the output of this module.

- Current time using highest precision possible
- Real-time system inputs that can be characterized as "random"
- Other entropy supplied directly by the user

Enumerations

4.0.45 SAI: Serial Audio Interface

4.0.45.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Serial Audio Interface (SAI) module of MCUXpresso SDK devices.

SAI driver includes functional APIs and transactional APIs.

Functional APIs target low-level APIs. Functional APIs can be used for SAI initialization, configuration and operation, and for optimization and customization purposes. Using the functional API requires the knowledge of the SAI peripheral and how to organize functional APIs to meet the application requirements. All functional API use the peripheral base address as the first parameter. SAI functional operation groups provide the functional API set.

Transactional APIs target high-level APIs. Transactional APIs can be used to enable the peripheral and in the application if the code size and performance of transactional APIs satisfy the requirements. If the code size and performance are a critical requirement, see the transactional API implementation and write a custom code. All transactional APIs use the sai_handle_t as the first parameter. Initialize the handle by calling the SAI_TransferTxCreateHandle() or SAI_TransferRxCreateHandle() API.

Transactional APIs support asynchronous transfer. This means that the functions SAI_TransferSendNonBlocking() and SAI_TransferReceiveNonBlocking() set up the interrupt for data transfer. When the transfer completes, the upper layer is notified through a callback function with the kStatus_SAI_TxIdle and kStatus_SAI_RxIdle status.

#Typical configurations(#SAIConfigurations)

Bit width configuration

SAI driver support 8/16/24/32bits stereo/mono raw audio data transfer. SAI EDMA driver support 8/16/32bits stereo/mono raw audio data transfer, since the EDMA doesn't support 24bit data width, so application should pre-convert the 24bit data to 32bit. SAI DMA driver support 8/16/32bits stereo/mono raw audio data transfer, since the EDMA doesn't support 24bit data width, so application should pre-convert the 24bit data to 32bit. SAI SDMA driver support 8/16/24/32bits stereo/mono raw audio data transfer.

Frame configuration

SAI driver support I2S, DSP, Left justified, Right justified, TDM mode. Application can call the api directly: SAI_GetClassicI2SConfig SAI_GetLeftJustifiedConfig SAI_GetRightJustifiedConfig SAI_GetTDMConfig SAI_GetDSPConfig

4.0.51 SMC: System Mode Controller Driver

4.0.51.1 Overview

The MCUXpresso SDK provides a peripheral driver for the System Mode Controller (SMC) module of MCUXpresso SDK devices. The SMC module sequences the system in and out of all low-power stop and run modes.

API functions are provided to configure the system for working in a dedicated power mode. For different power modes, SMC_SetPowerModexxx() function accepts different parameters. System power mode state transitions are not available between power modes. For details about available transitions, see the power mode transitions section in the SoC reference manual.

4.0.51.2 Typical use case

4.0.51.2.1 Enter wait or stop modes

SMC driver provides APIs to set MCU to different wait modes and stop modes. Pre and post functions are used for setting the modes. The pre functions and post functions are used as follows.

Disable/enable the interrupt through PRIMASK. This is an example use case. The application sets the wakeup interrupt and calls SMC function SMC_SetPowerModeStop to set the MCU to STOP mode, but the wakeup interrupt happens so quickly that the ISR completes before the function SMC_SetPowerMode-Stop. As a result, the MCU enters the STOP mode and never is woken up by the interrupt. In this use case, the application first disables the interrupt through PRIMASK, sets the wakeup interrupt, and enters the STOP mode. After wakeup, enable the interrupt through PRIMASK. The MCU can still be woken up by disabling the interrupt through PRIMASK. The pre and post functions handle the PRIMASK.

```
SMC_PreEnterStopModes();

/* Enable the wakeup interrupt here. */

SMC_SetPowerModeStop(SMC, kSMC_PartialStop);

SMC_PostExitStopModes();
```

For legacy Kinetis, when entering stop modes, the flash speculation might be interrupted. As a result, the prefetched code or data might be broken. To make sure the flash is idle when entring the stop modes, smc driver allocates a RAM region, the code to enter stop modes are excuted in RAM, thus the flash is idle and no prefetch is performed while entring stop modes. Application should make sure that, the rw data of fsl_smc.c is located in memory region which is not powered off in stop modes, especially LLS2 modes.

For STOP, VLPS, and LLS3, the whole RAM are powered up, so after woken up, the RAM function could continue excuting. For VLLS mode, the system resets after woken up, the RAM content might be re-initialized. For LLS2 mode, only part of RAM are powered on, so application must make sure that, the rw data of fsl_smc.c is located in memory region which is not powered off, otherwise after woken up, the MCU could not get right code to excute.

4.0.51.6 Function Documentation

4.0.51.6.1 static void SMC_SetPowerModeProtection (SMC_Type * *base,* uint8_t *allowedModes*) [inline], [static]

This function configures the power mode protection settings for supported power modes in the specified chip family. The available power modes are defined in the smc_power_mode_protection_t. This should be done at an early system level initialization stage. See the reference manual for details. This register can only write once after the power reset.

The allowed modes are passed as bit map. For example, to allow LLS and VLLS, use SMC_SetPowerModeProtection(kSMC_AllowPowerModeVlls | kSMC_AllowPowerModeVlps). To allow all modes, use SMC_SetPowerModeProtection(kSMC_AllowPowerModeAll).

4.0.53 UART Driver

4.0.53.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Universal Asynchronous Receiver/Transmitter (UART) module of MCUXpresso SDK devices.

The UART driver includes functional APIs and transactional APIs.

Functional APIs are used for UART initialization/configuration/operation for optimization/customization purpose. Using the functional API requires the knowledge of the UART peripheral and how to organize functional APIs to meet the application requirements. All functional APIs use the peripheral base address as the first parameter. UART functional operation groups provide the functional API set.

Transactional APIs can be used to enable the peripheral quickly and in the application if the code size and performance of transactional APIs can satisfy the requirements. If the code size and performance are critical requirements, see the transactional API implementation and write custom code. All transactional APIs use the uart_handle_t as the second parameter. Initialize the handle by calling the UART_TransferCreateHandle() API.

Transactional APIs support asynchronous transfer, which means that the functions UART_TransferSendNonBlocking() and UART_TransferReceiveNonBlocking() set up an interrupt for data transfer. When the transfer completes, the upper layer is notified through a callback function with the kStatus_UART_TxIdle and kStatus_UART_RxIdle.

Transactional receive APIs support the ring buffer. Prepare the memory for the ring buffer and pass in the start address and size while calling the UART_TransferCreateHandle(). If passing NULL, the ring buffer feature is disabled. When the ring buffer is enabled, the received data is saved to the ring buffer in the background. The UART_TransferReceiveNonBlocking() function first gets data from the ring buffer. If the ring buffer does not have enough data, the function first returns the data in the ring buffer and then saves the received data to user memory. When all data is received, the upper layer is informed through a callback with the kStatus_UART_RxIdle.

If the receive ring buffer is full, the upper layer is informed through a callback with the kStatus_UART_RxRingBufferOverrun. In the callback function, the upper layer reads data out from the ring buffer. If not, existing data is overwritten by the new data.

The ring buffer size is specified when creating the handle. Note that one byte is reserved for the ring buffer maintenance. When creating handle using the following code.

Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/uart In this example, the buffer size is 32, but only 31 bytes are used for saving data.

When the RX ring buffer is used, data received are stored into the ring buffer even when the user doesn't call the UART_TransferReceiveNonBlocking() API. If data is already received in the ring buffer, the user can get the received data from the ring buffer directly.

Note

When using the RX ring buffer, one byte is reserved for internal use. In other words, if `ringBufferSize` is 32, only 31 bytes are used for saving data.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
ringBuffer	Start address of the ring buffer for background receiving. Pass NULL to disable the ring buffer.

4.0.53.7.24 status_t UART_TransferSendNonBlocking (UART_Type * *base*, uart_handle_t * *handle*, uart_transfer_t * *xfer*)

This function sends data using an interrupt method. This is a non-blocking function, which returns directly without waiting for all data to be written to the TX register. When all data is written to the TX register in the ISR, the UART driver calls the callback function and passes the kStatus_UART_TxIdle as status parameter.

Note

The kStatus_UART_TxIdle is passed to the upper layer when all data is written to the TX register. However, it does not ensure that all data is sent out. Before disabling the TX, check the kUART_-TransmissionCompleteFlag to ensure that the TX is finished.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
xfer	UART transfer structure. See uart_transfer_t.

Return values

kStatus_Success	Successfully start the data transmission.
kStatus_UART_TxBusy	Previous transmission still not finished; data not all written to TX register yet.

4.0.53.7.25 void UART_TransferAbortSend (UART_Type * *base*, uart_handle_t * *handle*)

Parameters

base	UART peripheral base address.
handle	UART handle pointer.

4.0.53.7.26 status_t UART_TransferGetSendCount (UART_Type * *base*, uart_handle_t * *handle*, uint32_t * *count*)

4.0.53.7.27 status_t UART_TransferReceiveNonBlocking (UART_Type * *base*, uart_handle_t * *handle*, uart_transfer_t * *xfer*, size_t * *receivedBytes*)

This function receives data using an interrupt method. This is a non-blocking function, which returns without waiting for all data to be received. If the RX ring buffer is used and not empty, the data in the ring buffer is copied and the parameter `receivedBytes` shows how many bytes are copied from the ring buffer. After copying, if the data in the ring buffer is not enough to read, the receive request is saved by the UART driver. When the new data arrives, the receive request is serviced first. When all data is received, the UART driver notifies the upper layer through a callback function and passes the status parameter kStatus_UART_RxIdle. For example, the upper layer needs 10 bytes but there are only 5 bytes in the ring buffer. The 5 bytes are copied to the xfer->data and this function returns with the parameter `receivedBytes` set to 5. For the left 5 bytes, newly arrived data is saved from the xfer->data[5]. When 5 bytes are received, the UART driver notifies the upper layer. If the RX ring buffer is not enabled, this function enables the RX and RX interrupt to receive data to the xfer->data. When all data is received, the upper layer is notified.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
xfer	UART transfer structure, see uart_transfer_t.
receivedBytes	Bytes received from the ring buffer directly.

Return values

kStatus_Success	Successfully queue the transfer into transmit queue.

kStatus_InvalidArgument	Invalid argument.

4.0.53.7.28 void UART_TransferAbortReceive (UART_Type * *base*, uart_handle_t * *handle*)

This function aborts the interrupt-driven data receiving. The user can get the remainBytes to know how many bytes are not received yet.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.

4.0.53.7.29 status_t UART_TransferGetReceiveCount (UART_Type * *base*, uart_handle_t * *handle*, uint32_t * *count*)

4.0.57 VREF: Voltage Reference Driver

4.0.57.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Crossbar Voltage Reference (VREF) block of MCUXpresso SDK devices.

The Voltage Reference(VREF) supplies an accurate 1.2 V voltage output that can be trimmed in 0.5 mV steps. VREF can be used in applications to provide a reference voltage to external devices and to internal analog peripherals, such as the ADC, DAC, or CMP. The voltage reference has operating modes that provide different levels of supply rejection and power consumption.

To configure the VREF driver, configure vref_config_t structure in one of two ways.

1. Use the VREF_GetDefaultConfig() function.
2. Set the parameter in the vref_config_t structure.

To initialize the VREF driver, call the VREF_Init() function and pass a pointer to the vref_config_t structure.

To de-initialize the VREF driver, call the VREF_Deinit() function.

4.0.57.2 Typical use case and example

This example shows how to generate a reference voltage by using the VREF module.

Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/vref

- #define FSL_VREF_DRIVER_VERSION (MAKE_VERSION(2, 1, 2))

4.0.59.3 Macro Definition Documentation

4.0.59.3.1 #define MCG_CONFIG_CHECK_PARAM 0U

Some MCG settings must be changed with conditions, for example:

1. MCGIRCLK settings, such as the source, divider, and the trim value should not change when MCGIRCLK is used as a system clock source.
2. MCG_C7[OSCSEL] should not be changed when the external reference clock is used as a system clock source. For example, in FBE/BLPE/PBE modes.
3. The users should only switch between the supported clock modes.

MCG functions check the parameter and MCG status before setting, if not allowed to change, the functions return error. The parameter checking increases code size, if code size is a critical requirement, change MCG_CONFIG_CHECK_PARAM to 0 to disable parameter checking.

4.0.59.3.2 #define FSL_SDK_DISABLE_DRIVER_CLOCK_CONTROL 0

When set to 0, peripheral drivers will enable clock in initialize function and disable clock in de-initialize function. When set to 1, peripheral driver will not control the clock, application could control the clock out of the driver.

Note

All drivers share this feature switcher. If it is set to 1, application should handle clock enable and disable for all drivers.

4.0.59.5.24 static void CLOCK_SetSimSafeDivs (void) [inline], [static]

The system level clocks (core clock, bus clock, flexbus clock and flash clock) must be in allowed ranges. During MCG clock mode switch, the MCG output clock changes then the system level clocks may be out of range. This function could be used before MCG mode change, to make sure system level clocks are in allowed range.

Returns

The frequency of MCGFLLCLK.

4.0.59.5.27 uint32_t CLOCK_GetInternalRefClkFreq (void)

4.0.59.5.29 uint32_t CLOCK_GetPll0Freq (void)

This function gets the MCG PLL0 clock frequency in Hz based on the current MCG register value.

Returns

The frequency of MCGPLL0CLK.

4.0.59.5.30 static void CLOCK_SetLowPowerEnable (bool *enable*) [inline], [static]

Enabling the MCG low power disables the PLL and FLL in bypass modes. In other words, in FBE and PBE modes, enabling low power sets the MCG to BLPE mode. In FBI and PBI modes, enabling low power sets the MCG to BLPI mode. When disabling the MCG low power, the PLL or FLL are enabled based on MCG settings.

Parameters

enable	True to enable MCG low power, false to disable MCG low power.

4.0.59.5.31 status_t CLOCK_SetInternalRefClkConfig (uint8_t *enableMode*, mcg_irc_mode_t *ircs*, uint8_t *fcrdiv*)

This function sets the MCGIRCLK base on parameters. It also selects the IRC source. If the fast IRC is used, this function sets the fast IRC divider. This function also sets whether the MCGIRCLK is enabled in stop mode. Calling this function in FBI/PBI/BLPI modes may change the system clock. As a result, using the function in these modes it is not allowed.

Parameters

enableMode	MCGIRCLK enable mode, OR'ed value of _mcg_irclk_enable_mode.
ircs	MCGIRCLK clock source, choose fast or slow.
fcrdiv	Fast IRC divider setting (FCRDIV).

Return values

kStatus_MCG_Source-Used	Because the internal reference clock is used as a clock source, the configuration should not be changed. Otherwise, a glitch occurs.
kStatus_Success	MCGIRCLK configuration finished successfully.

4.0.59.5.32 status_t CLOCK_SetExternalRefClkConfig (mcg_oscsel_t *oscsel*)

Selects the MCG external reference clock source, changes the MCG_C7[OSCSEL], and waits for the clock source to be stable. Because the external reference clock should not be changed in FEE/FBE/BLPE/PBE/PEE modes, do not call this function in these modes.

Parameters

oscsel	MCG external reference clock source, MCG_C7[OSCSEL].

Return values

kStatus_MCG_Source-Used	Because the external reference clock is used as a clock source, the configuration should not be changed. Otherwise, a glitch occurs.
kStatus_Success	External reference clock set successfully.

4.0.59.5.33 static void CLOCK_SetFllExtRefDiv (uint8_t *frdiv*) [inline], [static]

Sets the FLL external reference clock divider value, the register MCG_C1[FRDIV].

Parameters

frdiv	The FLL external reference clock divider value, MCG_C1[FRDIV].

4.0.59.5.34 void CLOCK_EnablePll0 (mcg_pll_config_t const * *config*)

This function sets us the PLL0 in FLL mode and reconfigures the PLL0. Ensure that the PLL reference clock is enabled before calling this function and that the PLL0 is not used as a clock source. The function CLOCK_CalcPllDiv gets the correct PLL divider values.

Parameters

config	Pointer to the configuration structure.

4.0.59.5.35 static void CLOCK_DisablePll0 (void) [inline], [static]

This function disables the PLL0 in FLL mode. It should be used together with the CLOCK_EnablePll0.

4.0.59.5.36 uint32_t CLOCK_CalcPllDiv (uint32_t *refFreq*, uint32_t *desireFreq*, uint8_t * *prdiv*, uint8_t * *vdiv*)

This function calculates the correct reference clock divider (PRDIV) and VCO divider (VDIV) to generate a desired PLL output frequency. It returns the closest frequency match with the corresponding PRDIV/-VDIV returned from parameters. If a desired frequency is not valid, this function returns 0.

Parameters

refFreq	PLL reference clock frequency.
desireFreq	Desired PLL output frequency.
prdiv	PRDIV value to generate desired PLL frequency.
vdiv	VDIV value to generate desired PLL frequency.

Returns

Closest frequency match that the PLL was able generate.

4.0.59.5.37 void CLOCK_SetOsc0MonitorMode (mcg_monitor_mode_t *mode*)

Parameters

mode	Monitor mode to set.

4.0.59.5.38 void CLOCK_SetRtcOscMonitorMode (mcg_monitor_mode_t *mode*)

Parameters

mode	Monitor mode to set.

4.0.59.5.40 uint32_t CLOCK_GetStatusFlags (void)

This function gets the MCG clock status flags. All status flags are returned as a logical OR of the enumeration _mcg_status_flags_t. To check a specific flag, compare the return value with the flag.

Example:

```
* To check the clock lost lock status of OSC0 and PLL0.
* uint32_t mcgFlags;
*
* mcgFlags = CLOCK_GetStatusFlags();
*
* if (mcgFlags & kMCG_Osc0LostFlag)
* {
*     OSC0 clock lock lost. Do something.
* }
* if (mcgFlags & kMCG_Pll0LostFlag)
* {
*     PLL0 clock lock lost. Do something.
* }
*
```

Returns

4.0.59.6 Variable Documentation

4.0.59.6.1 volatile uint32_t g_xtal0Freq

The XTAL0/EXTAL0 (OSC0) clock frequency in Hz. When the clock is set up, use the function CLOCK_SetXtal0Freq to set the value in the clock driver. For example, if XTAL0 is 8 MHz:

```
* Set up the OSC0
* CLOCK_InitOsc0(...);
* Set the XTAL0 value to the clock driver.
* CLOCK_SetXtal0Freq(80000000);
*
```

This is important for the multicore platforms where only one core needs to set up the OSC0 using the CLOCK_InitOsc0. All other cores need to call the CLOCK_SetXtal0Freq to get a valid clock frequency.

4.0.59.6.2 volatile uint32_t g_xtal32Freq

The XTAL32/EXTAL32/RTC_CLKIN clock frequency in Hz. When the clock is set up, use the function CLOCK_SetXtal32Freq to set the value in the clock driver.

This is important for the multicore platforms where only one core needs to set up the clock. All other cores need to call the CLOCK_SetXtal32Freq to get a valid clock frequency.

4.0.60 Multipurpose Clock Generator (MCG)

The MCUXpresso SDK provides a peripheral driver for the module of MCUXpresso SDK devices.

4.0.60.1 Function description

MCG driver provides these functions:

- Functions to get the MCG clock frequency.
- Functions to configure the MCG clock, such as PLLCLK and MCGIRCLK.
- Functions for the MCG clock lock lost monitor.
- Functions for the OSC configuration.
- Functions for the MCG auto-trim machine.
- Functions for the MCG mode.

4.0.60.1.1 MCG frequency functions

MCG module provides clocks, such as MCGOUTCLK, MCGIRCLK, MCGFFCLK, MCGFLLCLK, and MCGPLLCLK. The MCG driver provides functions to get the frequency of these clocks, such as CLOCK_GetOutClkFreq(), CLOCK_GetInternalRefClkFreq(), CLOCK_GetFixedFreqClkFreq(), CLOCK_GetFllFreq(), CLOCK_GetPll0Freq(), CLOCK_GetPll1Freq(), and CLOCK_GetExtPllFreq(). These functions get the clock frequency based on the current MCG registers.

4.0.60.1.2 MCG clock configuration

The MCG driver provides functions to configure the internal reference clock (MCGIRCLK), the external reference clock, and MCGPLLCLK.

The function CLOCK_SetInternalRefClkConfig() configures the MCGIRCLK, including the source and the driver. Do not change MCGIRCLK when the MCG mode is BLPI/FBI/PBI because the MCGIRCLK is used as a system clock in these modes and changing settings makes the system clock unstable.

The function CLOCK_SetExternalRefClkConfig() configures the external reference clock source (MCG_C7[OSCSEL]). Do not call this function when the MCG mode is BLPE/FBE/PBE/FEE/PEE because the external reference clock is used as a clock source in these modes. Changing the external reference clock source requires at least a 50 microseconds wait. The function CLOCK_SetExternalRefClkConfig() implements a for loop delay internally. The for loop delay assumes that the system clock is 96 MHz, which ensures at least 50 micro seconds delay. However, when the system clock is slow, the delay time may significantly increase. This for loop count can be optimized for better performance for specific cases.

The MCGPLLCLK is disabled in FBE/FEE/FBI/FEI modes by default. Applications can enable the MCGPLLCLK in these modes using the functions CLOCK_EnablePll0() and CLOCK_EnablePll1(). To enable the MCGPLLCLK, the PLL reference clock divider(PRDIV) and the PLL VCO divider(VDIV) must be set to a proper value. The function CLOCK_CalcPllDiv() helps to get the PRDIV/VDIV.

4.0.60.1.3 MCG clock lock monitor functions

The MCG module monitors the OSC and the PLL clock lock status. The MCG driver provides the functions to set the clock monitor mode, check the clock lost status, and clear the clock lost status.

4.0.60.1.4 OSC configuration

The MCG is needed together with the OSC module to enable the OSC clock. The function CLOCK_InitOsc0() CLOCK_InitOsc1 uses the MCG and OSC to initialize the OSC. The OSC should be configured based on the board design.

4.0.60.1.5 MCG auto-trim machine

The MCG provides an auto-trim machine to trim the MCG internal reference clock based on the external reference clock (BUS clock). During clock trimming, the MCG must not work in FEI/FBI/BLPI/PBI/PEI modes. The function CLOCK_TrimInternalRefClk() is used for the auto clock trimming.

4.0.60.1.6 MCG mode functions

The function CLOCK_GetMcgMode returns the current MCG mode. The MCG can only switch between the neighbouring modes. If the target mode is not current mode's neighbouring mode, the application must choose the proper switch path. For example, to switch to PEE mode from FEI mode, use FEI -> FBE -> PBE -> PEE.

For the MCG modes, the MCG driver provides three kinds of functions:

The first type of functions involve functions CLOCK_SetXxxMode, such as CLOCK_SetFeiMode(). These functions only set the MCG mode from neighbouring modes. If switching to the target mode directly from current mode is not possible, the functions return an error.

The second type of functions are the functions CLOCK_BootToXxxMode, such as CLOCK_BootToFeiMode(). These functions set the MCG to specific modes from reset mode. Because the source mode and target mode are specific, these functions choose the best switch path. The functions are also useful to set up the system clock during boot up.

The third type of functions is the CLOCK_SetMcgConfig(). This function chooses the right path to switch to the target mode. It is easy to use, but introduces a large code size.

Whenever the FLL settings change, there should be a 1 millisecond delay to ensure that the FLL is stable. The function CLOCK_SetMcgConfig() implements a for loop delay internally to ensure that the FLL is stable. The for loop delay assumes that the system clock is 96 MHz, which ensures at least 1 millisecond delay. However, when the system clock is slow, the delay time may increase significantly. The for loop count can be optimized for better performance according to a specific use case.

4.0.60.2 Typical use case

The function CLOCK_SetMcgConfig is used to switch between any modes. However, this heavy-light function introduces a large code size. This section shows how to use the mode function to implement a quick and light-weight switch between typical specific modes. Note that the step to enable the external clock is not included in the following steps. Enable the corresponding clock before using it as a clock source.

4.0.60.3 Code Configuration Option

4.0.60.3.1 MCG_USER_CONFIG_FLL_STABLE_DELAY_EN

When switching to use FLL with function CLOCK_SetFeiMode() and CLOCK_SetFeeMode(), there is an internal function CLOCK_FllStableDelay(). It is used to delay a few ms so that to wait the FLL to be stable enough. By default, it is implemented in driver code like the following:

Refer to the driver examples codes located at <SDK_ROOT>/boards/<BOARD>/driver_examples/mcg Once user is willing to create his own delay funcion, just assert the macro MCG_USER_CONFIG_FLL-_STABLE_DELAY_EN, and then define function CLOCK_FllStableDelay in the application code.

4.0.61.7 Function Documentation

4.0.61.7.1 void DMAMGR_Init (dmamanager_handle_t * *dmamanager_handle*, DMA_Type * *dma_base*, uint32_t *channelNum*, uint32_t *startChannel*)

This function initializes the DMA manager, ungates the DMAMUX clocks, and initializes the eDMA or DMA peripherals.

Parameters

dmamanager_handle	DMA manager handle pointer, this structure is maintained by dma manager internal,users only need to transfer the structure to the function. And users shall not free the memory before calling DMAMGR_Deinit, also shall not modify the contents of the memory.
dma_base	Peripheral DMA instance base pointer.
dmamux_base	Peripheral DMAMUX instance base pointer.
channelNum	Channel numbers for the DMA instance which need to be managed by dma manager.
startChannel	The start channel that can be managed by dma manager.

4.0.61.7.2 void DMAMGR_Deinit (dmamanager_handle_t * *dmamanager_handle*)

This function deinitializes the DMA manager, disables the DMAMUX channels, gates the DMAMUX clocks, and deinitializes the eDMA or DMA peripherals.

Parameters

dmamanager_handle	DMA manager handle pointer, this structure is maintained by dma manager internal,users only need to transfer the structure to the function. And users shall not free the memory before calling DMAMGR_Deinit, also shall not modify the contents of the memory.

4.0.61.7.3 status_t DMAMGR_RequestChannel (dmamanager_handle_t * *dmamanager_handle,* uint32_t *requestSource,* uint32_t *channel,* void * *handle*)

This function requests a DMA channel which is not occupied. The two channels to allocate the mechanism are dynamic and static channels. For the dynamic allocation mechanism (channe = DMAMGR_DYNAMIC_ALLOCATE), DMAMGR allocates a DMA channel according to the given request source and startChannel and then configures it. For static allocation mechanism, DMAMGR configures the given channel according to the given request source and channel number.

Parameters

dmamanager_handle	DMA manager handle pointer, this structure is maintained by dma manager internal,users only need to transfer the structure to the function. And users shall not free the memory before calling DMAMGR_Deinit, also shall not modify the contents of the memory.

requestSource	DMA channel request source number. See the soc.h, see the enum dma_request_source_t
channel	The channel number users want to occupy. If using the dynamic channel allocate mechanism, set the channel equal to DMAMGR_DYNAMIC_ALLOCATE.
handle	DMA or eDMA handle pointer.

Return values

kStatus_Success	In a dynamic/static channel allocation mechanism, allocate the DMAMUX channel successfully.
kStatus_DMAMGR_NoFreeChannel	In a dynamic channel allocation mechanism, all DMAMUX channels are occupied.
kStatus_DMAMGR_ChannelOccupied	In a static channel allocation mechanism, the given channel is occupied.

4.0.61.7.4 status_t DMAMGR_ReleaseChannel (dmamanager_handle_t * *dmamanager_handle*, void * *handle*)

This function releases an occupied DMA channel.

Parameters

dmamanager_handle	DMA manager handle pointer, this structure is maintained by dma manager internal,users only need to transfer the structure to the function. And users shall not free the memory before calling DMAMGR_Deinit, also shall not modify the contents of the memory.
handle	DMA or eDMA handle pointer.

Return values

kStatus_Success	Releases the given channel successfully.
kStatus_DMAMGR_ChannelNotUsed	The given channel to be released had not been used before.

4.0.61.7.5 bool DMAMGR_IsChannelOccupied (dmamanager_handle_t * *dmamanager_handle*, uint32_t *channel*)

This function get a DMA channel status. Return 0 indicates the channel has not been used, return 1 indicates the channel has been occupied.

Parameters

dmamanager_handle	DMA manager handle pointer, this structure is maintained by dma manager internal,users only need to transfer the structure to the function. And users shall not free the memory before calling DMAMGR_Deinit, also shall not modify the contents of the memory.
channel	The channel number that users want get its status.

This function can be used for trnansfer direct/extend command. Please pay attention to the non-align data buffer address transfer, if data buffer address can not meet host controller internal DMA requirement, sdio driver will try to use internal align buffer if data size is not bigger than internal buffer size, Align address transfer always can get a better performance, so if application want sdio driver make sure buffer address align, please redefine the SDMMC_GLOBAL_BUFFER_SIZE macro to a value which is big enough for your application.

Parameters

4.0.63.7 Variable Documentation

4.0.64 SD Card Driver

4.0.64.1 Overview

The SDCARD driver provide card initialization/read/write/erase interface.

4.0.64.2 SD CARD Operation

error log support

Lots of error log has been added to sd relate functions, if error occurs during initial/read/write, please enable the error log print functionality with #define SDMMC_ENABLE_LOG_PRINT 1 And rerun the project then user can check what kind of error happened.

User configurable

```
        typedef struct _sd_card
        {
            SDMMCHOST_CONFIG host;
            sdcard_usr_param_t usrParam;
            bool isHostReady;
            bool noInteralAlign;
            uint32_t busClock_Hz;
            uint32_t relativeAddress;
            uint32_t version;
            uint32_t flags;
            uint32_t rawCid[4U];
            uint32_t rawCsd[4U];
            uint32_t rawScr[2U];
            uint32_t ocr;
            sd_cid_t cid;
            sd_csd_t csd;
            sd_scr_t scr;
            uint32_t blockCount;
            uint32_t blockSize;
            sd_timing_mode_t currentTiming;
            sd_driver_strength_t driverStrength;
            sd_max_current_t maxCurrent;
            sdmmc_operation_voltage_t operationVoltage;
} sd_card_t;
```

Part of The variables above is user configurable,

1. SDMMCHOST_CONFIG host Application need to provide host controller base address and the host's source clock frequency.
2. sdcard_usr_param_t usrParam Two member in the userParam structure, a. cd-which allow application define the card insert/remove callback function, redefine the card detect timeout ms and also allow application determine how to detect card. b. pwr-which allow application redefine the power on/off function and the power on/off delay ms. However, sdmmc always use the default setting if application not define it in application. The default setting is depend on the macro defined in the board.h.

3. bool noInteralAlign Sdmmc include an address align internal buffer(to use host controller internal DMA), to improve read/write performance while application cannot make sure the data address used to read/write is align, set it to true will achieve a better performance.
4. sd_timing_mode_t currentTiming It is used to indicate the currentTiming the card is working on, however sdmmc also support preset timing mode, then sdmmc will try to switch to this timing first, if failed, a valid timing will switch to automatically. Generally, user may not set this variable if you don't know what kind of timing the card support, sdmmc will switch to the highest timing which the card support.
5. sd_driver_strength_t driverStrength Choose a valid card driver strength if application required and call SD_SetDriverStrength in application.
6. sd_max_current_t maxCurrent Choose a valid card current if application required and call SD_SetMaxCurrent in application.

Board dependency

Sdmmc depend on some board specific settings, such as card detect - which is used to detect card, the card active level is determine by the socket you are using, low level is active usually, but some socket use high as active, please set the macro #define BOARD_xxxx_CARD_INSERT_CD_LEVEL (0U) According to your board specific if you cannot detect card even if card is inserted.

power control - Macro for USDHC only, SDHC/SDIF support high speed timing only, so please ignore the power reset pin for SDHC/SDIF. which is used to reset card power for UHS card, to make UHS timing work properly, please make sure the power reset pin is configured properly in board.h. #define BOARD_SD_POWER_RESET_GPIO (GPIO1) #define BOARD_SD_POWER_RESET_GPIO_PIN (5U) #define BOARD_USDHC_SDCARD_POWER_CONTROL_INIT() \

pin configurations - Function for USDHC only. which is used to switch the signal pin configurations include driver strength/speed mode dynamiclly for different timing mode, reference the function defined in board.c void BOARD_SD_Pin_Config(uint32_t speed, uint32_t strength)

Typical use case

~~~~~{.c} /* Save host information. */ card->host.base = BOARD_SDHC_BASEADDR; card->host.sourceClock_Hz = CLOCK_GetFreq(BOARD_SDHC_CLKSRC);

/*Redefine the cd and pwr in the application if required*/ card->usrParam.cd = card->usrParam.pwr = /* intial the host controller */ SD_HostInit(card); /*wait card inserted, before detect card you can power off card first and power on again after card inserted, such as*/ SD_PowerOffCard(card->host.base, card->usrParam.pwr); SD_WaitCardDetectStatus(card->host.base, card->usrParam.cd, true); SD_PowerOnCard(card->host.base, card->usrParam.pwr); /*call card initial function*/ SD_CardInit(card);

/* Or you can call below function directly, it is a highlevel init function which will include host initialize,card detect, card initial */

/* Init card. */ if (SD_Init(card)) { PRINTF("\r\nSD card init failed.\r\n"); }

/* after initialization finised, access the card with below functions. */
~~~~~

4.0.67 SPI based Secure Digital Card (SDSPI)

4.0.67.1 Overview

The MCUXpresso SDK provides a driver to access the Secure Digital Card based on the SPI driver.

Function groups

This function group implements the SD card functional API in the SPI mode.

Typical use case

```
/* SPI_Init(). */

/* Register the SDSPI driver callback. */

/* Initializes card. */
if (kStatus_Success != SDSPI_Init(card))
{
    SDSPI_Deinit(card)
    return;
}

/* Read/Write card */
memset(g_testWriteBuffer, 0x17U, sizeof(g_testWriteBuffer));

while (true)
{
    memset(g_testReadBuffer, 0U, sizeof(g_testReadBuffer));

    SDSPI_WriteBlocks(card, g_testWriteBuffer, TEST_START_BLOCK, TEST_BLOCK_COUNT);

    SDSPI_ReadBlocks(card, g_testReadBuffer, TEST_START_BLOCK, TEST_BLOCK_COUNT);

    if (memcmp(g_testReadBuffer, g_testReadBuffer, sizeof(g_testWriteBuffer)))
    {
        break;
    }
}

4.0.68 Debug Console

4.0.68.1 Overview

This chapter describes the programming interface of the debug console driver.

The debug console enables debug log messages to be output via the specified peripheral with frequency of the peripheral source clock and base address at the specified baud rate. Additionally, it provides input and output functions to scan and print formatted data. The below picture shows the laylout of debug console.

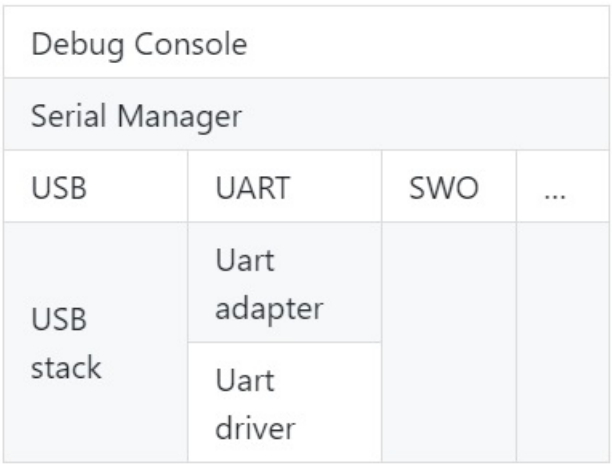

Figure 2: Debug console overview

4.0.68.2 Function groups

4.0.68.2.1 Initialization

To initialize the debug console, call the DbgConsole_Init() function with these parameters. This function automatically enables the module and the clock.

```
status_t DbgConsole_Init(uint8_t instance, uint32_t baudRate,
      serial_port_type_t device, uint32_t clkSrcFreq);
```

Select the supported debug console hardware device type, such as

```
typedef enum _serial_port_type
{
    kSerialPort_Uart = 1U,
    kSerialPort_UsbCdc,
    kSerialPort_Swo,
    kSerialPort_UsbCdcVirtual,
} serial_port_type_t;
```

After the initialization is successful, stdout and stdin are connected to the selected peripheral.

This example shows how to call the DbgConsole_Init() given the user configuration structure.

```
DbgConsole_Init(BOARD_DEBUG_UART_INSTANCE, BOARD_DEBUG_UART_BAUDRATE, BOARD_DEBUG_UART_TYPE,
                                BOARD_DEBUG_UART_CLK_FREQ);
```

4.0.68.2.2 Advanced Feature

The debug console provides input and output functions to scan and print formatted data.

- Support a format specifier for PRINTF following this prototype " %[flags][width][.precision][length]specifier", which is explained below

flags	Description
-	Left-justified within the given field width. Right-justified is the default.
+	Forces to precede the result with a plus or minus sign (+ or -) even for positive numbers. By default, only negative numbers are preceded with a - sign.
(space)	If no sign is written, a blank space is inserted before the value.
#	Used with o, x, or X specifiers the value is preceded with 0, 0x, or 0X respectively for values other than zero. Used with e, E and f, it forces the written output to contain a decimal point even if no digits would follow. By default, if no digits follow, no decimal point is written. Used with g or G the result is the same as with e or E but trailing zeros are not removed.
0	Left-pads the number with zeroes (0) instead of spaces, where padding is specified (see width sub-specifier).

Width	Description
(number)	A minimum number of characters to be printed. If the value to be printed is shorter than this number, the result is padded with blank spaces. The value is not truncated even if the result is larger.
*	The width is not specified in the format string, but as an additional integer value argument preceding the argument that has to be formatted.

.precision	Description
.number	For integer specifiers (d, i, o, u, x, X) precision specifies the minimum number of digits to be written. If the value to be written is shorter than this number, the result is padded with leading zeros. The value is not truncated even if the result is longer. A precision of 0 means that no character is written for the value 0. For e, E, and f specifiers this is the number of digits to be printed after the decimal point. For g and G specifiers This is the maximum number of significant digits to be printed. For s this is the maximum number of characters to be printed. By default, all characters are printed until the ending null character is encountered. For c type it has no effect. When no precision is specified, the default is 1. If the period is specified without an explicit value for precision, 0 is assumed.
.*	The precision is not specified in the format string, but as an additional integer value argument preceding the argument that has to be formatted.

length	Description
Do not support	

specifier	Description
d or i	Signed decimal integer
f	Decimal floating point
F	Decimal floating point capital letters
x	Unsigned hexadecimal integer
X	Unsigned hexadecimal integer capital letters
o	Signed octal
b	Binary value
p	Pointer address
u	Unsigned decimal integer
c	Character
s	String of characters
n	Nothing printed

- Support a format specifier for SCANF following this prototype " %[*][width][length]specifier", which is explained below

*	Description
An optional starting asterisk indicates that the data is to be read from the stream but ignored. In other words, it is not stored in the corresponding argument.	

width	Description
This specifies the maximum number of characters to be read in the current reading operation.	

length	Description
hh	The argument is interpreted as a signed character or unsigned character (only applies to integer specifiers: i, d, o, u, x, and X).
h	The argument is interpreted as a short integer or unsigned short integer (only applies to integer specifiers: i, d, o, u, x, and X).
l	The argument is interpreted as a long integer or unsigned long integer for integer specifiers (i, d, o, u, x, and X) and as a wide character or wide character string for specifiers c and s.
ll	The argument is interpreted as a long long integer or unsigned long long integer for integer specifiers (i, d, o, u, x, and X) and as a wide character or wide character string for specifiers c and s.
L	The argument is interpreted as a long double (only applies to floating point specifiers: e, E, f, g, and G).
j or z or t	Not supported

specifier	Qualifying Input	Type of argument
c	Single character: Reads the next character. If a width different from 1 is specified, the function reads width characters and stores them in the successive locations of the array passed as argument. No null character is appended at the end.	char *

specifier	Qualifying Input	Type of argument
i	Integer: : Number optionally preceded with a + or - sign	int *
d	Decimal integer: Number optionally preceded with a + or - sign	int *
a, A, e, E, f, F, g, G	Floating point: Decimal number containing a decimal point, optionally preceded by a + or - sign and optionally followed by the e or E character and a decimal number. Two examples of valid entries are -732.103 and 7.12e4	float *
o	Octal Integer:	int *
s	String of characters. This reads subsequent characters until a white space is found (white space characters are considered to be blank, newline, and tab).	char *
u	Unsigned decimal integer.	unsigned int *

The debug console has its own printf/scanf/putchar/getchar functions which are defined in the header file.

```
int DbgConsole_Printf(const char *fmt_s, ...);
int DbgConsole_Putchar(int ch);
int DbgConsole_Scanf(char *fmt_ptr, ...);
int DbgConsole_Getchar(void);
```

This utility supports selecting toolchain's printf/scanf or the MCUXpresso SDK printf/scanf.

```
#if SDK_DEBUGCONSOLE == DEBUGCONSOLE_DISABLE /* Disable debug console */
#define PRINTF
#define SCANF
#define PUTCHAR
#define GETCHAR
#elif SDK_DEBUGCONSOLE == DEBUGCONSOLE_REDIRECT_TO_SDK /* Select printf, scanf, putchar, getchar of SDK
      version. */
#define PRINTF DbgConsole_Printf
#define SCANF DbgConsole_Scanf
#define PUTCHAR DbgConsole_Putchar
#define GETCHAR DbgConsole_Getchar
#elif SDK_DEBUGCONSOLE == DEBUGCONSOLE_REDIRECT_TO_TOOLCHAIN /* Select printf, scanf, putchar, getchar of
      toolchain. */
#define PRINTF printf
#define SCANF scanf
#define PUTCHAR putchar
#define GETCHAR getchar
#endif /* SDK_DEBUGCONSOLE */
```

NOTE: The macro SDK_DEBUGCONSOLE_UART is use to decide whether provide low level IO implementation to toolchain printf and scanf. For example, within MCUXpresso, if the macro SDK_DEBUGCONSOLE_UART is defined, **sys_write and __sys_readc will be used when __REDLIB** is defined; _write and _read will be used in other cases. If the macro SDK_DEBUGCONSOLE_UART is not defined, the semihosting will be used.

4.0.68.3 Typical use case

Some examples use the PUTCHAR & GETCHAR function

```
ch = GETCHAR();
PUTCHAR(ch);
```

Some examples use the PRINTF function

Statement prints the string format.

```
PRINTF("%s %s\r\n", "Hello", "world!");
```

Statement prints the hexadecimal format/

```
PRINTF("0x%02X hexadecimal number equivalents 255", 255);
```

Statement prints the decimal floating point and unsigned decimal.

```
PRINTF("Execution timer: %s\n\rTime: %u ticks %2.5f milliseconds\n\rDONE\n\r", "1 day", 86400, 86.4);
```

Some examples use the SCANF function

```
PRINTF("Enter a decimal number: ");
SCANF("%d", &i);
PRINTF("\r\nYou have entered %d.\r\n", i, i);
PRINTF("Enter a hexadecimal number: ");
SCANF("%x", &i);
PRINTF("\r\nYou have entered 0x%X (%d).\r\n", i, i);
```

Print out failure messages using MCUXpresso SDK __assert_func:

```
void __assert_func(const char *file, int line, const char *func, const char *failedExpr)
{
    PRINTF("ASSERT ERROR \" %s \": file \"%s\" Line \"%d\" function name \"%s\" \n", failedExpr, file
       , line, func);
    for (;;)
    {}
}
```

Note:

To use 'printf' and 'scanf' for GNUC Base, add file **'fsl_sbrk.c'** in path: **..\{package}\devices\{subset}\utilities\fsl_sbrk.c** to your project.

4.0.69 Semihosting

Semihosting is a mechanism for ARM targets to communicate input/output requests from application code to a host computer running a debugger. This mechanism can be used, for example, to enable functions in the C library, such as printf() and scanf(), to use the screen and keyboard of the host rather than having a screen and keyboard on the target system.

4.0.69.1 Guide Semihosting for IAR

NOTE: After the setting both "printf" and "scanf" are available for debugging, if you want use PRINTF with semihosting, please make sure the SDK_DEBUGCONSOLE is disabled.

Step 1: Setting up the environment

1. To set debugger options, choose Project>Options. In the Debugger category, click the Setup tab.
2. Select Run to main and click OK. This ensures that the debug session starts by running the main function.
3. The project is now ready to be built.

Step 2: Building the project

1. Compile and link the project by choosing Project>Make or F7.
2. Alternatively, click the Make button on the tool bar. The Make command compiles and links those files that have been modified.

Step 3: Starting semihosting

1. Choose "Semihosting_IAR" project -> "Options" -> "Debugger" -> "J-Link/J-Trace".
2. Choose tab "J-Link/J-Trace" -> "Connection" tab -> "SWD".
3. Choose tab "General Options" -> "Library Configurations", select Semihosted, select Via semihosting.

1. Make sure the SDK_DEBUGCONSOLE_UART is not defined, remove the default definition in fsl_debug_console.h.

1. Start the project by choosing Project>Download and Debug.
2. Choose View>Terminal I/O to display the output from the I/O operations.

load semihosting_ARMGCC.elf
monitor reg pc = (0x00000004)
monitor reg sp = (0x00000000)
continue
```

(b) After the setting, press "enter". The PuTTY window now shows the printf() output.

4.0.70 SWO

Serial wire output is a mechanism for ARM targets to output signal from core through a single pin. Some IDEs also support SWO, such IAR and KEIL, both input and output are supported, see below for details.

4.0.70.1 Guide SWO for SDK

NOTE: After the setting both "printf" and "PRINTF" are available for debugging, JlinkSWOViewer can be used to capture the output log.

Step 1: Setting up the environment

1. Define SERIAL_PORT_TYPE_SWO in your project settings.
2. Prepare code, the port and baudrate can be decided by application, clkSrcFreq should be mcu core clock frequency:

```
DbgConsole_Init(instance, baudRate, kSerialPort_Swo, clkSrcFreq);
```

3. Use PRINTF or printf to print some thing in application.

Step 2: Building the project

Step 3: Download and run project

4.0.70.2 Guide SWO for IAR

NOTE: After the setting both "printf" and "scanf" are available for debugging.

Step 1: Setting up the environment

1. Choose project -> "Options" -> "Debugger" -> "J-Link/J-Trace".
2. Choose tab "J-Link/J-Trace" -> "Connection" tab -> "SWD".
3. Choose tab "General Options" -> "Library Configurations", select Semihosted, select Via SWO.
4. To configure the hardware's generation of trace data, click the SWO Configuration button available in the SWO Configuration dialog box. The value of the CPU clock option must reflect the frequency of the CPU clock speed at which the application executes. Note also that the settings you make are preserved between debug sessions. To decrease the amount of transmissions on the communication channel, you can disable the Timestamp option. Alternatively, set a lower rate for PC Sampling or use a higher SWO clock frequency.
5. Open the SWO Trace window from J-LINK,and click the Activate button to enable trace data collection.
6. There are three cases for this SDK_DEBUGCONSOLE_UART whether or not defined. a: if use uppercase PRINTF to output log,The SDK_DEBUGCONSOLE_UART defined or not defined will not effect debug function. b: if use lowercase printf to output log and defined SDK_DEBUGCONSOLE_UART to zero,then debug function ok. c: if use lowercase printf to output log and defined SDK_DEBUGCONSOLE_UART to one,then debug function ok.

NOTE: Case a or c only apply at example which enable swo function,the SDK_DEBUGCONSOLE_UART definition in fsl_debug_console.h. For case a and c, Do and not do the above third step will be not affect function.

1. Start the project by choosing Project>Download and Debug.

Step 2: Building the project

Step 3: Starting swo

1. Download and debug application.
2. Choose View -> Terminal I/O to display the output from the I/O operations.
3. Run application.

4.0.70.3 Guide SWO for Keil µVision

NOTE: After the setting both "printf" and "scanf" are available for debugging.

Step 1: Setting up the environment

1. There are three cases for this SDK_DEBUGCONSOLE_UART whether or not defined. a: if use uppercase PRINTF to output log,the SDK_DEBUGCONSOLE_UART definition does not affect the functionality and skip the second step directly. b: if use lowercase printf to output log and defined SDK_DEBUGCONSOLE_UART to zero,then start the second step. c: if use lowercase printf to output log and defined SDK_DEBUGCONSOLE_UART to one,then skip the second step directly.

NOTE: Case a or c only apply at example which enable swo function,the SDK_DEBUGCONSOLE_UART definition in fsl_debug_console.h.

1. In menu bar, click Management Run-Time Environment icon, select Compiler, unfold I/O, enable STDERR/STDIN/STDOUT and set the variant to ITM.
2. Open Project>Options for target or using Alt+F7 or click.
3. Select “Debug” tab, select “J-Link/J-Trace Cortex” and click “Setting button”.
4. Select “Debug” tab and choose Port:SW, then select "Trace" tab, choose "Enable" and click OK, please make sure the Core clock is set correctly, enable autodetect max SWO clk, enable ITM Stimulus Ports 0.

Step 3: Building the project

1. Compile and link the project by choosing Project>Build Target or using F7.

Step 4: Run the project

1. Choose “Debug” on menu bar or Ctrl F5.
2. In menu bar, choose "Serial Window" and click to "Debug (printf) Viewer".
3. Run line by line to see result in Console Window.

4.0.70.4 Guide SWO for MCUXpresso IDE

NOTE: MCUX support SWO for LPC-Link2 debug probe only.

4.0.70.5 Guide SWO for ARMGCC

NOTE: ARMGCC has no library support SWO.

4.0.71 Notification Framework

4.0.71.1 Overview

This section describes the programming interface of the Notifier driver.

4.0.71.2 Notifier Overview

The Notifier provides a configuration dynamic change service. Based on this service, applications can switch between pre-defined configurations. The Notifier enables drivers and applications to register callback functions to this framework. Each time that the configuration is changed, drivers and applications receive a notification and change their settings. To simplify, the Notifier only supports the static callback registration. This means that, for applications, all callback functions are collected into a static table and passed to the Notifier.

These are the steps for the configuration transition.

1. Before configuration transition, the Notifier sends a "BEFORE" message to the callback table. When this message is received, IP drivers should check whether any current processes can be stopped and stop them. If the processes cannot be stopped, the callback function returns an error.
   The Notifier supports two types of transition policies, a graceful policy and a forceful policy. When the graceful policy is used, if some callbacks return an error while sending a "BEFORE" message, the configuration transition stops and the Notifier sends a "RECOVER" message to all drivers that have stopped. Then, these drivers can recover the previous status and continue to work. When the forceful policy is used, drivers are stopped forcefully.
2. After the "BEFORE" message is processed successfully, the system switches to the new configuration.
3. After the configuration changes, the Notifier sends an "AFTER" message to the callback table to notify drivers that the configuration transition is finished.

This example shows how to use the Notifier in the Power Manager application.

```
#include "fsl_notifier.h"

// Definition of the Power Manager callback.
status_t callback0(notifier_notification_block_t *notify, void *data)
{

    status_t ret = kStatus_Success;

    ...
    ...
    ...

    return ret;
}
// Definition of the Power Manager user function.
status_t APP_PowerModeSwitch(notifier_user_config_t *targetConfig, void *userData)
{
    ...
    ...
    ...
}
```

```
...
...
...
...
...
// Main function.
int main(void)
{
    // Define a notifier handle.
    notifier_handle_t powerModeHandle;

    // Callback configuration.
    user_callback_data_t callbackData0;

    notifier_callback_config_t callbackCfg0 = {callback0,
                kNOTIFIER_CallbackBeforeAfter,
                (void *)&callbackData0};

    notifier_callback_config_t callbacks[] = {callbackCfg0};

    // Power mode configurations.
    power_user_config_t vlprConfig;
    power_user_config_t stopConfig;

    notifier_user_config_t *powerConfigs[] = {&vlprConfig, &stopConfig};

    // Definition of a transition to and out the power modes.
    vlprConfig.mode = kAPP_PowerModeVlpr;
    vlprConfig.enableLowPowerWakeUpOnInterrupt = false;

    stopConfig = vlprConfig;
    stopConfig.mode = kAPP_PowerModeStop;

4.0.71.4 Typedef Documentation

4.0.71.4.1 typedef void notifier_user_config_t

Reference of the user defined configuration is stored in an array; the notifier switches between these configurations based on this array.

4.0.71.4.2 typedef status_t(* notifier_user_function_t)(notifier_user_config_t *targetConfig, void *userData)

Before and after this function execution, different notification is sent to registered callbacks. If this function returns any error code, NOTIFIER_SwitchConfig() exits.

Parameters

targetConfig	target Configuration.
userData	Refers to other specific data passed to user function.

Returns

An error code or kStatus_Success.

4.0.71.4.3 typedef status_t(* notifier_callback_t)(notifier_notification_block_t *notify, void *data)

Declaration of a callback. It is common for registered callbacks. Reference to function of this type is part of the notifier_callback_config_t callback configuration structure. Depending on callback type, function of this prototype is called (see NOTIFIER_SwitchConfig()) before configuration switch, after it or in both use cases to notify about the switch progress (see notifier_callback_type_t). When called, the type of the notification is passed as a parameter along with the reference to the target configuration structure (see notifier_notification_block_t) and any data passed during the callback registration. When notified before the configuration switch, depending on the configuration switch policy (see notifier_policy_t), the callback may deny the execution of the user function by returning an error code different than kStatus_Success (see NOTIFIER_SwitchConfig()).

Parameters

notify	Notification block.
data	Callback data. Refers to the data passed during callback registration. Intended to pass any driver or application data such as internal state information.

Returns

An error code or kStatus_Success.

4.0.71.5 Enumeration Type Documentation

4.0.71.5.1 enum _notifier_status

Used as return value of Notifier functions.

Enumerator

kStatus_NOTIFIER_ErrorNotificationAfter An error occurs during send "AFTER" notification.

4.0.71.5.2 enum notifier_policy_t

Defines whether the user function execution is forced or not. For kNOTIFIER_PolicyForcible, the user function is executed regardless of the callback results, while kNOTIFIER_PolicyAgreement policy is used to exit NOTIFIER_SwitchConfig() when any of the callbacks returns error code. See also NOTIFIER_SwitchConfig() description.

Enumerator

kNOTIFIER_PolicyAgreement NOTIFIER_SwitchConfig() method is exited when any of the callbacks returns error code.

kNOTIFIER_PolicyForcible The user function is executed regardless of the results.

Used to notify registered callbacks

Enumerator

kNOTIFIER_NotifyRecover Notify IP to recover to previous work state.
kNOTIFIER_NotifyBefore Notify IP that configuration setting is going to change.
kNOTIFIER_NotifyAfter Notify IP that configuration setting has been changed.

4.0.71.5.4 enum notifier_callback_type_t

Used in the callback configuration structure (notifier_callback_config_t) to specify when the registered callback is called during configuration switch initiated by the NOTIFIER_SwitchConfig(). Callback can be invoked in following situations.

- Before the configuration switch (Callback return value can affect NOTIFIER_SwitchConfig() execution. See the NOTIFIER_SwitchConfig() and notifier_policy_t documentation).
- After an unsuccessful attempt to switch configuration
- After a successful configuration switch

Enumerator

kNOTIFIER_CallbackBefore Callback handles BEFORE notification.
kNOTIFIER_CallbackAfter Callback handles AFTER notification.

Returns

An error Code or kStatus_Success.

4.0.71.6.2 status_t NOTIFIER_SwitchConfig (notifier_handle_t * *notifierHandle*, uint8_t *configIndex*, notifier_policy_t *policy*)

This function sets the system to the target configuration. Before transition, the Notifier sends notifications to all callbacks registered to the callback table. Callbacks are invoked in the following order: All registered callbacks are notified ordered by index in the callbacks array. The same order is used for before and after switch notifications. The notifications before the configuration switch can be used to obtain confirmation about the change from registered callbacks. If any registered callback denies the configuration change, further execution of this function depends on the notifier policy: the configuration change is either forced (kNOTIFIER_PolicyForcible) or exited (kNOTIFIER_PolicyAgreement). When configuration change is forced, the result of the before switch notifications are ignored. If an agreement is required, if any callback returns an error code, further notifications before switch notifications are cancelled and all already notified callbacks are re-invoked. The index of the callback which returned error code during pre-switch notifications is stored (any error codes during callbacks re-invocation are ignored) and NOTIFIER_GetErrorCallback() can be used to get it. Regardless of the policies, if any callback returns an error code, an error code indicating in which phase the error occurred is returned when NOTIFIER_SwitchConfig() exits.

Parameters

notifierHandle	pointer to notifier handle
configIndex	Index of the target configuration.
policy	Transaction policy, kNOTIFIER_PolicyAgreement or kNOTIFIER_PolicyForcible.

Returns

An error code or kStatus_Success.

4.0.71.6.3 uint8_t NOTIFIER_GetErrorCallbackIndex (notifier_handle_t * *notifierHandle*)

This function returns an index of the last callback that failed during the configuration switch while the last NOTIFIER_SwitchConfig() was called. If the last NOTIFIER_SwitchConfig() call ended successfully value equal to callbacks number is returned. The returned value represents an index in the array of static call-backs.

Parameters

notifierHandle	Pointer to the notifier handle

Returns

Callback Index of the last failed callback or value equal to callbacks count.

4.0.72 Shell

4.0.72.1 Overview

This section describes the programming interface of the Shell middleware.

Shell controls MCUs by commands via the specified communication peripheral based on the debug console driver.

4.0.72.2 Function groups

4.0.72.2.1 Initialization

To initialize the Shell middleware, call the SHELL_Init() function with these parameters. This function automatically enables the middleware.

```
shell_status_t SHELL_Init(shell_handle_t shellHandle, serial_handle_t
       serialHandle, char *prompt);
```

Then, after the initialization was successful, call a command to control MCUs.

This example shows how to call the SHELL_Init() given the user configuration structure.

```
SHELL_Init(s_shellHandle, s_serialHandle, "Test@SHELL>");
```

4.0.72.2.2 Advanced Feature

- Support to get a character from standard input devices.

  ```
  static shell_status_t SHELL_GetChar(shell_context_handle_t *shellContextHandle, uint8_t *ch);
  ```

Commands	Description
help	List all the registered commands.
exit	Exit program.

4.0.72.2.3 Shell Operation

```
SHELL_Init(s_shellHandle, s_serialHandle, "Test@SHELL>");
SHELL_Task((s_shellHandle);
```

4.0.76.4 Function Documentation

4.0.76.4.1 serial_manager_status_t SerialManager_Init (serial_handle_t *serialHandle,* serial_manager_config_t * *config*)

This function configures the Serial Manager module with user-defined settings. The user can configure the configuration structure. The parameter serialHandle is a pointer to point to a memory space of size SERIAL_MANAGER_HANDLE_SIZE allocated by the caller. The Serial Manager module supports two types of serial port, UART (includes UART, USART, LPSCI, LPUART, etc) and USB CDC. Please refer to serial_port_type_t for serial port setting. These two types can be set by using serial_manager_config_t.

Example below shows how to use this API to configure the Serial Manager. For UART,

```
*   #define SERIAL_MANAGER_RING_BUFFER_SIZE          (256U)
*   static uint32_t s_serialHandleBuffer[((SERIAL_MANAGER_HANDLE_SIZE + sizeof(
      uint32_t) - 1) / sizeof(uitn32_t))];
*   static serial_handle_t s_serialHandle = (serial_handle_t)&s_serialHandleBuffer[0];
*   static uint8_t s_ringBuffer[SERIAL_MANAGER_RING_BUFFER_SIZE];
*
*   serial_manager_config_t config;
*   serial_port_uart_config_t uartConfig;
*   config.type = kSerialPort_Uart;
*   config.ringBuffer = &s_ringBuffer[0];
*   config.ringBufferSize = SERIAL_MANAGER_RING_BUFFER_SIZE;
*   uartConfig.instance = 0;
*   uartConfig.clockRate = 24000000;
*   uartConfig.baudRate = 115200;
*   uartConfig.parityMode = kSerialManager_UartParityDisabled;
*   uartConfig.stopBitCount = kSerialManager_UartOneStopBit;
*   uartConfig.enableRx = 1;
*   uartConfig.enableTx = 1;
*   config.portConfig = &uartConfig;
*   SerialManager_Init(s_serialHandle, &config);
*
```

For USB CDC,

```
*   #define SERIAL_MANAGER_RING_BUFFER_SIZE          (256U)
*   static uint32_t s_serialHandleBuffer[((SERIAL_MANAGER_HANDLE_SIZE + sizeof(
      uint32_t) - 1) / sizeof(uitn32_t))];
*   static serial_handle_t s_serialHandle = (serial_handle_t)&s_serialHandleBuffer[0];
*   static uint8_t s_ringBuffer[SERIAL_MANAGER_RING_BUFFER_SIZE];
*
*   serial_manager_config_t config;
*   serial_port_usb_cdc_config_t usbCdcConfig;
*   config.type = kSerialPort_UsbCdc;
*   config.ringBuffer = &s_ringBuffer[0];
*   config.ringBufferSize = SERIAL_MANAGER_RING_BUFFER_SIZE;
*   usbCdcConfig.controllerIndex =
      kSerialManager_UsbControllerKhci0;
```

```
*   config.portConfig = &usbCdcConfig;
*   SerialManager_Init(s_serialHandle, &config);
*
```

4.0.76.4.3 serial_manager_status_t SerialManager_OpenWriteHandle (serial_handle_t *serialHandle*, serial_write_handle_t *writeHandle*)

This function Opens a writing handle for the serial manager module. If the serial manager needs to be used in different tasks, the task should open a dedicated write handle for itself by calling SerialManager_OpenWriteHandle. Since there can only one buffer for transmission for the writing handle at the same time, multiple writing handles need to be opened when the multiple transmission is needed for a task.

Parameters

serialHandle	The serial manager module handle pointer. The handle should be 4 byte aligned, because unaligned access does not support on some devices.
writeHandle	The serial manager module writing handle pointer. The handle should be 4 byte aligned, because unaligned access does not support on some devices.

Return values

kStatus_SerialManager_Error	An error occurred.
kStatus_SerialManager_HandleConflict	The writing handle was opened.
kStatus_SerialManager_Success	The writing handle is opened.

Example below shows how to use this API to write data. For task 1,

```
*   static uint32_t s_serialWriteHandleBuffer1[((
      SERIAL_MANAGER_WRITE_HANDLE_SIZE + sizeof(uint32_t) - 1) /
* sizeof(uitn32_t))]; static serial_write_handle_t s_serialWriteHandle1 =
* (serial_write_handle_t)&s_serialWriteHandleBuffer1[0]; static uint8_t s_nonBlockingWelcome1[] = "This is
      non-blocking
* writing log for task1!\r\n"; SerialManager_OpenWriteHandle(serialHandle,
      s_serialWriteHandle1);
*   SerialManager_InstallTxCallback(s_serialWriteHandle1, Task1_SerialManagerTxCallback,
      s_serialWriteHandle1);
*   SerialManager_WriteNonBlocking(s_serialWriteHandle1, s_nonBlockingWelcome1, sizeof(
      s_nonBlockingWelcome1) - 1);
*
```

For task 2,

```
*   static uint32_t s_serialWriteHandleBuffer2[((
      SERIAL_MANAGER_WRITE_HANDLE_SIZE + sizeof(uint32_t) - 1) /
* sizeof(uitn32_t))]; static serial_write_handle_t s_serialWriteHandle2 =
* (serial_write_handle_t)&s_serialWriteHandleBuffer2[0]; static uint8_t s_nonBlockingWelcome2[] = "This is
      non-blocking
* writing log for task2!\r\n"; SerialManager_OpenWriteHandle(serialHandle,
      s_serialWriteHandle2);
*   SerialManager_InstallTxCallback(s_serialWriteHandle2, Task2_SerialManagerTxCallback,
      s_serialWriteHandle2);
*   SerialManager_WriteNonBlocking(s_serialWriteHandle2, s_nonBlockingWelcome2, sizeof(
      s_nonBlockingWelcome2) - 1);
*
```

4.0.76.4.4 serial_manager_status_t SerialManager_CloseWriteHandle (serial_write_handle_t *writeHandle*)

This function Closes a writing handle for the serial manager module.

Parameters

writeHandle	The serial manager module writing handle pointer.

Return values

kStatus_SerialManager_Success	The writing handle is closed.

4.0.76.4.5 serial_manager_status_t SerialManager_OpenReadHandle (serial_handle_t *serialHandle*, serial_read_handle_t *readHandle*)

This function Opens a reading handle for the serial manager module. The reading handle can not be opened multiple at the same time. The error code kStatus_SerialManager_Busy would be returned when the previous reading handle is not closed. And There can only be one buffer for receiving for the reading handle at the same time.

Parameters

serialHandle	The serial manager module handle pointer. The handle should be 4 byte aligned, because unaligned access does not support on some devices.
readHandle	The serial manager module reading handle pointer. The handle should be 4 byte aligned, because unaligned access does not support on some devices.

Return values

kStatus_SerialManager_Error	An error occurred.
kStatus_SerialManager_Success	The reading handle is opened.
kStatus_SerialManager_Busy	Previous reading handle is not closed.

Example below shows how to use this API to read data.

```
*   static uint32_t s_serialReadHandleBuffer[((SERIAL_MANAGER_READ_HANDLE_SIZE + sizeof(uint32_t) - 1) /
* sizeof(uitn32_t))]; static serial_read_handle_t s_serialReadHandle =
* (serial_read_handle_t)&s_serialReadHandleBuffer[0];
      SerialManager_OpenReadHandle(serialHandle, s_serialReadHandle);
*   static uint8_t s_nonBlockingBuffer[64];
*   SerialManager_InstallRxCallback(s_serialReadHandle, APP_SerialManagerRxCallback, s_serialReadHandle);
*   SerialManager_ReadNonBlocking(s_serialReadHandle, s_nonBlockingBuffer, sizeof(s_nonBlockingBuffer));
*
```

4.0.81 Serial Port Virtual USB

4.0.81.1 Overview

This chapter describes how to redirect the serial manager stream to application CDC. The weak functions can be implemented by application to redirect the serial manager stream. The weak functions are following,

USB_DeviceVcomInit - Initialize the cdc vcom.

USB_DeviceVcomDeinit - De-initialize the cdc vcom.

USB_DeviceVcomWrite - Write data with non-blocking mode. After data is sent, the installed TX callback should be called with the result.

USB_DeviceVcomRead - Read data with non-blocking mode. After data is received, the installed RX callback should be called with the result.

USB_DeviceVcomCancelWrite - Cancel write request.

USB_DeviceVcomInstallTxCallback - Install TX callback.

USB_DeviceVcomInstallRxCallback - Install RX callback.

USB_DeviceVcomIsrFunction - The hardware ISR function.

4.0.82.5.1 button_status_t BUTTON_Init (button_handle_t *buttonHandle,* button_config_t * *buttonConfig*)

This function configures the button with user-defined settings. The user can configure the configuration structure. The parameter buttonHandle is a pointer to point to a memory space of size BUTTON_HANDLE_SIZE allocated by the caller.

Example below shows how to use this API to configure the button.

```
*   uint32_t s_buttonHandleBuffer[((BUTTON_HANDLE_SIZE + sizeof(uint32_t) - 1) / sizeof(
      uitn32_t))];
*   button_handle_t s_buttonHandle = (button_handle_t)&s_buttonHandleBuffer[0

4.0.84.5 Function Documentation

4.0.84.5.1 led_status_t LED_Init (led_handle_t *ledHandle,* led_config_t * *ledConfig*)

This function configures the LED with user-defined settings. The user can configure the configuration structure. The parameter ledHandle is a pointer to point to a memory space of size LED_HANDLE_SIZE allocated by the caller. The LED supports two types LED, RGB and monochrome. Please refer to led_type_t. These two types can be set by using led_config_t. The LED also supports LED dimming mode.

Example below shows how to use this API to configure the LED. For monochrome LED,

```
*   uint32_t s_ledMonochromeHandleBuffer[((LED_HANDLE_SIZE + sizeof(uint32_t) - 1) / sizeof(
      uitn32_t))];
*   led_handle_t s_ledMonochromeHandle = (led_handle_t)&s_ledMonochromeHandleBuffer
      [0];
*   led_config_t ledMonochromeConfig;
*   ledMonochromeConfig.type = kLED_TypeMonochrome;
*   ledMonochromeConfig.ledMonochrome.monochromePin.
      dimmingEnable = 0;
*   ledMonochromeConfig.ledMonochrome.monochromePin.gpio.port = 0;
*   ledMonochromeConfig.ledMonochrome.monochromePin.gpio.pin = 1;
*   ledMonochromeConfig.ledMonochrome.monochromePin.gpio.pinStateDefault = 0;
*   LED_Init(s_ledMonochromeHandle, &ledMonochromeConfig);
*
```

For rgb LED,

```
*   uint32_t s_ledRgbHandleBuffer[((LED_HANDLE_SIZE + sizeof(uint32_t) - 1) / sizeof(
      uitn32_t))];
*   led_handle_t s_ledRgbHandle = (led_handle_t)&s_ledRgbHandleBuffer[0];
*   led_config_t ledRgbConfig;
*   ledRgbConfig.type = kLED_TypeRgb;
*   ledRgbConfig.ledRgb.redPin.dimmingEnable = 0;
*   ledRgbConfig.ledRgb.redPin.gpio.port = 0;
*   ledRgbConfig.ledRgb.redPin.gpio.pin = 1;
*   ledRgbConfig.ledRgb.redPin.gpio.pinStateDefault = 0;
*   ledRgbConfig.ledRgb.greenPin.dimmingEnable = 0;
*   ledRgbConfig.ledRgb.greenPin.gpio.port = 0;
*   ledRgbConfig.ledRgb.greenPin.gpio.pin = 2;
*   ledRgbConfig.ledRgb.greenPin.gpio.pinStateDefault = 0;
*   ledRgbConfig.ledRgb.bluePin.dimmingEnable = 0;
*   ledRgbConfig.ledRgb.bluePin.gpio.port = 0;
*   ledRgbConfig.ledRgb.bluePin.gpio.pin = 3;
*   ledRgbConfig.ledRgb.bluePin.gpio.pinStateDefault = 0;
*   LED_Init(s_ledRgbHandle, &ledRgbConfig);
*
```

For dimming monochrome LED,

```
*   uint32_t s_ledMonochromeHandleBuffer[((LED_HANDLE_SIZE + sizeof(uint32_t) - 1) / sizeof(
      uitn32_t))];
*   led_handle_t s_ledMonochromeHandle = (led_handle_t)&s_ledMonochromeHandleBuffer
      [0];
*   led_config_t ledMonochromeConfig;
*   ledMonochromeConfig.type = kLED_TypeMonochrome;
*   ledMonochromeConfig.ledMonochrome.monochromePin.
      dimmingEnable = 1;
*   ledMonochromeConfig.ledMonochrome.monochromePin.dimming.sourceClock =
      48000000;
*   ledMonochromeConfig.ledMonochrome.monochromePin.dimming.instance = 0;
*   ledMonochromeConfig.ledMonochrome.monochromePin.dimming.channel = 1;
*   ledMonochromeConfig.ledMonochrome.monochromePin.dimming.pinStateDefault = 0;
*   LED_Init(s_ledMonochromeHandle, &ledMonochromeConfig);
*
```

4.0.87.3 Typedef Documentation

4.0.87.3.1 typedef void(∗ hal_timer_callback_t)(void ∗param)

The timer adapter is built based on the timer SDK driver provided by the NXP MCUXpresso SDK. The timer adapter could provide high accuracy timer for user. Since callback function would be handled in ISR, and timer clock use high accuracy clock, user can get accuracy millisecond timer.

The timer adapter would be used with different HW timer modules like FTM, PIT, LPTMR. But at the same time, only one HW timer module could be used. On different platforms, different HW timer module would be used. For the platforms which have multiple HW timer modules, one HW timer module would be selected as the default, but it is easy to change the default HW timer module to another. Just two steps to switch the HW timer module: 1.Remove the default HW timer module source file from the project 2.Add the expected HW timer module source file to the project. For example, in platform FRDM-K64F, there are two HW timer modules available, FTM and PIT. FTM is used as the default HW timer, so ftm_adapter.c and timer.h is included in the project by default. If PIT is expected to be used as the HW timer, ftm_adapter.c need to be removed from the project and pit_adapter.c should be included in the project

4.0.89.6 Function Documentation

4.0.89.6.1 hal_uart_status_t HAL_UartInit (hal_uart_handle_t *handle*, hal_uart_config_t * *config*)

This function configures the UART module with user-defined settings. The user can configure the configuration structure. The parameter handle is a pointer to point to a memory space of size #HAL_UART_HANDLE_SIZE allocated by the caller. Example below shows how to use this API to configure the UART.

```
*   uint32_t g_UartHandleBuffer[((HAL_UART_HANDLE_SIZE + sizeof(uint32_t) - 1) / sizeof(uitn32_t))];
*   hal_uart_handle_t g_UartHandle = (hal_uart_handle_t)&g_UartHandleBuffer[0];
*   hal_uart_config_t config;
*   config.srcClock_Hz = 48000000;
*   config.baudRate_Bps = 115200U;
*   config.parityMode = kHAL_UartParityDisabled;
*   config.stopBitCount = kHAL_UartOneStopBit;
*   config.enableRx = 1;
*   config.enableTx = 1;
*   config.instance = 0;
*   HAL_UartInit(g_UartHandle, &config);
*
```

Parameters

handle	Pointer to point to a memory space of size #HAL_UART_HANDLE_SIZE allocated by the caller. The handle should be 4 byte aligned, because unaligned access does not support on some devices.

config	Pointer to user-defined configuration structure.

Return values

kStatus_HAL_Uart-BaudrateNotSupport	Baudrate is not support in current clock source.
kStatus_HAL_Uart-Success	UART initialization succeed

4.0.89.6.2 hal_uart_status_t HAL_UartDeinit (hal_uart_handle_t *handle*)

This function waits for TX complete, disables TX and RX, and disables the UART clock.

Parameters

handle	UART handle pointer.

Return values

kStatus_HAL_Uart-Success	UART de-initialization succeed

4.0.89.6.3 hal_uart_status_t HAL_UartReceiveBlocking (hal_uart_handle_t *handle,* uint8_t * *data,* size_t *length*)

This function polls the RX register, waits for the RX register to be full or for RX FIFO to have data, and reads data from the RX register.

Note

The function HAL_UartReceiveBlocking and the function #HAL_UartTransferReceiveNon-Blocking cannot be used at the same time. And, the function #HAL_UartTransferAbortReceive cannot be used to abort the transmission of this function.

Parameters

handle	UART handle pointer.

data	Start address of the buffer to store the received data.
length	Size of the buffer.

Return values

kStatus_HAL_UartError	An error occurred while receiving data.
kStatus_HAL_UartParity-Error	A parity error occurred while receiving data.
kStatus_HAL_Uart-Success	Successfully received all data.

4.0.89.6.4 hal_uart_status_t HAL_UartSendBlocking (hal_uart_handle_t *handle*, const uint8_t * *data*, size_t *length*)

This function polls the TX register, waits for the TX register to be empty or for the TX FIFO to have room and writes data to the TX buffer.

Note

The function HAL_UartSendBlocking and the function #HAL_UartTransferSendNonBlocking cannot be used at the same time. And, the function #HAL_UartTransferAbortSend cannot be used to abort the transmission of this function.

Parameters

handle	UART handle pointer.
data	Start address of the data to write.
length	Size of the data to write.

Return values

kStatus_HAL_Uart-Success	Successfully sent all data.

4.0.89.6.5 hal_uart_status_t HAL_UartEnterLowpower (hal_uart_handle_t *handle*)

This function is used to prepare to enter low power consumption.

Parameters

handle	UART handle pointer.

Return values

kStatus_HAL_Uart-Success	Successful operation.

This function is used to restore from low power consumption.

Parameters

handle	UART handle pointer.

Return values

kStatus_HAL_Uart-Success	Successful operation.
kStatus_HAL_UartError	An error occurred.
